Light-induced degradation (LID) is a severe problem for silicon photo-sensitive devices like solar cells and photo detectors. LID reaction kinetics may be explained by the  $A_{Si}$ -Si_i-defect model. [1] This model consists of seven states. The transitions between these states are assumed to be first order equilibrium reactions, which can be mathematically treated by a system of linear differential equation. [1] This is numerically solved and compared to the LID cycle using well-known together with some estimated reaction constants.

HL 24.7 Wed 17:00 H36 talum Nitride as a Photoanode for Solar En-

**Exploring Zirconium-doped Tantalum Nitride as a Photoanode for Solar Energy Conversion** – •OLIVER BRUNE, LAURA I. WAGNER, VERENA STREIBEL, and IAN D. SHARP — Walter Schottky Institut and Physics Department, Technical University of Munich, Am Coulombwall 4, 85748 Garching, Germany

Solar water splitting could pave the way to carbon-free hydrogen production as it allows for direct transformation of sunlight into chemical energy. While the oxygen evolution reaction is a crucial step in generating green hydrogen, there remains a lack of semiconductor photoanode materials that can simultaneously fulfill three key requirements: long-term chemical stability, high photocarrier extraction efficiencies, and appropriate bandgap for harvesting solar radiation. Nevertheless, among the various materials that have been investigated, the transition metal nitride Ta3N5 offers significant promise as an efficient n-type photoanode. Building upon this established material, we use reactive co-sputtering and subsequent ammonia annealing to introduce Zr into Ta3N5, with the aim of investigating how the ternary nitride character of Zr-Ta-N(O) enables tuning of key semiconductor properties. Using a range of complementary characterization methods, we show that synthesis parameters and Zr content have a significant influence on the crystal structure, morphology, and optoelectronic properties of this ternary compound. Based on these insights, we optimize the composition and synthesis processes to achieve a highly stable and efficient photoanode material, which is a key requirement for solar water splitting.

### HL 24.8 Wed 17:15 H36

**Defect-Engineered Atomic Layer Deposited TaO**_x **Protection Layers for Photoelectrochemistry** — •TIM RIETH, CLARA SCHERM, and IAN SHARP — Walter Schottky Institute and Physics Department, Technical University of Munich, Am Coulombwall 4, 85748 Garching, Germany

Photoelectrochemical (PEC) energy conversion provides a viable route to the generation of chemical fuels from solar light. In this approach, charge carriers generated within a semiconductor light absorber immersed in an electrolyte are used to drive water splitting or carbon dioxide reduction reactions. A particularly relevant PEC configuration uses photovoltaic absorbers coated with transparent and conductive protection layers that prevent chemical corrosion of the semiconductor components. However, ensuring that the protection layer simultaneously fulfills the criteria for chemical stability, electronic conductivity, and optical transparency remains a challenging task. Here, we utilize plasma enhanced atomic layer deposition (PE-ALD) to create defect engineered and ultrathin tantalum oxide  $(TaO_x)$  protection layers for PEC applications. In addition to their optical transparency, the  $TaO_x$  films form continuous coatings on the photoabsorber and provide improved chemical stability compared to titanium dioxide. A sufficiently high film conductivity is obtained by intentionally introducing electronic defects from hydrogen plasma sub-cycles during the ALD process. The demonstrated defect engineering mechanism and achieved TaO_x protection layers represent an advance towards efficient and stable PEC devices.

### HL 24.9 Wed 17:30 H36

Exploring novel ternary nitride semiconductor photoabsorbers for solar energy conversion applications — •LAURA I. WAGNER¹, ELISE SIROTTI¹, JOHANNA EICHHORN¹, CHANG-MING JIANG¹, MATTHIAS KUHL¹, VERENA STREIBEL¹, DAVID EGGER², and IAN D. SHARP¹ — ¹Walter schottky Institut und TUM, München, Germany — ²TUM, München, Germany

Solar water splitting offers the possibility to harvest the sunlight and store it in the chemical bonds of hydrogen. Exploratory research has revealed several possible photoanode materials, but until now no material meets the core requirements for photochemical stability, carrier extraction efficiency, and moderate band gap in the visible range. In this context, transition metal nitride semiconductors are

underexplored and offer promise as new photoanode materials candidates. As a non-equilibrium synthesis approach, reactive magnetron co-sputtering enables the synthesis of novel ternary nitride photoabsorbers. In this work, a new ternary metal nitride photoanode material, cubic bixbyite-type ZrTaN3, is presented. We observe the reactively sputtered ZrTaN3 thin films to exhibit an optical bandgap at 2.4 eV and n-type behavior. Most importantly, the resulting polycrystalline films exhibit appreciable photoactivity when implemented as a photoanode in a photoelectrochemical cell. Benefiting from the tunability of cation (Ta,Zr) ratio of reactive sputtering and anion (N,O) ratio with post annealing treatments, the solid solution of ZrxTa2-xN3(O) offers a large parameter space to tune and optimize optoelectronic properties for various applications, including for PEC applications.

HL 24.10 Wed 17:45 H36

Electrical transport across catalyst/defect-engineered titania corrosion protection layer interfaces for light-driven CO2 reduction — •JULIUS KÜHNE, OLIVER BIENEK, TIM RIETH, and IAN D. SHARP — Walter Schottky Institute and Physics Department, Technical University of Munich, Am Coulombwall 4, 85748 Garching, Germany

Producing value-added products via light-driven CO2 reduction represents a promising approach to sustainably address increasing CO2 emissions and meet the growing global energy demand. However, such solar fuels systems require passivating layers to chemically protect semiconductor light absorbers from harsh reaction environments. Despite great progress in the development of atomic layer deposited (ALD) protection layers, the factors governing efficient charge injection into the catalytic component are not yet well understood. Here, the charge transport characteristics between various defect-engineered TiO2 protection layers grown with ALD and metal catalyst layers including Ag, Au, Pt, Ni and Ti are analyzed. This work aims to get a deeper understanding of the interface between catalyst and protection layer in terms of contact resistivity, carrier transport, and interface kinetics. Additionally, results of EC and PEC measurements are compared to assess the stability and activity of these systems under CO2 reduction conditions in a two-compartment cell with ion exchange membrane. The selectivity of selected catalyst layers is evaluated by gas chromatography of the reaction products, thereby enabling a quantification of their overall performance characteristics.

#### HL 24.11 Wed 18:00 H36

Finite supercell charge correction for electronic transitions in defects including electronic and ionic screening — •CHRISTOPH FREYSOLDT¹, BAOYING DOU¹, STEFANO FALLETTA², and JÖRG NEUGEBAUER¹ — ¹Max-Planck-Institut für Eisenforschung GmbH, Max-Planck-Str. 1, 40237 Düsseldorf — ²Ecole Polytechnique Fédérale de Lausanne (EPFL), CH-1015 Lausanne, Switzerland

Charged point defects play an important role in the function of (opto)electronic devices. Theoretical investigations have proven valuable to understand quantitatively their stability, electrical and optical properties, and hence their beneficial or detrimental role in device performance. Electronic transitions involving localized defect states have recently moved into the focus. Similar to formation energies, also the transition energies suffer from artifacts due the long-range Coulomb interactions and the artificial periodicity in supercell models of defects. While the initial charge state is subject to full electronic and ionic screening, the changes upon the transition are screened by electrons only. Yet, the required charge corrections cannot be derived by cleverly combining traditional corrections for formation energies of initial and final state. I will present an overview of how these artifacts can be understood and corrected for. I will show applications for vertical transitions and non-radiative carrier capture.

### HL 24.12 Wed 18:15 H36

Influence of Sr concentration on atomic, magnetic, and electronic structure of Ruddlesden-Popper oxide  $La_{2-x}Sr_xCo_{1-y}Fe_yO_4 - \bullet$ DINA I. MAZITOVA¹, DEBALAYA SARKER^{1,2}, and SERGEY V. LEVCHENKO¹ - ¹Moscow, Russia - ²UGC-DAE CSR, Indore, India

Ruddlesden-Popper oxides were demonstrated to be promising catalysts for oxygen evolution reaction. There are numerous attempts in the literature to find descriptors for predicting a catalytic activity. However, the descriptors may depend on the distribution of ions of different types in these multi-component systems.

We calculated atomic, electronic, and magnetic structure of La₂Co_{0.5}Fe_{0.5}O₄, LaSrCo_{0.5}Fe_{0.5}O4 (LSCFO), and Sr₂Co_{0.5}Fe_{0.5}O₄ for different distributions of iron and cobalt using all-electron DFT in GGA and GGA+U approximations. Our calculations show that the favorable distribution of transition metal cations depends on the amount of Sr substituted in the A site. The electronic and magnetic structures depend strongly on the Fe/Co distribution. For example, GGA-RPBE calculations in LSCFO showed charge-ordered ferromagnetic structure in the Co layer and antiferromagnetic structure in the Fe layer when Co and Fe layers interchange with one another, but for uniform distribution of iron and cobalt ions, LSCFO becomes ferromagnetic.

HL 25.1 Wed 18:00 P2

A versatile transfer printing toolbox for 2D material stacking — •IOANNIS CALTZIDIS, MAJA GROLL, JULIUS BÜRGER, MARC SATISON, JÖRG K. N. LINDNER, and KLAUS D. JÖNS — Institute for Photonic Quantum Systems, Center for Optoelectronics and Photonics Paderborn, and Department of Physics, Paderborn University, 33098 Paderborn, Germany

2D materials are of great interest to scientists due to the versatile integration with other materials into, for example, Van-der-Waals heterostructures. The resulting nanoscale Moiré superlattices have applications in electronic and photonic quantum technologies. In 2D materials, the electronic band structure is generally determined by the number of layers, species of materials, as well as their angular and relative translational orientation. Transfer printing 2D materials on top of each other or onto different platforms is a frequently used fabrication method for 2D devices in state-of-the-art laboratories worldwide. Here we show how our transfer printing apparatus can be used to deterministically transfer tungsten diselenide (WSe₂) on transmission electron microscope (TEM) grids for high-resolution differential phase contrast measurements, revealing the electronic field distribution. We employ water-assisted and dry transfer methods with WSe₂ on a polyvinylalcohol (PVA) - polymethylmethacrylate (PMMA) or polydimethylsiloxane (PDMS) polymer substrate. The transfer stage's translational, rotational, and azimuthal degrees of freedom enable deterministic positioning and control in the fabrication process.

### HL 25.2 Wed 18:00 P2

Enhancement of Raman and Defect Photoluminescence Emission in Hexagonal Boron Nitride (h-BN) — •FELIX SCHAUMBURG, MARCEL ZÖLLNER, VASILIS DERGAINLIS, AXEL LORKE, MARTIN GELLER, and GÜNTHER PRINZ — Faculty of Physics and CENIDE, University Duisburg-Essen, Germany

Optical spectroscopy, especially Raman- and photoluminescence (PL)spectroscopy, is commonly used to study the optical properties of twodimensional materials. In order to obtain the highest Raman/PL-signals, it is important to reduce the reflection of the excitation laser. We studied a number of exfoliated h-BN flakes with different thicknesses on a Si substrate with a 300 nm SiO₂ top-layer. By changing the h-BN layer-thickness, we found a specific thickness, where all Raman signals showed maximum intensity, whereas the backscattered laser light was almost completely suppressed. To explain the increased intensities, we calculated the reflectivity of the layer system (air, h-BN, SiO₂, Si) for different h-BN layer thicknesses and used the transfer-matrixalgorithm. For our 532 nm excitation laser, the minimum reflectivity was found for a h-BN flake thickness of about 160 nm. Using AFM measurements, we were able to confirm that the thickness of the h-BN flakes having the strongest Raman signals correspond almost exactly to the calculated thickness. Our results suggest, that the PL from defects will also be strongly enhanced for an h-BN thickness of 160 nm and an excitation laser wavelength of 532 nm. This optimal thickness for the defect state PL emission can easily be calculated for other excitation laser wavelengths, as well as for other materials.

### HL 25.3 Wed 18:00 P2

Surface acoustic wave modulation of optical and electrical properties in TMDC monolayers — •CLEMENS STROBL, BENJAMIN MAYER, HENDRIK LAMBERS, URSULA WURSTBAUER, and HUBERT KRENNER — Institute of Physics, University of Münster, Germany

Two-dimensional transition metal dichalcogenides (TMDCs) such as WSe2 exhibit large exciton binding energies combined with a high sensitivity of their bandgap energy to mechanical stimuli [1]. Excitons in these materials can be generated either optically by above band-gap illumination or via two electrodes. Similarly, excitons in TMDCs can be studied optically via photoluminescence and absorption spectroscopy, electrically by detecting a photocurrent or via the interaction with surface acoustic waves (SAWs).

The aim of this project is to investigate SAW-dependent photoconductance in exfoliated monolayers [2] and to determine the influence of SAWs on the optical and optoelectronic properties in TMDCs. We study the SAW-driven exciton transport in monolayers and thus the change in the exciton decay rate [1]. For all experiments lithium niobite (LiNbO3) substrates and interdigitated electrodes (IDTs) operating at a frequency range from 300MHz up to 1GHz are used.

### HL 25.4 Wed 18:00 P2

Raman fingerprint of twisted TMDC bilayers — •SINA BAHMANYAR, NIHIT SAIGAL, HENDRIK LAMBERS, LAURA SCHUSSER, CLEMENS STROBL, and URSULA WURSTBAUER — Institute of Physics, University of Münster, Münster, Germany The discovery of superconductivity and other correlated phases in twisted bilayer graphene opened up a new field of research aimed at understanding the many body physics and strong electronic interactions in twisted van der Waals bilayers. [1] Such bilayer systems provide an ideal platform for simulation of Hubbard model physics and its control using the relative twist angle between the layers [2] in order to tune interlayer interaction and electronic correlations. [1,2] We have fabricated twisted WSe2 bilayers with various twist angles between the monolayers and characterized them using low and high energy Raman spectroscopy and photoluminescence spectroscopy. The low-frequency Raman spectra shows the shear modes that are highly sensitive to the twist angle and interlayer coupling between the monolayers. Our measurements establish Raman spectroscopy as a non-destructive way to characterize the interlayer coupling in twisted TMDC bilayers to study electronic and excitonic correlation physics [3]. We acknowledge financial support via WU 637/7-1 and SPP2244. [1] Y. Cao et al., Nature 556, 23 (2018). [2] Y. Tang et al., Nature 579, 353 (2020) [3] L. Sigl. et al. Phys. Rev. ### HL 25.5 Wed 18:00 P2

**Nonlinear spectroscopy of valley polarization in transition metal dichalcogenides** — •PAUL HERRMANN¹, SEBASTIAN KLIMMER¹, and GIANCARLO SOAVI^{1,2} — ¹Institute of Solid State Physics, Friedrich Schiller University Jena, Jena, Germany — ²Abbe Center of Photonics, Friedrich Schiller University Jena, Jena, Germany

Valleytronics is the branch of science that aims at controlling the valley (i.e., local maximaminima in the valenceconduction bands) degree of freedom to store, manipulate and read information. Monolayer transition metal dichalcogenides (TMDs) are promising candidates for valleytronic applications their hexagonal symmetry in the real and reciprocal space leads to the appearance of two energetically degenerate but non-equivalent valleys at the K and -K points. In addition, their direct bandgap nature in the monolayer limit enables direct optical excitation into these valleys, which can be achieved in a highly selective fashion by means of circularly polarized light [1]. All-optical control of the valley population would enable information processing at optical frequencies, thus over-

271

### Location: P2

coming by three to six orders of magnitude the speed of current electronic devices [2]. Here, we perform non-linear and time-resolved optical spectroscopy to study the purity and temporal evolution of the valley population in TMDs. In particular, we combine 2-photon-photoluminescence and time-resolved second harmonic measurements to investigate the impact of intra-valley relaxation and inter-valley scattering on the degree of valley polarization.

**Charge carrier dependent Raman response in WS2 monolayers** — •HENDRIK LAMBERS, NIHIT SAIGAL, and URSULA WURSTBAUER — Institute of Physics, University of Münster, Münster, Germany

Semiconducting transition metal dichalcogenides such as WS2 and MoS2 are among the most widely studied 2D materials due to their unique optical and electronic properties. Monolayers of these materials show a large exciton dominated light matter coupling. Exciton-phonon and electron-phonon interaction effects are prone to modification of the charge carrier density and impacts the optical and electronic behavior of the atomically thin semiconductors [1]. Here we report on a detailed Raman study of the charge carrier dependent evolution of the phonon modes in WS2 monolayer embedded in a field effect structure using a solid-state electrolyte [2]. The optimized field effect structure using a polymer electrolyte top gating allows tuning the fermi-energy cross the band gap and hence enables ambipolar doping.

We acknowledge financial support via DFG WU 637/7-1 and SPP2244.

Tuning exciton recombination rates in doped transition metal dichalcogenides — •THERESA KUECHLE, SEBASTIAN KLIMMER, MARCO GRUENEWALD, and GIANCARLO SOAVI — Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany

Monolayer transition metal dichalcogenides (TMDs) are direct gap semiconductors that hold great promise for advanced applications in photonics and optoelectronics such as integrated, flexible and high-speed light emitting devices [1]. Understanding the interplay between their radiative and non-radiative recombination pathways is thus of crucial importance not only for fundamental studies but also for the design of future nanoscale on-chip devices. Here, we investigate the interplay between doping and exciton-exciton annihilation (EEA) and their impact on the photoluminescence quantum yield in different TMD samples and related heterostructures. We demonstrate that the EEA threshold increases in highly doped samples, where the radiative and non-radiative recombination of trions dominates [2]. The results are interpreted with a rate equation model that takes into account all radiative and non-radiative recombination pathways of excitons and trions in TMDs as a function of doping (*i.e.*, trion concentration) and generation rate (*i.e.*, photoexcited carrier concentration).

**Destructive Photon Echo Formation in Six-Wave Mixing Signals Induced by Local Field Effects** — •THILO HAHN¹, JACEK KASPRZAK², TILMANN KUHN¹, and DANIEL WIGGER³ — ¹Institute of Solid State Theory, University of Münster, Germany — ²Université Grenoble Alpes, CNRS, France — ³School of Physics, Trinity College Dublin, Ireland

The optical properties of transition metal dichalcogenides have emerged as an outstanding topic in nanoscience. In these materials, tightly bound excitons dominate the optical response. Ultrafast nonlinear spectroscopy is an ideal tool to study the excitonic properties and their dynamics. To model the dynamics of excitonic transitions we use a few-level system with an additional local field (LF) effect to describe exciton-exciton interaction [1]. Effectively, the LF shifts the transition energy depending on the exciton occupation, which is directly visible in pump-probe experiments [2]. In this contribution we consider six-wave mixing spectroscopy [3], where we discover a new destructive photon echo effect, that is produced by the LF contribution. In contrast to the traditional echo formed by constructive interference [4], the signal is temporarily suppressed due to destructive quantum interference.

Signature of lattice dynamics in twisted 2D homo/hetero-bilayers — •YANG PAN^{1,2}, SHUTONG LI³, MAHFUJUR RAHAMAN^{1,2}, ILYA MILEKHIN^{1,2}, and DIET-RICH R. T. ZAHN^{1,2} — ¹Semiconductor Physics, Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany — ²Center for Materials, Architectures, and Integration of Nanomembranes (MAIN), Chemnitz, Germany — ³Department of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, Minnesota, USA Twisted 2D bilayer materials are created by artificial stacking of two monolayer crystal networks of 2D materials with a desired twisting angle  $\theta$ . The material forms a moiré superlattice due to the periodicity of both top and bottom layer crystal structure. The optical properties are modified by lattice reconstruction and phonon renormalization, which makes optical spectroscopy an ideal characterization tool to study novel physics phenomena. Here, we report a Raman investigation on a full period of the twisted bilayer (tB) WSe₂ moiré superlattice (*i.e.*  $0^{\circ} \leq \theta \leq 60^{\circ}$ ). We observe that the intensity ratio of two Raman peaks,  $B_{2g}$  and  $E_{2g}/A_{1g}$  correlates with the evolution of moiré period. Using a series of temperature-dependent Raman and photoluminescence (PL) measurements as well as *ab initio* calculations, the intensity ratio  $I_{B_{2g}}/I_{E_{2g}/A_{1g}}$  is explained as a signature of lattice dynamics in tB WSe₂ moiré superlattices. By further exploring different material combinations of twisted hetero-bilayers, the results are extended for all kinds of Mo- and W-based TMDCs.

HL 25.10 Wed 18:00 P2

Transport Measurements on Twisted Graphene Heterostructures around Magic Angle – •BEI ZHENG, XIAO YUE ZHANG, JUN HUI HUANG, LINA BOCK-HORN, and ROLF J. HAUG – Institut für Festkörperphysik, Leibniz Universität Hannover, 30167 Hannover, Germany

The twisting of graphene layers opens up a whole new field of rich physics [1]. Especially, the electronic properties of twisted (double Bernal-stacked) bilayer graphene layers depend strongly on the twist angle, owing to the energy band modulation from the corresponding Moiré superlattice [2,3]. Furthermore, twisted graphene structures around the magic angle were the first systems that show new many-body phases, as e. g. superconductivity or Mott insulator phases [4].

We fabricated twisted graphene heterostructures around the magic angle encapsulated in hexagonal boron via 'tear and stack' method and investigated their transport characteristics at low temperature down to 1.5 K. The longitudinal resistance was observed to periodically change with charge carrier concentration. The periodicity is relative to the superlattice density  $n_s$  and depends on how the degenerated superlattice sub-bands are filled.

Rashba Splitting Modulated by Tuned Intrinsic Dipole Moment in MoSSe/WSSe Heterostructures — •HAMID MEHDIPOUR and PETER KRATZER — Faculty of Physics, University of Duisburg-Essen, Lotharstrasse 1, 47057 Duisburg, Germany

First-principles calculations in the framework of the density-functional theory are performed to study the van der Waals heterostructures of two Janus transition metal dichalcogenide (TMDC) monolayers, MoSSe and WSSe. Sixteen possible heterostructures of the two monolayers and their associated stackings (AA, AB) are studied. Thermal stability and electric and optical properties of all possible heterostructure configurations are investigated and compared. Owing to the lack of structural mirror symmetry in this class of TMDCs, a non-zero electric dipole moment exists for each Janus monolayer. The intrinsic dipole moments of the monolayers could build up an inter-monolayer coupling, which varies in magnitude across the possible heterostructure configuration spectrum. The total electric moment modulated by stacking could impact the overall stability of the heterostructures and their electronic and linear optical responses. Most intriguing for this class of material is the Rashba splitting of band structures for each Janus monolayer, which strongly depends on the intrinsic electric field associated with the non-zero electric moment due to the lack of mirror symmetry. By combining the DFT calculation and charge analysis, we quantify the Rashba effect for each heterostructure of MoSSe/WSSe and bring into the spotlight the role the stacking plays in modulating this effect.

#### HL 25.12 Wed 18:00 P2

Valley dynamics in WSe₂ monolayers and MoSe₂-WSe₂ heterobilayers — •PHILIPP PARZEFALL, MATTHIAS BREM, and CHRISTIAN SCHÜLLER — Institut für Experimentelle und Angewandte Physik, Universität Regensburg, Deutschland

We have performed an in depth study of the valley coherence and polarization in hBN-encapsulated WSe_2 monolayers, which shall be extended to WSe_2-MoSe_2 heterostructures.

Therefore, we investigate first the excitonic properties and possible exciton-phonon coupling in hBN-encapsulated WSe₂ monolayers via micro-photoluminescence and resonant Raman spectroscopy measurements with excitation energies close to the A-exciton's fine-structure. Hereby, the valley polarization and -coherence are of special interest as possible resonant phonon excitation influences the valley dynamics behavior tremendously.

Afterwards, the resulting understanding is used to investigate interlayer excitons and trions on  $MoSe_2$ -WSe₂ heterobilayers with 0° or 60° relative twist between the layers, similarly, with an excitation energy close to the resonances of the WSe₂'s A-exciton.

### HL 25.13 Wed 18:00 P2

Electrical control of orbital and vibrational interlayer coupling in bi- and trilayer 2H-MoS₂. — JULIAN KLEIN^{1,2}, JAKOB WIERZBOWSKI¹, •PEDRO SOUBELET¹, THOMAS BRUMME^{3,4}, LORENZO MASCHIO⁵, AGNIESZKA KUC^{6,7}, KAI MÜLLER¹, ANDREAS V. STIER¹, and JONATHAN J. FINLEY¹ — ¹Walter Schottky Institut, TU München, Germany — ²Department of Materials Science and Engineering, MIT, USA. — ³Wilhelm-Ostwald-Institute for Physical and Theoretical Chemistry, Leipzig University, Germany. — ⁴Faculty for Chemistry and Food Chemistry, TU Dresden, Germany. — ⁵Dipartimento di Chimica and Centre of Excellence NIS, Università di Torino, Italy. — ⁶Helmholtz-Zentrum Dresden-Rossendorf, Abteilung Ressourcenökologie, Forschungsstelle Leipzig, Germany — ⁷Department of Physics and Earth Sciences, Jacobs University Bremen, Germany.

Manipulating electronic interlayer coupling in layered vdW materials is essential for designing optoelectronic devices. Here, we control vibrational and electronic interlayer coupling in bi- and trilayer 2H-MoS₂ using large external electric fields in a microcapacitor device. The electric field lifts Raman selection rules and activates phonon modes in excellent agreement with ab initio calculations. Through polarization resolved photoluminescence spectroscopy, we observe a strongly tunable valley dichroism. By modeling our result using rate equations, we have explained the valley dichroism tunability using realistic material parameters.

### HL 25.14 Wed 18:00 P2

Assigning excitonic transitions in reconstructed  $MoSe_2$ -WSe₂ heterostacks — •Christos Paspalides¹, Mirco Troue¹, Lukas Sigl¹, Johannes Figueiredo¹, Manuel Katzer², Malte Selig², Florian Sigger¹, Roland Gillen³, Jonas Kiemle¹, Andreas Knorr², Ursula Wurstbauer⁴, and Alexander Holleitner¹ — ¹TU Munich — ²Technische Universität Berlin — ³Friedrich-Alexander-Universität Erlangen-Nürnberg — ⁴University of Münster

Transition metal dichalcogenide monolayers exhibit strong light-matter interactions, which promotes them as ideal candidates for novel 2D optoelectronic applications. The vertically stacked Van der Waals heterostacks facilitate the emergence of a type-II band alignment, which leads to the formation of longlived interlayer excitons. We present g-factors for three distinct interlayer exciton emissions in MoSe₂-WSe₂ heterostacks measured up to 9 T. Theoretical considerations including density functional theory lead to the assignment of the characteristic emission lines to optical transitions inside an atomically reconstructed *H*-type heterostack with a near-zero twist-angle. Here, the  $H_h^h$  atomic registry is able to fill sizable commensurate domains within the reconstructed lattice while the corresponding selection rules are found to govern the optical response of the system.

Following the attribution of the interlayer exciton emissions, we provide a deeper insight into the effect of atomic reconstruction in MoSe₂-WSe₂ heterostacks and discuss the possibility for a macroscopic occupation of the ground-state leading to unique many-body effects of interlayer excitons in such systems.

#### HL 25.15 Wed 18:00 P2

Fabrication and Characterization of Twisted TMDC Bilayer — •LAURA NICO-LETTE SCHUSSER, SINA BAHMANYAR, NIHIT SAIGAL, HENDRIK LAMBERS, HOS-SEIN OSTOVAR, and URSULA WURSTBAUER — Institute of Physics, University of Münster, Münster, Germany

Semiconducting 2D materials such as transition metal dichalcogenides (SC-TMDCs) excel due to their strong exciton dominated light matter interaction [1]. Van der Waals (VdW) heterobilayers prepared from SC-TMDCs are ideal systems for the realization and study of dense exciton ensmebles [2,3] and correlated phases phases of matter [4]. We are working to improve the fabrication protocol for high-quality twisted TMDC bilayers. We obtain monolayers by micromechanical exfoliation along with a deterministic pick-up and dry transfer using a viscoelastic stamp and to create vdW heterostacks with several layers. The twist angle between the layers is precisely controlled by a using a rotation stage. We use hexagonal boron nitride (hBN) as an encapsulating material. Photoluminescence (PL) spectroscopy combined with Raman spectroscopy is utilized for characterization. While the former technique probes the intralayer and interlayer exciton transitions, the latter one is used for the investigation of the phonon fingerprints of the system. [1] [1] U. Wurstbauer et al. J. Phys. D: Appl. Phys. 50, 173001 (2017). [2] L. Sigl et al. Physical Review Research 2, 042044(R) (2020). [3] J. Kiemle et al. Phys. Rev. B 101, 121404(R) (2020). [4] Y. Optical characterization of van der Waals WS2 Monolayer- Pyrenemethylammonium chloride few-layer vertical heterointerfaces — •MOHAMMED ADEL ALIX^{1,2}, HILARY MASENDA^{1,3}, ARSLAN USMAN^{1,4}, BETTINA WAGNER⁵, JOHANNA HEINE⁵, MARINA GERHARD¹, and MARTIN KOCH¹ — ¹Department of Physics and Materials Sciences Center, Philipps-Universität, Marburg, 35032 Germany — ²Department of Physics, Faculty of Science, Ain Shams University, Cairo, 11566 Egypt — ³School of Physics, University of the Witwatersrand, Johannesburg, 2050 South Africa — ⁴Department of Physics, COMSATS University Islamabad - Lahore Campus, Lahore, 54000 Pakistan — ⁵Department of Chemistry and Material Sciences Center, Philipps-Universität Marburg, 35043 Marburg, Germany

Van-der-Waals transition metal dichalcogenides(vdW-TMDCs) layered materials have received huge attention due to their strong light-matter interaction. Moreover, combining 2D TMDCs with different organic materials opened a new line in heterostructure(Hs) research, providing unprecedented tunability for heterostructure(Hs) engineering. Few layers Pyrenemethylammonium chloride (PyMACL) is an emerging exfoliable organic material that offers distinct properties and could be attractive for photonic and optoelectronic applications. Here, we present our work on WS2/PyMACL vdW-HS. We have investigated our specimen using micro-photoluminescence and time-resolved photoluminescence shedding light on exciton dynamics in such structures, and possible recombination channels. Moreover, investigating possible charge transfer between the different layers of the Hs.

**Modification of charge transport in single layer MoS2** — •ZAHRA FEKRI¹, PHANISH CHAVA¹, GREGOR HLAWACEK¹, VIVEK KOLADI², TOMMASO VENANZI³, WAJID AWAN¹, ANTONY GEORGE⁴, ANDREY TURCHANIN⁴, KENJI WATANABE⁵, TAKASHI TANIGUCHI⁵, MANFRED HELM¹, and ARTUR ERBE¹ — ¹Helmholtz Zentrum Dresden Rossendorf, Dresden, Germany — ²Imec, Leuven, Belgium — ³Sapienza University of Rome, Rome, Italy — ⁴Friedrich Schiller University, Jena, Germany — ⁵National Institute for Materials Science, Tsukuba, Japan

Ion beam irradiation is a technique that can be used to alter the electrical and optical properties of two-dimensional (2D) materials through defect creation. In this work, we used 5-7.5 keV helium and neon ions to modify charge transport in monolayer molybdenum disulfide ( $MoS_2$ ). Electrical characterization was performed in-situ immediately after ion beam irradiation. Raman and photoluminescence spectroscopy were implemented to further characterize the effect of ion irradiation on  $MoS_2$ . Our experiments show that the electrical properties of  $MoS_2$ -based transistors strongly depend on the nature of the substrate and the specific ion and dose used. Although  $10^{12}-10^{13}$  helium ions/cm² contribute to the increase in the current level, a similar dose of neon ions deteriorates the channel. To examine the role of the substrate, few-layer hexagonal boron nitride (h-BN) was used as an intermediate layer between  $MoS_2$  and the Si/SiO₂ substrate.  $MoS_2$  samples on h-BN show different electrical behaviour during ion irradiation as compared to the  $MoS_2$  flakes which were directly placed on  $SiO_2$ .

### HL 25.18 Wed 18:00 P2

**Tunable THz-absorption and gain in transition metal dichalcogenides** — •JOSEFINE NEUHAUS, TINEKE STROUCKEN, and STEPHAN W. KOCH — Philipps University, Marburg, Germany

Exhibiting linear optical spectra that are dominated by strongly bound excitonic features, transition metal dichalcogenides have attracted considerable interest in the past decade. In a properly pre-excited system, it is possible to study intra-excitonic transitions between optically bright *s*- and dark *p*-type excitons by their THz-absorption. In particular, as *p*-type states lie energetically below *s*-type states of equal main quantum number, not only absorptive but also gain features can be observed. Furthermore, the application of an external magnetic field perpendicular to the sample results in a shift of the various excitonic resonances. As the induced Zeeman shift depends on the angular momentum quantum number, the magnetic field induced shift differs for *s*- and *p*-type excitonic states, enabeling a tunability of the intra-excitonic transitions. Here, we study the tunability of the dielectric environment and the material parameters by means of a combined approach based on DFT and a Semiconductor-Bloch equation approach.

### HL 25.19 Wed 18:00 P2

**Contact engineering of black phosphorus field-effect transistors** — •YAGNIKA VEKARIYA¹, PHANISH CHAVA¹, ZAHRA FEKRI¹, KENJI WATANABE³, TAKASHI TANIGUCHI³, SIBYLLE GEMMING², and ARTUR ERBE¹ — ¹Helmholtz Zentrum Dresden Rossendorf, 01328 Dresden, Germany — ²Technische Universität Chemnitz, 09126 Chemnitz, Germany — ³National Institute for Materials Science, Tsukuba 305-0044, Japan

Black phosphorus (BP) has recently emerged as new semiconducting twodimensional (2D) material because of its unique properties such as tunable direct bandgap, high field-effect mobility, and good on/off ratio. In this work, we fabricated and characterized field-effect transistors (FETs) based on a few layers of black phosphorus, in order to evaluate the performance of devices using different contact materials like Graphene, Nickel (Ni), Titanium (Ti), and Chromium (Cr). We observed that the polarity and mobility value of transistors strongly depend on the contact material. Single photon emitters study in hBN via low power implantation approach — •RENU RANI¹, MINH BUI^{1,2}, BILAL MALIK^{1,2}, MANUEL AUGE³, THORSTEN BRAZDA¹, HANS HOFSÄSS³, DETLEV GRÜTZMACHER^{1,2}, and BEATA KARDYNAŁ^{1,2} — ¹Peter Grünberg Institut-9, Forschungszentrum Jülich, Jülich — ²Department of Physics, RWTH Aachen, Aachen — ³II. Physikalisches Institut, Georg-August-Universität Göttingen

A discovery of quantum emitters in hexagonal boron nitride (hBN) has recently incited immense interest in the field of quantum technologies. It offers not only a platform for fundamental science but is of interest for applications in quantum photonics owing to its robust single photon emission at room temperature. Recent studies have suggested that these SPEs are associated with intrinsic defects, which led to efforts to engineer the SPE in hBN by various such as plasma treatment, annealing, laser, e-beam and ion irradiation methods. Despite these efforts, the origin of single photon emission and the correlation of emission with particular defects still need to be scrutinized. Here we propose to use low-energy ion implantation to introduce the different defects in hBN. We will show results of optical characterization of hBN implanted with various noble gas ions with different energies, which depending on their atomic mass generate different vacancies and at different depths. We will discuss the viability of creating localized emitters throughout the surface, not only edges or grain boundaries. We will use Raman spectra to show that implanted material is free of contamination and damage associated with energetic particle beams.

#### HL 25.21 Wed 18:00 P2

Twist angle dependent proximity induced spin-orbit coupling in graphene/WSe₂/hBN heterostructures — •TOBIAS ROCKINGER¹, ANTONY GEORGE², ANDREY TURCHANIN², ZIYANG GAN², KENJI WATANABE³, TAKASHI TANIGUCHI³, DIETER WEISS¹, and JONATHAN EROMS¹ — ¹University of Regensburg, DE-93040 Regensburg, Germany — ²Friedrich-Schiller-Universität, DE-07743 Jena, Germany — ³NIMS, Tsukuba 305-0044, Japan

Recently, theoretical calculations predicted a strong dependence of the proximity-induced SOC on the twist angle between SLG and TMDCs [1]. To prove this, we fabricated SLG/WSe2/hBN heterostructures with well-defined twist angles between the SLG and WSe2 layers in two ways. For the first type, we exfoliated SLG and WSe2 which often break along zigzag or armchair edges [2]. This was used to align and estimate the rotation angles between the flakes (zigzag/armchair edges not distinguishable). For the other type of samples, we used CVD-grown WSe2 on anisotropically etched SLG to align and determine the twist angles exactly (zigzag/armchair edges distinguishable) [3]. Strong SOC causes weak anti-localization, which we used to determine the strength of the Rasbha type SOC ( $\lambda_R$ ) and the valley-Zeeman type SOC ( $\lambda_{VZ}$ ). We found that samples with an angle around 15° or 22° show a much stronger SOC in both cases, for  $\lambda_R$  as well as for  $\lambda_{VZ}$ , compared to samples, with twist angles around 0°/30° or 11°. This is in qualitative agreement with theoretical predictions [1]. [1]Y. Li and M. Koshino, Phys. Rev. B 99, (2019) 075438; [2]Y. Guo et al., ACS Nano 10, (2016) 8980; [3]P. Incze et al., Nano Res 3, (2010) 110

#### HL 25.22 Wed 18:00 P2

Nucleation of hBN on HOPG in conventional MBE — •CONSTANTIN HILBRUNNER, JULI ZHANG, JOERG MALINDRETOS, and ANGELA RIZZI — IV. Physikalisches Institut - Georg-August-Univiersität Göttingen

Due to its large bandgap of around 5.9 eV and due to its high breakdown voltage as well as its natural inertness, hexagonal boron nitride (hBN) is a promising substrate and encapsulation material to study the intrinsic properties of twodimensional materials. Due to thermodynamics, the growth of hBN requires very high substrate temperatures. At present, the hBN films grown by molecular beam epitaxy (MBE) on non-metallic substrates with highest structural quality were fabricated using substrate temperatures between 1300°C and 1600°C not achievable using conventional systems.

In a different approach, we intend to utilize laser assisted heating during MBE. Here, we report on our preliminary results concerning the nucleation of hBN on HOPG at conventional substrate temperatures for varying B fluxes and the heating characteristic of the substrate surface in response to ns laser pulses.

### HL 25.23 Wed 18:00 P2

Ultra-sensitive extinction measurements of optically active defects in monolayer  $MoS_2 - \bullet$ INES AMERSDORFFER¹, FLORIAN SIGGER², ALEXANDER HÖTGER², MANUEL NUTZ¹, ALEXANDER HÖGELE¹, DAVID HUNGER³, THOMAS HÜMMER¹, and CHRISTOPH KASTL² - ¹Faculty of physics, Ludwig-Maximilians-Universität Munich, Germany - ²Walter Schottky Institute and Physics Department, Technical University of Munich, Germany - ³Physikalisches Institut, Karlsruhe Institute of Technology, Germany

Measurements of the marginal absorption of nanomaterials are challenging. One way to address this issue is the use of an optical resonator in which the light passes the sample multiple times and thereby enhances the absorption of nanoscale objects to a measurable amount. Here, we demonstrate how a high-finesse microcavity can be exploited in order to measure the extinction by defects in monolayer  $MoS_2$ . Such atomistic defects embedded in nanomaterials are a promising

candidate for single-photon sources. However, to make them optically accessible, it is beneficial to know their absorption properties. To this end, we performed wavelength-dependent extinction measurements. The absolute values of extinction were recorded with a detection limit of down to 0.01% and agree in the order of magnitude with theoretical predictions. In case of neglectable scattering, the extinction values can be interpreted as absorption. The results show advances towards routine hyperspectral absorption measurements on the nanoscale.

### HL 25.24 Wed 18:00 P2

Electrical tuning of excitonic complexes in twisted van-der-Waals heterostructures — •BARBARA ROSA, CHIRAG PALEKAR, and STEPHAN REITZEN-STEIN — Institute of Solid State Physics, Technische Universität Berlin, D-10623 Berlin, Germany

Moiré excitons arising from transition metal dichalcogenides (TMDs) bilayers are directly controlled by the twist angle between the monolayers[1]. Noteworthy features of that new class of excitons, such as their ultrafast formation and charger transfer, long population recombination lifetimes, and binding energy of ~150 meV[2,3], turn TMD heterostructures into an attractive device for the study and manipulation of optical and transport properties via electrical fields. Here, we explore the ability to modulate interlayer exciton states in homoand heterobilayers (HB) throughout electrical tuning. By fabricating TMD heterostructures using CVD and exfoliated monolayers, we study the effects of an out-of-plane applied electrical field in heterostructures with distinct twist angles. Our work aims to achieve control of optical and transport properties of interlayer excitons, which have shown energy tunability that ranges over several hundreds of meV[2,3]. Furthermore, we intend to discuss our first results in exploring light-matter interaction of an HB embedded in a photonic microcavity by electrically manipulating the Moiré excitonic response.

### HL 25.25 Wed 18:00 P2

**Optical excitations in 2D material heterostructures under pressure** — •DEVIKA SIVANKUTTY, PAUL STEEGER, JOHANN PREUSS, ROBERT SCHMIDT, STEFFEN MICHAELIS DE VASCONCELLOS, and RUDOLF BRATSCHITSCH — University of Münster, Institute of Physics and Center for Nanotechnology, Wilhelm-Klemm Str. 10, 48149 Münster

Heterostructures of transition metal dichalcogenides (TMDCs) have attracted a lot of attention due to their unique optical and electronic properties and easy fabrication by stacking distinct TMDC monolayers on top of each other. Depending on the material choice, the heterostructures can also exhibit interlayer excitons, where the hole resides in one layer and the electron in the other. The coupling between the layers, and thereby the optical and electronic properties of the heterostructure, are expected to be strongly dependent on the interlayer distance, which can be tuned by applying pressure to the heterostructure. Here, we investigate the optical properties of TMDC heterostructures under high pressure in a diamond anvil cell. We use a home-built stamping setup to fabricate the heterostructures and perform optical spectroscopy at various pressure values to investigate the excitonic resonances.

### HL 25.26 Wed 18:00 P2

**Optical properties of multilayer MoS**₂ **under high pressure** — •PAUL STEEGER¹, ROBERT SCHMIDT¹, ILYA KUPENKO², CARMEN SANCHEZ-VALLE², STEFFEN MICHAELIS DE VASCONCELLOS¹, and RUDOLF BRATSCHITSCH¹ — ¹University of Münster, Institute of Physics and Center for Nanotechnology, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany — ²University of Münster, Institute for Mineralogy, Corrensstr. 24, 48149 Münster, Germany

Vertically stacked homo- and heterostructures of 2D semiconductors have recently attracted a lot of attention. One of the most critical parameters affecting their optical and electronic properties is the interlayer coupling. Controlling the distance between the layers by applying pressure to the sample allows to tune the interlayer interaction in-situ and opens up new ways to investigate its influence on the physical properties of multi-layered 2D materials. Here, we use a diamond anvil cell to measure how absorption and emission properties of multilayer MoS₂ crystals change under pressure, highlighting the differences between inter- and intralayer excitons.

### HL 25.27 Wed 18:00 P2

**Deterministic creation of strain gradients in 2D materials** — •ROBERT SCHMIDT, JOHANNES KERN, JANNIS BENSMANN, PAUL STEEGER, ROBERT SCHNEIDER, HELGE GEHRING, WOLFRAM H. P. PERNICE, STEFFEN MICHAELIS DE VASCONCELLOS, and RUDOLF BRATSCHITSCH — University of Münster, Institute of Physics and Center for Nanotechnology, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany

Strain is a powerful tool to modify the optical and electrical properties of 2D materials. While the controlled application of homogeneous strain to 2D materials is feasible, the creation of deterministic strain gradients over distances of several micrometers is still challenging. Commonly, monolayers or few-layers

are manually transferred onto a pre-patterned substrate, which often results in strain gradients differing from sample to sample.

In this work, we imprint structures into 2D materials. Using a homebuilt nanoimprint setup and  $SiO_2$  stamps produced by reactive ion etching, we print into 2D materials with lateral precision below one micrometer. The strain fields induced by this deformation are analyzed using optical absorption mapping.

### HL 25.28 Wed 18:00 P2

### "Ghupft und Gschobm": An ab initio multi-scale approach to bands and electron-phonon coupling in twisted WSe₂ bilayers — •MICHAEL WINTER and TIM WEHLING — I. Institute of Theoretical Physics, Universität Hamburg

Transition metal dichalcogenide bilayers host electron correlation effects like superconductivity, exciton condensation, and Mott insulation. These phenomena are tuneable via charge doping, optical excitation, dielectric environment, and twist angle. The complex interplay of Coulomb and electron-phonon interactions with multi-orbital and multi-valley physics behind the aforementioned correlation effects remains to be understood.

We study the twisted homo-bilayer of tungsten diselenide by construction of many-body quantum lattice models describing the electronic and phonon degrees of freedom as well as their coupling. From ab initio DFT and DFPT calculations with subsequent Wannier constructions on untwisted snapshots of commensurate structures corresponding lattice models are compiled. With an automated interpolation we are able to address twisted systems.

#### HL 25.29 Wed 18:00 P2

Ultrafast dynamics of dark states in photocurrent of TMD heterostructures — •DENIS YAGODKIN, ELIAS ANKERHOLD, ABHIJEET KUMAR, JOHANNA RICHTER, FIRAS BEN MOUSSA, CORNELIUS GAHL, and KIRILL BOLOTIN — Freie Universitat Berlin

We study the photocurrent response of TMD heterostructures MoS₂/MoSe₂ with 150 femtosecond time resolution. In order to study the dynamics of transport at the interface of the heterostructure, we tune one pulse to MoS₂ excitation resonance and the second, time-delayed pulse, to that of MoSe₂. We find stark asymmetry between negative and positive delays. We attribute this asymmetry to the formation of interlayer excitons. Using a simple model of charge carriers decaying in optically dark states we successfully describe both time-resolved reflectivity and photocurrent response of heterostructures. Extracted formation time of interlayer excitons is similar to that observed in ARPES and TR-THz at room temperature. Strong response to interlayer excitons shows the potential of our technique in detecting other dark states promising for information storing and processing.

### HL 25.30 Wed 18:00 P2

Charge carrier localization in nanobubbles of atomically thin TMD semiconductors — Christian Carmesin¹, Michael Lorke^{1,2}, Matthias Florian¹, •Daniel Erben¹, and Frank Jahnke¹ — ¹Institute for Theoretical Physics, University of Bremen — ²Bremen Center for Computational Materials Science, University of Bremen

Atomically thin transition metal dichalcogenides on nanostructured substrate like nanopillar arrays have gained attention as they show single photon emission. In contrast to a prestructured substrates, we investigate TMD nanobubbles that form naturally during stacking processes. Upon optical excitation these bubbles also exhibit quantum light emission, which indicates strong charge carrier confinement.

Starting from atomistic modelling of the strain field and electronic confinement potential of the nanobubble structure, we calculate the excitation spectrum for different bubble geometries. The microscopic origin of this carrier confinement lies in the bending rigidity of these materials leading to wrinkling of the surface. The resulting strain field facilitates nanoscale carrier localization due to its pronounced influence on the band gap. This localization mechanism is supported by local changes of the dielectric environment. As a result, strongly localization signature allows for experimental identification of this mechanism, which has also been demonstrated in spatially resolved photoluminescence experiments.

### HL 25.31 Wed 18:00 P2

**Tunable 2D phononic crystals** — •YUEFENG YU, JAN KIRCHHOF, BIANCA HOFER, OGUZHAN YUCEL, and KIRILL BOLOTIN — Department of Physics, Freie Universität Berlin, 14195 Berlin, Germany

In the field of phononics, periodic patterning controls vibration and thereby flow of heat and sounds based on its phononic band structure. This kind of structures name as phononic crystals (PnCs). Bandgaps of PnCs arise their potentials in low-dissipation mechanical states towards efficient waveguide and stable mechanical qubit. By combining highly flexible suspended two-dimension (2D) materials and PnCs into 2D-capacitor framework, applying pressure through voltage and thereby changing the unit size of periodic pattern to tune the phononic bandgap is accomplishable. For now, we are playing the PnCs in graphene and 2D MoS2 with hexagonal lattice and microscale cavity. From cavity interferometric measurement, the periodic pattern can effectively block a frequency-range of vibration modes and establish the 1.5MHz-wide phononic bandgap of 2D-MoS2 PnCs. By varying the incident-laser power and gating voltage, position of bandgap moves in MHz-frequency-range. With the supporting of simulation, graphene shows a much higher tunability of the width and position in frequency of phononic bandgap than MoS2. All of these suggests a potential playground for quantum information and phase transition in mechanical.

#### HL 25.32 Wed 18:00 P2

Effect of gallium content on the grain boundary properties of polycrystalline Cu(In,Ga)Se2 absorber layers in thin-film solar cells — •SINJU THOMAS¹, WOLFRAM WITTE², DIMITRIOS HARISKOS², STEFAN PAETEL², CHANG-YUN SONG³, HEIKO KEMPA³, NORA EL-GANAINY⁴, and DANIEL ABOU-RAS¹ — ¹Helmholtz Zentrum Berlin für Materialien und Energie (HZB) — ²Helmholtz Zentrum Berlin für Materialien und Energie GmbH, Hahn-Meitner-Platz 1, 14109 Berlin, Germany — ³Martin-Luther-Universität Halle-Wittenberg, Institut für Physik, Fachgruppe Photovoltaik — ⁴Competence Centre Photovoltaics Berlin (PVcomB)/(HZB)

In the present work, we apply several scanning electron microscopy techniques in a correlative manner on five solar cells with different ([Ga]/([Ga]+[In]) GGIs (0.13, 0.34, 0.51, 0.67, and 0.83) in the Cu(In,Ga)Se2 photoabsorbers, in addition to time-resolved photoluminescence and quantum-efficiency measurements. Grain sizes, electron lifetimes, grain-boundary (GB) recombination velocities, elemental distributions within the absorber layer, as well as luminescence emission distributions were assessed for all five samples. Owing to much reduced grain size at a GGI of 0.83,there is a high density of GBs that serve as active recombination centers. At this GGI, Voc losses via non-radiative recombination deteriorates the device efficiency However, the effective GB recombination velocity does not vary linearly with the increasing GGI. Distribution of the recombination velocities at individual GBs suggests that upward and downward band bending at GBs is independent of the Ga concentration

HL 25.33 Wed 18:00 P2 **Phonon Transport in Thin Homoepitaxial**  $\beta$ -Ga₂O₃ Films — •ROBIN AHRLING¹, OLIVIO CHIATTI¹, RÜDIGER MITDANK¹, ZBIGNIEW GALAZKA², AN-DREAS POPP², and SASKIA F. FISCHER¹ — ¹Novel Materials Group, Humboldt-Universität zu Berlin, 10099 Berlin, Germany — ²Leibniz Institute for Crystal Growth, 12489 Berlin, Germany

As a wide-band gap semiconductor with a high breakthrough field, gallium oxide (Ga₂O₃) has shown to be a promising material for applications in high power electronics. However, due to the materials low thermal conductivity [1,2] heat dissipation is a challenge for future device applications. By photolithography, magnetron sputtering and subsequent liftoff we prepare structures for investigating the thermal transport in the bulk Ga₂O₃ substrate and the thin homoepitaxial  $\beta$ -Ga₂O₃ films by applying the 2- $\omega$  and 3- $\omega$  measurement techniques.

For the substrate, we observe a dominance of phonon-phonon Umklapp scattering for high temperatures (>90 K) and a combination of point defect scattering and boundary effects for low temperatures. The phonon mean free path reaches a limit for low temperatures that can be explained with the crystal thickness. We aim to investigate the thermal transport exclusively in the thin films by producing sub- $\mu$ m heater widths using electron beam lithography and performing measurements at higher frequencies.

[2] M. Handwerg et al., Semicond. Sci. Technol. 31, (2016) 125006

HL 25.34 Wed 18:00 P2

Towards Heat Transport in Exfoliated β-Ga₂O₃ Flakes — •SAKHIR SHIBLI¹, ROBIN AHRLING¹, OLIVIO CHIATTI¹, RÜDIGER MITDANK¹, ZBIGNIEW GALAZKA², and SASKIA F. FISCHER¹ — ¹Novel Materials Group, Humboldt-Universität zu Berlin, 10099 Berlin, Germany — ²Leibniz Institute for Crystal Growth, 12489 Berlin, Germany.

Heat transport is known as a diffusive process that is characterized as a slow process compared to other physical processes. Nevertheless, heat transport can also occur ballistically in the speed of sound within a material over distances comparable to the phonon's mean free path, known as Casimir limit [1]. Therefore, thin-layer materials are of interest for detecting ballistic heat transport [2]. As a model system with large potential of application, e.g. in power electronics, we are investigating exfoliated thin-layer flakes of  $\beta$ -Ga₂O₃ single crystal [3][4]. As a wide-band gap semiconductor with a high-breakthrough field,  $\beta$ -Ga₂O₃ has shown to be a promising material for applications in high power electronics [5]. In this work, we fabricate and pattern micro-heater lines in order to employ the  $3\omega$ - and  $2\omega$ - methods [3].

### HL 25.35 Wed 18:00 P2

Investigation of pinhole defects in ALD  $TiO_{2-x}$  corrosion protection layers on III-V semiconductor photocathodes — •NICOLA TAFFERTSHOFER, TIM RIETH, and IAN SHARP — Walter Schottky Institute and Physics Department, Technical University of Munich, Am Coulombwall 4, 85748 Garching, Germany

The application of semiconducting photoabsorbers for photoelectrochemistry (PEC) provides a relevant path to solar fuel generation. However, a major challenge is the chemical instability of many potentially suitable semiconductors in PEC applications. Titania  $(TiO_{2-x})$  protection layers with defined properties can be conformally deposited by atomic layer deposition (ALD) and have been shown to improve chemical stability of photoelectrodes in PEC cells. Despite these benefits, TiO_{2-x} ALD protection layers exhibit structural imperfections, including pinholes, that limit the long-term stability of underlying semiconductor photoelectrodes under PEC conditions. In our work, we quantify the pin-hole density in TiO_{2-x} ALD protection layers, synthesized under different growth conditions, by combining controlled etching experiments with inductively coupled plasma mass spectrometry (ICP-MS). Using the high sensitivity of ICP-MS, the unprotected substrate area associated with existing and emerging pinholes can be deduced by an increase of the substrate elements concentrations dissolved in liquid. Overall, this method provides crucial information for the development of pinhole mitigation strategies in the TiO_{2-x} ALD growth process and, hence, is an important step towards an increased lifetime of photoelectrodes.

### HL 25.36 Wed 18:00 P2

Investigation of Electrically-Active Dopants in Sulfur-Hyperdoped Silicon Using Resistance Measurements — •SKROLLAN DETZLER, CHRISTOPH FLATH-MANN, and MICHAEL SEIBT — 4th Institute of Physics - Solids and Nanostructures, University of Goettingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

Due to its abundance and particularly adjustable electric properties, silicon has become the dominating material in solar cell fabrication as of today. One approach to further increase the efficiency of silicon solar cells is to introduce an intermediate band into the band gap, allowing for broader absorption of the sunlight spectrum. This could be realized by doping the material with deep-level impurities far beyond its equilibrium solubility limit. In this study, we analyze sulfur-hyperdoped silicon, produced by femtosecond pulsed laser annealing, resulting in inhomogeneous regions reaching from the surface into the bulk material. To gain information on electrically-active dopants across different regions, resistance measurements using micromanipulators and scanning electron mic croscopy imaging were performed.

#### HL 25.37 Wed 18:00 P2

Automation of band structure simulations to determine Si-dopant efficiency in AlGaAs — •MAXIMILIAN KRISTO, NICO BROSDA, ANDREAS D. WIECK, and ARNE LUDWIG — Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum, D-44801 Bochum, Germany

The potential landscape for electrons in semiconductor heterostructures is represented by its band structure. Their simulations can significantly help in the design of devices with new functionality. In order to systematically evaluate the doping efficiency in heterostructure samples, we automatized band structure calculations in a feedback loop with experimentally determined Hall parameters. These were determined by Van der Pauw measurements at 4.2 K.

The effective dopant concentration in the simulations was adapted to fit the experimental results and thus allowed to determine the effective dopant efficiency of Si doped AlGaAs HEMT structures to be compared with the dopant efficiency in Si doped GaAs samples. A majority of the dopant atoms are present in AlGaAs (with an aluminium concentration above 20 %) as deep impurities (Donor CompleX (DX) centers), which do not contribute to the electrical conductivity at 4.2 K if cooled in dark without bias. Therefore, these DX centers in Si doped Al-GaAs lower the doping efficiency compared to Si doped GaAs. For AlGaAs with an aluminium concentration of 34 %, an average dopant efficiency of 14  $\pm$  3 % and a negative correlation of -0.83 with the thickness of the doped layer could be found this way.

### HL 25.38 Wed 18:00 P2

Electrochemical epitaxial (200) PbSe submicron plates on single layer graphene for ultrafast infrared response — •CHAN YANG, SHUANGLONG FENG, YINYE YU, JUN SHEN, XINGZHAN WEI, and HAOFEI SHI — Chongqing Institute of Green and Intelligent Technology, Chinese Academy of Sciences

Highly efficient near and medium-wave infrared detection at room temperature is considered one of the most intensive studies due to their robust detection in foggy weather or other low visibility conditions. 2D atomic layer graphene has an unconventional broad optical spectrum and high carrier mobility properties for the next generation electronics and optoelectronics device. The singlelayer graphene has a lower quantum efficiency, and the PbSe has a direct narrow bandgap with a highly sensitive infrared response. Here, we examine the growth mechanism of high quality-oriented (200) PbSe crystals on a single atomic layer graphene using the electrochemical atomic layer epitaxy growth method in an aqueous electrolyte. The crystalline phase and density of nucleating seeds controlled by changing electrodeposition parameters are crucial for determining the submicron-crystal geometry. It is revealed that the controllable growth orientation and nucleation of PbSe crystals are realized by combining underpotential deposition of Pb and overpotential deposition of Se. The PbSe crystals/graphene hybrid photodetector indicates the benefit of infrared absorption. The extraordinary response speed of 1.8 ms, photo-responsivity in exceeding 36 AW⁻¹, and figure-of-merit detectivity  $D^* > 2.7 \times 10^9$  Jones have been demonstrated in 2.7  $\mu$ m at room temperature.

#### HL 25.39 Wed 18:00 P2

Reconstructions of the As-terminated GaAs(001) surface exposed to atomic hydrogen — MARSEL KARMO¹, ISAAC AZAHEL RUIZ ALVARADO², WOLF GERO SCHMIDT², and •ERICH RUNGE¹ — ¹Technische Universität Ilmenau — ²Universität Paderborn

We explore the atomic structures and electronic properties of the As-terminated GaAs(001) surface in the presence of hydrogen based on ab-initio density functional theory. We calculate a phase diagram dependent on the chemical potentials of As and H, showing which surface reconstruction is the most stable for a given set of chemical potentials. The findings are supported by the calculation of energy landscapes of the surfaces, which indicate possible H bonding sites as well as the density of states, which show the effect of hydrogen adsorption on the states near the fundamental band gap [1]. Extension to the GaAs_xP_{1-x}(001) surfaces are presented.

### HL 25.40 Wed 18:00 P2

Remote Heteroepitaxy of In(x)Ga(1-x)As on Graphene Covered GaAs(001) Substrates — •Tobias Henksmeier¹, Friedemann Schulz², Elias Kluth², Martin Feneberg², Rüdiger Goldhahn², and Dirk Reuter¹ – ¹Paderborn University, Warburger Str. 100, 33089 Paderborn, Germany —  2 Otto von Guericke University, Magdeburg, Universitätsplatz 2, 39106 Magdeburg, Germany Recently, remote epitaxy on monolayer graphene covered substrates has attracted considerable attention as a way to improve lattice mismatched growth. It was reported that placing a monolayer graphene on a substrate offers a relaxation pathway different to the creation of crystal defects. Here, we present a study on solid source molecular beam epitaxy of In(x)Ga(1-x)As-layers (0<x<0.5) on chemical vapor deposition monolayer-graphene covered GaAs-(001) substrates. We show detailed investigations on the low temperature In(x)Ga(1-x)As nucleation and on the strain relaxation of 200 nm thick In(x)Ga(1-x)As-layers on graphene coved GaAs and for comparison on bare GaAs. The samples were analyzed by atomic force microscopy (AFM), scanning electron microscopy (SEM), Ramanspectroscopy and high-resolution X-ray diffraction measurements (HRXRD). We see the same crystal orientation and similar root-mean-square roughness for films grown on graphene and on bare GaAs substrates. Further, the layers grown on graphene show a more symmetric strain relaxation and a larger degree of strain relaxation compared to films grown on bare GaAs where the strain relaxation is larger along [110].

Nonlinear dynamics of Dirac fermions in topological HgTe structures — •TATIANA AURELIIA UAMAN SVETIKOVA¹, ALEXEJ PASHKIN¹, THALES OLIVEIRA¹, FLORIAN BAYER², CHRISTIAN BERGER², LENA FÜRST², HART-MUT BUHMANN², LAURENS W. MOLENKAMP^{2,3}, MANFRED HELM¹, TO-BIAS KIESSLING², STEPHAN WINNERL¹, SERGEY KOVALEV¹, and GEORGY V. ASTAKHOV¹ — ¹HZDR, Dresden, Germany — ²Physikalisches Institut (EP3), Universität Würzburg, Würzburg, Germany — ³Institute for Topological Insulators, Würzburg, Germany

High harmonic generation has applications in various fields, including ultrashort pulse measurements, material characterization and imaging microscopy. Strong THz nonlinearity and efficient third harmonic generation (THG) were demonstrated in graphene [1], therefore it is natural to assume the presence of the same effect in other Dirac materials, such as topological insulators (TI)[2].

We used a series of HgTe samples corresponding to three qualitatively different cases: 2D trivial and topological structures and 3D TIs. By using moderate THz fields, the presence of highly efficient THG was measured at different temperatures and THz powers. This provides insight into physical mechanisms leading to THG in TIs. For in-depth understanding of Dirac fermions dynamics and dominating scattering mechanisms in HgTe TI, we conducted THz pump-probe experiments that reveal several relaxation time scales.

**Graphitic Carbon Nitride/Semiconductor Quantum Dots 2D/0D Heterostructures** — •THUY LINH NGUYEN THI, OLEKSANDR SELYSHCHEV, and DIETRICH R.T. ZAHN — Semiconductor Physics, TU Chemnitz, Chemnitz D-09107, Germany

The 2D semiconductor graphitic carbon nitride (g-C3N4) is of great interest due to its photocatalytic properties and potential application in optoelectronic devices. However, a relatively large bandgap of 2.7 eV [1] requires its additional sensibilization to extend the photosensitivity to entire visible range. Here, we investigate heterostructures of n-type g-C3N4 and p-type semiconductor quantum dots (QDs), e.g. AgInS2. The single-layered g-C3N4 flakes exfoliated from bulk material using tetraethylammonium hydroxide (TEA-OH) ligands [1] and AgInS2 QDs with a size of ~3.5 nm [2] were used in aqueous solutions. X-ray Diffraction (XRD) indicates the intercalation of TEA-OH ligands between the flakes of g-C3N4. The thickness of the carbon nitride flakes of 0.3 +/- 0.1 nm, corresponding to a monolayer, and lateral sizes in the range of 35 - 55 nm are confirmed by Atomic Force Microscopy (AFM). Photoluminescence (PL) quenching of both g-C3N4 and QDs indicates an electronic interaction. A model photodetector device based on a thin film of a g-C3N4 and QD mixture, a TiO2 transport layer, indium-tin-oxide and gold electrodes was utilized for investigating the photoconductivity.

HL 25.43 Wed 18:00 P2

**Contactless mapping of the sheet resistance of GaAs samples** — •TIMO A. KURSCHAT, ARNE LUDWIG, and ANDREAS D. WIECK — Angewandte Festkörperphysik, Ruhr-Universität Bochum, Universitätsstraße 150, D-44780 Bochum Measurements of the sheet resistance without the need to break the sample and integrate electrical contacts enable the evaluation of the homogeneity and quality of samples before further processing. Spatially resolved maps can be created without destroying or modifying the wafer.

The sheet resistance is measured by placing the sample on top of two circular electrodes. These couple capacitively with the conducting layer through the substrate. When applying a high frequency alternating voltage at one electrode, a signal can be measured at the other one. The sheet resistance is measured by sweeping the frequency from 1 MHz to 400 MHz and applying a fit. The setup works for sheet resistances between 300  $\Omega/\Box$  and 50 k $\Omega/\Box$ .

The measured resistance and the coupling capacitances depend on the geometry of the sample and the electrodes. The changes at the edges of a sample are shown with line scans across a quarter 3" wafer and across a 5 mm wide sample. To show the effect of changes in the sheet resistance, the conducting layer was partly removed by etching. This shows artifacts especially if one electrode is completely below an isolating region. The spatial resolution depends strongly on the orientation of the electrodes.

### HL 25.44 Wed 18:00 P2

**GW benchmarks** — •MARYAM AZIZI, MATTEO GIANTOMASSI, and XAVIER GONZE — Université Catholique de Louvain, Louvain-la-Neuve, Belgium GW is presently the best available first-principles methodology for the prediction of electronic structure, including band gaps. However, dealing with GW calculations is always challenging, not simply due to unfavorable scaling with system size, or possible lack of symmetry, but also due to the large number of parameters of such calculations. As a consequence, systematic GW benchmarks for large sets of materials are much more limited than for density-functional theory.

In the present work, we pave the way beyond the study of Van Setten and coworkers, who examined 70 materials, however aiming to a limited target accuracy. Indeed we consider a convergence criterion of 0.02 eV in the GW band gap, more stringent than the 0.05 eV target of this previous study. Moreover, the latter relied on a plasmon-pole model, while the present analysis also focus on contour-deformation and analytic continuation methodologies which are computationally more expensive and theoretically better justified. Like Van Setten et al, we use ABINIT, and stay at the non-self-consistent  $G_0W_0$  level. Besides, the parallel speedup and efficiency of the implementation have been investigated.

#### HL 25.45 Wed 18:00 P2

**Two-Photon Absorption Induced Photoluminescence in CuI Single Crystals** — •ANDREAS MÜLLER¹, EVGENY KRÜGER¹, LUKAS TREFFLICH¹, STEF-FEN BLAUROCK², HARALD KRAUTSCHEID², MARIUS GRUNDMANN¹, and CHRIS STURM¹ — ¹Felix-Bloch-Institut für Festkörperphysik, Universität Leipzig — ²Institut für Anorganische Chemie, Universität Leipzig

The intrinsically *p*-type copper iodide (CuI) with a direct band gap of 2.95 eV at 300 K [1] and high exciton binding energy is a promising material for transparent semiconductor devices. The photoluminescence (PL) emission properties of CuI crystals have been recently reported [2]. However, the PL emission induced by two-photon absorption (TPA-PL) has not been discussed in detail, so far.

We report on TPA-PL phenomena in CuI single crystals. A redshift compared to the conventional PL emission was observed. The TPA-PL spectrum can be nicely described by means of a simplified approach which takes into account the internal emission spectrum at the focal point, the propagation of the emitted photons inside the crystal and the absorption coefficient of CuI (determined by ellipsometry and taken from [2]). For the entire TPA-PL intensity we observed a non-linear power dependence, namely  $I \propto P^{\gamma}$ . The exponent  $\gamma$  depends on the excitation wavelength and ranges from 2 (expected for TPA-PL excitation via a

virtual state) down to 1.5. The latter value was justified by a two-step TPA-PL process via a real state i.e. defect level.

HL 25.46 Wed 18:00 P2

Time-Resolved Nanoscale X-ray Analysis to Investigate Luminescence Dynamics of Co in ZnO-Material Systems — •Adrian Nowotnick¹, Christian Plass¹, Valentina Bonino², Maurizio Ritzer¹, Lukas Jäger¹, Jaime Segura-Ruiz², Gema Martinez-Criado², and Carsten Ronning¹ — ¹Institut für Festkörperphysik, Friedrich-Schiller-Universität Jena, Max-Wien-Platz 1, 07743, Jena — ²ESRF - The European Synchrotron, 71 Avenue des Martyrs, 38043 Grenoble, France

High resolution synchrotron based methods like X-ray fluorescence (XRF) and X-ray exited optical luminescence (XEOL) are well established characterization techniques. A highly focused X-ray nanobeam at the ID16B-NA station of the European Synchrotron Radiation Facility provides an excellent spatial resolution of about 50nm. This enables compositional mapping of nanometerials. Uniquely, the beam line was equipped with a streak camera allowing analysis of the spectral dynamics of optical luminescence. Consequently, one can investigate the influence of elemental compositions and local environments on the emission properties of e.g. color centers in semiconductor nanomaterials. These are able to provide high quality single photon emitters, which have drawn a lot of interest in recent years. Simultaneous XRF and XEOL measurements of Co in ZnO systems were conducted and by analyzing the emitted X-ray fluorescence radiation together with the corresponding optical luminescence could be determined depending on the Cobalt concentration and the system morphology.

### HL 25.47 Wed 18:00 P2

**Photoluminescence observation of Erbium implanted semiconductor nanostructures** — •NICO BROSDA, CRISTIAN DÜPUTELL, ARNE LUDWIG, and AN-DREAS WIECK — Lehrstuhl für angewandte Festkörperphysik, Ruhr-Universität Bochum, D-44801 Bochum, Germany

The rare earth element Erbium is known for its spectral transitions around 1.5  $\mu$ m. This wavelength region coincides with the absorption minimum of optical fibers. How to maximize the photoluminescence of Er doped semiconductor nanostructure is therefore a reasonable research topic.

The doping of GaAs semiconductor structures was achieved with focussed ion beam implantation. To recover the crystal structure and activate the Er atoms the samples are thermally annealed. Finding the optimal annealing parameters requires PL measurements in the near-infrared regime. A suitable PL setup was build around an InGaAs detector and a He-flow cryostat, allowing to measure the PL signal of Er. A 805 nm laser diode was used for the excitation. Optical parts in the setup were chosen with an antireflection coating for light around 1.5  $\mu$ m.

The comparison between different annealing respectively implantation parameters allowed to identify values resulting in a brighter PL spectrum of the Er.

### HL 25.48 Wed 18:00 P2

Semiclassical and quantum optical field dynamics in an optical cavity with a finite number of quantum emitters — •KEVIN JÜRGENS¹, FRANK LENGERS¹, DANIEL GROLL¹, DORIS E. REITER^{1,2}, DANIEL WIGGER³, and TILMANN KUHN¹ — ¹Institute of Solid State Theory, University of Münster, Germany — ²Condensed Matter Theory, Technische Universität Dortmund, Germany — ³School of Physics, Trinity College Dublin, Ireland

Ensembles of quantum emitters (QE) coupled to the quantized light field inside a photonic cavity are promising building blocks in quantum technologies. Due to the interaction of several QEs with a single light mode, the emitters can produce interesting collective behavior. We calculate the spectra and dynamics of such an ensemble with up to N = 60 emitters after excitation by a short external laser pulse within the Tavis-Cummings model and compare the findings with those obtained in the semiclassical limit  $(N \rightarrow \infty)$  [1]. When increasing the pulse amplitude we find a sharp transition in the semiclassical limit from exciton-polariton-like behavior to Rabi oscillations. The full quantum calculations reproduce such a transition behavior independent of N, but in particular for smaller N the transition between these regimes is broadened over a certain range of pulse amplitudes.

Wigner functions are calculated to investigate the properties of the light field and show the emergence of quantum features [1]. On longer time scales we see the formation of N + 1 quasi coherent states with Schrödinger-cat-like interferences between each pair.

### HL 25.49 Wed 18:00 P2

**Temperature dependence of phonons of CuI** — •R. HILDEBRANDT¹, M. SEIFERT², S. BOTTI², C. STURM¹, and M. GRUNDMANN¹ — ¹Universität Leipzig, Felix Bloch Institute for Solid State Physics, Germany — ²Fridrich-Schiller-Universität Jena, Institute of Condensed Matter Theory and Optics, Germany Cuprous iodide (CuI) is unique as intrinsic transparent p-type semiconductor with high figure of merit regarding various optical and electrical properties [1].

Properties and processes like thermal conductivity, electron-phonon coupling, phonon scattering, phonon-decay and elastic constants are influenced or mediated by different types of phonons. Their characteristics will be investigated here by Raman scattering.

We present temperature dependent Raman scattering spectra for CuI by using a 532nm incident laser source on solution grown single crystals. The allowed TO and LO modes are observed as well as the weaker second order Raman spectrum, which contains the full information of CuI's phonon dispersion [2]. It is used to determine the energy of the - usually forbidden - acustic and optic zone boundary phonons by modeling the two-phonon sum spectrum [3].

Up to about 170 K the temperature dependence of the acustic phonons could be tracked and compared with computational as well as other experimental results [3]. All results are in agreement and provide high accuracy information for the phonon dispersion of CuI.

#### HL 25.50 Wed 18:00 P2

Manipulating light-emission in direct band gap hexagonal Silicon Germanium nanowire arrays — •David Busse¹, Victor van Lange², Elham Fadaly², Wouter Peeters², Marco Vettori², Jos Haverkort², Erik Bakkers², Gregor Koblmüller¹, and Jonathan Finley¹ — ¹Walter Schottky Institut, Garching near Munich, Germany — ²Eindhoven University of Technology, Eindhoven, Netherlands

We present results on the redistribution and enhancement of light within a 2D photonic crystal array formed by a hexagonal array of standing  $Si_{1-x} - Ge_x$  nanowires (NWs). It was previously shown that these NWs are direct bandgap semiconductors when the crystal lattice has a hexagonal crystal structure. Fully 3D FDTD-simulations were performed to calculate the frequency of the photonic bands and their dependence on the lattice pitch and radius of the NW array. Essentially, the peak of the photoluminescence (PL) emission from the  $Si_{1-x} - Ge_x$  NWs at 0.352eV, can be continuously tuned through the dielectric and air photonic band edges by changing lattice pitch and radius. For NW radius r=210nm, length l=6mu and variable distance between the NWs (pitch a = 0.8mu up to 1.95mu) we tune the photonic band edges through NW PL emission. Crucially, for situations close to resonance we observe an increase in the time-integrated PL intensity and transient carrier recombination dynamics measured using time-resolved pump-probe reflectance spectroscopy.

#### HL 25.51 Wed 18:00 P2

Influence of encapsulation material on organic magnetoconductance effect in organic light emitting diodes (OLED) — •ANNIKA MORGENSTERN¹, DO-MINIK WEBER², APOORVA SHARMA¹, DANIEL SCHONDELMAIER², DIETRICH R.T. ZAHN^{1,3}, and GEORGETA SALVAN^{1,3} — ¹Semiconductor Physics, TU Chemnitz, 09107 Chemnitz, Germany — ²Nanotechnology and Functionalized Surfaces, Westsächsische Hochschule Zwickau, 08056 Zwickau, Germany — ³Center of Materials, Architectures and Integration of Nanomembranes, TU Chemnitz, 09126 Chemnitz, Germany

Organic semiconductors are the basic building block of organic light-emitting diodes (OLED). It was reported that certain OLEDs based on Alq3, P3HT, etc. when exposed to an external magnetic field show a change in the electrical resistance. This phenomenon is called the organic magnetoconductance (OMC) effect, which stems from the influence of the magnetic field on the charge carrier density and/or mobility. OLEDs are also known to degrade due to the influration of oxygen and moisture into the constituting layers. In this work, we present a systematic study of the influence of polymethyl methacrylate (PMMA) and soda-lime glass encapsulation layer on the OMC effect, using a homebuilt electrical test bench based on a magnetic field modulation technique to remove the time-dependent change in the current. Additionally, we compare the passivation efficacy of the studied OLEDs were measured using a test setup equipped with a photodiode, allowing to record the OLED light output over time.

### HL 25.52 Wed 18:00 P2

The Impact of Mechanical Stress on Structural, Morphological and Electrical Properties of Transferable Organic Semiconductor Nanosheets — •VERONIKA REISNER, SIRRI BATUHAN KALKAN, and BERT NICKEL — Faculty of Physics and CeNS, Ludwig-Maximilians-Universität, Geschwister-Scholl-Platz 1, 80539 Munich, Germany

Recently, we presented a technique to transfer organic small-molecule nanosheets using a sacrificial water-soluble polymer layer. This approach enables

the transfer of highly ordered organic films on substrates, which are unfavorable for direct growth by physical vapor deposition. However, the transferable nanosheets experience a considerable amount of mechanical stress during the release and transfer process. Here, we investigate the structural and morphological changes induced in the transferable nanosheets to optimize the transfer technique. For this purpose, we use pentacene films as stress sensors. Pentacene films show a distinct response to the mechanical stress by an irreversible phase change from the thin-film phase to the Campbell bulk phase. To reveal these structural and morphological changes, we employ X-ray diffraction analysis and atomic force microscopy technique. We find that thinner pentacene nanosheets show a lower Campbell bulk phase contribution after the transfer process. Finally, we use an optimized transfer technique to fabricate transistors based on the transferable organic small-molecule DNTT. DNTT nanosheets are more brittle compared to pentacene nanosheets but exhibit superior device performance.

#### HL 25.53 Wed 18:00 P2

Damping and detecting vibrational modes in organic semiconductors with tunable graphene cavities — •LUKAS RENN and THOMAS WEITZ — I. Physical Institute, Georg-August-University, Friedrich-Hund-Platz 1, 37077, Göttingen The true nature of charge transport in organic semiconductors (OSC) is still not fully understood. A novel picture to describe the charge transport is the socalled transient localization, where the charge transport is intrinsically limited by inter- and intramolecular vibrations, which are a direct consequence of the weak van der Waals interactions in OSCs. Recently it was discovered that the mobility in OSCs is mainly hampered by single low-frequency sliding modes, which in some molecules contribute more than 80% of the total thermal disorder. (1) The aim of this work is to first detect the lattice vibrations in OSCs and subsequently manipulate them using 2D cavities. To this end, we deposit monolayer thin, highly crystalline OSC films (PDI1MPCN2) from solution onto graphene flakes, which should result in quenching of a broad spectral range of IR-active vibrational modes in the OSC. First measurements show that we are able to detect the vibrational modes via Raman and a SNOM-based Nano-FTIR measurement setup. One step further, we want to tune the plasmon frequencies of the graphene cavities via lithography-patterning and thereby selectively couple to molecular vibrations in this frequency range and measure their relative impact on the charge carrier mobility. (1) Schweicher et al., Adv. Mat. 1902407 (2019)

### HL 25.54 Wed 18:00 P2

Towards charge-carrier transport studies in organic semiconductors strongly coupled to the electromagnetic vacuum field — •DANIEL VITROLER^{1,2}, JAMES W. BORCHERT¹, and R. THOMAS WEITZ¹ — ¹Universität Göttingen, Göttingen, Deutschland — ²LMU München, München, Deutschland

Strong coupling between the vacuum field and an excitonic transition in a semiconductor using plasmonic resonators or optical cavities leads to the formation of exciton polaritons [1]. Among the many prospective uses of strong coupling, recent studies have demonstrated that the formation of polaritons is an intriguing potential approach for improving charge transport in e.g. organic semiconductors [2]. However, there have so far been limited experimental demonstrations of strongly-coupled organic transistors [3], leaving many questions about the detailed physics of charge-carrier transport in these devices. In this work, we investigate light-matter coupling in thin films based on a perylene diimide derivate (PDI1MPCN2) which has previously shown electron mobilities as high as 4 cm²/Vs in organic transistors [4]. Tuned Fabry-Pérot cavities were implemented to achieve strong coupling to an excitonic transition of PDI1MPCN2 dispersed in a polymer matrix.

HL 25.55 Wed 18:00 P2

Influence of the probe-to-semiconductor contact on the electrical characterization of nanowire structures — •JULIANE KOCH¹, LISA LIBORIUS², PETER KLEINSCHMIDT¹, NILS WEIMANN², WERNER PROST², and THOMAS HANNAPPEL¹ — ¹Fundamentals of energy materials, Ilmenau University of Technology, Germany — ²Components for high frequency Electronics (BHE), University of Duisburg-Essen, Germany

For the purpose of well-defined III-V semiconductor junctions, various sophisticated tip-based methods such as multi-tip scanning tunnelling microscopy (MT-STM) can be employed to study the electrical behaviour with high spatial resolution. We investigated a variety of upright, freestanding GaAs-based axial as well as co-axial nanowires on the growth substrates covered with native oxide. Based on our studies with MTSTM, we demonstrate that in tip-based measurement methods, the probe-to-semiconductor contact is essential for interpreting the properties of the sample. Our investigation reveals charging currents at the interface between the measuring tip and the semiconductor via the native insulating oxide, which acts as a MIS-capacitor in the operating voltage range. All the samples investigated displayed a strong dependency of the overall electrical behaviour on the condition of the tip-to-semiconductor contact. We analyse in HL 25.56 Wed 18:00 P2

Efficient spectral separation of single and entangled photons — •PATRICIA KALLERT, LUKAS HANSCHKE, EVA SCHÖLL, BJÖRN JONAS, and KLAUS D. JÖNS — Institute for Photonic Quantum Systems, Center for Optoelectronics and Photonics Paderborn, and Department of Physics, Paderborn University, 33098 Paderborn, Germany

Experiments and protocols based on single-photons with different properties are crucial to develop photonic quantum technologies. Semiconductor quantum dots are a promising platform for the emission of single, indistinguishable, and entangled photons. The efficient routing and filtering of frequency-mismatched photons, for example, from the biexciton-exciton cascade, is crucial to facilitate the full potential of quantum dots. The separation of photons of different energies allows for efficient entanglement swapping and teleportation experiments, which rely on multiphoton coincidences. Spectral separation and simultaneous detection of adjacent wavelengths are complex to realise. Here we exploit a strategy to build a blaze grating-based transmission spectrometer with outstanding figures of merit. We shed light on the basic principle and the pitfalls that lead to a severe decrease of the efficiency or deterioration of the resolution and how to overcome them. Balancing the main properties, our overall efficiency exceeds 66 %, and our resolution is 21 GHz. Simultaneously, wavelengths distanced by 0.2 nm can be separated. Our self-built setup offers all functionalities to characterise single-photon sources and efficiently incorporate them in modern quantum optics experiments.

### HL 25.57 Wed 18:00 P2

**Telecom wavelength InP based quantum dots: Growth and characterization** — •RANBIR KAUR, MOHANAD ALKAALES, JOHANN PETER REITHMAIER, and MOHAMED BENYOUCEF — Institute of Nanostructure Technologies and Analytics, University of Kassel, Kassel, Germany

InP-based semiconductor quantum dots (QDs) represent an attractive light source for quantum communication applications due to their ability to emit photons at the telecom C-band. Self-assembled low-density QDs can be realized by careful control of the growth conditions. Here, we investigate the effect of different growth parameters to optimize telecom wavelengths

InP-based QD structures using molecular beam epitaxy with controlled properties in photonic and pin-diode structures. The QDs structures with and without doping were grown on distributed Bragg reflectors to enhance the light emission. Using proper doping levels, high-quality QDs can be embedded in pindiode structures. Low-temperature *-PL measurements show bright single QD emission around 1.55 *m with narrow linewidth and low fine-structure splitting. Furthermore, studies related to doped QD structures and fabrication of pin-diode structures emitting at telecom wavelength are presented.

#### HL 25.58 Wed 18:00 P2

Energy dependent tunnel coupling of QDs to a reservoir at elevated temperatures — •ISMAIL BÖLÜKBASI¹, IBRAHIM ENGIN¹, PATRICK LINDNER², ARN BAUDZUS¹, ANDREAS D. WIECK¹, BJÖRN SOTHMANN³, and ARNE LUDWIG¹ — ¹Ruhr-Universität Bochum, D-44780 Bochum, Germany — ²TU Dortmund, D-44221, Dortmund, Germany — ³Theoretische Physik, Universität Duisburg-Essen and CENIDE, D-47048 Duisburg, Germany

Quantum dots have interesting physical properties and allow research in zero dimensional systems. They are used in modern displays and are highly efficient sources of high-fidelity single photons [1]. For their applicability, it is advantageous to understand the electrical properties and tunnelling behaviours of QDs coupled to a charge reservoir. Capacitance-voltage spectroscopy is used to characterize quantum dots by electronically accessing the quantized states. A resonance shift with temperature in the ground-state charging peaks, the s-type states [2] originates from the degeneracy of the one- and two electron quantum states. An approach to model these measurements with a master equation [3] can describe these shifts including excitonic and non-equilibrium states. It is however limited to constant tunnel-coupling. We present experimental observations like frequency dependent peak shifts that need an extended model and propose an improved master equation approach to address this behaviour.

[1] Tomm et al. (2021) Nat. Nanotechnol. 16(4) [2] Brinks et al. (2016) New Journal of Physics, 18(12). [3] Valentin et al. (2018) Physical Review B, 97(4).

#### HL 25.59 Wed 18:00 P2

Auger Recombination Rate: Magnetic Field Dependence in a Self-Assembled Quantum Dot — •FABIO RIMEK¹, HENDRIK MANNEL¹, MARCEL ZÖLLNER¹, ARNE LUDWIG², ANDREAS D. WIECK², AXEL LORKE¹, and MARTIN GELLER¹ — ¹Faculty of Physics and CENIDE, University Duisburg-Essen, Germany — ²Chair of Applied Solid State Physics, Ruhr-University Bochum, Germany

A quantum dot (QD) is an ideal system to study electron-electron interaction in a confined nanostructure [1]. The Auger recombination is a special case, where the recombination energy is transferred to a third charge carrier that leaves the dot

In this work, we investigate how the Auger rate is affected by an external magnetic field, applied perpendicular to the plane of the dots. In the magnetic field, the trion transition of a QD is no longer spin degenerate and splits up. We use two-color, time-resolved resonance fluorescence to investigate the quenching of the trion recombination by the Auger effect. Two-color excitation allows us to excite two quantum dot transitions and neglect spin relaxation as well as spinflip Raman scattering. This ensures that we can directly measure the Auger and the tunneling rate of an electron into the dot.

HL 25.60 Wed 18:00 P2

Effects of bias-cooling on charge noise in gated Si/SiGe quantum dots — •JULIAN FERRERO¹, DANIEL SCHROLLER¹, THOMAS KOCH¹, VIKTOR ADAM¹, RAN XUE², INGA SEIDLER², LARS SCHREIBER², HENDRIK BLUHM², and WOLF-GANG WERNSDORFER¹ — ¹Physikalisches Institut, KIT Karlsruhe — ²II. Physikalisches Institut, RWTH Aachen

Electron spins in gated Si/SiGe quantum dots provide a great potential in scalable quantum-computing platforms due to their long coherence times and wide tunability. However, charge noise in the vicinity of the qubit region decreases the two-qubit gate fidelities that are needed for up-scaled error correction. Furthermore, the devices drift to different working points and need to be retuned regularly. The source of fast charge noise is thought to arise from twolevel fluctuators in the aluminium oxide dielectric, whereas the drift can be caused by slow charging of the silicon cap. A feasible possibility to suppress such noise and drift is the application of a bias voltage on all gates during cool down. This project strives to investigate the effects of different bias-coolings on charge noise using simultaneous current spectroscopy and peak tracking of two single electron transistors. Since the involved processes range on a wide time scale, the noise spectrum is investigated between 50 microhertz and 1 kilohertz.

### HL 25.61 Wed 18:00 P2

**Characterization of InGaAs quantum dots as active region for edge emitting laser with emission in the telecom O-band** — •PHILIPP NOACK — Institut für Halbleiteroptik und funktionelle Grenzflächen, Universität Stuttgart, Deutschland

Generally, laser diodes with quantum dots as active region are superior to quantum well laser diodes in terms of threshold current and temperature stability. Additionally, stacking of quantum dot layers can provide a broad gain spectrum, which can be ideally used for the fabrication of tunable laser devices with large bandwidth.

To this end, indium gallium arsenide quantum dots with emission in the telecom O-band wavelength range around 1300nm are grown at high densities with MOVPE and characterized with photoluminescence and atomic force microscopy measurements. We have designed edge emitting structures with waveguide simulations and characterized them using the segmented contact method. Parameters for the growth, like the V/III material ratio, were adjusted to create high density InGaAs quantum dots in a single layer. The emission intensity was further enhanced by the incorporation of a dots in well structure, an arsine interruption during growth and vertical stacking of quantum dot layers.

Following the design of the laser device, characterizations of edge emitting structures with one and multiple QD layer with regards to absorption characteristics were performed, which allowed for the characterization of the intrinsic losses of differently structured devices.

Wavelength tuning mechanisms in GaAs based-photonic integrated circuits — •ULRICH PFISTER¹, FLORIAN HORNUNG¹, STEPHANIE BAUER¹, ERIC REUTTER², MICHAEL JETTER¹, SIMONE L. PORTALUPI¹, JÜRGEN WEIS², and PETER MICHLER¹ — ¹Institut für Halbleiteroptik und Funktionelle Grenzflächen (IHFG), Center for Integrated Quantum Science and Technology (IQST) and SCoPE, Universität Stuttgart — ²Max-Planck-Institut für Festkörperforschung (MPI)

InGaAs quantum dots (QDs) grown in GaAs-based photonic integrated circuits are promising candidates to fulfill the requirements for basic on-chip photonic quantum computing gates. The necessary optical elements like beam splitters, on-chip detectors and waveguide structures have already been realized. An important step towards more complex experiments is to control the emission wavelength of the QDs. Recently, we matched the emission wavelength of a QD with a cavity-waveguide mode by applying strain with piezo electric actuators, resulting in Purcell enhancement [1]. Additionally, we discuss other tuning mechanisms like the crystallization of HO₂ which has been already demonstrated for self-standing GaAs waveguides [2].

### HL 25.63 Wed 18:00 P2

High-resolution spectroscopy of single photons from a self-assembled quantum dot — •LUCAS STAHL¹, HENDRIK MANNEL¹, FABIO RIMEK¹, MARCEL ZÖLLNER¹, ANDREAS WIECK², ARNE LUDWIG², MARTIN GELLER¹, and AXEL LORKE¹ — ¹Faculty of Physics and CENIDE, University of Duisburg-Essen, Duisburg, Germany — ²Chair of Applied Solid State Physics, Ruhr-University Bochum, Germany

Self-assembled quantum dots (QD) are highly promising as building blocks for applications in future quantum information technologies, where single confined spin states can form a qubit that can be transferred to a single photon. This requires long spin and photon coherence times [1], which have been demonstrated to be limited by spin- and charge-noise as well as co-tunneling with a reservoir [1]. These dephasing mechanisms affect the linewidth of the emitted photons.

In order to study various dephasing processes that occur on the exciton and trion transition in resonance fluorescence on a single dot, we set up a laserstabilized high-finesse Fabry-Perot-interferometer. By using a single-photon detector in combination with a picosecond time-tagger and a newly-developed post-processing method for stabilization, we obtained an interferometer resolution of 8 MHz.

This high-resolution enables us to detect dephasing mechanisms in the linewidth of the dot and to understand the influence of the Auger-scattering [2] of the trion transition in resonance fluorescence.

### HL 25.64 Wed 18:00 P2

Growth and characterisation of local droplet etched InAs quantum dots in an InGaAs matrix — •NIKOLAI SPITZER, ARNE LUDWIG, and ANDREAS WIECK — Ruhr- Universitaet Bochum, Lehrstuhl fuer Angewandte Festkoerperphysik, Universitaetsstraße 150, 44801 Bochum, Germany

We present a new local droplet etching (LDE) method for selforganized InGaAs quantum dots (QDs). We use gallium droplets to etch on an InGaAs matrix layer and fill the nanoholes with InAs. The impact of the indium concentration in the InGaAs-layer and of the deposited InAs amount after etching is investigated by atomic force microscopy and photoluminescence spectroscopy.

### HL 25.65 Wed 18:00 P2

Three-photon excitation of InGaN quantum dots — •VIVIANA VILLAFANE¹, BIANCA SCAPARRA¹, MANUEL RIEGER¹, STEPHAN APPEL¹, RAHUL TRIVEDI², TONGTONG ZHU³, JOHN JARMAN³, RACHEL OLIVER³, ROBERT TAYLOR⁴, JONATHAN FINLEY¹, and KAI MUELLER¹ — ¹Walter Schottky Institut, TUM, Garching, Germany — ²Max-Planck-Institute for Quantum Optics, Garching, Germany — ³Department of Materials Science, University of Cambridge, UK — ⁴Clarendon Laboratory, University of Oxford, UK

Solid-state quantum emitters are prominent examples of systems showing excellent agreement between theoretical predictions and experimental measurements, being commonly taken as evidence that the fundamental physics of quasi two-level quantum emitters is almost fully understood. In our work, we explore multi-photon absorption selection rules in semiconductor quantum dots within the dipole approximation. It can be proven that given a two-level quantum system, if the excitation scheme involves N-photons of the same energy and polarization, either all even or odd resonances are enhanced, based on the parity of the ground and excited states. We demonstrate that semiconductor quantum dots can be excited efficiently in a resonant three-photon process, whilst resonant two-photon excitation is highly suppressed. Time-dependent Floquet theory is used to quantify the strength of the multi-photon excitation scheme alows us to measure directly the radiative lifetime of InGaN QDs and obtain a greater degree of linear polarization.

### HL 25.66 Wed 18:00 P2

Lattice thermal expansion of as-grown GaAs nanowires due to optical excitation measured by X-ray pump probe experiment — •TASEER ANJUM^{1,2}, FRAN-CISCA LARGO², WAHEED SALEHI¹, MATTHIAS RÖSSLE³, OLIVER BRANDT², LUTZ GEELHAAR², and ULLRICH PIETSCH¹ — ¹Festkörperphysik, Universität Siegen, Siegen, Germany — ²Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Berlin, Germany — ³Helmholtz-Zentrum Berlin für Materialien und Energie, Wilhelm-Conrad-Röntgen Campus, BESSY II, Berlin, Germany

We investigated the transient structural response in the ensemble of AlxIn1xAs/GaAs core-shell NWs, grown on Si (111) substrate when irradiated with femtosecond laser pulses via x-ray pump-probe experiment at KMC3-XPP & P08 beamlines of Bessy II & PETRA III respectively. Femtosecond laser irradiation of solids excites photoelectrons from valance band to conduction and triggers a cascade of fundamental dynamical processes that occur on the picosecond to nanosecond time scales such as excitation and thermal equilibration of phonons. We observe a linear behavior of strain and temperature for the first few hundreds of picoseconds followed by the thermal relaxation up to few ns. Thinner NWs cool down slowly in comparison to thicker NWs which suggests a direct dependence of thermal conductivity on the diameter. Through time-resolved x-ray pump-probe experiments we identified the thermal relaxation processes and the dynamics of the structural response of two NW samples.

#### HL 25.67 Wed 18:00 P2

Investigation of the Correlation between Quantum Dot Density and Photoluminescence Intensity — •SIMON SCHLOMBS, NIKOLAI SPITZER, NIKOLAI BART, ANDREAS WIECK, and ARNE LUDWIG — Angewandte Festkörperphysik, Ruhr-Universität Bochum, Universitätsstraße 150, D-44780 Bochum

Semiconductor devices based on quantum dots (QDs) require good knowledge of the QD density. Capacitance voltage spectroscopy (C(V)) enables the measurement of buried QDs; however, it requires extensive prior processing of the samples and only allows small areas to be measured. In this work the correlation between QD density and photoluminescence (PL) intensity is investigated. For this purpose, the quantum dot density along a density gradient has been determined and compared to PL measurements. The measured intensity is strongly dependent on the sample structure (absorption, thin-film interference). Because of this the intensity is corrected by an experimentally determined factor. The results allow for an optical determination of the QD density of entire wafers for an arbitrary sample structure.

### HL 25.68 Wed 18:00 P2

**Metallic nanowires assembled by DNA Origami** — •BORJA RODRÍGUEZ-BAREA¹, SHIMA JAZAVANDI-GHAMSARI¹, ARCHA JAIN¹, TÜRKAN BAYRAK¹, JINGJING YE², RALF SEIDE², ENRIQUE SAMANO³, and ARTUR ERBE¹ — ¹Institute of Ion Beam Physics and Material Science, Helmholtz-Zentrum Dresden-Rossendorf, Germany — ²Peter Debye Institute for Soft Matter Physics, Universität Leipzig, Germany — ³Centro de Nanociencias y Nanotecnología-UNAM, Ensenada, B.C., México

In the pursuing to increase the processing power, electronic circuits look for new bottom-up strategies. Namely, (DNA) nanotechnology has shown valuable tools for the creation of nanostructures of arbitrary shape that can be used as templates. Here we demonstrate the formation of 1D Au nanostructures based on DNA Origami templates. DNA nanomolds are employed, inside which gold deposition is employed by site-specific attached seeds. To prove their metallic nature, top-down approach allows us to perform temperature-dependent charge transport measurements along the nanostructures. Transport through these assemblies is strongly nonlinear and shows a decrease in conductance towards low temperatures. Thanks to the converging of both fabrication approaches, the shape of the nanowires can be controlled and measured. We use DNA-origami templates which are functionalized on their surface in order to create desired shapes of the metallic nanostructures and the nanoparticles show temperature dependent charge transport measurements reveal the dominating charge transport mechanisms along these wires.

### HL 25.69 Wed 18:00 P2

**Multi-Orbital Kondo Effect in Few-Electron Quantum Dots** — •OLFA DANI¹, JOHANNES BAYER¹, TIMO WAGNER¹, GERTRUD ZWICKNAGL², and ROLF J. HAUG¹ — ¹Institut für Festkörperphysik, Leibniz Universität Hannover, Germany — ²nstitut für Mathematische Physik, Technis- che Universität Braunschweig, Germany

The Kondo effect is a many particle entangled system, that involves the interaction between a localized spin in the quantum dot and free electrons in the electron reservoirs. This entanglement can be calculated using simplifying assumptions concerning the electronic structure of the quantum dot.

We investigate a lateral quantum dot with a small number of electrons, formed electrostatically in a two-dimensional electron gas using top-gates. A quantum point contact was operated as a sensitive charge detector allowing the detection of single-electron tunneling through the system, which enables us to know the exact number of electrons N in the quantum dot. The latter is varied by changing the applied gate voltage.

For a strong coupling to the leads and possible symmetrical tunnel barriers, a Zero-bias anomaly (ZBA) is observed. This Kondo resonance appears for successive N showing a deviation from the conjectured odd-even behavior. The observed ZBA is strongest for N=9 and displays a particle-hole symmetry for N=7,..,11. It is absent for N=6 and N= 12. This observations indicate the influence of the shell structure of the electronic states in the quantum dot where orbital degeneracy is present.

### HL 25.70 Wed 18:00 P2

**Grating Couplers on a III-V Semiconductor Platform for Single-Photon Applications** — •VALENTINO MERKL, STEPHANIE BAUER, ROBERT SITTIG, SIMONE LUCA PORTALUPI, MICHAEL JETTER, and PETER MICHLER — Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology ( $IQ^{ST}$ ) and SCoPE, University of Stuttgart, Allmandring 3, 70569 Stuttgart

Photonic quantum computing is one of the most studied fields of the 21st century, with the potential to revolutionize computation as we know it today. Using integrated quantum photonics to miniaturize setups, it is possible to increase the computation complexity drastically. For this purpose a III-V semiconductor platform is highly advantageous, as it enables the possibility of integrating quantum dots as single photon sources, which cannot be done on silicon based platforms. They utilize the beneficial aspects of non-classical light for the computation. In some applications it is necessary to couple light from a chip into single mode fibers or vice versa. For this purpose, grating couplers, which demonstrated high coupling efficiencies of up to 89% on the silicon platform, are a highly versatile and promising method. In this contribution, we will present simulation results, fabrication steps and measurements on grating couplers constructed on the GaAs/AlOx platform. Using 2D and 3D FDTD simulations, these structures are optimized to have high coupling efficiencies in the near infrared regime and common telecom frequencies matching the emission wavelength of the QDs.

### HL 25.71 Wed 18:00 P2

Heat Radiation of Semiconductor Wafers — •BASTIAN SCHMÜLLING, TIMO KRUCK, ANDREAS D. WIECK, and ARNE LUDWIG — Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Uni Bochum

This work is about the struggles of pyrometer measurements of substrate temperature during molecular beam epitaxy (MBE) growth. During the growth of a typical GaAs wafer, a substrate temperature of 300 to 650 degree celsius is required. In our setup, a wafer is mounted in front of a radiation heater. To measure the substrate temperature, a pyrometer measures the thermal radiation. During growth, the substrate temperature is of utmost importance. However, the reflectivity and thus the emissivity changes with each additional layer deposited and the temperature measured by the pyrometer varies accordingly. These pyrometer measurements can be used to measure the growth rate. We plan to combining reflectometry and pyrometry during growth, to determine the actual temperature of the wafer.

HL 25.72 Wed 18:00 P2 **Density Modulation of InAs/GaAs Quantum Dots and Pre Dots** — •PETER ZAJAC¹, NIKOLAI BART¹, CHRISTIAN DANGEL², KAI MÜLLER³, ANDREAS D. WIECK¹, JONATHAN FINLEY², and ARNE LUDWIG¹ — ¹Ruhr-Universität Bochum, Universitätsstraße 150, 44801 Bochum, Germany — ²Walter Schottky Institut and Physik Department, Technische Universität München, Am Coulombwall 4, 85748 Garching, Germany — ³Walter Schottky Institut and Department of Electrical and Computer Engineering, Technische Universität München, Am Coulombwall 4, 85748 Garching, Germany

Epitaxial layer-by-layer growth without rotation of the substrate creates a thickness gradient along the surface with alternating smooth and rough layer areas. InAs quantum dots (QDs) grown on top of a GaAs gradient layer exhibit a density modulation along this gradient, which is studied with macro photoluminescence spectroscopy and atomic force microscopy (AFM). The periodicity of the modulation can be varied from a few hundred microns to several millimeters, depending on the thickness of the underlying gradient layer. Automated AFM measurements, covering multiple modulation periods along the gradient allow the investigation of wetting layer roughness, QD density and density of a smaller species of QDs, termed pre dots. AFM data analysis and extraction of parameters such as QD and monolayer step density is presented.

### HL 25.73 Wed 18:00 P2

Calibrating Photoluminescence Yield for Quantum Emitters in Planar Photonic Heterostructures — •TIMO KRUCK, HANS-GEORG BABIN, DANIAL KOHMINAEI, SAYED SADAT, ANDREAS D. WIECK, and ARNE LUDWIG — Ruhr-Universität-Bochum; Lehrstuhl für angewandte Festkörperphysik, Bochum, Deutschland

When performing photoluminescence (PL) measurements, the spectral intensity of the emitted radiation strongly depends on the dielectric structure sourrounding the quantum emitter. Here we show a method for calibrating PL measurements to obtain the unaltered spectrum of the optically active medium. For this purpose, the spectral reflectivity and the wavelength dependent standing wave field are used. The reflectivity is determined by reflectometer measurements and a simulation based on the transfer matrix method are used to compensate for the true layer thickness. This is then used to calculate the standing wave field, the outcoupling efficiency and the quantum yield. To validate the method, the calibrated spectra are compared with cleaved-edge PL measurements where the QDs are excited from the side and the light is also collected from the side.

#### HL 25.74 Wed 18:00 P2

Development of deterministic fabrication of quantum systems for single photon delay at Cesium wavelength — •AVIJIT BARUA¹, MONICA PENGERLA¹, LUCAS BREMER¹, LUCAS RICKERT¹, JIN-DONG SONG², and STEPHAN REITZENSTEIN¹ — ¹Technische Universität Berlin, Berlin, Germany — ²Korea Institute of Science and Technology, Seoul, Republic of Korea

Semiconductor QDs are extensively investigated as single-photon sources for photonic quantum technology. The information that is encoded in single pho-

tons may be used as quantum interfaces between stationary and flying qubits. Here, we develop bright and strain-tunable QD single-photon sources at the Cs D1 transition wavelength (894 nm) to explore the storage ability of semiconductor QD in atomic quantum memories. The devices are designed and numerically optimized to maximize the extraction efficiency using the FEM solver JCMSuite. By considering circular Bragg resonators with up to 2 rings with integrated QDs and an Au-backside mirror we numerically demonstrate a photon extraction efficiency as high as 65% (NA = 0.4) and a Purcell factor of 0.72. In the experimental development, we realized hybrid CBGs which facilitate Piezo-strain tuning of the QD device. We then implement in-situ electron-beam lithography to precisely integrate the selected single QD at 894 nm in such a structure to create bright single-photon sources. Furthermore, the emission from the developed structures is studied by means of photon autocorrelation measurements, and light-matter interaction with Cs vapor is investigated.

#### HL 25.75 Wed 18:00 P2

Purcell enhanced two indistinguishable emissions from two separated quantum dots for on-chip complex photonics quantum circuits — •YUHUI YANG¹, SHULUN LI^{1,2}, JOHANNES SCHALL¹, SVEN RODT¹, ZHICHUAN NIU², and STEPHAN REITZENSTEIN¹ — ¹Institut für Festkörperphysik, TU Berlin, Berlin, Germany — ²State Key Laboratory for Superlattice and Microstructures, Institute of Semiconductors, Chinese Academy of Sciences, Beijing, China

Quantum dots (QDs) are excellent single-photon emitters with a close to ideal quantum nature of emission. For large-scale integrated photonic quantum circuits, indistinguishable and bright single photons emitted by independent QDs are required. In this regard, QDs integrated into nanocavities that are compatible with on-chip waveguide systems are highly interesting since they have a small footprint while providing strong Purcell enhancement.

Here, we demonstrate the deterministic integration of two spectrally similar single QDs in separate, one-dimensional photonic crystal nanobeam cavities with significant Purcell enhancement. Our flexible and accurate deterministic fabrication concept allows us to combine the nanobeam waveguides with integrated QDs into a 2 2 on-chip multimode interferometer (MMI) beam splitter with a 50/50 splitting ratio to perform on-chip Hanbury Brown and Twiss (HBT) and Hong-Ou-Mandel (HOM) measurements. The obtained results demonstrate that our approach is very promising toward two-photon interference from monolithic independent single-photon emitters, and fully integrated photonic quantum circuits.

### HL 25.76 Wed 18:00 P2

**Experimental and numerical investigation of the evanescent coupling between an integrated micropillar laser and a ridge waveguide** — •Léo Roche¹, IMAD LIMAME¹, CHING-WEN SHIH¹, YUHUI YANG¹, SHULUN LI^{1,2}, and STEPHAN REITZENSTEIN¹ — ¹Institut für Festkörperphysik, Technische Universität Berlin, Hardenbergstraße 36, 10623 Berlin, Germany — ²State Key Laboratory for Superlattice and Microstructures, Institute of Semiconductors, Chinese Academy of Sciences, Beijing 100083, China

Integrated Quantum Photonic Circuits (IQPCs) are very promising candidates for scalable and flexible on-chip quantum computation and quantum communication hardware. One critical requirement for their realization is the scalable integration of on-demand indistinguishable single-photon emitters. This is potentially possible through the resonant excitation of an integrated QD in a waveguide by means of an on-chip integrated coherent light microlaser. Towards this goal, we investigate the coupling and lasing properties of coherent light laterally emitted from a whispering gallery mode (WGM) type micropillar laser evanescently coupled to a single mode ridge waveguide. Using finite element method (FEM) simulations, we investigate the coupling efficiency and the Q-factor of the pillar-waveguide system for different angular mode number and various pillarwaveguide air gap distances. The III-V semiconductor type nanostructures composed of a GaAs cavity with InAs QDs and distributed Bragg reflectors are carefully processed using electron beam lithography and then measured using microphotoluminescence spectroscopy.

### HL 25.77 Wed 18:00 P2

Building charge detection in indium antimonide nanowires for scanning tunneling microscopy using gate-defined quantum dots — •Kanji Furuta¹, Felix Jekat¹, Benjamin Pestka¹, Sasa Gazibegovic², Diana Car², Sebastian Heedt³, Marcus Liebmann¹, Thomas Schäpers³, Erik Bakkers², and Markus Morgenstern¹ — ¹II. Phys. Inst. B, RWTH Aachen Univ., Germany — ²Dept. of Appl. Phys., Eindhoven Univ., The Netherlands — ³PGI-9, FZ Jülich, Germany

InSb nanowires are investigated with respect to suitability as a charge detector to be combined with scanning tunneling microscopy. Mechanically exfoliated hexagonal boron nitride (h-BN) as a dielectric is placed onto bottom finger gates (50 nm wide, 30 nm spacing). The nanowires are then aligned and placed mechanically onto h-BN. We present transport measurements on gate-defined quantum dots at temperatures down to 300 mK. Due to the dielectric, the time stability of our device improved to around 5  $\mu$ eV/h. The charge stability diagram shows Coulomb diamonds with a charging energy of 2.5 meV and an orbital energy of 0.3 meV. Depending on the gate and magnetic field, additional transport channels are occasionally observed, causing additional lines in the charge stability diagram and a shift of the Coulomb peak pattern around a magnetic field of  $\approx$  400 mT. This points to the presence of an unintentional second quantum dot in the gate region. Different configurations are discussed in terms of their coupling to the leads and the main dot, and their effects on charge detection.

#### HL 25.78 Wed 18:00 P2

**Coherent manipulation of GaAs quantum dot spin qubits using microwaves** — •ANKITA CHOUDHARY¹, NAND LAL SHARMA¹, MORITZ LANGER¹, GHATA SATISH BHAYANI¹, URI VOOL², and CASPAR HOPFMANN¹ — ¹Leibniz Institute for Solid State and Materials Research, Dresden — ²Max Planck Institute for Chemical Physics of Solids, Dresden

Spin qubits in semiconductor quantum dots are attractive resources for performing quantum computations. In these systems single optically addressable spin qubits can be realized by single confined charge carriers, electrons, heavy holes, and their excited states. The quantum dot spin qubit coherence is however limited due to their semiconductor environment due to spin-orbit coupling to the magnetic moments of the atomic nuclei. Our goal is to facilitate the heralded and deterministic spin state preparation as well as to minimize the decoherence. While the all-optical heralded preparation of spin states in GaAs quantum dots has been demonstrated by us [1], the latter may be achieved by coherent manipulation of the spin states using the spin echo technique [2]. Our immediate goal is therefore to enable coherent manipulation of quantum dot spin qubits via injection of microwave pulses by superconducting co-planar waveguide structures. This technique will allow us to achieve full manipulation of the quantum dot and we expect to be able to achieve strong interaction between microwaves and quantum dot spin qubits, which could enable the coherent coupling between superconducting and quantum dot qubits. [1] C. Hopfmann et al, PRB 104, 75301 (2021). [2]F. H. L. Koppens et al, PRL 100 (2008).

### HL 25.79 Wed 18:00 P2

Synthesis of ZnS nanoparticles investigated by in-situ X-ray scattering and spectroscopy — •LARS KLEMEYER, TJARK GROENE, OLGA VASYLIEVA, FRANCESCO CADDEO, SANI HAROUNA-MAYER, and DOROTA KOZIEJ — Universität Hamburg, Insititut für Nanostruktur- und Festkörperphysik, Center for Hybide Nanostructures, Luruper Chaussee 149, 22761 Hamburg

Transition metal sulfides are promising materials for a variety of applications. Especially the electronic configuration of the d-orbitals leads to unique electronic properties of transition metals and their compounds. Zinc sulfide (ZnS) is one of the most widely used transition metal sulfide due to its broad availability and relatively low toxicity as well as saturated d-orbitals. However, the synthesis approaches of ZnS nanoparticles in solution are not fully understood. We show complementary analysis with in-situ pair distribution function (PDF) and in-situ X-ray spectroscopy of the solvothermal synthesis of ZnS for a comprehensive picture of the nucleation and growth from precursors to nanoparticles.

#### HL 25.80 Wed 18:00 P2

Efficient frequency filtering of quantum dot photons using a self-constructed transmission grating monochromator — •MORITZ MEINECKE, SVEN HÖFLING, and TOBIAS HUBER — Lehrstuhl für Technische Physik, Universität Würzburg, 97074 Würzburg, Germany

Many spectroscopic measurements for characterizing quantum dot emission lines require spectral signal filtering that is narrower or matched to the expected line widths to analyze photons from different single excitonic charge complexes. Furthermore, to use the quantum dot photons for applications, this filtering should be efficient. A classical reflection monochromator is not ideal for this purpose, since it often comes with a low filter efficiency when the light is coupled to fiber, which is required for photon detection with superconducting nanowire detectors and for usage in any application. Furthermore, a reflection monochromator is strongly polarization dependent, which limits its use to non-polarization sensitive measurements, or requires polarization projection before frequency filtering. Alternative filter optics, like bandpass filters, have low flexibility and often need time consuming adjustments.

Here, we present a self-constructed transmission grating monochromator. It allows efficient, frequency filtering of quantum dot emission lines in the near infrared region. It is fully automatized and precise in approaching any filter position. Furthermore, the nearly polarization independent performance allows for polarization sensitive measurements.

### HL 25.81 Wed 18:00 P2

**Establishment of a method to make PL measurements on optically active layers in different dielectric structures comparable** — •SAYED SHKEEBUL-LAH SADAT, DANIAL KOHMINAEI, TIMO KRUCK, HANS-GEORG BABIN, ANDREAS WIECK, and ARNE LUDWIG — Ruhr-Universität Bochum, Bochum, Deutschland To improve extraction of photoemission from optically active layers such as quantum dots (QDs) or quantum wells (QWs) one can e.g. grow them inside dielectric structures (DBR - distributed Bragg reflector). However, the emerging wavelength-dependent standing wave field alters the spectral intensity of the quantum emitters, which means straightforward comparisons of photoluminescence (PL) measurements are no longer possible. Therefore we present a method by which you can obtain the unaltered spectrum. To calculate the standing field we determine the specific reflectivity first and adjust it to the true thickness of the layers. From here it is possible to determine the efficiency of the photon extraction and thus the quantum yield, which allows us to calibrate and transfer the spectra back to its unmodified form. Since this can be performed on any dielectric structure it now is possible to compare the calibrated spectra with each other. Furthermore there is a possibility to automate this process, allowing the instantaneous comparison of PL measurements on optically active layers in DBR surroundings. To verify the validity of this method the calibrated spectrum is compared to the spectra of cleaved-edge probes, where the DBR has no notable influence since the photons are detected from the side here.

### HL 25.82 Wed 18:00 P2

Quantum efficiency boost by photoneutralization of charges in GaAs quantum dots based entangled photon emitters — JINGZHONG YANG¹, •TOM FANDRICH¹, FREDERIK BENTHIN¹, ROBERT KEIL², NAND LAL SHARMA², WEIJIE NIE², CASPAR HOPFMANN², OLIVER G. SCHMIDT^{2,3,4}, MICHAEL ZOPF¹, and FEI DING^{1,5} — ¹Institut für Festkörperphysik, Leibniz Universität Hannover — ²Institute for Integrative Nanosciences, Leibniz IFW Dresden — ³Material Systems for Nanoelectronics, Technische Universität Chemnitz — ⁴Nanophysics, Faculty of Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden — ⁵Laboratorium für Nano- und Quantenengineering, Leibniz Universität Hannover

Single- and entangled-photon sources are a key component of photonic applications in i.e. quantum communication. GaAs quantum dots are very promising candidates because of their compatibility to integrated photonic structures and the ability to generate photons on demand with low multiphoton emission, near-unity entanglement fidelity and high indistinguishability. One limiting factor is the emission blinking of the resonance fluorescence. This reduces the efficiency and limits the scalability in quantum networks. The neutral biexciton is resonantly excited via two-photon excitation displaying such blinking behavior. By introducing an additional weak off-resonant excitation, the balance of free charges close to the quantum dot was controlled. This leads to a reduction of blinking caused by the intrinsic Coulomb blockade due to captured charges. This method increases the excitation efficiency by 30% while maintaining the fidelity of the entangled-photon pairs.

### HL 25.83 Wed 18:00 P2

**Frequency Shift of Electronic Resonances in Self Assembled InAs Quantum Dots** — **•I**BRAHIM AZAD ENGIN¹, ISMAIL BÖLÜKBASI¹, ARN BAUDZUS¹, PATRICK LINDNER², ANDREAS WIECK¹, BJÖRN SOTHMANN³, and ARNE LUDWIG¹ — ¹Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum, 44801 Bochum — ²Experimentelle Physik 2, Technische Universität Dortmund, 44227 Dortmund — ³Fakultät für Physik, Universität Duisburg-Essen, 47048 Duisburg Self-assembled InAs quantum dots (SAQD) proved to be promising semiconductor structures for applications as single-photon sources [1]. Especially, charge stabilization by coupling to a reservoir is important for quantum memory resources [2].

In this contribution, we investigate InAs SAQDs in a diode structure coupled to an electron reservoir by capacitance-voltage-spectroscopy to electrically probe QD energy levels and vary parameters like ac-frequency and bath temperature. For the lowest energy s-states a thermal shift in equilibrium has been reported [3]. Non-equilibrium coupling has been observed and described with a master equation [4], where resonance shifts at higher frequencies and temperature remain unexplored. We rectify this here by proposing a more elaborated model and experimental data interpretation.

**Droplet epitaxy of InGaAs quantum dots for spin-photon interface devices** — •XUELIN JIN^{1,2}, DAVID FRICKER^{1,2}, NILS VON DEN DRIESCH^{1,3}, ALEXANDER PAWLIS^{1,3}, RENU RANI^{1,3}, MINH BUI^{1,3}, DETLEV GRÜTZMACHER^{1,2}, and BEATA KARDYNAL^{1,2} — ¹PGI 9, Forschungszentrum Jülich, 52425 Jülich, Germany — ²Department of Physics, RWTH Aachen, 52074 Aachen, Germany — ³PGI 10, Forschungszentrum Jülich, 52425 Jülich, Germany

Abstract. Quantum networks use photonic qubits to send information, that means photonic qubits need to be converted into stationary qubits at the network nodes. A transfer information from a photonic to a spin qubit has been already demonstrated. Here we study the possibility of transferring photonic qubits into spin qubits which offer a potential of scaling into quantum processors, ones in gate-defined quantum dots in GaAs. Since gate-defined quantum dots do not confine holes, a direct conversion of photon qubits into spin qubits in these quantum dots is not possible. Here, we explore the possibility of using self-assembled InGaAs quantum dots grown by droplet epitaxy as an optical interface to the gated quantum dots defined in GaAs. We will discuss the con-

ditions that the heterostructure has to fulfil to facilitate tunable tunnel coupling between the two quantum dots and we will show the progress in its growth and characterisation. In order to maintain the stable operation of the gated quantum dots, we use droplet epitaxy to grow InGaAs QDs. We will show that this method allows us to create quantum dots with energies suitable for tunnel coupling and minimize the impact of the wetting layer on the two-dimensional electron gas.

### HL 25.85 Wed 18:00 P2

Deterministic Coupling of Gold Nanorods with GaAs Quantum Dots — •YINAN WANG¹, PENGJI LI¹, CHENXI MA¹, ANDREAS SCHELL^{1,2}, MICHAEL ZOPF¹, and FEI DING^{1,2} — ¹Institut für Festkörperphysik, Leibniz Universität Hannover, Appelstraße 2, 30167 Hannover, Germany — ²Laboratorium für Nano- und Quantenengineering, Leibniz Universität Hannover, Schneiderberg 39, 30167 Hannover, Germany

Coupling single-photon sources with metal nanoparticles is an emerging topic in quantum optics. Thus the deterministic fabrication of metal nanoantennas is crucial. Here we report our recent efforts on coupling single gold nanorods to single GaAs quantum dots. Two different techniques were investigated: (1) drop-casting a gold nanorod containing solution on the quantum dot sample, and (2) deterministic nano-manipulation of gold nanorods via Pick-and-Place functionalities of an atomic force microscope. We observed the modified photoluminescence of quantum dots, due to their coupling to the localized surface plasmons of the gold nanoparticles. The experimental details and also kinetic modeling will be also shown in detail.

Measurement and calculation of spectral emissivity of semiconductor quantum emitters in dielectric environments — •DANIAL KOHMINAEI, SAYED SHKEEBULLAH SADAT, TIMO KRUCK, HANS-GEORG BABIN, ANDREAS D. WIECK, and ARNE LUDWIG — Ruhr-Universität Bochum; Lehrstuhl für angewandte Festkörperphysik, Deutschland

Quantum dots (QDs) emit light divergently. For improved outcoupling of this photon emission, QDs are grown above so-called distributed Bragg reflectors (DBRs), which have a maximum reflectivity at the wavelength of the light of the QDs. Reflection also occurs unwantedly at the interface of the semiconductor to the vacuum. Therefore, when performing photoluminescence (PL) measurements, the measured spectral intensity of the emitted radiation strongly depends on the (dielectric) structure of the sample. Here we show a method for calibrating PL measurements to obtain the unaltered spectrum of the optically active medium. First, the spectral reflectivity is determined by reflectometer measurements, and compared to a simulation based on the transfer matrix method for the true layer thickness. This is then used to calculate the wavelength dependent standing wave field, the outcoupling efficiency and the quantum yield. Furthermore, the influence of the absorption of the exciting laser light in the semiconductor, on the overall spectrum will be analyzed. To validate the method, the calibrated spectra are compared with cleaved-edge PL measurements, where the QDs are excited from the side and the light is also collected from the side.

### HL 25.87 Wed 18:00 P2

Fabrication & Electrical Characterization of Silicon-Germanium Nanowire Schottky Barrier Transistors — •MUHAMMAD MOAZZAM KHAN¹, OLIVER STEUER¹, SLAWOMIR PRUCNAL¹, and YORDAN M GEORGIEV^{1,2} — ¹Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstraße 400, D-01328 Dresden, Germany — ²Institute of Electronics at the Bulgarian Academy of Sciences, 72, Tzarigradsko chaussee blvd, 1784-Sofia, Bulgaria

CMOS scaling is reaching physical limits in near future. Therefore, new approaches are required to continue achieving high speed and high performance devices. Replacing silicon with silicon-germanium alloy as a channel material having higher mobility contributes to faster and energy-efficient devices. In this work, we are investigating the transistor properties built from silicon germanium based nanowire channel. Schottky Barrier Field Effect Transistors are fabricated, which also have an additional functionality of re-configurability. This means that a single device can be operated as an N or P channel just by controlling the electric potential applied at the gate terminals. The devices are fabricated by top-down approach with nickel metal pads on both sides of the silicon-germanium nanowire. To form schottky junctions, flash lamp annealing is performed to diffuse metal into the nanowires. The schottky junctions formed at the interface between nickel-germano-silicide and nanowire are electrically controlled to operate the device. Transfer characteristics of these devices are measured to investigate the transistor properties.

### HL 25.88 Wed 18:00 P2

realization of on-chip wavelength multiplexing with self-assembly InGaAs quantum dot in telecom C-band — •DONGZE WANG, STEPHANIE BAUER, MICHAEL JETTER, SIMONE PORTALUPI, and PETER MICHLER — Institut für Halbleiteroptik und Funktionelle Grenzflächen, Stuttgart, Germany

Photonic integrated circuits (PIC) are a highly appealing platform for the realization of quantum photonic devices on a scalable dimension. The technology of PIC has enabled the generation, processing, and detection of the quantum state of light. Several different material platforms for the realization of PIC were proposed and are currently under intense investigation. Gallium arsenidebased (GaAs) PIC provides a straightforward combination with a self-assembled quantum dot (QD), which can serve as an efficient on-demand single-photon source with high purity and indistinguishability. In this work, we present a wavelength-division multiplexing system based on indium gallium arsenide (In-GaAs) waveguides containing self-assembled InGaAs QDs located at the telecom C-band. The waveguide core is deposited on aluminum gallium arsenide (Al-GaAs), which provides large refractive index contrast resulting in good confinement for the propagating photons. The dimensional parameters of the singlemode waveguide were simulated by a finite-difference time-domain method. Afterwards, standard semiconducting nanofabrication processes including electron beam lithography and inductively coupled plasma-reactive ion etching technology were used to fabricate the InGaAs photonic chip.

### HL 25.89 Wed 18:00 P2

Magnetotransport in narrow-gap semiconductors with nanostructured constrictions — •OLIVIO CHIATTI¹, JOHANNES BOY¹, CHRISTIAN RIHA¹, CHRISTIAN HEYN², WOLFGANG HANSEN², and SASKIA F. FISCHER¹ — ¹Novel Materials Group, Humboldt-Universität zu Berlin, 10099 Berlin, Germany — ²Institut für Nanostruktur- und Festkörperphysik, Universität Hamburg, 20355 Hamburg, Germany

Measurements in magnetic fields are an effective tool to investigate transport properties of low-dimensional electron systems. We investigate the magnetotransport of semiconductor heterostructures and nanostructures with spin-orbit interaction (SOI), under the influence of in-plane and out-of-plane electric fields. The nanostructures are quantum point contacts (QPCs) etched in Hall-bars with in-plane gates. The Hall-bars and the constrictions were defined by micro-laser photolithography and wet-chemical etching from an InGaAs/InAlAs quantum well with an InAs-inserted channel [1]. We have performed transport measurements at low temperatures in the combined QPC and Hall-bar structures in magnetic fields. We can tune the gate-voltages to control the filling-factor mismatch between bulk Hall-bar and QPC. We observe a crossover from reflection to transmission of the quantum Hall edge channels at the QPC and a tunneling across the QPC between reflected edge states, which depends on the magnitude and direction of the in-plane electric field.

Acquisition and analysis of photocurrent spectra for 850 nm oxide-confined vertical-cavity surface-emitting lasers — Arndt JAEGER¹, MARWAN BOU Sanayeh², Helmut Meinert¹, •Manuel Haerer¹, Oleg Yu. Makarov², Ilya E. Titkov 2 , Nikolay Ledentsov Jr. 2 , and Nikolay N. Ledentsov 2  — ¹Esslingen University of Applied Sciences, Flandernstrasse 101, 73732 Esslingen, Germany — ²VI Systems GmbH, Hardenbergstrasse 7, 10623 Berlin, Germany Vertical-cavity surface-emitting lasers (VCSELs) are of utmost importance as key components for high-speed datacom, sensor and free-space applications. Therefore, for a successful further optimization of their performance, understanding their aging behavior is of crucial importance. The 850 nm oxide-confined VCSELs used in this study were intentionally operated at extreme conditions to accelerate their degradation until reaching optical damage. For monitoring operation-induced changes, a photocurrent spectroscopy (PCS) setup was established and applied before and after accelerated aging. The PCS results at different reverse biases reveal changes that can be explained by non-radiative recombination centers generated during accelerated aging. This finding contributes to the understanding of the aging mechanisms in these tiny devices.

#### HL 25.91 Wed 18:00 P2

Polariton condensation with extreme confinement of light — •MARIA VIT-TORIA GURRIERI¹, PHILIP KRISTENSEN¹, JESPER MORK¹, and EMIL DENNING² — ¹Department of Electrical and Photonics Engineering, Technical University of Denmark, 2800 Kgs. Lyngby, Denmark — ²Nonlinear Optics and Quantum Electronics, Technical University of Berlin, 10623 Berlin, Germany

Strong coupling between light and electronic excitations mixes the constituent eigenstates into hybrid polaritonic quasiparticles. Under certain conditions it is possible to predict the formation of a polariton condensate with macroscopic occupation number and spontaneous coherence in the ground state. This condensate is a source of coherent matter waves and photons.

In this work we theoretically investigate the possibility of achieving polariton condensation in an extended sheet of 2D semiconductor coupled to a novel dielectric nanocavity with deep subwavelength confinement and featuring a spectrally isolated mode. Such coupling leads to the formation of a spatially localized polariton state, which interacts with the continuum of excitons through Coulomb interaction. The system is modelled by a Born-Markov master equation for the polariton subsystem, where the exciton continuum is traced out. This enables the derivation of a rate equation model to describe the dynamics of the lower polariton population.

### HL 25.92 Wed 18:00 P2

Time resolved spin dynamics in lead halide hybrid organic perovskite **Fa**_{0.9}**Cs**_{0.1}**PbI**_{2.8}**Br**_{0.2} — •**E**RIK KIRSTEIN¹, EIKO EVERS¹, VASILII V. BELYKH^{1,2}, EVGENY A. ### HL 25.94 Wed 18:00 P2

Spin noise spectroscopy of a single InGaAs quantum dot at high magnetic fields — •KAI HÜHN, PAVEL STERIN, JENS HÜBNER, and MICHAEL OESTREICH — Institut für Festkörperphysik, Leibniz Universität Hannover, Appelstraše 2, 30167 Hannover, Germany

Single holes in InGaAs quantum dots hold great promise as potential qubits due to the slow relaxation of selected spin degrees of freedom. However, the impact of phonon induced spin relaxation and occupancy noise for high magnetic fields remained unclear so far. Here, we use the method of spin noise spectroscopy (SNS) to gain a detailed insight into such mechanisms and measure the spin and charge dynamics for magnetic fields up to 4T and temperatures between 1.8K and 10K. Here, we combine, the quasi non-disturbant measurement scheme of SNS with an extrapolation to truly zero disturbance of the QD system. We find that the total noise power originates not just only from the hole-spin but from several processes including the relaxation of the hole spin and the charge state dynamics of the QD due to Auger recombination. In addition, our measurements indicate a long term stability of the intrinsic hole spin life time on the order of months. We compare our results with theoretical calculations which explicitly address one and two phonon processes as the limiting mechanism of the intrinsic hole spin relaxation.

### HL 25.95 Wed 18:00 P2

Thermal Transport in c-plane GaN Membranes Characterized by Raman Thermometry — •WILKEN SEEMANN¹, JOACHIM CIERS², ISABELL HÜLLEN¹, MAHMOUD ELHAJHASAN¹, JEAN-FRANÇOIS CARLIN³, NICOLAS GRANDJEAN³, ÅSA HAGLUND², and GORDON CALLSEN¹ — ¹Institute of Solid State Physics, University of Bremen, Germany — ²Department of Microtechnology and Nanoscience, Chalmers University of Technology, Gothenburg, Sweden — ³Institute of Physics, École Polytechnique Fédérale de Lausanne (EPFL), Switzerland

Excess heat often limits the lifetime or stability of semiconductor devices, like laser structures, e.g. by affecting the refractive index or defect formation. It

is therefore vital to understand how thermal energy is dissipated from the active region. In this contribution, we analyze the in-plane thermal transport in GaN-based membranes which can be applied in UV-visible light emission. The temperature of the material is probed by the shift and width of Raman modes under heating with a UV laser. This method allows for a contactless characterization without the need for additional processing steps often needed for alternative thermometry. We find, that the thermal conductivity,  $\kappa$ , is significantly reduced compared to bulk GaN due to the finite thickness of the analyzed membranes. Phonon scattering due to roughness and porosity of the membrane is found to further reduce  $\kappa$ . Studying in-plane thermal transport lays the foundation for subsequent thermal studies on entire device structures; exploiting a subtle balance of in- and cross-plane thermal transport which could improve device designs.

### HL 25.96 Wed 18:00 P2

A ultrafast Optical-pump/THz-probe spectrometer based on sub-diffraction field confinement — •JULIA A. LANG, MICHAEL SEIDEL, and GEORG HERINK — Experimental Physics VIII, University of Bayreuth, Germany

Time-resolved THz spectroscopy is a powerful tool for characterizing transient carrier dynamics in electronic materials and devices. In this contribution, we present an optical-pump/THz-probe spectrometer based on a high-repetition rate femtosecond fiber laser and photoconductive antennas combined with resonant microstructures for signal amplification. In particular, this approach exploits sub-diffraction Terahertz confinement in metallic microstructures to reduce the large mismatch between optical and THz foci. We demonstrate local spectroscopy of carrier dynamics in a semiconductor material inside a single resonator and corroborate our findings with finite-element simulations.

### HL 25.97 Wed 18:00 P2

In depth comparison of Raman and Hall measurements for the determination of the electrical transport parameters of N-doped 4H-SiC — •HANNES HERGERT^{1,2}, MATTHIAS T. ELM^{1,2,3}, and PETER J. KLAR¹ — ¹Institute of Experimental Physics I, Giessen, Germany — ²Center for Materials Research, Giessen, Germany — ³Institute of Physical Chemistry, Justus Liebig University, 35392 Giessen, Germany

A precise characterisation of the impact of doping on the electronic transport properties is necessary for the application of silicon carbid (SiC) in semiconductor devices. Hall effect measurements yield reliable results for mobility and carrier density but electrical contacts are needed. These are often not desired. An alternative approach is the analysis of the longitudinal optical phonon electron plasma coupled (LOPC) mode using Raman spectroscopy. This approach also delivers non-invasively information about the charge carrier density and the electron mobility. In this work, we compare the results obtained by Hall and Raman measurements. We show that the effective carrier density and the mobility obtained by Hall measurements deviate from those determined using Raman spectroscopy. The deviations arise as only electrons in the conduction band couple to the LO mode, while electrons in the impurity band do not, but still contribute to the electrical transport. To extract the charge carrier density in the conduction band from Hall measurements, a three-band model is employed. In addition, the two measurement methods yield different values of the mobility due to its frequency-dependence.

### HL 25.98 Wed 18:00 P2

Electrical characterization of core/shell GaAs/InAs/Al nanowire-based **Josephson junctions** — •FARAH BASARIC¹, ANTON FAUSTMANN¹, MARVIN M. JANSEN¹, ALEXANDER PAWLIS^{1,2}, ERIK ZIMMERMANN¹, HANS LÜTH^{1,2}, DETLEV GRÜTZMACHER^{1,2}, and THOMAS SCHÄPERS^{1,2} — ¹Peter Grünberg Institut (PGI-9), Forschungszentrum Jülich, 52425 Jülich, Germany — ²JARA-Fundamentals of Future Information Technology, Jülich-Aachen Research Alliance, Forschungszentrum Jülich and RWTH Aachen University, Germany Epitaxially grown phase-pure GaAs/InAs core/shell nanowires offer uniformity in their electrical, mechanical and optical properties. High electron mobility, large g-factor and strong Rashba spin-orbit coupling in combination with phasepure wurtzite GaAs core offer heterostructure with transport properties governed by the presence of confined states in the InAs shell. A Josephson junction was realized by wet chemical etching of an *in-situ* deposited Al half-shell. Clean semiconductor-superconductor interface by such deposition was important for obtaining high critical current and good electrical transport control. The nanowire system was fabricated fully *in-situ* in a state-of-the-art nanofabrication clustertool, enabling precisely defined interfaces. Magnetotransport measurements at variable temperature regime were carried out for structures with normal and superconducting contacts under applied in-plane magnetic field, with varying gate potential. Such hybrid structure represents a promising candidate in realizing superconducting qubits and Majorana circuits.

HL 26.1 Thu 9:30 H32

All-optical polarization control of single photons emitted by a quantum dot — •Björn Jonas, Dirk Heinze, Eva Schöll, Patricia Kallert, Timo Langer, Sebastian Krehs, Alex Widhalm, Klaus D. Jöns, Dirk Reuter, Stefan Schumacher, and Artur Zrenner — Paderborn University, Physics Department, Warburger Straße 100, 33098 Paderborn, Germany

In our work we employ an all-optical approach based on nonlinear principles to control the polarization of single photon emission from a single quantum dot. To achieve this, we make use of a nonlinear down-conversion process from the biexciton to the ground state [1]. This opens an alternative decay path in addition to the biexciton cascade. Previous theoretical work suggests the possibility to manipulate the properties of the emitted photons by tuning the respective properties of a control laser [2].

By exploiting this mechanism, we were able to demonstrate polarization control of the emitted photons for linear and circular polarization. Our findings show no influence of the fine-structure splitting on the polarization of the emitted photons. We furthermore present a theoretical model to describe our results and we find excellent agreement between experiment and theory.

### HL 26.2 Thu 9:45 H32

**Temporal evolution of line broadening in charge controlled quantum dots** — •TIM STROBEL¹, JONAS H. WEBER¹, MARCEL SCHMIDT², LUKAS WAGNER¹, ANDREAS D. WIECK², MICHAEL JETTER¹, SIMONE L. PORTALUPI¹, ARNE LUDWIG², and PETER MICHLER¹ — ¹Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Science and Technology (IQST) and SCOPE, University of Stuttgart, Allmandring 3, 70569 Stuttgart, Germany — ²Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum, D-44780 Bochum, Germany

Self-assembled semiconductor quantum dots (QDs) present themselves as an attractive platform for the implementation of scalable hybrid quantuminformation schemes. On-demand emission of high-quality single photons demonstrates the potential of such systems. Sources of noise, caused by the interaction with the solid-state environment can lead to an inhomogeneous broadening of the emission line. The magnitudes and timescales of such dephasing mechanisms vary strongly with the material composition and heterostructure of a sample. Here, we employ Photon-correlation Fourier spectroscopy as a powerful experimental method to study the spectral dynamics of single emitters, with high spectral and temporal resolution. In particular, the broadening mechanisms of QDs embedded in a novel type of gated structure, based on a n-i-n-diode are investigated.

### HL 26.3 Thu 10:00 H32

High-quality single-photons from hybrid MOVPE/MBE grown n-i-n quantum-dot structures —  $\bullet$ LUKAS WAGNER¹, TIM STROBEL¹, MARCEL SCHMIDT², JONAS H. WEBER¹, LENA ENGEL¹, ANDREAS D. WIECK², MICHAEL JETTER¹, SIMONE L. PORTALUPI¹, ARNE LUDWIG², and PETER MICHLER¹ — ¹Institut für Halbleiteroptik und Funktionelle Grenzflächen (IHFG), Center for Integrated Quantum Science and Technology (IQST) and SCOPE, University of Stuttgart, Allmandring 3, 70569 Stuttgart, Germany — ²Lehrstuhl für angewandte Festkörperphysik, Ruhr-University Bochum, Universitätsstraße 150, 44801 Bochum, Germany

Photonic quantum operations require sources of photons with Fourier-limited linewidth and high brightness. Stark-shift tuning of the emission wavelength can be of interest in upscaling the complexity, employing multiple quantum dots (QDs) tuned at the same emission wavelength. QDs in gated structure can provide a stabilization of the electric field environment, pushing the photon linewidth close to the Fourier limit. In addition, the embedding diode structure can be used to electrically tune the emission wavelength. The growth of self-assembled semiconductor QDs is usually carried out via metal-organic vapor-phase epitaxy (MOVPE) or molecular-beam epitaxy (MBE). This work combines MOVPE and MBE techniques for hybrid growth of gated semiconductor QD samples. This provides spectrally tunable InAs QDs with narrow emission linewidth. High single-photon purity and indistinguishability are proven via Hanbury-Brown and Twiss, and Hong-Ou-Mandel experiments in resonant excitation.

### HL 26.4 Thu 10:15 H32

Ultrafast electric control of cavity mediated photons from a semiconductor quantum-dot — •DAVID BAUCH¹, DIRK HEINZE¹, JENS FÖRSTNER¹, KLAUS D. JÖNS¹, and STEFAN SCHUMACHER^{1,2} — ¹Department of Physics and CeOPP, Paderborn University, Germany — ²College of Optical Sciences, University of Arizona, Tucson, USA

on pairs are essential for quar

On demand sources for single photon and photon pairs are essential for quantum communication protocols. Exciton and cascaded biexciton-exciton transitions in semiconductor quantum dots offer the potential for optically controlled generation of a single photon [1] and polarization-entangled twin photons [2]. In addition to pure optical control, externally applied time-dependent electric fields enable control of the (bi-)exciton resonance through the quantum confined Stark effect, resulting in changes of the (bi-)exciton dynamics and the resulting photon emission. Here we investigate theoretically the optical excitation of the (bi-)exciton state off-resonant to a cavity mode followed by ultrafast control of the states, which then allows for cavity-resonant emission of the photons. Our scheme allows for high preparation fidelities followed by the generation of highly indistinguishable single photons and polarization entangled twinphotons via the biexciton-exciton cascade and biexciton two-photon emission with high emission probabilities [3].

Sub- and Superradiant Effects in Bimodal Quantum-Dot Microcavity Lasers — •ISA HEDDA GROTHE and JAN WIERSIG — Institut für Physik, Otto-von-Guericke-Universität Magdeburg, Germany

In standard nanolasers with a single cavity mode a strong influence of interemitter correlations on the input-output dynamics as well as the statistical properties of the emitted light has been described [1]. Below threshold subradiant emission emerges with superthermal values of the autocorrelation function  $g^{(2)}(0)$ , which is associated with strong bunching of the emitted photons. Similarly high values of  $g^{(2)}(0)$  have also been found for the weak mode in micropillar lasers with two orthogonally polarized modes [2,3]. Here, however, this phenomenon is rooted in the interaction of both modes with a common gain medium which leads to gain competition between the two modes.

Making use of a theoretical semiconductor laser model based on the clusterexpansion method, we include correlations between the emitters in the description of bimodal microcavity lasers. This enables us to compare the influence of sub- and superradiant effects on the emission of bimodal lasers to that on lasers with a single mode. Additionally, we are able to distinguish features of the statistical properties of the emitted light that characterize either subradiance or gain competition as the source of superthermal photon bunching in bimodal lasers.

HL 26.6 Thu 10:45 H32

GaAs Droplet Epitaxy Quantum Dots as Deterministic Single Photon Sources for Entangling SiV-Centers in Diamond — •MANUEL RIEGER¹, VIVIANA VILLAFANE¹, ANDREAS NICKL¹, CHRISTIAN DANGEL¹, HANS-GEORG BABIN², TIM SCHRÖDER³, ARNE LUDWIG², ANDREAS WIECK², KAI MÜLLER¹, and JONATHAN FINLEY¹ — ¹Walter Schottky Institut/Physik Department, TUM, 85748 Garching, Germany — ²Physik Department, RU Bochum, Universitätsstraße 150, 44801 Bochum, Germany — ³Physik Department, HU Berlin, Newtonstraße 15, 12489 Berlin, Germany

Quantum algorithms promise acceleration of tasks like computational chemistry and machine learning. In this context, diamond-based quantum hardware capable of interfacing spins and photons in a scalable network [1] is particularly advantageous since it combines excellent coherence times, gate fidelities and the possibility for on-chip integration. We demonstrate GaAs based quantum dot (QD) deterministic single photon sources grown using droplet epitaxy (DE) and resonant with the the SiV- center in diamond at 737nm. By characterizing single dots using low temperature optical spectroscopy, we measure a non-classical second order photon intensity correlation function ( $g^2(0)<0.3$ ), demonstrate electrical tunability of the charge occupancy and show wide tunability of the emission frequency over 250GHz. Furthermore, we show that the optical lifetimes of the DE-QDs lie in the range 1-1.5ns, similar to those of SiV⁻ (1-2ns), a prerequisite for high-fidelity photon mediated entanglement [1,2]. [1] K. Nemoto et al., Phys. Rev. X (2014). [2] C. Dangel et al., arXiv preprint (2022).

In the Rabi scheme, off-resonant excitations of a two-level system do not lead to a full inversion, when no further auxiliary particles are participating. Surprisingly, the Swing-UP of the quantum EmitteR population (SUPER) scheme uses off-resonant excitations to fully bring a two-level system from the ground to excited state [PRX Quantum 2, 040354 (2021)]. The scheme relies on a gradual swing-up, which can be achieved by modulation of the excitation frequency or amplitude. Here, we discuss the theory of the SUPER scheme and how it can implemented for a semiconductor quantum dot by using a two-color excitation with pulses detuned by several meV. Due to the electron-phonon interaction, the SUPER scheme results in the emission of phonon wave packets [pssb, 2100649 (2022)], but overall the phonon influence is rather small. The experimental realization of SUPER scheme [arXiv:2203.00712 (2022)], as will be presented in a different contribution, shows great agreement with the theoretical prediction.

### HL 26.8 Thu 11:45 H32

**Internal Photoeffect from a Single Quantum Emitter** — PIA LOCHNER¹, JENS KERSKI¹, ANNIKA KURZMANN², HENDRIK MANNEL¹, •MARCEL ZÖLLNER¹, ANDREAS D. WIECK³, ARNE LUDWIG³, MARTIN P. GELLER¹, and AXEL LORKE¹ — ¹University of Duisburg-Essen and CENIDE, Germany — ²RWTH Aachen University, Germany — ³Ruhr-University Bochum, Germany

As quantum information technologies require long spin coherence times in qubits and highly indistinguishable photons [1], we present a new and mostly neglected mechanism in self-assembled quantum dots that fundamentally limits the coherence times in optical quantum devices. By time-resolved resonance fluorescence (RF) measurements on a single quantum dot, we demonstrate an internal photoeffect [2] that emits electrons from the dot by an intra-band excitation. While the tunneling rate of an electron into the quantum dot is constant for increases linearly with increasing excitation intensity. This way, the emission rate is tunable over several orders of magnitude by adjusting the non-resonant laser excitation intensity.

Our findings show that a process, which is well known in single atom spectroscopy (i.e. photo ionization) can also be observed for a solid-state quantum emitter and has to be avoided or reduced to push the limits towards long qubit coherence times.

### HL 26.9 Thu 12:00 H32

Nuclear Spin Polarization by Electron Spin Mode Dragging in an Ensemble of (In,Ga)As Quantum Dots — •EIKO EVERS¹, NATALIIA E. KOPTEVA^{1,2}, IRINA A. YUGOVA^{2,3}, DMITRI R. YAKOVLEV^{1,4}, MANFRED BAYER¹, and ALEX GREILICH¹ — ¹Experimentelle Physik 2, TU Dortmund, 44221 Dortmund, Germany — ²Spin Optics Laboratory of St. Petersburg State University, 198504 St. Petersburg, Russia — ³St. Petersburg, Russia

The electron-nuclear spin system in singly charged (In,Ga)As quantum dots (QDs) promises to combine the efficient optical electron spin (ES) orientation with the long coherence time in the nuclear spin (NS) system [1]. To come closer

to a state of large NS polarization, we synchronize an ensemble of QDs, inhomogeneous in size, g factor, and resident ES precession frequency in a transverse external field, to a laser with a pulse repetition frequency of 1 GHz. As a result, the ensemble of ESs is homogenized by focusing it on a single precession mode by nuclei-induced frequency focusing [2]. In a substantial external field range, the single mode is fixed by a simultaneous build-up of an anti-parallel Overhauser field  $B_N$  caused by the polarization of NSs. The Overhauser field achievable in each QD differs and leads to the surprising emergence of equally spaced ES precession components in the ensemble.

### HL 26.10 Thu 12:15 H32

Auger-assisted electron spin-flips in a single quantum dot — •HENDRIK MANNEL¹, JENS KERSKI¹, PIA LOCHNER¹, MARCEL ZÖLLNER¹, FABIO RIMEK¹, ARNE LUDWIG², ANDREAS WIECK², AXEL LORKE¹, and MARTIN GELLER¹ — ¹Faculty of Physics and CENIDE, University of Duisburg-Essen, Duisburg, Germany — ²Chair of Applied Solid State Physics, Ruhr-University Bochum, Germany

A long electron spin coherence lifetime is the key requirement for future solidstate spin qubits. However, for instance, in self-assembled quantum dots the coupling to nuclei, co-tunneling with a nearby reservoir, and spin-orbit coupling limit the spin-lifetime.

Using resonance fluorescence, we here demonstrate an additional fundamental process that can lead to a single electron spin-flip via an Auger recombination [1]. The quantum dot is placed in a magnetic field in Faraday geometry and charged with one (spin-up or spin-down) electron [2]. In time-resolved resonant fluorescence measurements and using a rate equation model, we can determine the Auger and spin-flip rates in a magnetic field.

Our results reveal an additional, so far neglected Auger-assisted spin-flip process: Auger recombination with subsequent electron tunneling from the reservoir. The present dot is weakly coupled to an electron reservoir. A strong coupling will enhance this Auger-assisted spin-flip rate and thus reveal an important mechanism limiting the spin lifetime due to a strong coupling to a nearby reservoir.

Spin control of single spins in semiconductor quantum dots placed in a microcavity — •MARCO DE GREGORIO, TOBIAS HUBER, and SVEN HÖFLING — Technische Physik, Julius-Maximilians-Universität, Würzburg, Deutschland Implementation of secure communication with entangled photons is a continuously evolving field. Different platforms have been investigated during the last decades and quantum dots have been proven to be a promising candidate as source for entangled photons. Despite their deterministic photon creation and excellent multi-photon suppression, quantum dot sources suffer from outcoupling efficiencies, when not embedded into photonic structures. Here, we present a low quality factor micropillar cavity, which is broadband, but still enhances the photon extraction efficiency. Analysis of deterministically placed low-q micropillars, characterization and optimization of the emission behavior and control of the spin are necessary steps paving the way towards the generation of a quantum repeater.

### HL 27: Focus Session: Perspectives in Cu(In,Ga)Se 1

The chalcopyrite Cu(In,Ga)Se2 is currently one of the few photovoltaic materials with an active participation in the market share of thin-film technologies, offering also the advantage of having a low production carbon footprint. After a rapid increase in its record power conversion efficiency during the last decade, the technology seems to have stagnated at 23.4 percent, a record achieved in 2019. Several strategies, which have been partially responsible of the newest record efficiencies, have been developed in order to push Cu(In,Ga)Se2 further by targeting the improvement of the bulk properties and the interfaces: post-deposition treatments with heavy alkali metal fluorides, incorporation of other metals like silver and the mixture with other chalcogens like sulfur, are just some examples. The aim of this focus session is to bring Cu(In,Ga)Se2 experts together in order to discuss the current limitations and propose new routes and concepts that could lead to a further improvement in this technology.

Organized by AK-jDPG (Aubin Prot, Omar Ramirez and Taowen Wang)

Time: Thursday 9:30-11:00

Invited TalkHL 27.1Thu 9:30H33What limits state-of-the-art chalcopyrite solar cells?- •SUSANNE SIEBEN-<br/>TRITT — Laboratory for Photovoltaics, Department of Physics and Materials<br/>Science, University of Luxembourg

Chalcopyrite solar cells have reached 23.4% efficiency, less than Si solar cells. Why are chalcopyrite solar cells not better? State of the art chalcopyrite solar cells

Location: H33

are based on an absorber with a band gap gradient in depth, to keep electrons from the back contact and to reduce non-radiative recombination at the back contact. However, this graded band gap profile can decrease the short circuit current because of a rather low absorptance near the absorption edge. Additionally, the gradual increase of the absorptance leads to radiative loss in the open circuit voltage (VOC). Additional fluctuations and disorder lead to exponential band tails and to radiative and non-radiative VOC losses. These Urbach tails are larger in polycrystalline films than in epitaxial films, indicating a contribution of grain boundaries, however, the difference is only a few meV in Urbach energy, indicating a common source independent of grain boudaries. The dependence of the Urbach energy on the net doping level hints to electrostatic fluctuations as a main source of tail states. In addition to these limitations of the short circuit current and the open circuit voltage, the diode factor of most chalcopyrite solar cells is high, implying a low fill factor. It became only recently clear, that metastable defects contribute massively to the increased diode factor of these solar cells.

### Invited Talk HL 27.2 Thu 10:00 H33 Approaches to improve CIGS absorber quality and the CIGS/buffer interface to reach 24% efficiency and beyond — •WOLFRAM WITTE — Zentrum für Sonnenenergie- und Wasserstoff-Forschung Baden-Württemberg (ZSW),

Stuttgart, Germany Cu(In,Ga)Se2 (CIGS) thin-film solar cells with polycrystalline absorber layers exhibit high power conversion efficiencies above 23% for small-area devices. The bandgap energy (Eg) of CIGS is tunable and the material can be used either as bottom cell within a tandem device, e. g. in combination with perovskite as a top cell or the CIGS cell can be applied as wide-bandgap top cell and combined with e. g. a silicon bottom cell. In spite of their excellent photovoltaic (PV) performance, it is apparent, when comparing the PV parameters of record single junction CIGS devices with the theoretical radiative limit, that various loss mechanisms are present in the devices. As few examples, the open-circuit voltage (Voc) and the fill factor (FF) are limited by non-radiative recombination and additional parasitic absorption takes place in the buffer and adjunct high-resistive (HR) layer, which can limit the short-circuit current (Jsc).

This contribution gives an overview on approaches to improve CIGS singlejunction solar cells beyond 24%. Increasing grain size and/or eliminate the Ga/(Ga+In) grading in the absorber can reduce Voc losses and alloying of silver to CIGS can increase FF values.

To overcome parasitic absorption of the standard buffer system CdS/i-ZnO, the application of wide-bandgap buffer or HR materials such as Ga2O3 with Eg>4 eV can be an option to increase Jsc further.

HL 27.3 Thu 10:30 H33 Role of Na in interconnection between chemical composition and electrical properties of grain boundaries in Cu(In, Ga)Se2 — •AZAM KARAMI¹, MARCIN MORAWSKI², HEIKO KEMPA², ROLAND SCHEER², and OANA COJOCARU-MIRÉDIN¹ — ¹RWTH Aachen University, Aachen, Germany — ²Martin-Luther-Universität Halle-Wittenberg, Halle, Germany Nowadays, the polycrystalline Cu(In,Ga)Se2 thin-film solar cells have attained increased interest due to their lower costs and higher cell efficiency in energy conversion. These polycrystalline absorbers contain a large ratio of grain boundaries which can be detrimental (increase in recombination activity compared to the bulk), neutral (no change in electrical properties relative to grains) or benign (increase in electrical properties) for the cell performance. In the present work, different techniques such as atom probe tomography and electron backscattered diffraction are used to investigate different grain boundaries in order to illustrate the relation between the chemical composition and the electrical properties of the grain boundaries. It is shown that the elemental changes at the grain boundaries such as Cu depletion, In enrichment and segregation of alkali dopants like Na, can directly affect their beneficial behavior in favor of cell performance. The experimental findings prove the significant role of Na addition in improving the cell parameters such as open circuit voltage and fill factor. Although it is also shown that the excessive addition of Na dopant can have a detrimental effect on the cell efficiency by increasing the density of dislocations and interference of deep defects with dopants.

### HL 27.4 Thu 10:45 H33

Electronic properties of the back contact in Cu(In,Ga)Se2 solar cells -Torsten Hölscher, Thomas Schneider, Merve Demir, Julia Horstmann, MELINA KRISTEN, HEIKO KEMPA, and •ROLAND SCHEER - Martin-Luther-Universität Halle/Wittenberg, Naturwissenschaftliche Fakultät II, Institut für Physik, Fachgruppe Photovoltaik, Von-Danckelmann-Platz 3, 06120 Halle/Saale Cu(In,Ga)Se2 solar cells are interesting for single junction and multi-junction (tandem) photovoltaic energy conversion. Although not being ideal, their back contact may exhibit a secondary junction. This is the case for low bandgap Cu(In,Ga)Se2 with a molybdenum back contact. Here, the secondary junction leads to a certain admittance step, a saturation in the Voc(T) plot, but has little impact on the device performance for thick Cu(In,Ga)Se2 layers: The barrier typically is small enough to allow for majority carrier transport and sufficiently far away from the main junction to impede minority carrier recombination. Only for ultrathin Cu(In,Ga)Se2 solar cells, the barrier can limit the device performance. For wide bandgap Cu(In,Ga)Se2 on molybdenum, the barrier appears to be even smaller. The situation is much less clear for Cu(In,Ga)Se2 on a transparent ITO back contact for tandem applications. For low bandgap Cu(In,Ga)Se2, no barrier is to be detected by admittance and Voc(T) experiments. For widegap Cu(In,Ga)Se2, the barrier formation in addition depends on the type of dopant. In this contribution, we used different experimental techniques in order to develop electronic models for opaque (Molybdenum) and transparent (ITO) back contacts.

### HL 28: Organic Semiconductors 1

### HL 28.1 Thu 9:30 H34

Dual-color organic LEDs for on demand activation and inhibition of cellular activity — •GIUSEPPE CICCONE¹, ILENIA MELONI², RODRIGO GASTON FERNANDEZ LAHORE³, HANS KLEEMAN¹, PETER HEGEMANN³, KARL LEO¹, and CAROLINE MURAWSKI² — ¹Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute for Applied Physics, Technische Universität Dresden, Dresden, Germany. — ²Kurt-Schwabe-Institut für Messund Sensortechnik Meinsberg e.V., Waldheim, Germany — ³Institute for Biology, Experimental Biophysics, Humboldt-Universität zu Berlin, Berlin, Germany

Optical stimulation of light sensitive proteins in neurons allows optogenetics to stimulate and probe cellular activity with high spatial and temporal resolution. Multiple light sources with different wavelengths are usually required to stimulate light-sensitive proteins that combine a cation-conducting and an anion-conducting channel. Here, we present two stacked OLED architectures that can emit light with two different emission colors from the same pixel, addressing the single domains of bidirectional ion channels expressed in Drosophila melanogaster larvae and ND7/23 cells with one single, organic device. Tuning of microcavities allowed us to well match the OLED emission spectra to the activation spectra of the combined photo-sensitive proteins BiPOLES and BiPOLES-ChRmine. Our work shows that OLEDs can provide narrowband light emission with minimal crosstalk between sub-pixels, enabling us to switch between optogenetic activation and inhibition of living systems with a single device.

 $\label{eq:HL28.2} HL 28.2 \ \ Thu \ 9:45 \ \ H34$  Revealing the origin of short channel effects in organic electrochemical transistors — •Anton Weissbach¹, HSIN TSENG¹, LAURIE E. CALVET², HANS KLEEMANN¹, and KARL Leo¹ — ¹Technische Universität Dresden, Germany — ²Université Paris-Saclay-CNRS, Palaiseau, France

Organic electrochemical transistors (OECTs) emerged as promising building blocks for brain-inspired hardware. Several studies demonstrated the synaptic-like properties of OECTs. However, the fabrication of integrated hardware with OECTs is hampered by the nature of the electrolyte. In particular, liquid electrolytes are prone to evaporation and cover multiple devices. Here, we present an OECT with photopatternable solid electrolyte that we structure down to 10 micrometer resolution. The patternability of the electrolyte allows us to integrate OECTs in circuitry without crosstalk between devices. On the single-device-level, it exhibits an on-off ratio of  $10^6$ , and a subthreshold swing of 61 mv/dec, close to the thermodynamic minimum.

Moreover, we show that these devices exhibit short channel effects, even at large channel lengths up to 100 micrometers. We reveal that the origin lies in the capacitive coupling of the drain electrode with the electrolyte. We then quantify and systematically study the strength of the coupling and show that it can be altered by the overlap of the semiconductor with the drain electrode. Our results reveal that the capacitive drain coupling can be more than 50 % compared to the gate coupling. Based on that, we provide a design principle for diminishing the detrimental short channel effect in OECTs.

HL 28.3 Thu 10:00 H34

Laser induced fluorescence spectroscopy of TIPS pentacene attached to rare gas cluster —  $\bullet$ Michelbach Moritz, Demianenko Alexander, Hartweg Sebastian, and Stienkemeier Frank — Institute of Physics, University of Freiburg, Germany

In the recent years bis(triisopropylsilylethynyl (TIPS)) pentacene has gained interest in the field of singlet fission. Originally developed for field-effect transistors, the TIPS side groups of the pentacene lead to favourable intermolecular orientation, high hole mobility in thin films and better solubility in organic solvents [1]. We present a comparison study of the pentacene and its derivate, in which we cover the energetic structure of the excited states, the influence of the

Location: H34

surrounding medium and the effect of neighbouring molecules. Especially the collective effects are investigated with a lifetime analysis and give a direct hint for lifetime reducing effects like superradiance and singlet fission [2], [3].

### HL 28.4 Thu 10:15 H34

Heterostructure photodiodes of PbS nanocrystals with different types of ligands — •SHAIMAA ABDALBAQI¹, FLORIAN GRASSL¹, ALEXANDER HOFMANN¹, AHMED MANSOUR², ALADIN ULLRICH¹, NORBERT KOCH², ANDREAS OPITZ², MARCUS SCHEELE³, and WOLFGANG BRÜTTING¹ — ¹Institut für Physik, Universität Augsburg, Germany — ²Institut für Physik & IRIS Adlershof, Humboldt-Universität zu Berlin, Berlin, Germany — ³Institut für Physikalische und Theoretische Chemie, Universität Tübingen, Tübingen, Germany

The influence of the ligands in coupled organic-inorganic nanostructures (COINs) on the performance of optoelectronic devices is investigated. We fabricate photodiodes based on pentacene and PbS nanocrystals coupled to organic ligands like 1,2-ethanedithiol (EDT) and tetrabutylammonium iodide (TBAI) and a combination of both as a heterostructure. These ligands were first separately used to fabricate a single ligand-type of organic-inorganic device and later compared with a heterostructure of PbS-EDT and PbS-TBAI. To tune the optical energy gap of COINs to align with the triplet level of pentacene, it was necessary to choose the suitable particle size. For this purpose, ultraviolet photo-emission spectroscopy (UPS) was used to determine the energy of the highest occupied molecular orbital (HOMO) and the work function of COINs. Devices with heterostructure COINs achieve a higher short circuit current than COINs with a single type of ligands. Incident photon to current efficiency (IPCE) shows different excitonic absorption peaks in the visible range for different stacks.

HL 28.5 Thu 10:45 H34

**Development of an OLED as excitation light source for photocatalytic active materials** — •DOMINIK WEBER¹, DANIEL SCHONDELMAIER¹, DIETRICH R.T. ZAHN², TERESA ISABEL PICOTO PENA MADEIRA², SALVAN GEORGETA², and AN-NIKA MORGENSTERN² — ¹Westsächsische Hochschule Zwickau, Faculty of Physical Engineering and Computer Sciences/ Nanotechnology, Zwickau, Deutschland — ²Technische Universität Chemnitz, Physics Department / Semiconductor Physics, Chemnitz, Deutschland

Since its first publication in 1987 by Tang and VanSlyke, organic light-emitting diodes (OLEDs) have been in the focus of science for more than 3 decades and have been continuously improved. Especially in the field of RGB OLEDs, substantial progress has been achieved in terms of lifetime and efficiency, which is why they are used today in particular in the display and solid-state lighting technology.

The work presented focuses on the optimization of UV-to-blue OLEDs for use as an illumination source and a source of excitation for photocatalytic active layers. Therefore, an OLED with a suitable characteristic (wavelength, lifetime, efficiency) is developed, by studying the influences of different materials, layer systems, and the integration of nanostructures. Additionally, the photocatalytic active layer titanium dioxide is generated and optimized (absorption behavior, effectiveness), which can be realized by thermally excited phase conversion. The relationship between photocatalytic activity and the phase composition will be investigated here.

### HL 28.6 Thu 11:00 H34

Photoexcited charge carrier and spin dynamics in methylammonium lead bromide doped by magnetic transition metals — •STANISLAV BODNAR¹, JONATHAN ZERHOCH^{1,2}, ANDRII SHCHERBAKOV^{1,2}, SHANGPU LIU^{1,2}, LISSA EYRE¹, and FELIX DESCHLER^{1,2} — ¹Walter Schottky Institut, Physik Department, Technische Universität München, Garching, Germany — ²Heidelberg University, Heidelberg, Germany

One of the most challenging tasks for LED applications is emitting 100% polarized light from the device. Typically, this is achieved by introducing an additional layer of polarization filter which leads to losing half of the light intensity. To overcome this issue, one has to find a system with a high degree of photoluminescence (PL) polarization. A promising approach here is using magnetic metal doping in combination with a highly efficient semiconductor. We have chosen to use transient absorption (TA) spectroscopy at cryogenic temperatures to investigate changes in the optical properties induced by magnetic metal doping in CH3NH3PbBr3 since it gives spectral information about the energies of electronic states and dynamic properties of the photoexcited carriers. We find a change in the main ground state bleach (GSB) peak position in doped CH3NH3PbBr3, which depends on the transition metal used. The main GSB peak of pure CH3NH3PbBr3 at 4 K is at 2.32 eV. Doping CH3NH3PbBr3 with Mn leads to a shift of the main peak to lower energies by 0.04 eV and 0.08 eV, respectively. The modifications of the TA spectra are associated with changes in the bandgap energy, which is the result of doping-induced lattice expansion.

#### HL 28.7 Thu 11:15 H34

Ultrastrong light-matter interaction of J-aggregated squaraine in an open cavity for polariton lattices — •Christoph Bennenhei¹, Lukas Lackner¹, Moritz Gittinger¹, Heiko Knopf², Falk Eilenberger², Jennifer Zablocki³, Arne Lützen³, Christoph Lienau¹, Martin Silies¹, Martin Esmann¹, and Christian Schneider¹ — ¹Institute of Physics, University of Oldenburg — ²Institute of Applied Physics, Abbe Center of Photonics, Friedrich Schiller University, Jena — ³Kekulé Institute of Organic Chemistry and Biochemistry, University of Bonn

Organic molecule exciton-polaritons in artificial lattices are an emerging platform to emulate complex electronic Hamiltonians at ambient conditions. We present J-aggregated squaraine dye (SQ) thin films [1] as a promising candidate for exciton-polaritons in optical cavities due to its high oscillator strength and tunable resonance. Using white light reflection spectroscopy, we demonstrate tunable ultrastrong coupling of light to the SQ thin film in an open cavity at room temperature [2], which we support by transfer matrix calculations. In ongoing experiments, we introduce structured photonic lattices to the open cavity to investigate the coupling of the polaritons to tailored potential landscapes.

Location: H36

# **Exploring the Device Physics of Photomultiplication in Organic Photodetectors** – •LOUIS CONRAD WINKLER, JONAS KUBLITSKI, JOHANNES BENDUHN, and KARL LEO – TU Dresden, Germany

Recently, photomultiplication (PM) in organic photodetectors has been achieved, but working mechanism and physics are not fully understood. Contrary to inorganic photodiodes, impact ionization and avalanche breakdown cannot be achieved in organic semiconductors. Instead, the accumulation of one charge carrier type close to an electrode leads to a strong energy level bending, which increases the tunnelling probability of the opposite charge carrier type under reverse bias from the metal contact into the device. In this contribution, we investigate the well-known donor-acceptor system ZnPc:C60, using the acceptor as an electron trapping state to inject holes into the donor phase. Since the effective electron mobility is strongly decreased, we investigate whether shifting the generation location influences the device operation, e.g. the response speed and external quantum efficiency. Furthermore, a gradient donor-acceptor mixing ratio is introduced to increase both response speed and free charge carrier generation efficiency via an enlarged donor-acceptor interface. We also investigate the effect of trapping time being larger than the carrier transit time, leading to reduced cut-off frequencies.

**Twist angle engineering of proximity exchange in graphene/Cr**₂**Ge**₂**Te**₆ **bilayers** — •KLAUS ZOLLNER and JAROSLAV FABIAN — Institute for Theoretical Physics, University of Regensburg, 93053 Regensburg, Germany

Van der Waals heterostructures composed of twisted monolayers promise great tunability of electronic, optical, and magnetic properties. The most prominent example is twisted bilayer graphene, exhibiting magnetism and superconductivity due to strong correlations [1]. In addition, twistronics has already demonstrated its potential in tuning proximity spin-orbit coupling in graphene/TMDC heterostructures [2]. In this talk, we present the twist-angle and gate dependence of the proximity exchange coupling in graphene/ $Cr_2Ge_2Te_6$  bilayers from first principles [3]. The proximitized Dirac band dispersions of graphene show a continuous tunability of the ferromagnetic exchange from 4 to -4 meV, when twisting from 0° to 30°. Remarkably, at 19.1° the induced exchange coupling becomes even antiferromagnetic. Further tuning is provided by a transverse electric field and the interlayer distance.

This work was supported by DFG SFB 1277, DFG SPP 2244, and the EU Horizon 2020 Research and Innovation Program (Graphene Flagship).

#### HL 29.2 Thu 9:45 H36

Direct observation of ultraclean tunable band gaps in bilayer graphene — •Eike Thomas Icking^{1,2}, Luca Banszerus^{1,2}, Philipp Schmidt^{1,2}, Corinne Steiner^{1,2}, Frederike Wörtche¹, Frank Volmer¹, Stephan Engels^{1,2}, Jonas Hesselmann¹, Matthias Goldsche^{1,2}, Kenji Watanabe³, Takashi Taniguchi⁴, Christian Volk^{1,2}, Bernd Beschoten¹, and Christoph Stampfer^{1,2} – ¹RWTH Aachen University, Germany – ²Forschungszentrum Jülich, Germany – ³Research Center for Functional Material, Japan – ⁴International Center for Materials Nanoarchitectonics, Japan

Control over the charge carrier density and the band gap size of a semiconductor paves the way for a wide range of applications, such as highly-tunable transistors, photodetectors, and lasers. Bernal-stacked bilayer graphene (BLG) allows tuning the band gap by an out-of-plane electric displacement field. The first evidence of this unique band gap tunability was found ten years ago, but it took until recently to fabricate sufficiently clean heterostructures to use the band gap to suppress electric current or confine charge carriers. We present a detailed study of the tunable band gap in gated BLG characterized by temperature-activated transport and finite-bias spectroscopy measurements. The latter method allows comparing different gate materials and device technologies that directly affect the effective disorder potential. We show that in graphite-gated BLG there are as good as no sub-gap states resulting in ultraclean band gaps with values in good agreement with theory, allowing to achieve band gaps up to 120 meV.

HL 29.3 Thu 10:00 H36 Domain determination of rhombohedral multilayer graphene devices for magnetotransport measurements — •CHRISTIAN ECKEL, ANNA SEILER, FRANCESCA FALORSI, NIKLAS KOHLRAUTZ, and THOMAS WEITZ — 1. Physikalische Institut, Universität Göttingen, Friedrich-Hund Platz 1 37077 Göttingen

Graphene as the most prominent example of a 2D-material exhibits relatively different electronic band properties compared to its bulk counterpart. For monolayer, bi-layer or tri-layer the electronic properties have already been explored by multiple groups in the past. However, studies on higher layer number rhombohedral graphene (5 layers in this work) with respect to magnetoelectrical transport measurement are still pending. Finding and determining the rhombohedral domains in mechanically exfoliated flakes is the first bottleneck in the fabrication procedure. Raman spectroscopy is a well-established technique for layer number determination but often lacks a high lateral resolution. Kelvin-probe-force- microscopy (KPFM) allows a lateral resolution of the domains where the different stackings exhibit a distinguishable 15meV work function difference. Additionally, a cryogenic scanning near field optical microscopy (Cryo-SNOM) allows to depict the domains in a temperature dependent manner. The combination of all measurements will be discussed on the poster. A second challenge is the fabrication process of high quality devices for magnetotransport measurements in the milli Kelvin regime. Therefore, encapsulation in hexagonal Boron Nitride (hBN) together with graphite contacts and gates are necessary.

#### HL 29.4 Thu 10:15 H36

All-optical modulation of third harmonic generation in graphene — •OMID GHAEBI¹, SEBASTIAN KLIMMER¹, HABIB ROSTAMI², and GIANCARLO SOAVI¹ — ¹Institute of Solid-State Physics, Friedrich Schiller University, Jena, Germany — ²Nordita, KTH Royal Institute of Technology and Stockholm University, Sweden Graphene is a unique platform for non-linear optics thanks to its linear band dispersion that allows gate tunable resonant light-matter interactions [1]. While the gate tunability of THG have been investigated in recent years [1], less is known about the possibility to realize all-optical nonlinear modulators, which could provide higher modulation speed (THz) compared to electrical modulators (GHz) [2]. In this work, we show all-optical TH modulation in graphene at

different values of the Fermi level and with a modulation depth up to 85%. First, we demonstrate that it is possible to actively control the THG recombination dynamics by tuning the graphene Fermi level. This is due to phase-space filling and quenching of the scattering between hot electrons and optical phonons [3]. In addition, we reveal the interplay between TH modulation due to increase in the electronic temperature and due to Pauli blocking at different values of the Fermi level. This work offers new insights for the understanding of TH all-optical modulation and thus for the realization of ultrafast frequency converters and nonlinear modulators. [1] Soavi, G. et al. Nature Nanotechnology 13, 583-588 (2018). [2] Cheng, Y. et al. Nano Letters 20, 8053-8058 (2020). [3] Pogna, E. A. et al. ACS Nano 15, 11285-11295 (2021).

#### HL 29.5 Thu 10:30 H36

Anisotropic transport in 1D graphene superlattices — •JULIA AMANN¹, KENJI WATANABE², TAKASHI TANIGUCHI², DIETER WEISS¹, and JONATHAN EROMS¹ -¹Institute of Experimental and Applied Physics, University of Regensburg, Regensburg, Germany — ²National Institute for Materials Science, Tsukuba, Japan One-dimensional superlattices (1DSL) in graphene were predicted to show intriguing effects, such as anisotropy in transport, additional Dirac points and a distorted Fermi contour. In contrast to two-dimensional graphene superlattices, which have been widely studied, only very few experiments on graphene 1DSLs have been reported. We use a patterned few-layer graphene gate underneath an encapsulated monolayer graphene to create a 1DSL. With the combined action of a global silicon backgate and the patterned bottom gate we are able to control superlattice potential strength and charge carrier density independently. We show low temperature transport measurements on a gate tunable 1DSL in graphene with a period of 50 nm in directions parallel and perpendicular to the modulation as we use an L-shaped Hall bar. The typical Dirac cone shape gets distorted, and we observe anisotropic transport in x and y direction. We observe the emergence of multiple Dirac points in modulation direction due to band flattening with increasing superlattice potential. These extra Dirac points are represented as additional Landau fans in magnetotransport. Further, Weiss oscillations can be observed which confirm the 1D superlatice modulation and the anisotropy.

#### HL 29.6 Thu 10:45 H36

Topological Phenomena in Self Assembled Folded Graphene — •LINA BOCKHORN¹, SUNG JU HONG², BEI ZHENG¹, JOHANNES C. RODE¹, and ROLF J. HAUG¹ — ¹Institut für Festkörperphysik, Leibniz Universität Hannover, 30167 Hannover, Germany — ²Division of Science Education, Kangwon National University, Chuncheon, 24341, Republic of Korea

The stacking- and folding angle of 2D materials to 3D structures has emerged as an important, novel tuning parameter for the tailoring of optical, mechanical, electronic and magnetic properties. Here, we investigate the final interlayer configurations of self-assembled folded graphene structures generated via atomic force microscopy technique [1, 2] and its electronic properties [3, 4].

Self-assembled folded graphene shows not only the typical electronic properties of twisted graphene layers but also phenomena due to the folded region [3, 4]. In our magnetotransport measurements, we observe e.g. an additional peak next to the charge neutrality peak which is independent of the magnetic field. This peak at a certain charge carrier density is attributed to the compressive strain due the folded edge [3].

**NV**⁻ **center in the vicinity of linear defects in diamond** — •REYHANEH GHASSEMIZADEH¹, WOLFGANG KRÖRNER¹, DANIEL URBAN¹, and CHRISTIAN ELSÄSSER^{1,2} — ¹Fraunhofer Institute for Mechanics of Materials IWM, Wöhlerstr. 11, 79108 Freiburg, Germany — ²University of Freiburg, Freiburg Materials Research Center (FMF), Stefan-Meier-Straße 21, 79104 Freiburg, Germany

The NV⁻ center is a point-defect complex in the diamond crystal with an excellent potential for implementing qubits in future quantum computing hardware. However, the structuring of point defects on the atomic scale remains an experimental challenge. Here we study theoretically the interaction between dislocations and the NV⁻ center. We evaluate to which extent dislocation lines that are naturally present in the diamond crystal may be used for structuring NV⁻ center as a first step towards a NV-based quantum register. Using density functional theory (DFT) we model  $\mathrm{NV}^-$  centers in the vicinity of the most common dislocations in diamond and calculate the defect formation energy, structural geometry, defect levels and zero-field (ZFS) parameters. Our simulations reveal that dislocations potentially trap the  $\mathrm{NV}^-$  with an energy release of up to 3 eV. Although the analysis of geometry, defect levels and ZFS parameters of NV⁻ centers being close to dislocations in general show strong deviations from their values in the perfect bulk structure, the lowest energy configuration of a NV⁻ center at the reconstructed dislocation cores have ZFS values with less than 5% deviation from their NV⁻ bulk values. Our results opens new insights for the design of NV-based quantum computing devices.

Quantifying Quantum Coherence in Polariton Condensates — •CAROLIN LÜDERS¹, MATTHIAS PUKROP², ELENA ROZAS¹, CHRISTIAN SCHNEIDER³, SVEN HÖFLING⁴, JAN SPERLING⁵, STEFAN SCHUMACHER^{2.6}, and MARC ASSMANN¹ — ¹Experimentelle Physik 2, TU Dortmund, Germany — ²Department of Physics and Center for Optoelectronics and Photonics Paderborn (CeOPP), Universität Paderborn, Germany — ³Institute of Physics, University of Oldenburg, Germany — ⁴Technische Physik, Physikalisches Institut and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, Germany — ⁵Integrated Quantum Optics Group, Institute for Photonic Quantum Systems (PhoQS), Paderborn University, Germany — ⁶Wyant College of Optical Sciences, University of Arizona, USA

We theoretically and experimentally investigate quantum features of an interacting light-matter system from a multidisciplinary perspective, unifying approaches from semiconductor physics, quantum optics, and quantum information science. As an example of a hybrid light-matter interface, we drive a polariton microcavity across the condensation threshold and observe the transition from an incoherent thermal state to a coherent state in the emission. By analyzing the phase-space distributions of the emitted light, we quantify the amount of quantum coherence that results from the quantum superposition of Fock states, constituting a measure of the resourcefulness of the produced state for modern quantum protocols.[1]

Machine Learning enhanced in-situ electron beam lithography of photonic nano-structures — •JAN DONGES, MARVIN SCHLISCHKA, CHING-WEN SHIH, MONICA PENGERLA, IMAD LIMAME, JOHANNES SCHALL, LUCAS RICKERT, SVEN RODT, and STEPHAN REITZENSTEIN — Technische Universitaet Berlin, Hardenbergstr. 36, 10623 Berlin, Germany

The unique in-situ electron beam lithography (iEBL) nanotechnology concept enables us to embed single quantum emitters into photonic nano-structures with a 34nm precision. To obtain the fitted position of the quantum emitter with high accuracy, the signal-to-noise ratio of their catholuminescence (CL) needs to be well above unity even for ms integration times. Here we show that for samples with dark quantum emitters, such as telecom quantum dots or low planar photon-extraction efficiency, machine learning (ML) is very well suited to drastically improve the performance of iEBL at low CL intensities. The machine learning software utilizes computer algorithms, which were trained through data samples to denoise data with a barely visible quantum dot emission. We present experimental results for InGaAs quantum dots, which could be successfully embedded into circular Bragg grating structures with the assistance of machine learning. Our experimental results yield that by using ML, the CL sensitivity and the alignment accuracy could be increased by more than an order of magnitude compared to standard iEBL.

**Photon propagation between quasinormal mode cavities** — •ROBERT FUCHS, SEBASTIAN FRANKE, ANDREAS KNORR, and MARTEN RICHTER — Technische Universität Berlin, Berlin, Germany

Quasinormal modes (QNMs) provide a useful and intuitive way to define modes for open cavities. They have been utilized for a variety of problems both in classical electrodynamics, and recently used in a fully quantized description for three dimensional geometries.

We show that a multi-cavity extension of the QNM quantization is possible if the cavities are far away from each other so that retardation effects are important. However, this quantization approach leads to a set of non-bosonic operators with a continuous spectrum. In the multi-cavity theory, this continuum serves as a bath which can be used to describe photon propagation between the separately quantized cavities.

Using a fourth-order Nakajima-Zwanzig equation, we point out how to get equations of motion for the system density matrix that include dissipation as well as inter-cavity transfer terms with significant retardation delays described by microscopic QNM parameters.

Sionludi - A table-top dilution refrigerator — •VIKTOR ADAM, ALEXANDER ZILZ, and WOLFGANG WERNSDORFER — KIT, Wolfgang-Gaede-Str. 1, 76131 Karlsruhe

Dilution cryostats are the only technology that provides continuous cooling performance from room temperature down to several mK. These devices utilize the endothermic process of diluting liquid  $\text{He}^3$  into liquid  $\text{He}^4$ , which occurs even at 0 K. By evaporating  $\text{He}^3$  from this mixture and returning it to the mixing chamber, the refrigerator can be operated continuously.

The Sionludi dilution refrigerator is a unique platform for low-temperature research. The table-top design combined with its small dimensions of approximately 25 cm in diameter and 50 cm in height allow for comfortable mounting of experiments and periphery to the cryostat. The key advancement of this cryostat is the fast injection line, which allows direct cooling of the dilution stage of the cryostat by the circulation of 4 K cold mixture during precooling without affecting the operation at lowest temperatures. As a result, the Sionludi features fast cool-down and warm-up times of less than 3 and 1.5 hours, respectively, while providing cooling powers of up to  $200 \,\mu$ W at 100 mK as well as base temperatures of below 20 mK. The fast turnaround time can accelerate sample throughput and thus progress in many research applications such as quantum sensing or quantum computing.

#### HL 30.6 Thu 11:00 P3

Telecom-band single photons from functionalized carbon nanotubes coupled to a an open cavity — •LUKAS HUSEL¹, JULIAN TRAPP¹, XIAOJIAN WU², MANUEL NUTZ³, THOMAS HÜMMER³, YUHUANG WANG², DAVID HUNGER⁴, and ALEXANDER HÖGELE^{1,5} — ¹Ludwig-Maximilians-Universität, 80539 München — ²University of Maryland, 20742 Maryland, USA — ³Qlibri GmbH, 80337 München — ⁴Karlsruher Institut für Technologie, 76131 Karlsruhe — ⁵Munich Center for Quantum Science and Technology, 80799 München

Quantum light at telecom wavelengths is of fundamental relevance in science and technology. A promising room temperature source of telecom single photons are functionalized carbon nanotubes (CNTs). In this system, dephasing and spectral diffusion limit spectral purity and indistinguishability of the generated photons, which can in principle be overcome by coupling the emitters to a cavity. Here, we demonstrate spectrally narrow single photon emission at wavelengths around 1460 nm from single CNT defects coupled to a fiber-based Fabry-Pérot resonator. We operate the cavity at ambient conditions and in the regime of low Purcell enhancement. By changing the cavity length, we tune the emission wavelength over a range of tens of nm, and the power spectral density by a factor of six. The coherence time of the generated photons matches the cavity linewidth, which constitutes an increase compared to the expected dephasinglimited free-space linewidth. Our results represent a step towards CNT-based sources of telecom-band single photons with high purity and indistinguishability.

Bright Electrically Controllable Quantum-Dot-Molecule Devices Fabricated by In Situ Electron-Beam Lithography — •JOHANNES SCHALL¹, MARIELLE DECONINCK¹, NIKOLAI BART², MATTHIAS FLORIAN³, MARTIN VON HELVERSEN¹, CHRISTIAN DANGEL⁴, RONNY SCHMIDT¹, LUCAS BREMER¹, FREDERIK BOPP⁴, ISABELL HÜLLEN³, CHRISTOPHER GIES³, DIRK REUTER⁵, ANDREAS D. WIECK², SVEN RODT¹, JONATHAN J. FINLEY⁴, FRANK JAHNKE³, ARNE LUDWIG², and STEPHAN REITZENSTEIN¹ — ¹IFKP, TU Berlin, Germany — ²LS AFP, Ruhr-Universität Bochum, Germany — ⁵Department Physik, Universität Paderborn, Germany

In quantum repeater networks it is of central importance to temporarily store and retrieve quantum information. Concepts based on quantum dot molecules (QDMs) promise storage times in excess of 1 ms. To make use of QDM based quantum memories, efficient coupling to flying qubits needs to be realized while maintaining precise electrical control. We report on the development of electrically tunable single-QDM devices with strongly enhanced broadband photon extraction efficiency. The quantum devices are based on stacked quantum dots in a pin-diode structure underneath a deterministically defined circular Bragg grating using in situ electron beam lithography. We determine the photon extraction efficiency, demonstrate bias voltage dependent spectroscopy and measure excellent single-photon emission properties. The metrics make the developed QDM device an attractive building block for use in future photonic quantum networks.

#### HL 30.8 Thu 11:00 P3

Machine Learning-Based Optimization of Chiral Photonic Nanostructures: Evolution- and Neural Network-Based Designs — OLIVER MEY¹, •MANAN SHAH², and ARASH RAHIMI-IMAN² — ¹Fraunhofer IIS/EAS, Fraunhofer Institute for Integrated Circuits, Division Engineering of Adaptive Systems, Dresden — ²I. Physikalisches Institut und Zentrum für Materialwissenschaften, Justus-Liebig Universität Gießen, D-35392, Germany

Machine learning (ML) techniques such as deep learning (DL) and evolutionary algorithms (EA) exhibit unprecedented capabilities in the scientific ML realm. DL uses artificial neural networks to infer unintuitive solutions for complicated design requirements and specific functionalities. Likewise, the EA attempts to find the optimized solution by utilizing principles such as mutation of parameters and extinction of less promising solutions. These approaches are faster and more effective in the inference of nanostructure design parameters for desired properties, such as wavelength coverage and peculiar response functions, compared to conventional numeric simulations.

We present a nano-patterned GaP dielectric substrate that favors singlehanded circularly polarized light (CPL) in reflection or transmission [1]. The optimization in chiral dichroism (CD) by neural networks is compared with the evolutionary algorithm. The increased CD in simulated spectra for designs with stronger reflectivity of right CPL and lower transmissivity of left CPL makes the ML techniques effective to optimize a myriad of properties for metamaterials and photonic nanostructures. [1] Phys. Status Solidi RRL 2022, 16, 2100571.

#### HL 30.9 Thu 11:00 P3

Strain-tunable GaAs quantum dot-based circular Bragg gratings towards entangled photon pairs with high indistinguishability — •CHENXI MA¹, JINGZHONG YANG¹, CONSTANTIN SCHMIDT¹, XIN CAO¹, YITENG ZHANG¹, MAX-IMILIAN HELLER¹, JÜRGEN BECKER², EDDY P. RUGERAMIGABO¹, MICHAEL ZOPF¹, and FEI DING^{1,3} — ¹Institut für Festkörperphysik, Leibniz Universität Hannover, Hannover, Germany — ²Institut für Mikroproduktionstechnik, Leibniz Universität Hannover, Garbsen, Germany — ³Laboratorium für Nano- und Quantenengineering, Leibniz Universität Hannover, Hannover, Germany

The on-demand generation of bright entangled photon pairs is an attractive goal for the realization of quantum communication networks. Epitaxial GaAs quantum dots (QDs), grown via local droplet etching and nanohole infilling, are promising candidates because they are symmetric and strain-free. This leads to small exciton fine structures and high entanglement fidelities of photons emitted from the biexciton-exciton cascade. However, the photon indistinguishability is intrinsically limited in this scheme. GaAs QDs also suffer from inefficient photon extraction, which was addressed by embedding QDs in circular Bragg gratings. Here, we propose to engineer the cavity mode to match the biexciton transition with the assistance of strain-tuning techniques. The resulting asymmetric Purcell enhancement will increase the decay rate of the biexciton transition and consequently improve the photon indistinguishability. This heterogeneous photon indistructure can serve as a blueprint for future quantum communication devices.

#### HL 30.10 Thu 11:00 P3

GaAs heterostructures for coupling of spin qubits to self-assembled quantum dots — •SELMA DELIĆ^{1,2}, PRIYABRATA MUDI^{1,2}, SEBASTIAN KINDEL², PAOLA ATKINSON³, DETLEV GRÜTZMACHER¹, and BEATA KARDYNAŁ^{1,2} — ¹Peter Grünberg Institute 9, Forschungszentrum Jülich, 52425 Jülich, Germany

²Department of Physics, RWTH Aachen University, 52074 Aachen, Germany
 ³Institut des Nano Sciences de Paris, CNRS UMR 7588, Sorbonne Université, 75005 Paris, France

Operation of quantum networks relies on encoding qubits on photons. These photons can be converted into spin qubits in many material systems. Yet, in order to take full advantage of the electrons with information encoded in their spins, the spin qubits should be scalable or the spin should be transferred to spin qubits that can be scaled into quantum processors. Here, we use singlet-triplet (S-T) qubits defined in a GaAs/AlGaAs gate-defined quantum (double-) dot (GDQD) as a scalable qubit. While GaAs is suitable for a qubit exchange with photons due to its direct bandgap, the GDQD does not confine holes. Therefore, we use a GaAs droplet dot (QD) to achieve a coherent transfer of information between a photon and a spin of an electron before the electron is transferred to the S-T qubit. In this contribution, we show the design of heterostructure that can be used to fabricate S-T qubit coupled to epitaxial GaAs QD. We further report on the progress in optical and electrical characterisation of the device in gated structures aligned to the GaAs QD.

#### HL 30.11 Thu 11:00 P3

GaN/AlGaN/GaN solution gate field effects transistors as pH- and enzymatic sensors — •GENRIETTA STEINGELB, ALEXANDER HINZ, STEPHAN FIGGE, and MARTIN EICKHOFF — Institute of Solid State Physics, University of Bremen, Otto-Hahn-Allee 1, 28359 Bremen, Germany

A GaN/AlGaN/AlGaN-heterostructure solution gate field effect transistors (SGFETs) as pH-sensors will be presented. We discuss the performance of differential sensors realized by one SGFET with passivated gate and one with a bare GaN cap layer as a gate on one chip. The compensation of drift-effects such as like persistent photocurrent and temperature dependence will be discussed.

We have used such devices to study the time-dependent response of covalently immobilized enzymes on the gate surface towards the presence of their specific substrate molecules with acetylcholinesterase and penicillinase as examples.

#### HL 30.12 Thu 11:00 P3

Impact of GaN barrier thickness on indium incorporation in GaInN/GaN multiple quantum wells grown via MBE — •FAROUK ALJASEM, HEIKO BREMERS, UWE ROSSOW ROSSOW, and ANDREAS HANGLEITER — Institut für Angewandte Physik & Laboratory for Emerging Nanometrology, Technische Universität Braunschweig, Germany

The internal quantum efficiency (IQE) of optical devices based on GaInN is highly sensitive to the thickness of GaInN quantum well. The main way to increase the emission wavelength of GaInN quantum wells is to increase the indium content in the quantum well by enhancing the incorporation rate of indium. We grew fivefold GaInN MQWs at a substrate temperature of 580°C and the GaN barrier layer was grown in two steps. The first step is at the same growth temperature of GaInN quantum wells (580°C), called the low-temperature GaN (LT-GaN) layer and the second step is the high-temperature GaN (HT-GaN), which was grown after the ramping of the substrate temperature up to 725°C. From high-resolution XRD and high-resolution TEM measurements, we found that the thickness of the GaInN wells increased significantly with the increase of the growth time of the LT-GaN layer. The effects of changing the growth time of the LT-GaN layer include changing the indium content of the GaInN well and the thickness of the barrier layer. The analysis of GaInN/GaN MQWs samples using different characterization methods such as HR-XRD, HR-TEM, AFM, and PL provides a detailed understanding of the role of the indium adlayer and its impact on the growth mechanism at low temperatures.

#### HL 30.13 Thu 11:00 P3

Aging of GaN-based laser diodes investigated by micro-EL and micro-PL spectroscopy – •LUKAS UHLIG¹, CONNY BECHT¹, ERIK FREIER², JI-HYE KANG², VEIT HOFFMANN², CHRISTOPH STÖLMACKER², SVEN EINFELDT², and ULRICH T. SCHWARZ¹ – ¹Institut für Physik, Technische Universität Chemnitz, 09126 Chemnitz, Germany – ²Ferdinand-Braun-Institut gGmbH, Leibniz-Institut für Höchstfrequenztechnik, 12489 Berlin, Germany

For the work towards long-time reliable GaN-based ridge waveguide laser diodes it is essential to understand the specific degradation effects that occur after some time of operation. Among the reported aging mechanisms are the generation of point defects in the active layer and a decrease in p-side conductivity.

To clarify this, we compare a previously stressed device with a similar but unstressed laser diode using micro-electroluminescence (EL) and confocal microphotoluminescence (PL) spectroscopy. The devices are mounted p-side-down and the metal layer on the n-side is polished away to allow optical characterization in the plane of the quantum wells.

In contrast to the homogeneous EL-emission from the non-stressed device, the stressed laser diode exhibits bright and dark areas along the ridge on the scale of few 10  $\mu$ m. The systematic correlation of high intensity with a spectral blueshift and vice versa indicates local changes in the charge carrier density that we attribute to inhomogeneous electrical pumping. The micro-PL-measurements show an increased defect density in the active region.

HL 30.14 Thu 11:00 P3

Spectral and temporal behavior of the near field of 10  $\mu m$  broad area blue laser diodes — •DOMINIC J. KUNZMANN¹, LUKAS UHLIG¹, JANNINA J. TEPASS¹, ANNA KAFAR^{2,3}, SZYMON STANCZYK^{2,3}, PIOTR PERLIN^{2,3}, and ULRICH T. SCHWARZ¹ — ¹University of Technology Chemnitz, 09126 Chemnitz, Germany — ²Institute of High Pressure Physics PAS, Warsaw, Poland — ³TOP-GAN Ltd., Warsaw, Poland

We investigate the near field for the laser diodes driven in pulsed conditions with pulse lengths in the range of a few 10 ns up to 100 ns and currents from 1.5  $I_{\rm th}$  to 4  $I_{\rm th}$ . A streak camera image and a high resolved longitudinal mode spectrum are taken at each point of a near field scan for blue laser diodes with a 10  $\mu$ m broad ridge.

The combination of the streak camera setup and the high resolution spectrometer allows us to investigate: the spectral-lateral-temporal behavior with complex dynamics due to lateral-longitudinal mode competition, the wavelength shift at the lasing onset and on the other hand to get the longitudinal mode spectrum. Different mode combs are interacting in this longitudinal mode spectrum and the predominating mode comb changes for different parts of the spectrum.

An increasing laser current leads to a broadening of the spectrum as well as to the filling of the gain volume, while for higher currents the lateral distribution seems to be similar across the whole spectrum. Comparing these results to previously measured devices with a 40  $\mu$ m broad ridge, we observe a less homogeneous near field distribution with a slight systematic asymmetry.

#### HL 30.15 Thu 11:00 P3

**Molecular beam epitaxy of ScGaN on 6H-SiC** — •Аагол Giess, Fabian Ullмалл und Stefan Krischok — Institut für Mikro und Nanotechnologien, Institut für Physik, TU Ilmenau

Group III-nitrides are well-suited semiconductors for optoelectronic and sensor devices. Among them, Sc-containing nitrides are of recent interest as well. In this contribution we report on our present progress in ScGaN PAMBE growth. We grow ScGaN using plasma-assisted molecular beam epitaxy on Si-faced 6H-SiC. Prior growth the SiC-surface is cleaned by a HF-Dip and a gallium anneal. Compared to GaN growth the implementation of scandium poses significant challenges: (i) ScN inclines to cubic growth and (ii) Gallium tends to form liquid droplets. In order to find optimal growth conditions, parameters such as substrate-temperature and nitrogen as well as Sc and Ga flux have been systematically varied. During growth, reflection high-energy electron diffraction (RHEED) diffraction patterns have been monitored. Further characterization has been performed by X-Ray photoelectron spectroscopy (XPS) and scanning electron microscopy (SEM). In future we plan systematic studies on the electronic properties of high quality epitaxial ScGaN thin films as well as their interaction with molecules.

#### HL 30.16 Thu 11:00 P3

MOVPE-grown optoelectronic devices with GaN:Mg/GaN:Ge tunnel junctions — •CHRISTOPH BERGER, ARMIN DADGAR, JÜRGEN BLÄSING, GORDON SCHMIDT, HANNES SCHÜRMANN, PETER VEIT, FRANK BERTRAM, JÜRGEN CHRIS-TEN, and ANDRÉ STRITTMATTER — Otto-von-Guericke-Universität Magdeburg, Deutschland

We report on low resistive GaN-based tunnel junctions (TJ) and TJ optoelectronic devices grown by metalorganic vapor phase epitaxy. Very high donor concentrations, which are mandatory for low-resistive TJs, are achieved by using germanium instead of commonly used silicon. For efficient activation of GaN:Mg, a growth process was developed that includes an in-situ activation step and overgrowth of the p-type GaN with GaN:Ge in nitrogen ambient to prevent the repassivation of the buried p-type layer. Electrical and optical characterization of the fabricated LEDs shows that GaN:Mg is efficiently activated and additional ex-situ activation is expendable. Tunnel-junction LEDs show an improved light output by approximately 20 % in comparison to conventional LEDs with semitransparent contacts and exhibit a comparable differential resistance of  $1.2 x 10^{-2} \ \Omega cm^2$  at a current density of 100  $A cm^{-2}$  without voltage penalty. Such tunnel-junctions were implemented in laser diode structures and were used to realize cascaded LEDs with up to three pn-junctions stacked on top of each other. We will present our latest results on the growth, the challenges and the characteristics of these sophisticated optoelectronic devices.

#### HL 30.17 Thu 11:00 P3

object detection of patterned GaN using convolutional neural networks and synthetic data — •MAHDI KHALILI HEZARJARIBI, UWE ROSSOW, MARKUS ET-ZKORN, HEIKO BREMERS, and ANDREAS HANGLEITER — Institut für Angewandte Physik, Technische Universität Braunschweig

Employing a practical object detection algorithm, we have developed a process to detect GaN pyramid structures, extracted from SEM images. A procedure has been developed to generate synthetic images for training the algorithm instead of the drudgery of multiple imaging of samples. These synthetic data include noise, blurring, and other contributing factors in order to realize images that are accurate enough to train an object detection algorithm. A MobileNet algorithm has been employed for the Object detection process. The synthetic database proved pragmatic leading to a promising confidence value of 75% for detecting real objects.

#### HL 30.18 Thu 11:00 P3

Nominally identical GaInN/GaN single quantum wells : variations of optical and structural properties — •RODRIGO DE VASCONCELLOS LOURENCO^{1,2}, MALTE SCHRADER^{1,2}, UWE ROSSOW¹, HEIKO BREMERS^{1,2}, and ANDREAS HANGLEITER^{1,2} — ¹Institute of Applied Physics, Technische Universität Braunschweig, Germany — ²Laboratory for Emerging Nanometrology, Braunschweig, Germany

We have unexpectedly observed differences in luminescence and structural properties in GaInN/GaN single quantum wells (SQW), grown under nominally identical conditions. This may be related to specific growth condition such as variation in substrate temperature or doping level; or substrate characteristics, e.g. bowing and offcut; as well as the status of the growth system. The samples were grown in low-pressure metalorganic vapour-phase epitaxy (MOVPE) on c-plane sapphire substrate. The differences in emission wavelength of the SQWs suggest that either there is a discrepancy in In content or in doping level. From the reference multiple quantum wells samples, a variation of 5 % in In concentration was observed. This fluctuation in In content may explain variations in the lattice constants of the SQWs measured by high-resolution X-ray diffraction (HRXRD). We aim to understand how the In content and among other attributes could influence the internal quantum efficiency at room temperature of GaInN/GaN SQWs ranging from 0.6 to 47%.

#### HL 30.19 Thu 11:00 P3

Skull-melting technique for the crystal growth of high-melting oxides — •DEMIAN RANFTL, KLAUS-DIETER LUTHER, and CORNELIUS KRELLNER — Physikalisches Institut, Goethe-Universität Frankfurt, 60438 Frankfurt/Main, Germany

For growing high melting oxide single crystals a quasi crucible-free induction melting technique can be used. Within a so-called skull-oven a high frequency electric field is applied to a powdered sample. A metallic part in the center of the powder will absorb the field and increase in temperature while also increasing the temperature of the oxides surrounding it. By cooling the outer sections of the sample it is possible to create a melt of a semiconductor in a crucible made out of its own sintered material, thus avoiding integration of unwanted crucible elements and enabling melts even at temperatures where no crucible material exist. This method was developed for the growth of, for example,  $ZrO_2$  crystals with a melting temperature of 2700°C [1].

In this contribution we will present the working principles of the skull-oven built at the Physikalisches Institut (Goethe Universität, Frankfurt) together with a brief introduction to skull-melting and its features. Additionally, we will present first attempts of the single crystal growth of pure titanium(IV) oxide using this skull-melting technique.

#### HL 30.20 Thu 11:00 P3

Investigation into the electric properties of  $\alpha$ -Ga₂O₃ based Schottky diodes with various Schottky metals — •S. KÖPP, C. PETERSEN, H. VON WENCKSTERN, and M. GRUNDMANN — Universität Leipzig, Felix Bloch Institute for Solid State Physics, Semiconductor Physics Group, Leipzig, Germany

We present current-voltage measurements of  $\alpha$ -Ga₂O₃:Sn based Schottky diodes with various Schottky metals and show on/off current ratios of up to 8 orders of magnitude. We thereby evaluate the effective Schottky barrier height by temperature dependent measurements in the range of 40K up to 400K.

Due to its possible applications in high-power electronics, a great deal of attention has been drawn to the wide bandgap semiconductor  $Ga_2O_3$ . In recent years, in addition to the well-researched thermodynamically stable monoclinic polymorph  $\beta$ -Ga₂O₃ the metastable corundum-structured  $\alpha$ -phase of Ga₂O₃ has shown to have promising physical properties. With a bandgap of 5.0-5.3 eV [1] and a predicted breakdown field of 8 MV/cm [2] it surpasses the theoretical limits of  $\beta$ -Ga₂O₃ in terms of Baliga's figure of merit [1]. Further,  $\alpha$ -Ga₂O₃ is isostructural to  $\alpha$ -Al₂O₃ and hence epitaxial growth on cost-efficient sapphire substrates is possible.

HL 30.21 Thu 11:00 P3 Copper tin oxide: An amorphous ternary oxide with tunable optical and electrical properties — •ARNE JÖRNS, HOLGER VON WENCKSTERN, and MAR-IUS GRUNDMANN — University of Leipzig, Felix Bloch Institute for Solid State Physics, Semiconductor Physics Group Due to the mismatching crystal structures of copper oxide (CuO) and stannic oxide (SnO₂) an amorphous alloy can form when these materials are combined. Few reports show that the resulting alloy exhibits p-type behavior, but low hole mobility results in unreliable Hall measurements [1]. Nevertheless, optical and electrical properties can be tuned by the alloy composition.

In this work we investigated copper tin oxide thin films deposited by pulsed laser deposition of ceramic CuO and SnO₂ targets at room temperature and in oxygen atmosphere. The resulting samples are highly disordered and *n*-type semiconducting with room temperature mobilities up to  $11 \text{ cm}^2 \text{V}^{-1} \text{s}^{-1}$ . Optical and electrical properties can be tuned in a wide range by varying composition ratio and chamber pressure. Temperature dependent Hall-measurement for different cation contents and a first approach on Schottky diodes will be reported. [1] P. J. M. Isherwood *et al.*, J. Appl. Phys., **118**, 105702, 2015

#### HL 30.22 Thu 11:00 P3

**Indium oxide metal-semiconductor field-effect transistors** — •FABIAN SCHÖPPACH, HOLGER VON WENCKSTERN, and MARIUS GRUNDMANN — Felix Bloch Institute for Solid State Physics, Universität Leipzig, Germany

Indium oxide  $(In_2O_3)$  combines promising physical properties such as high carrier mobility and transparency in the visible. However,  $In_2O_3$  is generally challenging to use in active devices. This is mainly due to its tendency to form an electron accumulation layer on its surface (SEAL) which is reported to be caused by surface near oxygen vacancies [1]. Both, compensating Mg doping and oxygen plasma treatment can be used to suppress the SEAL formation [2,3]. Moreover, as a sesquioxide,  $In_2O_3$  is a very robust material that resists classical patterning processes and cannot be patterned by wet chemical processes.

In this work,  $In_2O_3$  films grown by pulsed laser deposition are structured via dry-etching techniques. With that field-effect transistors were fabricated for the first time, reaching on-off ratios of over 5 orders of magnitude and low sub-threshold swings of about 110 mV/dec. For the source and drain contacts, gold was deposited by inert ambient sputtering. Schottky gate diodes were fabricated in a reactive sputtering process, which is a prerequisite for obtaining electrically rectifying contacts to  $In_2O_3$  [4].

#### HL 30.23 Thu 11:00 P3

Electrical transport properties of Sn, Si and Ge doped  $\alpha$ -Ga2O3 — •THORBEN SLOTOSCH, CLEMENS PETERSEN, HOLGER VON WENCKSTERN, and MARIUS GRUNDMANN — Universität Leipzig, Felix Bloch Institute for Solid State Physics, Semiconductor Physics Group, Leipzig, Germany

We present Schottky barrier diodes based on PLD-grown  $\alpha-Ga_2O_3$  thin films, doped with the effective mass donors Sn, Si and Ge. By employing temperature dependent current-voltage measurements, Hall-effect measurements and thermal admittance spectroscopy of the space charge region we investigate the electric transport properties of  $\alpha-Ga_2O_3$  in relation to the doping levels provided by the combinatorial PLD method.

Materials with large bandgaps (> 3.4 eV) have attracted scientist's interest more and recently. With it's high bandgap of 4.6-5.3 eV Ga₂O₃ is well suited for appilcations in high-power devices [1]. Numerous studies have already reported on the thermodynamically stable monoclinic  $\beta$ -phase of gallium oxide. However the metastable  $\alpha$ -polymorph has gained scientist's attention. It's corundum structure allows  $\alpha$ -Ga₂O₃ to form alloys with other corundum-structured materials like  $\alpha$ -Al₂O₃ over the whole composition range to tune the bandgap energy up to 8.75 eV [2]. In order to grow  $\alpha$ -Ga₂O₃ combinatorial pulsed laser deposition can be employed, which offers the advantage of a precise dopant incorporation and lateral continuous doping gradients [3].

Characterization and optimization of MgZnO thin films with steep lateral composition gradient — •LAURENZ THYEN, MAX KNEISS, HOLGER VON WENCKSTERN, and MARIUS GRUNDMANN — Universität Leipzig, Felix-Bloch-Institut für Festkörperphysik, Linnéstraße 5, 04103 Leipzig, Germany

The materials magnesium- and zinc-oxide have been widely investigated in the past. Corresponding step graded ternary alloy thin films of  $Mg_xZn_{1-x}O$  have been of great interest [1]. Pulsed laser deposition (PLD) has been used to grow laterally and vertically graded thin films [2]. The precise control of its chemical composition is of great importance for possible applications. Additionally, in the course of miniaturization of electrical devices like wavelength-selective multichannel UV photodetectors, a well-defined steep slope of the material gradient will be beneficial [3,4].

In this contribution the properties of  $Mg_xZn_{1-x}O$  thin films with lateral compositional gradient grown by pulsed laser deposition will be discussed. In order to obtain information about the material composition of the thin films, energy-dispersed X-ray spectroscopy, spatially resolved ellipsometry and microphotoluminescence spectroscopy measurements have been conducted. Moreover, steep lateral gradients with a slope of up to 20 % Mg content per millimeter were realised.

HL 30.25 Thu 11:00 P3

Characterization of Schottky barrier contacts on a (Mg,Zn)O thin film with lateral composition gradient — •MAURICIO BASSALLO, LAURENZ THYEN, MAX KNEISS, HOLGER VON WENCKSTERN, and MARIUS GRUNDMANN — Universität Leipzig, Felix-Bloch-Institut für Festkörperphysik, Linnéstraße 5, 04103 Leipzig, Germany

A lateral chemical gradient composition structure based on (Mg,Zn)O is a promising material that allows a spectrally resolved detection of UV photons due to a systematic shift of the absorption edge with the position. In that sense, N different photodetectors, fabricated at different positions of the gradient, would be sensitive to specific photon energies [1]. Due to the challenges of stable p-type (Mg,Zn)O fabrication with high conductivity and mobility, metal-semiconductor-metal (MSM) structures are preferentially chosen for (Mg,Zn)O-based photodetectors [2]. These consist of two small interdigitated coplanar Schottky contacts, which are  $10\mu$ m wide and  $10\mu$ m apart and whose simplicity in fabrication makes the MSM structure promising for photodetection. In this contribution the electrical properties of the Schottky contacts are discussed using the current-voltage measurements. Additionally, the influence of the surface characteristics on the contacts are discussed using Atomic Force Microscopy measurements.

HL 30.26 Thu 11:00 P3

**Porosity Analysis of Mesoporous Silicon by SEM Images of Polished Cross Sections** — •STEFANIE LAWUNDY^{1,2}, WALDEMAR SCHREIBER¹, and STEFAN JANZ¹ — ¹Fraunhofer ISE, Freiburg i. Br., Germany — ²University of Freiburg, Germany

Porous silicon fabricated by electrochemical etching is a material known for decades with a wide field of applications ranging from photovoltaics to medicine. Nevertheless, the determination of its key property porosity is still an issue that is to be refined.

Especially, the spatially resolved porosity analysis of layered mesoporous silicon stacks are challenging due to the small structures of only about 10 nm. Current measurement techniques as gas adsorption are not appropriate for such structures since they cannot fully penetrate the pores, cannot resolve the porosity profile over layer depth and lead to no information about the pore morphology.

In order to account for these challenges a new approach has been developed. It is based on the analysis of SEM cross section images where contrast and homogeneity are enhanced by a preceding polishing procedure. Pores are defined by using an image processing software and porosity profiles are calculated.

Results of this procedure are assumed to be an important step towards an accurate description of the etching process.

#### HL 30.27 Thu 11:00 P3

Temperature dependent light beam induced current (LBIC) investigation of PCMO-STNO interfaces — •SOPHIE SCHAIBLE¹, TOBIAS WESTPHAL¹, FELIX MÜLLER¹, STEPHAN MELLES², CHRISTIAN JOOSS², and MICHAEL SEIBT¹ — ¹IV. Physical Institute, University of Goettingen, Göttingen, Germany — ²Institute for Materials Physics, University of Goettingen, Göttingen, Germany

Pn-heterojunctions of calcium doped praseodymium manganite  $Pr_{0.66}Ca_{0.34}MnO_3$  and niobium doped strontium titanite  $SrTi_{0.998}Nb_{0.002}O_3$ (PCMO-STNO) are used as a model system to investigate next generation solar cells going beyond the Shockley-Queisser limit by harvesting hot polaron-type charge carriers. In order to study the photovoltaic response in combination with the temperature and wavelength dependent generation of charge carriers, LBIC is used on a specially grown wedge-shaped PCMO thin film. A position dependent signal is obtained, which translates into the variation of the absorber thickness. PCMO has a perovskite structure and exhibits strong electronphonon coupling leading to stable polarons. At the charge ordering temperature  $(T_{CO} \approx 230 \text{ K})$  PCMO undergoes a phase transition from the semiconducting paramagnetic to the charge ordered phase [1]. Liquid nitrogen cooling of the LBIC setup enables temperature dependent LBIC measurements below room temperature and thus gives insights into this transition. Comparison with temperature dependent electron beam induced current (EBIC) measurements highlights differences between photon and electron excitation. [1] L. Wu et al., Phys. Rev. B 76, 174210 (2007)

## HL 30.28 Thu 11:00 P3

Mapping Excitonic and Ionic Dynamics in Lead Halide Perovskite Thin Films — •YENAL YALCINKAYA¹, PASCAL ROHRBECK¹, EMILIA SCHÜTZ², LUKAS SCHMIDT-MENDE², and STEFAN A.L. WEBER¹ — ¹Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany — ²Department of Physics, University of Konstanz, Universitätsstr. 10, 78464, Germany

Understanding the dynamics of excitons and ions is crucial for improving the lead halide perovskites and related devices. In this study, we fabricated triple cation lead halide perovskite half cells (ITO/SnO2/Perovskite) with small and large grain sizes. We obtained nearly 100  $\mu m$  large grains by heat treating perovskite films under methylamine gas atmosphere. Since the grain boundaries are known to be the main source of defects and ion migration in lead halide perovskites, a certain change between charge carrier and defect behaviour between these two types of films is expected. Therefore, we utilized Time-resolved Kelvin Probe Force Microscopy (Tr-KPFM) for mapping the recombination of free charge carriers and ion migration in triple cation lead halide perovskite films with varying grain sizes. Mapping these excitonic and ionic components of photovoltage allowed us to map the defects within the perovskite films. Our results showed a significant increase in free electron-hole lifetimes in large grained perovskite films. Furthermore, we demonstrate the ion migration was suppressed by having fewer grain boundaries within the film. Our study shows how grain sizes affect the free charge carrier movements and how we can track these changes on nanoscale via KPFM.

#### HL 30.29 Thu 11:00 P3

The Effects of Residual Lead Iodide on the Stability of Perovskite Solar Cells — •XIONGZHUO JIANG and PETER MÜLLER-BUSCHBAUM — TU München, Physik-Department, Lehrstuhl für Funktionelle Materialien, 85748 Garching, Deutschland

Over the past few years, hybrid organic-inorganic lead halide perovskite materials have attracted tremendous interest as its excellent photovoltaic properties in perovskite solar cells (PSCs) with record power conversion efficiency. The residual lead iodide is easy to form during the fabrication of perovskite layer, especially for the two-step deposition method. In addition, residual lead iodide has been universally used in the state-of-the-art devices to boost the device performance. However, the effects of residual lead iodide on the stability of PSCs has not been fully understood and, therefore, needs to be deeply investigated for further improvement of device performance. Herein, it is shown that residual lead iodide exhibits insufficient stability under continuous light radiation and heating. The photodecomposition products (lead and iodine) of lead iodide pose a threat to the efficiency and stability of devices. Thus, unstable lead iodide under light radiation and heating is one of the main reasons for the degradation of perovskite device. Therefore, carefully controlling or eliminating the residual lead iodide in perovskite film is one of the critical methods to improve the long-term stability of PSCs.

HL 30.30 Thu 11:00 P3 **Multi-photon induced ultrafast absorption dynamics of optical excitons in 2D inorganic-organic hybrid semiconductor** – •MOHAMMAD ADNAN^{1,2}, RUDOLF BRATSCHITSCH², and GADDAM VIJAYA PRAKASH¹ – ¹Nanophotonics Lab, Department of Physics, Indian Institute of Technology Delhi, Hauz Khas, New Delhi 110016 India – ²Institute of Physics, University of Münster, Wilhelm-Klemm-Straße 10 48149 Münster, Germany

Two-dimensional inorganic-organic (IO) hybrid semiconductors have attracted prodigious attentions due to unique crystal structural packing and tunable exciton characteristics and exhibit strong optical exciton features at room temperature due to their large exciton binding energies (200-250 meV) [1]. These optical excitons are highly sensitive to the layer thickness and demonstrate distinct excitonic behaviors from surface and bulk regions. Multi-photon absorption spectroscopy is a novel probing tool which can monitor excitons from the deeper energy levels [1]. Nonlinear one-photon (3.54 eV), two-photon (1.55 eV) and three-photon (1.21 eV) transient absorption studies have been carried out to have better understanding of hot-carrier relaxations from different lower lying exciton energy levels. Fluence-dependent studies clearly demonstrate various nonlinear effects such as hot phonon bottleneck effect, exciton-exciton annihilation and Auger processes at higher fluences [2]. The results presented here may find interesting applications in developing advanced optoelectronic devices.

#### HL 30.31 Thu 11:00 P3

**Electron Beam Induced Current (EBIC) Investigations of Femtosecond Laser Sulfur Hyperdoped Silicon** — •MENGRU SUN¹, TOBIAS WESTPHAL¹, SIMON PAULUS², SÖREN SCHÄFER², STEFAN KONTERMANN², and MICHAEL SEIBT¹ — ¹University of Goettingen, IV. Physical Institute, Göttingen, Germany — ²Institute for Microtechnologies (IMtech), University of Applied Sciences Rhein-Main, Rüsselsheim, Germany

S hyperdoped Si formed by fs-laser irradiation improves the absorption of the Si-based optoelectronic devices to infrared wavelengths. A p-n junction is cre-

ated between the B doped p-type Si wafer and the S hyperdoped n-type region produced as a result of fs-laser pulse irradiation of the Si wafer surface under SF₆ atmosphere. The structural and electronic properties of the fs-laser hyperdoped S depend strongly on the laser-processing parameters such as the number of pulses per spot and laser fluence. In this contribution, we focus on S hyperdoped Si fabricated via fs-laser irradiation at 800nm wavelength and various laser processing parameters. Electron Beam Induced Current (EBIC) performed in plan-view and cross-section geometry is used for characterizing the electronic properties of the sample like excess minority carrier diffusion length. Combining EBIC with SEM images, the correlations between electronic properties and the surface textures can be observed. The results of this work show the important role of processing parameters on the surface macro- and microstructure. EBIC data further indicates the different behaviors of the excess carriers within the ridges and the valleys at the surface.

#### HL 30.32 Thu 11:00 P3

Spin Polarization Dynamics of Photo-excited Carriers in CsPbX3 Nanocrystals — •AHMET TOSUN, SIMONE STROHMAIR, ANJA BARFÜSSER, QUINTEN AKKERMAN, TUSHAR DEBNATH, AMRITA DEY, and JOCHEN FELDMANN — Chair for Photonics and Optoelectronics, Nano-Institute Munich and Department of Physics, Ludwig-Maximilians-Universität (LMU), Königinstr. 10, 80539 Munich, Germany

We present results on spin relaxation dynamics of photoexcited carriers in CsPbX3 nanocrystals by employing time-resolved differential transmission spectroscopy. After photoexcitation with circularly polarized light we observe a pronounced spin polarization in CsPbI3 nanocrystals. This spin-polarization is caused by selectively exciting spin-allowed transitions and is lost during thermalization and cooling of the photoexcited charge carriers. From temperaturedependent experiments we conclude that carrier-spin relaxation in CsPbI3 nanocrystals is predominantly caused by carrier-LO phonon scattering and can be described by the Elliot-Yafet mechanism.

#### HL 30.33 Thu 11:00 P3

Characterizing the conductive channels of 2D perovskite field-effect transistors with Kelvin probe force microscopy — •KONSTANTINOS BIDINAKIS, SHUANGLONG WANG, PAUL W.M. BLOM, WOJCIECH PISULA, TOMASZ MARSZA-LEK, and STEFAN A.L. WEBER — Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany

Perovskite-based field-effect transistors (FETs) are a promising class of electronic materials, which also provide a basis for understanding the lateral charge transport within perovskites. Specifically, FETs of 2D perovskite materials exhibit diminished ion migration and improved stability against moisture compared to their 3D counterparts, due to their specific structure. The performance of the transistors is strongly influenced by the nanoscale morphology of the perovskite film. We used Kelvin probe force microscopy (KPFM) to correlate the local morphology and crystallinity with the potential distribution across a bottom-gate top-contact perovskite FET channel under operating conditions. The measured potential distribution from source to drain can indicate unwanted losses, e.g. at grain boundaries or at the electrodes.

In order to increase the crystalline quality of a Sn-based perovskite film, an additive with high Lewis alkalinity is used in the precursor solution, which coordinates with the Sn cation and retards crystallization. Using KPFM, we examined devices with and without such an additive and correlated the measured potential profiles with the charge transport characteristics, as well as ion migration and behavior at the perovskite grain boundaries.

#### HL 30.34 Thu 11:00 P3

**Cross linkable hole transport materials for p-i-n perovskite solar cells** — •Mohsen Hosseini Fard, Manuel Neubauer, Ervin Aljic, Simon Ewertowski, Selina Olthof, Dirk Hertel, and Klaus Meerholz — Department of Chemistry, University of Cologne, Germany

The use of hole transport materials (HTMs) in perovskite solar cells (PSCs) is indispensable. Many reports illustrate the importance of layer thickness, energy level alignment, doping and mobility of HTMs on PSCs performance. However, there are ambiguities regarding the properties of HTMs, which invoke further fundamental studies. Here, we investigate a series of cross-linkable hole transport materials (x-HTMs), TPD and TAPC derivatives, with different HOMO and LUMO energy positions. The advantage of HOMO and LUMO tunability of the above-mentioned compounds by exchanging molecular substituents is applied to investigate their hole extraction and electron blocking abilities. J-V characterization was used to investigate changes in the device characteristics. Major improvement in fill factor and Voc of MAPbI3 based solar cells was demonstrated by adjusting the thickness of x-HTMs. As a result, large improvements were observed in power conversion efficiency (PCE). A thin layer application of x-HTMs showed competitive results in PCE performance compared to the commonly used, commercially available materials like PTAA. Nevertheless, the application of a thin layer of QUPD (less than 5 nm) leads to high-efficient PSCs with a shown record PCE up of 19.56% using MAPbI3 as absorber, similar to the performance of a PTAA-based device.

#### HL 30.35 Thu 11:00 P3

Effect on Surface Morphology on 1.7eV-GaInAsP-layers on GaAs by surfactant-assisted MOVPE growth — •Ivo Rahlff, Patrick Schygulla, Jens Ohlmann, and David Lackner — Fraunhofer ISE, Freiburg i. B., Germany

III-V-compound multi junction solar cells hold record efficiencies since many decades. Recently, we have demonstrated a GaInP(1.9eV)/AlGaAs(1.44eV)//GaInAsP(1.09eV)/GaInAs(0.74eV) 4-junction wafer bonded solar cell that reaches 47.6% under a concentration of 665 suns (AM1.5d). All subcells are epitaxially deposited by MOVPE. To further increase the realistic efficiency potential above 50% a 6-junction device with the following bandgaps (1.94eV/1.71eV/1.42eV//1.19eV/0.98eV/0.74eV) is suggested. One promising candidate for the 1.71eV junction is GaInAsP. The challenge for this material system lies in the compositional regime between 1.60eV and 1.75eV, where phase separation has been reported.

In this work we investigate the effect of surfactant-assisted growth of GaInAsP alloys on the surface morphology during MOVPE growth. It is found that the GaInAsP growth without surfactant leads to severe surface roughening which is believed to be due to the onset of phase separation. XRD measurements revealed further decreasing tensile strain with increasing TMSb/III ratios which is expected, since the surfactant alters the atomic incorporation. Further investigations on the effect of the opto-electrical quality of the surfactant on the GaInAsP 1.7eV material is currently in progress.

#### HL 30.36 Thu 11:00 P3 Getting started in Perovskite Solar Cells - The little complications that are unmentioned — •MAXIMILIAN SPIES, SIMON BIBERGER, and FABIAN PANZER — University of Bayreuth, Bayreuth, Germany

Due to the current interest in highly efficient perovskite solar cells (PSCs), many groups are attempting to produce such PSCs based on published recipes. Since these recipes often assume a lot of prior knowledge or do not consider environmental conditions in sufficient detail, resulting efficiencies are low. This work shows some of the complications one faces when attempting to build a PSC in n-i-p-structure, considering especially the transport layers. Starting from low single digit power conversion efficiency (PCE), we exceeded PCEs of 12% due to modifications of the production process. We tested different variations of the hole transport layer "on device", including a relatively new approach of solution-based CO₂-doping. With the detrimental factor of humidity to perovskite being known, we show systematically the impact of in-glovebox-processing on PCE and V_{OC}. Further, we found that surface properties of the bottom electrode critically influence the fillfactor.

#### HL 30.37 Thu 11:00 P3

**First-principles study of perovskite/halide interfaces** — •SAMUELE SPREAFICO and BERND MEYER — Interdisciplinary Center for Molecular Materials and Computer Chemistry Center, FAU Erlangen-Nürnberg, Germany

Lead halide perovskites are a promising new class of semiconductors, which are easy and cheap to process and show high efficiency in optoelectronic applications. Photovoltaic engineering requires a controlled integration of the photoactive perovskite into a multi-layer heterostructure or quantum dot composite [1]. However, the interfaces in these devices unavoidably affect their optical response, for example the photoluminescence quantum yield. Here we present a density-functional theory investigation on the properties of the interfaces in a composite of CsPbBr₃ quantum dots embedded in a CsBr or NaBr matrix. First we performed a systematic screening of the structure and chemical composition of the interfaces. For the most stable configurations we determined the band alignments and we show how the band offsets at these interfaces depend on the interface structure, which can be tuned by changing synthesis conditions. #### HL 30.38 Thu 11:00 P3

**Energy Transfer in Stability-Optimized Perovskite Nanocrystals** — •MICHÈLE G. GREINER, ANDREAS SINGLDINGER, NINA HENKE, CAROLA LAMPE, ULRICH LEO, MORITZ GRAMLICH, and ALEXANDER S. URBAN — Nanospectroscopy Group and Center for Nanoscience (CeNS), Nano-Institute Munich, Department of Physics, Ludwig Maximilians University Munich, Koeniginstr. 10, 80539 Munich, Germany

Halide perovskites nanocrystals (NCs) are auspicious materials for low-cost, high efficient photovoltaic and light-emitting devices. Nevertheless, the fast degradation in contact with moisture is one critical issue. Another problem constitutes the inefficient charge transfer between different layers. To counteract both problems, we employ micelles made of diblock copolymers filled with methylammonium lead bromide (MAPbBr3) NCs. With this approach, we bypass the charge transfer issue by exploiting energy transfer (ET) between CsPbBr3 nanoplatelets and the MAPbBr3 micelles. We chose micelles with different diameters to find the best balance between protection and ET efficiency. As a result, we found an increase in stability by around 56% form the smallest to the thickest shell and a transfer efficiency up to 73.6% for the smallest mi-

celle. These findings could help improve different optoelectronic devices, such as perovskite-based solar cells or light-emitting devices.

#### HL 30.39 Thu 11:00 P3

Probing structural dynamics in optically excited 2D heterostructures by Ultrafast Electron Diffraction — •MASHOOD TARIQ MIR, ARNE UNGE-HEUER, AHMED HASSANIEN, LUKAS NÖDING, ARNE SENFTLEBEN, and THOMAS BAUMERT — University of Kassel, 34132 Kassel, Germany

Layered transition metal dichalcogenides (TMDs) host a rich collection of physical properties, opening many different applications with atomically thin films such as sensors, electronic switching, or energy storage. Among those materials, 1T-TaS2 exhibits a complex phase diagram depending on temperature encompassing charge density waves (CDW) with diverse commensurabilities. New phenomena have been observed and are further expected from combining different materials to 2D heterojunctions. We aim to use femtosecond laser pulses to induce rapid structural changes and probe them with ultrafast electron diffraction (UED). In this work, free-standing single-crystalline heterostructure samples were prepared down to a few nanometre thicknesses to allow electron diffraction in transmission mode. The preparation method was optimized using atomic force microscopy and optical microscopy to isolate atomically thin flakes. In addition, we present an initial UED study of CDW heterostructure (1T-TaS2 / Graphite). Upon lattice heating, the CDW material undergoes several phase transitions. We focus on the reversible phase transition of 1T-TaS2 from the nearly commensurate to the incommensurate phase and study the effect of interlayer coupling of stacked 1T-TaS2 / Graphite heterostructures.

#### HL 30.40 Thu 11:00 P3

Theory of non-integer high-harmonic generation in a topological surface state — •MAXIMILIAN GRAML¹, MAXIMILIAN NITSCH^{1,2}, ADRIAN SEITH¹, FERDINAND EVERS¹, and JAN WILHELM¹ — ¹Institute of Theoretical Physics, University of Regensburg — ²NanoLund and Solid State Physics, Lund University, Sweden

High-harmonic emission from a topological insulator has been observed recently [1] opening a platform to explore topology and relativistic quantum physics using strong laser fields. Strikingly, the higher order resonance frequencies can be continously shifted to non-integer multiples of the driving frequency by varying the carrier-envelope phase (CEP) of the driving field. Based on a semiclassical model we explain this finding as a characteristic property of the Dirac dispersion. We complement analytical results with numerical simulations based on the semiconductor Bloch equations.[2]

#### HL 30.41 Thu 11:00 P3

**Ultrafast spectroscopy of single quantum dots utilizing synchronized GHz-Oscillators** — •VALENTIN DICHTL, MICHAEL SEIDEL, GERHARD SCHÄFER, and MARKUS LIPPITZ — Experimental Physics III, University of Bayreuth, Germany

Ultrafast transient absorption or reflection spectroscopy of single semiconductor quantum dots is a well established technique, typically based on laser oscillators with about 80 MHz repetition rate. The excited state lifetime of the emitter is however much shorter than the pulse separation in these experiments. Most of the time one thus waits for the next laser pulse.

Here we present a modified setup based on two synchronized Ti:Sa lasers operating at 1 GHz repetition rate and a line camera with a spectral rate of 127 kHz. Noise suppression is accomplished via double modulation using a field programmable gate array (FPGA) for synchronizing AOMs with the line camera.

We demonstrate the perturbed free induction decay of single AlGaAs quantum dots at temperatures below 20 K. The total integration time is less than three minutes – currently software limited.

#### HL 30.42 Thu 11:00 P3

Non-linear optimization and error estimation for the dynamical modelling of photoluminescence spectra — •SEBASTIAN BOHM¹, MAX GROSSMANN¹, STEFAN HEYDER¹, KLAUS SCHWARZBURG², PETER KLEINSCHMIDT¹, ERICH RUNGE¹, and THOMAS HANNAPPEL¹ — ¹Fakultät für Mathematik und Naturwissenschaften, Technische Universität Ilmenau, Ehrenbergstraße 29, 98693 Ilmenau — ²Institut Solare Brennstoffe, Helmholtz-Zentrum Berlin für Materialien und Energie, Hahn-Meitner-Platz 1, 14109 Berlin

Modern compute power and improved algorithms allow to determine, e.g., the parameters of a kinetic model of time-resolved photoluminescence spectroscopy (TRPL) via the simultaneous fit of many excitation-dependent TRPL spectra. Since our method is based on a maximum likelihood estimator, we obtain information on the reliability of the derived values as well. As example, we use a TRPL model of M. W. Gerber and R. N. Kleiman [J. Appl. Phys. 122, 095705 (2017), URL 10.1063/1.5001128].

#### HL 30.43 Thu 11:00 P3

Pulse-driven non-adiabatic tunneling in nanocontacts: quasiclassical approach — Sangwon Kim¹, Tobias Schmude², Guido Burkard², and •ANDREY S. MOSKALENKO¹ — ¹KAIST, Daejeon, Korea — ²University of Konstanz, Konstanz, Germany

We develop a general quasiclassical theory for the description of the tunneling through time-dependent barriers induced by ultrashort light pulses and apply it to the tunneling induced by such pulses in nanocontacts [1]. In particular, we analyze the situation when the tunneling is driven by ideal half-cycle pulses. Among the numerous solutions that contribute to the tunneling probability, we choose two main solution branches with the largest contributions: The 1st solution exhibits the "tunneling" behavior of a wave packet whereas the 2nd solution exhibits the "evanescent-wave" behavior. For a large enough intercontact distance, the 1st solution dominates in terms of the tunneling probability. However, for minute distances and small field strengths, when the electron does not manage to escape from the classically forbidden region, the 2nd solution starts to dominate. Finally, we study a situation when the tunneling is driven by realistic few-cycle pulses. We see that the direction of the electron transport in the nanocontacts may be altered in dependence on the carrier-envelope phase of the driving pulse. We also find that the time when the electron effectively emerges from under the barrier does not necessarily exactly coincide with one of the peaks of the driving electric field.

[1] Sangwon Kim et al., New J. Phys. 23, 083006 (2021).

#### HL 30.44 Thu 11:00 P3

Time-resolved broadband transient reflectivity studies in ultrathin bismuth films — •ALEXANDER KASSEN¹, FABIAN THIEMANN¹, GERMÁN SCIANI², and MICHAEL HORN-VON HOEGEN¹ — ¹University of Duisburg-Essen, Lotharstr. 1, 47057 Duisburg, Germany — ²University of Waterloo, 200 University Avenue West, ON N2L 3G1, Canada

Bismuth, through its Peierls-Jones distorted lattice, offers the possibility to excite coherent phonon modes upon irradiation with ultra-short laserpulses. The optical  $A_{1g}$  mode at  $\approx 3$  THz is triggered by the displacive excitation mechanism due to transient changes of the atomic potential energy surface. These changes arise from optical excitation of the electron system and thus lead to a strong coupling between the phonons and charge carriers. The density of excited charge carriers, which depends on the incident fluence and film thickness, alters the equilibrium position of the atoms and softens the potential energy surface, leading to a redshift of the  $A_{1g}$  mode. Conversely, in an all optical pump-probe experiment with a measurement of the relative change of reflectivity  $\Delta R/R_0$ , we utilized the redshift of the  $A_{1g}$  mode to determine the level of excitation of the electron system. In the next step, this allowed us to compare the relaxation behavior and transient optical properties of films with different thicknesses leading to a broader insight in the phonon and carrier excitation mechanisms.

#### HL 30.45 Thu 11:00 P3

Dimensionality Reduction Techniques in Femtosecond Time-Resolved Ellipsometry Data Analysis and Theory — •NOAH STIEHM¹, YIXUAN ZHANG², ERICH RUNGE³, STEFAN KRISCHOK¹, HONGBIN ZHANG², and RÜDIGER SCHMIDT-GRUND¹ — ¹Technische Universität Ilmenau, Fachgebiet Technische Physik I, Weimarer Straße 32, 98693 Ilmenau, Germany — ²Technische Universität Darmstadt, Research Group Theory of Magnetic Materials, Otto-Berndt-Straße 3, 64287 Darmstadt — ³Technische Universität Ilmenau, Fachgebiet Theoretische Physik I, Weimarer Straße 32, 98693 Ilmenau, Germany

Physical modeling and interpretation of the transient dielectric function obtained from femtosecond time-resolved spectroscopic ellipsometry [1] poses a significant challenge, as it consists of many temporally and spectrally overlapping processes that need to be reliably separated to obtain stable and physically meaningful fit results. Ab-initio theory can help to separate these processes, but is not available for the whole time scale ( $\approx 100$  fs to several ns) of the experiment, due to the associated computational costs.

To help overcome these challenges we investigate the use of dimensionality reduction techniques like dynamic mode decomposition and manifold learning methods like locally-linear embeddings and autoencoders to be applied I) in model approximation of the experimental data and II) on ab-initio results from time-dependent density functional theory to cover larger time scales. By this we identify strategies for a reliable modeling pipeline with minimal human intervention.

#### HL 30.46 Thu 11:00 P3

Numerically exact simulations of quantum devices coupled to arbitrary environments using tensor networks — •MORITZ CYGOREK¹, VOLLRATH MARTIN AXT², BRENDON W. LOVETT³, JONATHAN KEELING³, and ERIK M. GAUGER¹ — ¹Heriot-Watt University, Edinburgh, UK — ²Universität Bayreuth, Germany — ³University of St Andrews, UK

Reliable predictions of the dynamics in nanoscale quantum devices with applications in photonics, transport, quantum information and communication require a careful consideration of environment effects. Here, we present the novel numerical method Automated Compression of Environments (ACE): The open quantum systems dynamics is expressed in terms of a tensor network, where the influence of the environment is incorporated into a matrix product operator in time, the so-called process tensor. ACE provides a direct way to calculate this process tensor numerically exactly with numerical errors originating only from time discretization and matrix product operator compression. As the numerical procedure starts directly from the microscopic Hamiltonian, no problemspecific derivations are required. Thus, as we show on a series of examples, one and the same computer code can be used to simulate the dynamics of open quantum systems with environments as diverse as photons, phonons, electrons, and spins, as well as combinations of multiple environments. This proof of principle demonstrates the tremendous potential of tensor network approaches as onesize-fits-all solutions to open quantum systems dynamics.

Transient negative thermal expansion in HgTe/CdTe heterostructures by heating of transverse phonons — •MATTHIAS RÖSSLE¹, MARC HERZOG², JAN PUDELL^{1,3}, WOLFRAM LEITENBERGER², MAXIMILIAN MATTERN², LUKAS LUNCZER⁴, CLAUS SCHUMACHER⁴, HARTMUT BUHMANN⁴, LAURENS MOLENKAMP⁴, and MATIAS BARGHEER^{1,2} — ¹Helmholtz-Zentrum Berlin, Germany — ²Institut für Physik und Astronomie, Universität Potsdam, Germany — ³European XFEL Facility GmbH, Schenefeld, Germany — ⁴Physikalisches Institut EP3, Universität Würzburg, Germany

We investigate the transient negative thermal expansion of semimetallic HgTe and semiconducting CdTe by using synchrotron-based time-resolved X-ray diffraction. At T = 20 K, far below the Debye temperature of both materials, the selective optical excitation of the HgTe top layer with an ultrashort near-infrared laser pulse leads to a rapid expansion of HgTe that is followed by a long lasting contraction. The CdTe substrate is compressed by the HgTe thin film expansion, and subsequently CdTe contracts due to thermally excited transverse phonon modes. This shows that negative thermal expansion is manifest on ultrafast timescales, consistent with the negative Grüneisen coefficient for transverse phonons in semiconducting materials with sphalerite crystal structure. At T = 200 K, far above the Debye temperature of both materials, the expansion driven by longitudinal acoustic phonons is prevalent. We simulate the lattice dynamics in an elastic model where transient thermal stresses are calculated via heat diffusion based on equilibrium thermoacoustic properties.

#### HL 30.48 Thu 11:00 P3

**Resonant and phonon-assisted ultrafast coherent control of a single hBN color center** — •DANIEL GROLL¹, JOHANN A. PREUSS², ROBERT SCHMIDT², THILO HAHN¹, PAWEŁ MACHNIKOWSKI³, RUDOLF BRATSCHITSCH², TILMANN KUHN¹, STEFFEN MICHAELIS DE VASCONCELLOS², and DANIEL WIGGER^{3,4} — ¹Institute of Solid State Theory, University of Münster, Germany — ²Institute of Physics, University of Münster, Germany — ³Department of Theoretical Physics, Wrocław University of Science and Technology, Poland — ⁴School of Physics, Trinity College Dublin, Ireland

For the development of scalable quantum technologies, reliable single-photon emitters in solid state systems are required. In this context, promising candidates are the recently discovered color centers in the van der Waals insulator hBN. These single photon emitters are attracting increasing attention due to their quantum performance at room temperature and wide range of transition energies. Here we report on our recent results on the ultrafast optical coherent state manipulation of a single hBN color center [1]. By combining experiment and theory we achieve a sound understanding of the impact of environment noise and the coupling to phonons on the emitter's coherence. Specifically, we detect the decoherence of optical phonon-assisted transitions, stemming in part from the finite lifetime of these phonons. The creation of acoustic phonons manifests in a rapid decrease of the emitter coherence during their emission and can lead to an ultrafast beat of the coherent control signal.

#### HL 30.49 Thu 11:00 P3

Coherent acoustic phonons in a Graphite-hBN heterostructure observed by ultrafast electron diffraction — •ARNE UNGEHEUER¹, NORA BACH², AHMED HASSANIEN¹, MASHOOD MIR¹, LUKAS NÖDING¹, SASCHA SCHÄFER², THOMAS BAUMERT¹, and ARNE SENFTLEBEN¹ — ¹University of Kassel, Institute of Physics, Kassel, Germany — ²University of Oldenburg, Institute of Physics, Oldenburg, Germany

We investigate the dynamics of photoexcited coherent acoustic phonon modes in a graphite- hexagonal boron nitride (hBN) heterostructure. Since the hBN layer is transparent at our excitation central wavelength of 785 nm we assume that the optically induced stress pulse occurs mainly in the graphite layer. Subsequent lattice coupling to the hBN layer depends on the coupling strength at the bilayer interface and determines the nanomechanical resonance frequencies of the system. Observation of specific coherent acoustic phonon modes in the individual layers is interpreted within the framework of ultrafast electron diffraction [1] and experimental results are compared with numerical simulations based on a discrete numerical linear chain model [2]. [1] Gerbig, C., et al. New Journal of Physics 17.4 (2015): 043050. [2] Bach, N., and S. Schäfer, Structural Dynamics 8.3 (2021): 035101.

HL 30.50 Thu 11:00 P3

Unraveling electron-phonon and exciton-phonon couplings in transition metal dichalcogenides. — •AHMED HASSSANIEN, ARNE UNGEHEUER, MAS-HOOD TARIQ MIR, LUKAS NÖDING, ARNE SENFTLEBEN, and THOMAS BAUMERT — University of Kassel, Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), D - 34132 Kassel, Germany The observation of coherent phonons following resonant electronic excitation is a clear sign of the coupling between the electronic and the lattice degrees of freedom [1]. Using a highly compact femtosecond electron diffractometer developed in our group [2], we were able to differentiate between the electron-phonon and exciton-phonon couplings in mechanically exfoliated few-layers WSe2. Based on our results, both free and bound charge carriers couple to the interlayer vibrational modes. Further analysis of our results unveiled the specific modes coupled to either type of charge carrier.

HL 30.51 Thu 11:00 P3 Measuring ultrashort electron pulse durations by streaking with free electrons — •Lukas Nöding, Arne Ungeheuer, Ahmed Hassanien, Mashood Tariq Mir, Arne Senftleben, and Thomas Baumert — Institute of Physics; Experimental Physics III, Kassel University

Ultrafast electron diffraction is a well-known method for time-resolved measurements on molecules and condensed matter. The duration of the electron pulse directly determines the temporal resolution of the UED setup as it works like the shutter speed of a camera. A streaking setup utilizing free electrons is implemented to measure the duration of the electron pulse. For this, a new measurement device was designed. It consists of an aperture and a metal surface behind the aperture, parallel to the path of the electron pulse. A femtosecond laser pulse is focused onto the metal surface. As the beam incides, electrons are released from the metal surface. Because of their momentum at first, they separate from the surface, create an electric field perpendicular to the surface and then recombine. This short-lived electric field is used to streak the electron pulse. The electron pulse at the front of the pulse should experience a different field strength than the electrons at the end. By that the duration of the pulse is mapped into a spatial extension of the pulse. The spatial and temporal overlap for the electron pulse and the laser beam had to be set exactly. The results are shown with their evaluation and compared to simulations.

# HL 31: 2D Materials 5 (joint session HL/CPP/DS)

Time: Thursday 11:15–12:15

#### HL 31.1 Thu 11:15 H36

**Generating extreme electric fields in 1 2D materials by dual ionic gating** — •BENJAMIN ISAAC WEINTRUB¹, YU-LING HSIEH^{1,2}, JAN N. KIRCHHOF¹, and KIR-ILL I. BOLOTIN¹ — ¹Department of Physics, Freie Universität Berlin, Berlin, Germany — ²Department of Mechanical Engineering, National Central University, Taoyuan City, Taiwan

We demonstrate a new type of dual gate transistor to induce record electric fields through two-dimensional materials (2DMs). At the heart of this device is a 2DM suspended between two volumes of ionic liquid (IL) with independently controlled potentials. The potential difference between the ILs falls across an ultrathin layer consisting of the 2DM and the electrical double layers above and below it, thereby producing an intense electric field across the 2DM. We determine the field strength via i) electrical transport measurements and ii) direct measurements of electrochemical potentials of the ILs using semiconducting 2DM, WSe2. The field strength across a bilayer WSe2 sample reaches ~2.5 V/nm, the largest static electric field through the bulk of any electronic device to date. Additionally, we create electric fields strong enough to close the bandgap of 3-layer and 4-layer WSe2 (~1.4 V/nm and ~0.9 V/nm respectively). Our approach grants access to previously-inaccessible phenomena occurring in ultra-strong electric fields.

#### HL 31.2 Thu 11:30 H36 Tip-enhanced Raman spectroscopy combined with other Scanning Probe Microscopy Methods: Focus on 2D Materials — •JANA KALBACOVA — HORIBA Jobin Yvon GmbH, Neuhofstr. 9, Bensheim 64625, Germany

New two dimensional materials are on the rise. After the wonder material graphene, new materials such as MoS2, MoSe2, WSe2 have an intrinsic bandgap and as such are opening new doors for semiconductor applications. Raman spectroscopy offers information on the chemical structure of materials but cannot provide information on the electronic properties such as surface potential or photocurrent of our sample. Co-localized measurements combining scanning probe microscopy (SPM) with Raman spectroscopy can already bring a wealth of information; however, further improvements can be obtained by a tip that will act as an antenna and amplify the Raman signal and thus breaking the diffraction limit in a method called Tip-enhanced Raman spectroscopy (TERS). Typically spatial resolution of 10 - 20 nm can be achieved. In this contribution, we investigate different 2D materials by a combination of TERS, tip-enhanced photoluminescence, Kelvin probe microscopy, and other SPM methods to show very locally for example doping variations or defects that would otherwise go unnoticed with other macro- and microscopic techniques.

HL 31.3 Thu 11:45 H36

 $\begin{array}{l} \textbf{Defects in 2D WS}_2 \ \textbf{monolayers} & - \text{Aswin Asaithambi}^1, \text{Roland Kozubek}^1, \\ \text{Francesco Reale}^2, \ \text{Erik Pollmann}^1, \ \text{Marcel Zöllner}^1, \ \text{Cecilia} \\ \text{Mattevi}^2, \ \text{Marika Schleberger}^1, \ \text{Axel Lorke}^1, \ \text{and} \ \textbf{Günther Prinz}^1 \\ - \ ^1\text{Fakultät für Physik und CENIDE, Universität Duisburg-Essen, Germany} \\ - \ ^2\text{Department of Materials, Imperial College London, UK} \end{array}$ 

In this presentation, we report about optical characterization and manipulation of defects in tungsten disulfide (WS₂) monolayers. WS₂ is one prominent member of the 2D transition metal dichalcogenides (TMDC). In these materials, defects and adsorbates can easily modify e.g., conductivity, optical properties, or even create single photon emitters. For this study we used high quality WS₂ CVD-grown monolayers to purposely introduce defects via irradiating them with Xe³⁰⁺ ions with different fluences [1]. Low temperature photoluminescence (PL) spectra of these irradiated WS₂ monolayers show two defect related broad bands, beside the excitonic contribution. By exposing these flakes to laser light with powers up to 1.5mW, the intensity of these two PL bands can be reduced. By comparing the intensity of the excitonic contribution before and after this laser processing, we don't observe an increase in intensity, leading us to conclude, that the defects aren't getting healed. If the samples are heated to room temperature, the defect luminescence recovers. To interpret our observation, we suggest that the defects might be attributed to vacancy defects together with adsorbates at different defect sites.

HL 31.4 Thu 12:00 H36 Large perpendicular field in bilayer TMD via hybrid molecular gating — •SVIATOSLAV KOVALCHUK¹, ABHIJEET KUMAR¹, SIMON PESSEL¹, KYRYLO GREBEN¹, DOMINIK CHRISTIANSEN², MALTE SELIG², ANDREAS KNORR², and KIRILL BOLOTIN¹ — ¹Department of Physics, Quantum Nanoelectronics of 2D Materials, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany — ²Institut für Theoretische Physik, Nichtlineare Optik und Quantenelektronik, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin, Germany

We consider structures in which bilayer TMDs are sandwiched between a layer of molecules and Si gate. We show that these structure allow increasing, by a factor of 2, maximum electric field achievable in this 2D material. This in turn, allows reaching electric field >0.2 V/nm. In MOS2 this is sufficient to bring interlayer excitons IX into resonance with either A or B intralayer excitons. We study coupling between these excitons, and give an outlook on the new technique to achieve large perpendicular electric fields detectable in optical measurements.

HL 32.1 Thu 15:00 H31

Atomically Thin Sheets of Lead-Free 1D Hybrid Perovskites Feature Tunable White-Light Emission from Self-Trapped Excitons — •PHILIP KLEMENT¹, NATALIE DEHNHARDT², CHUAN-DING DONG³, FLORIAN DOBENER¹, JULIUS WINKLER², SAMUEL BAYLIFF⁴, DETLEV M. HOFMANN¹, PETER J. KLAR¹, STEFAN SCHUMACHER^{3,5}, SANGAM CHATTERJEE¹, and JOHANNA HEINE² — ¹Institute of Experimental Physics I and Center for Materials Research (ZfM), Justus Liebig University Giessen, Giessen, Germany — ²Department of Chemistry and Material Sciences Center, Philipps-Universität Marburg, Marburg, Germany — ³Department of Physics and Center for Optoelectronics and Photonics Paderborn (CeOPP), Paderborn University, Paderborn, Germany — ⁴Department of Chemistry and Biochemistry, University of Oklahoma, Norman, OK, USA — ⁵College of Optical Sciences, The University of Arizona, Tucson, AZ, USA

One of the major current challenges in 2D materials' synthesis is the intentional design of building blocks to introducing superior chemical and physical properties. The limiting factor in this approach is the commonly-believed paradigm that in-plane covalent interactions are strictly necessary to form 2D materials, limiting the number of candidates. Here, we go beyond the paradigm that atomically thin materials require in-plane covalent bonding and report single layers of the one-dimensional organic-inorganic perovskite [C7H10N]3[BiCl5]Cl. Its unique 1D-2D structure enables single layers and the formation of self-trapped excitons which show white-light emission.

HL 32.2 Thu 15:15 H31

Multiple spin-flip Raman scattering in bulk lead halide perovskites — •MAREK KARZEL¹, DENNIS KUDLACIK¹, NATALIA E. KOPTEVA¹, INA KALITUKHA², MAKSYM V. KOVALENKO³, DMITRI R. YAKOVLEV¹, and MANFRED BAYER¹ — ¹Experimentelle Physik 2, Technische Universität Dortmund, 44227 Dortmund, Germany — ²St. Petersburg, Russia — ³Laboratory of Inorganic Chemistry, ETH Zürich, 8093 Zürich, Switzerland

Lead halide perovskites like FACs are promising competitors for conventional semiconductors in spintronics due to their highly efficient light absorption and emission properties. We study spin-flip Raman scattering (SFRS) of resident carriers and investigate possible carrier exchange interactions. The measurements are performed at low temperatures around 1.6 K and external magnetic fields up to 10 T in Faraday and tilted geometries. This method allows us to observe Raman shifts in high magnetic fields which according to [1] are attributed to the g-factors of resident electrons and holes. The SFRS efficiency significantly increases for resonant probing of the free exciton resonances. We conduct from our measurements, that the creation of the free exciton is the essential requirement for observation of multiple spin-flip Raman scattering.

#### HL 32.3 Thu 15:30 H31

Stability Enhancement of perovskite nanoplatelets via crosslinking of ligands — •MAXIMILIAN GRUBER, ULRICH LEO, NINA HENKE, PATRICK GAN-SWINDT, MICHAEL LICHTENEGGER, CONNOR HEIMIG, and ALEXANDER UR-BAN — Nanospectroscopy Group and Center for Nanoscience (CeNS), Nano-Institute Munich, Department of Physics, Ludwig-Maximiliäns-Universitat München, Königinstr. 10, 80539 Munich, Germany

In recent years lead halide perovskite nanoplatelets (NPL) have attracted a lot of attention due to low-cost production and excellent spectral tuning. Additionally, perovskite NPLs exhibit the benefit of exciton energy tunability via quantum confinement as well as large photoluminescence quantum yield. The high surface to volume ratio of the NPLs, however, makes them susceptible to degradation by water, air and ion migration.

One solution to these issues of degradation investigated here is a process called crosslinking. Hereby the exposure of a film of NPLs to a dose of electron radiation induces intermolecular bonds between the organic ligands attached to the individual nanocrystals, hence forming a protective matrix around a film of pristine perovskite NPLs.

Varying dosages of irradiation of three monolayer CsPbBr3 NPLs were investigated followed by an exposure to other halides, NPLs with a different halide composition as well as different solvents, showing a drastic increase in stability of the crosslinked compared to untreated NPLs. This enables the possibility of a future application of lead halide perovskite NPLs under ambient conditions.

#### HL 32.4 Thu 15:45 H31

Enhancing the optical performance of perovskite nanoplatelets — •Stefan Martin¹, Carola Lampe¹, Nina Henke¹, Ioannis Kouroudis², Milan Harth², Alessio Gagliardi², and Alexander Urban¹ — ¹LMU Munich, Nanospectroscopy Group — ²TU Munich

Lead halide perovskites have been drawing a lot of interest during the last few years due to their unique properties. Their excellent optical performance combined with easy and cost-efficient production are interesting for both light-emitting devices and solar cells. Perovskite nanoplatelets are furthermore convincing with high photoluminescence quantum yields and narrow emission linewidths tunable from 430 to 505 nm. The thickness of these nanoplatelets can be tuned with a monolayer precision and determines the absorption and emission profile of the sample.

By using different machine learning approaches the synthesis parameters were investigated and optimized based on the emission spectrum. With this method, the emission properties of nanoplatelets with thicknesses reaching from 2 to 8 monolayers were enhanced. Additionally, the emission wavelengths can be finetuned using a post-synthetic enhancement treatment comprising a lead halide ligand solution. Depending on the time interval between synthesis and enhancement, a redshift of controllable extent can be introduced while further reducing the emission linewidth. With these strategies, a narrow and symmetric emission peak can be achieved at any desired wavelength. This is particularly interesting for the implementation in optoelectronic devices.

#### HL 32.5 Thu 16:00 H31

Extensive study on sequential physical vapor deposition of mixed-cation perovskite (Cs,FA)PbI_3 – •KARL HEINZE¹, TOBIAS SCHULZ¹, ROLAND SCHEER¹, and PAUL PISTOR² – ¹Institute of Physics, Martin-Luther-University Halle-Wittenberg, von-Danckelmann-Platz 3, 06120 Halle (Saale), Germany -²Universidad de Pablo Olivade, Carretera de Utrera 1, 41013, Sevilla, Spain Sequential deposition via physical vapor deposition (PVD) is underexplored, even though it offers precise adjustment of components and composition and a variety of routes to investigate the optimization of perovskite growth. We combine in situ XRD and in situ laser light scattering to monitor phase evolution of (Cs,FA)PbI3 during PVD. We study the influence of deposition sequence of the components PbI2, FAI and CsI on CsFAPbI3 growth. Noticeably, the sequence strongly influences the orientation of deposited components. Similarly, diffusion before and during annealing as well as resulting alpha phase share depend on the evaporation sequence. When depositing PbI2 first, conversion to the perovskite phase was not achieved, unless an over stoichiometric share of FAI was deposited. Depositing FAI first and PbI2 later resulted in a high probability of layer conversion to the perovskite phase without secondary phases being detected. A striking feature during our investigation was the absence of the delta phase during deposition and annealing, seemingly caused solely by the preparation method. We deliver important insight into this poorly investigated preparation path and provide a foundation for further research based on our detailed study of sequence-dependent crystalline growth.

HL 32.6 Thu 16:15 H31

Ultrafast transient spectroscopy of Cu(In,Ga)Se₂ coupled to different buffer layers. — •PIRMIN SCHWEIZER, RICARDO ROJAS-AEDO, ALICE DEBOT, PHILIP DALE, and DANIELE BRIDA — Department of Physics and Materials Science, University of Luxembourg, 162a avenue de la Faïencerie, L-1511 Luxembourg, Luxembourg

The dynamic parameters of photo-induced electron-hole pairs, such as recombination time and charge conductivity, play a major role in the efficiency of photovoltaic devices. Among thin film materials for photovoltaics, one of the most interesting is the p-type Cu(In,Ga)Se2 alloy (CIGS) on which an n-type buffer layer is deposited, forming the initial part of the device p-n junction. The intermaterial transport dynamics strongly depend on how the band structure is affected by the buffer layer, and also on the quality of the CIGS \ buffer layer interface which may contain defects. In our experiments we have compared the ultrafast transient reflectivity on CIGS epitaxially grown on a GaAs substrate. New Cd free buffer layers In₂S₃ and band offset tunable Zn(O,S), are compared to the most commonly used buffer layer, CdS. The transient reflection measurements allows for the extraction of the electronic transport dynamics at the interface with the buffer. This study allows us to draw conclusions about the pair formation capacity mediated by the transport properties between the CIGS and the buffer layer. The results can guide the development of Cd free buffer layers thus reducing the environmental impact caused by CdS in traditional CIGS solar cells.

#### HL 33.1 Thu 15:00 H32

**Implementation of the Bethe-Salpeter Equation using Crystal Symmetries** — •JÖRN STÖHLER^{1,2}, DMITRII NABOK¹, STEFAN BLÜGEL¹, and CHRISTOPH FRIEDRICH¹ — ¹Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich, Germany — ²RWTH Aachen University, Germany The Bethe-Salpeter equation (BSE) and *GW* approximation are two many-body perturbation theory techniques that together form the state-of-the-art method to include electron-hole interaction in periodic systems. The BSE has proven to be the most accurate tool to compute optical absorption for the valence and core energy region, as well as electron energy loss.

We have implemented the BSE in the SPEX code, a full-potential linearized augmented planewave (FLAPW) code that supports Green-function based methods including the *GW* approximation, optical spectra in the random phase approximation, and more. We use crystal symmetries to achieve a significant computational speedup for the construction and diagonalization of an effective electron-hole Hamiltonian in the Tamm-Dancoff approximation, from which we obtain symmetric exciton wavefunctions and energies.

Our code is parallelized and has been tested for various bulk, layered and monolayer semiconductors, among them LiF and MoS₂, and includes spin-orbit coupling. The results agree with available theoretical and experimental spectra from the literature.

#### HL 33.2 Thu 15:15 H32

The Berry dipole photovoltaic demon and the thermodynamics of photocurrent generation within the optical gap of metals — L1-KUN SH1¹, OLES MATSYSHYN^{2,1}, JUSTIN C. W. SONG², and •INTI SODEMANN VILLADIEGO^{3,1} — ¹Max-Planck-Institut fur Physik komplexer Systeme — ²Division of Physics and Applied Physics, Nanyang Technological University, Singapore — ³Institut fur Theoretische Physik, Universitat Leipzig

Berry phase driven photo-voltaic effects offer novel mechanisms that could allow to engineer a new generation of opto-electronic technologies.

We will show that there is a large class of bulk photovoltaic mechanisms that make possible to produce a net rectified photo-voltaic current even when the impinging radiation has a frequency that resides within the optical gap of the material, in contrast to previous claims. We will describe the thermodynamics of these in-gap rectification effects and show that most of these mechanisms are necessarily accompanied by a small but finite irreversible photon absorption in order for them to be consistent with the laws of thermodynamics. There is, however, one remarkable exception: the intra-band non-linear Hall effect arising from the anomalous velocity induced by the Berry curvature. This non-linear Hall effect allows to have a photovoltaic mechanisms whose maximum allowed efficiency can be 100% for the conversion of circularly polarized light onto electricity. More remarkably, because it is a reversible process, this same mechanism can be conversely used as a a highly efficient electrical amplifier of circularly polarized light.

#### HL 33.3 Thu 15:30 H32

Nonlinear photocurrents induced by terahertz radiation in twisted bilayer **graphene** — •Stefan Hubmann¹, Philipp Soul¹, Giorgio di Battista², Marcel Hild¹, Kenji Watanabe³, Takashi Taniguchi³, Dmitri Efetov², and SERGEY GANICHEV  1  —  1 Terahertz Center, University of Regensburg, 93040 Regensburg, Germany —  2 ICFO, Castelldefels, Barcelona 08860, Spain — ³National Institute for Materials Science, 1-1 Namiki, Tsukuba 305-0044, Japan We report on the observation of nonlinear photocurrent and photoconductivity in twisted bilayer graphene (tBLG) with twist angles below 1°. We show that excitation of the tBLG bulk causes a photocurrent, whose sign and magnitude are controlled by the orientation of the radiation electric field and the photon helicity. The developed theory shows that the current is formed by asymmetric scattering in gyrotropic tBLG. For the observed photocurrents, we demonstrate the emergence of pronounced oscillations upon variation of the gate voltage, which correlate with the oscillations of the sample resistance. These photocurrent oscillations originate in interband transitions between a multitude of subbands in tBLG. Furthermore, at higher radiation intensities, we detected a nonlinear intensity dependence of bulk photogalvanic current and photoconductivity. These nonlinear photoresponses are caused by the interplay between interband, intersubband, and intraband transition. This interplay is controlled by the Fermi level position with respect to the Moiré subbands. We show that the photosignals saturate with rising intensity, while contributions from different transitions differ in their respective saturation behavior.

#### HL 33.4 Thu 15:45 H32 **Dielectric function of \operatorname{CuBr_x I_{1-x}} thin films** — •E. Krüger¹, M. Seifert², M. Bar¹, S. Merker³, P. Bischoff¹, H. Krautscheid³, S. Botti², M. Grundmann¹, and C. Sturm¹ — ¹Universität Leipzig, Felix-Bloch-Institut für Festkörperphysik, Germany — ²Friedrich-Schiller-Universität Jena, Institut für

Festkörpertheorie und -optik, Germany —  3 Universität Leipzig, Institut für Anorganische Chemie, Germany

Copper halides such as CuI and CuBr are promising p-type semiconductors for transparent optoelectronic devices, especially due to the recently proposed hole density tunability [1]. Here, we present the dielectric function of  $\text{CuBr}_x I_{1-x}$  thin films ( $0 \le x \le 1$ ) determined by spectroscopic ellipsometry in the spectral range from 0.7 eV to 6.5 eV at room temperature. The observed features in the dielectric function are attributed to various electronic transitions in the Brillouin zone [2]. Non-monotonic behavior is observed for the band gap energy as a function of alloy composition revealing a quadratic bowing parameter of 0.5 in good agreement with literature [3]. The spin-orbit splitting decreases linearly from 650 meV for CuI to 150 meV for CuBr. The experimental results are compared with DFT-calculated band structures for different alloy compositions. The effects of bond length mismatches, chemical disorder, and different contributions of metal and halogen atoms to the upper valence bands are discussed in detail.

Neutralisation of detrimental effects on the Rydberg exciton absorption spectrum — •Katharina Brägelmann, Mariam Harati, Binod Panda, Julian Heckötter, and Marc Assmann — Experimentelle Physik II, Technische Universität Dortmund, 44225 Dortmund

We report on the neutralisation of charged impurities by excitation of Rydberg excitons with surprisingly small laser powers. Rydberg excitons are highly excited states in  $Cu_2O$  with principal quantum numbers of up to n = 30 [1] with extensions in  $\mu m$  range. The wellknown theories propose an  $n^{-3}$  scaling for both oscillator strengths and linewidths of the excitons. Usually the highest states (n = 16 and above) show some deviation from those theories, as oscillator strengths are smaller and linewidths are wider than expected, which leads to an reduced absorption of these states. Those deviation are known to stem from the presence of charged impurities in the material [2]. Here, we show a way to increase the absorption and to minimize the deviations mentioned above. This increase of absorption happens when the system is pumped in an extremly narrow energy region around the band gap (less than 1 meV) with very small powers of only  $0.1 - 10 \,\mu$ W. This effect indicates a 'purification' of the illuminated volume as the naturally charged impurities have less detrimental impact on the high excitonic states. This research contributes to a deeper understanding of impurity exciton interactions.

#### 15 min. break

Driven by the field of cavity quantum electrodynamics there is an ever-growing quest for systems with extreme light-matter coupling. In the regimes of ultraand deep strong coupling the coupling strength becomes comparable to the bare excitation energy, leading to exotic phenomena like virtual photons in the ground state and the breakdown of the Purcell effect. Here, we discuss how ultrastrong coupling is systematically achieved in materials, without the need for external cavities. We introduce densely packed supercrystals of gold nanopartic cles as an artificial material where the coupling strength can be tuned from ultrato deep strong coupling. Using a unified theory of dipole-active material excitations, we show that light-matter coupling gets maximized in three-dimensional materials, setting an upper limit for the coupling strength in cavities. From a large set of experimental data, we identify phonons in ferroelectrics, excitons in molecular crystals, and plasmons in metallic supercrystals as excitations where light-matter coupling is so strong that it affects the material ground state, eventually leading to phase transitions and changing the mechanical properties.

HL 33.7 Thu 17:00 H32 Optical Characterization of Phase-Pure Wurtzite GaAs/II-VI Core/Shell Nanowires — •MIKE KÜLKENS, MARVIN MARCO JANSEN, DETLEV GRÜTZ-MACHER, and ALEXANDER PAWLIS — Peter-Grünberg-Institut (PGI-9), Forschungszentrum Jülich GmbH, Germany

Self-catalysed III/V semiconductor core/shell nanowires (NWs) grown by molecular beam epitaxy (MBE) provide enormous potential to develop miniatur-

ized electronic and optoelectronic devices. Following our recent demonstration of WZ-phase-pure GaAs NW growth we investigated a novel type of hybrid NWs composed of a WZ-type GaAs core with various WZ-type II/VI-semiconductor shells. The shell provides excellent confinement and passivation of the GaAs core due to the large bandgap energy difference between the two materials and allows to tune the optical bandgap of the GaAs core by tensile strain within a range of several 100 meV.

Here we report on the structural and optical properties of WZ-phase-pure grown  $GaAs/Zn_{1-x}Mg_xSe$  core/shell NWs.  $\mu$ -PL investigations reveal the presence of tensile strain in the GaAs core induced by the  $Zn_{1-x}Mg_xSe$  shell, which can be engineered via the magnesium concentration and the shell thickness. The measured redshift of the near-band emission from the GaAs core was verified by evaluation of the strain and its effect on the GaAs bandgap, using a hydrostatic strain model. The results presented here pave the way for applications of WZphase-pure GaAs/II-VI core/shell NWs for optoelectronic devices with tunable wavelength in the infrared spectral range.

ZnSe-Based Microdisk Resonators in Novel Supported Geometry - • WILKEN SEEMANN¹, CHRISTIAN TESSAREK¹, SIQI QIAO², NILS VON DEN DRIESCH², Alexander Pawlis², Gordon Callsen¹, and Jürgen Gutowski¹ ¹Institute of Solid State Physics, University of Bremen, Germany — ²Peter Grünberg Institute (PGI-9), Forschungszentrum Jülich, Germany

Microdisk resonators often suffer from thermal problems due to the limited contact of the underetched structure to the substrate. In order to circumvent this, ZnSe-based microdisks were fabricated in a supported geometry, i.e., in contact to the substrate over their whole bottom facet. This is achieved by growing a ZnSe:Cl quantum well (QW) encapsulated in ZnMgSe barriers on an AlAs underlayer. Oxidation of the underlayer to Al₂O₃ after disk fabrication increases the refractive index difference between the resonator and the substrate.

Scanning electron microscopy reveals a high structural quality of the fabricated microdisks. Micro-photoluminescence measurements show that the resulting resonators support high-Q resonances near the band edge emission of the ZnSe:Cl QW and a large number of whispering gallery modes on the defect emission band. The latter can be reproduced using a plane-wave model. Raman measurements of microdisks, as well as the as-grown ZnSe-based structure on the oxidized and non-oxidized AlAs underlayer, are used to analyze the mechanical properties of the disk and the influence of the oxidation process on the strain in the QW structure.

Enhancing directivity in optical waveguide antennas — •HENNA FARHEEN¹, Lok-Yee Yan², Till Leuteritz², Siqi Qiao², Florian Spreyer¹, Christian Schlickriede¹, Viktor Quiring¹, Christof Eigner¹, Thomas Zentgraf¹, STEFAN LINDEN², VIKTOR MYROSHNYCHENKO¹, and JENS FÖRSTNER¹ -¹Paderborn University, Paderborn, Germany — ²Universität Bonn, Germany

We show the numerical and experimental realization of optimized broadband optical traveling-wave antennas made from low-loss dielectric materials. The antennas are composed of a director and reflector placed over a glass substrate and a dipole emitter located in the feed gap between them serves as an internal source of excitation. Our studies reveal that the highly directive nature of our antennas comes from two dominant guided TE modes excited in the waveguide-like director of the antenna, in addition to the leaky modes. Furthermore, our numerical results are in excellent agreement with the experimental measurements of the antennas that were fabricated using a two-step electron beam lithography. Compared to the previously studied plasmonic antennas for photon emission, our all-dielectric approach demonstrates a new class of highly directional, low loss, and broadband optical antennas.

HL 33.10 Thu 17:45 H32 First-principles study of momentum-forbidden excitons in bulk 2H-MoX2  $(X = S, Se) - \cdot RAVI KAUSHIK^{1,2}$  and SERGEY ARTYUKHIN¹ - ¹Italian Institute of Technology, Genova, Italy — ²University of Genova, Genova, Italy

Coulomb-bound electron-hole pairs (excitons) dominate the optical response of atomically thin transition metal dichalcogenide (TMD) semiconductors. While Mo-based TMDs monolayers have a direct gap, bulk MoS2 and MoSe2 possess an indirect gap, with momentum-forbidden lowest energy excitonic transitions. Here we study how the effects of translational symmetry breaking by thermal phonons and in scanning spectroscopies can lead to a violation of the usual optical selection rules.

# HL 34: Focus Session: Perspectives in Cu(In,Ga)Se 2

#### Invited Talk

HL 34.1 Thu 15:00 H33 Super-high efficiency CIGS devices: current status and pathways forward •ROMAIN CARRON — Laboratory for Thin Films and Photovoltaics, Empa, Duebendorf, Switzerland

In this contribution, we discuss the limitations to the photovoltaic performance of Cu(In,Ga)Se2 (CIGS) devices, and possible pathways to boost cell efficiencies towards 25% and beyond. Starting from a comparison of record CIGS cells to other photovoltaic technologies, we evaluate the potential for improvement of each of the individual parameters Voc, Jsc, and FF towards the Shockley-Queisser limit. Then we walk through the main causes for losses for each of the individual parameters, connect them to the last decade's progress, and suggest pathways for future improvements. The open-circuit voltage is discussed in particular depth, including the prediction of its value, the role of impurities and alkali elements in high-efficiency devices, the impact of other absorber modifications, and of advanced optical management. Finally, we discuss how the layer sequence of a CIGS solar cell differs from its functional structure. On this basis, we describe potentially advantageous modifications to the device architecture and the related challenges.

#### **Invited Talk**

HL 34.2 Thu 15:30 H33 Highlights from the development of the world record Cd-free CIGSSe 30x30cm2 solar module — • ANASTASIA ZELENINA — AVANCIS GmbH, Otto-Hahn-Ring 6, 81739 Munich, Germany

In this contribution, the R&D process of 30x30 cm2 CIGSSe solar modules will be discussed [1]. One of the main advantages of the process is the application of an environmentally friendly dry Zn(O,S) buffer, which is applied as an alternative to the widely used CdS chemical bath deposition (CBD) process. Over the past few years, our development of the 30x30 cm2 CIGSSe modules has been focused on the optimization of the absorber properties. An increased absorber thickness has been applied, with the aim to increase absorption and increase the short circuit current density (JSC). The Jsc-improvement was combined with enhancing the absorber quality through the optimization of the elemental absorber depth profile. The enhanced absorber quality lead to better diode parameters and higher JSC*VOC product values. Furthermore, the absorber surface homogeneity was improved for this increased absorber thickness leading to an enhancement of the Fill Factor (FF) values. The improved absorber homogeneity results

mostly from tuning the rapid thermal annealing (RTP) process. The combination of these development steps lead to the achievement of a world record efficiency of 19.8% [2]. This new process developments on 30x30cm2 sized modules will also be the basis for the power development on production-sized modules and will be used for further production upgrades.

Overcoming current limitations of Cu(In,Ga)Se2 photovoltaic devices -•DANIEL ABOU-RAS — Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Hahn-Meitner-Platz 1, 14109 Berlin, Germany

Recently, a review paper entitled "CIGS photovoltaics: reviewing an evolving paradigm" (Stanbery et al 2022 J. Phys. D: Appl. Phys. 55 173001, doi: 10.1088/1361-6463/ac4363) has provided an overview of various issues to be improved in Cu(In,Ga)Se2 (CIGS) thin-film solar cells to reach power-conversion efficiencies of 25% and beyond. The authors of this contribution highlight the necessity of implementing device concepts already in use for the established Si and GaAs photovoltaic technologies also for CIGS devices. Possible ways of enhancing the collection and reducing nonradiative recombination in CIGS solar cells are described. I intend to give a brief insight into the main aspects of this review paper in the planned Focus Session.

HL 34.4 Thu 16:15 H33

Identification of nonradiative recombination centers in CuInSe2 and Cu-**GaSe2** — •BAOYING DOU¹, STEFANO FALLETTA², CHRISTOPH FREYSOLDT¹, and JÖRG NEUGEBAUER¹ — ¹Max-Planck-Institut für Eisenforschung GmbH — ²Ecole Polytechnique Fédérale de Lausanne

Cu(In,Ga)Se2 is a promising solar absorber for thin-film solar cell applications. Nonradiative carrier recombination is one of the key processes that limits the device efficiency. To achieve high performance, it is crucial to identify the critical defects and quantify their induced nonradiative recombination rates. Prior firstprinciple calculations proposed that the antisites InCu and GaCu, are donors

#### Semiconductor Physics Division (HL)

with a transition levels in the band gap, so they may act as nonradiative recombination centers. However, the existence of transition levels in the band gap does not necessarily trigger nonradiative recombination. Using first-principles methods, we quantitatively show that internal conversion in the neutral charge state to the distorted DX center configuration plays a crucial role in carrier recombination by opening an efficient hole capture pathway. The positive charge state returns to the anti-site configuration without barrier to complete the entire recombination cycle. However, our calculations show that the DX center is only stable in CuGaSe2, not in CuInSe2. We discuss the consequences of these findings for defect engineering in CuInSe2, CuGaSe2, and its alloys.

#### 30 min. break

#### Invited Talk HL 34.5 Thu 17:00 H33 Digital Twins - a simulation model for Cu(In,Ga)Se2 solar cells of high and moderate efficiency — •MATTHIAS MAIBERG¹, CHANG-YUN SONG¹, MARCIN MORAWSKI¹, FELIX NEDUCK¹, JOSHUA DAMM¹, HEIKO KEMPA¹, DIMITRIOS HARISKO², WOLFRAM WITTE², and ROLAND SCHEER¹ — ¹Institute of Physics, Martin-Luther-University Halle-Wittenberg, von-Danckelmann-Platz 3, 06120 Halle (Saale), Germany — ²Zentrum für Sonnenenergie- und Wasserstoffforschung Baden-Württemberg, Meitnerstraße 1, 70563 Stuttgart, Germany

To overcome the current record efficiency of Cu(In,Ga)Se2 (CIGSe) solar cells, loss mechanisms need to be identified through comprehensive device models. The development of such models, however, is hampered by the complex film microstructure of CIGSe as well as its multi-component device structure. In the first part of our talk, we present one-dimensional models for CIGSe solar cells with high efficiency at around 19 % and moderate efficiency at around 16 %. These models have been obtained by a fitting routine for a set of experimental data which calls the simulation tool Synopsys TCAD as the subprogram. As an outcome, we obtain material parameters of CIGSe. The minority carrier lifetime, for example, exhibits values of >15 ns in the highly efficient cells while it is only 3 ns in the moderately efficient device. In the solar cells. Here, we address the non-radiative recombination as origin of electronic losses as well as the band gap grading and the window layers as origins for optical losses.

A hybrid (Al)GaAs-LiNbO₃ surface acoustic wave resonator for cavity quantum dot optomechanics — •EMELINE NYSTEN¹, ARMANDO RASTELLI², and HUBERT KRENNER¹ — ¹Physikalisches Institut, WWU Münster, Germany — ²Institute of Semiconductor and Solid-State Physics, Johannes Kepler Universität Linz, Austria

Surface acoustic waves (SAW) are a useful tool to control the emission of quantum dots (QDs). In particular, SAWs enable the modulation of their energy levels through the deformation potential coupling [1]. Here, we explore the possibility to enhance the interaction between the SAW and the QDs by transferring them on a strong piezoelectric LiNbO₃ substrate by epitaxial lift-off [2,3]. Additionally, the membrane is transferred inside a SAW resonator confining the acoustic field inside the cavity. High acoustic quality factors of Q > 4000 are demonstrated for the SAW resonator for an operation frequency of f = 300 MHz and stay high even after the hybridization. The frequency and position dependent optomechanical coupling of single quantum dots with the resonator modes is also observed [4]. [1] Appl. Phys. Lett. 93, 081115 (2008) [2] Phys. Rev. B 88, 085307 (2013) [3] J. Phys. D: Appl. Phys. 50, 43LT01 (2017) [4] Appl. Phys. Lett. 117, 121106 (2020)

Determining Amplitudes of Standing Surface Acoustic Waves via Atomic Force Microscopy — •JAN HELLEMANN¹, FILIPP MÜLLER¹, MADELEINE MSALL², PAULO V. SANTOS¹, and STEFAN LUDWIG¹ — ¹Paul-Drude-Institut für Festkörperelektronik, Berlin, Deutschland — ²Bowdoin College, Maine, USA Our aim is the realization of strong coupling between cavity phonons and a few electron double quantum dot as an on-chip hybrid system for quantum information applications. For this purpose, we develop radio frequency surface-phonon cavities containing a double quantum dot laterally defined in a GaAs/AlGaAs heterostructure. To characterize a phonon cavity we generate standing surface

acoustic waves (SSAW) by driving the cavity defining interdigital transducers and image the SSAW using atomic force microscopy (AFM), which is able to resolve submicron wavelengths of the SSAW at a few GHz. Alternative techniques are discussed in a related contribution by N. Ashurbekov.

Here, we focus on the AFM cantilever deflection, which substantially overestimates the SSAW amplitude because the cantilever with an eigenfrequency in the kHz range is driven by energy transfer from the much faster oscillating surface. We demonstrate a method to nevertheless determine the actual SSAW amplitude by comparing the hystereses of force curve measurements with model predictions based on solving the equation of motion of the driven cantilever [1]. Finally we present our first characterization measurements of a double quantum dot coupled to a phonon cavity.

HL 35.3 Thu 15:30 H34

Location: H34

**Radio Frequency Surface Acoustic Wave Cavities near 6 GHz** — •NAZIM ASHURBEKOV¹, MICHAEL HANKE¹, EDOARDO ZATTERIN², MADELEINE MSALL³, JAN HELLEMANN¹, PAULO SANTOS¹, TOBIAS SCHULLI², and STEFAN LUDWIG¹ — ¹Paul-Drude-Institut, Berlin, Germany — ²European Synchrotron, Grenoble, France — ³Bowdoin College, Maine, USA

Aiming at strong coupling between confined phonons and confined electrons in hybrid quantum circuits, we develop radio frequency (rf) surface-phonon cavities. The cavities are defined by focusing surface gate Bragg mirrors. They also serve as interdigital transducers, which we use to generate standing surface acoustic waves (SSAWs) for characterizing the cavities. At frequencies >3 GHz corresponding to wavelengths <1  $\mu$ m most methods to measure the SSAWs become increasingly difficult.

Here, we explore two experimental methods with superior resolutions, scanning X-ray diffraction microscopy (SXDM) and atomic force microscopy (AFM). We present AFM measurements of focused rf SSAWs near 6 GHz and compare them with SXDM measurements. While AFM provides a basic char-

measuring CV profiles. Those changes are caused by metastable transitions, accounted by the shift of the majority fermi level upon illumination, which in turn increases the diode factor. There are several methods to determine this parameter, namely, from an analysis of the current-voltage curves (JV) [2], using the diode equation or from the slope of the Voc dependence with illumination intensity: Jsc-Voc [3]. Within this work, those methods are tested in a set of CIGSe, Cu poor samples, grown with the three-stage process, with good efficiencies (without any post-deposition treatment) in the range from 15% to 17%. For the analysis of the JV curves under dark, the two-diode model [4] is implemented. Using a 1-diode fit always results in a high value (>1.5), indicating dominant recombination in the space charge region. We use a 2-diode fit to obtain information on the diode factor originating from recombination in the quasi-neutral zone, which is affected by the metastable effects. In the case of JV under illumination, the extraction of the diode factor seems to be hampered by the cross-over between light and dark JV characteristics, which in CIGSe cells might be due to a change in an energetic barrier under light [5]. Therefore, the diode factor under illumination is determined more reliably from Jsc-Voc measurements.

HL 34.7 Thu 17:45 H33

**Exact determination of Quasi-Fermi Level splitting from absolute photoluminescence and absorptance spectra** — •SEVAN GHARABEIKI, TAOWEN WANG, AJAY SINGH, ALEX REDINGER, and SUSANNE SIEBENTRITT — Department of Physics and Materials Science, University of Luxembourg, 4422 Belvaux, Luxembourg

Photoluminescence (PL) is a powerful tool to investigate the Quasi-Fermi level splitting (QFLS) in absorbers and hence the upper limit of the open-circuit voltage (Voc) in a solar cell. Planck's generalized law and external radiative (ERE) method are the two most common ways to determine the QFLS. Planck's generalized law uses a high energy slope of the PL spectrum and assumes the absorptance (A) to be unity for the photons with energy sufficiently higher than the absorber bandgap. However, in CIGSe solar cells, which employ a graded bandgap, and poly-crystalline perovskite solar cells, the assumption A=1 is no more valid. On the other hand, the ERE method makes use of the radiative bandgap. Many studies consider the PL emission peak position to be the radiative bandgap which is not accurate. Herein, we present a combination of PL and absorptance measurements to accurately determine the QFLS in the CIGSe and methylammonium tin-triiodide Perovskite (MASI) absorbers. Then, we compare our QFLS values from the Plancks generalized law and the ERE method. We emphasize that the radiative bandgap and PL maximum are not the same, and using the PL maximum as a radiative bandgap can result in errors in QFLS extraction.

acterization of the SSAW, SXDM in addition yields its complete 3D strain field, relevant for the electron-phonon coupling.

Finally, comparing our experimental results with finite elements method simulations allows us to explore design variations for future optimizations of the electron-phonon coupling in quantum devices.

Influence of (N,H)-terminated surfaces on stability, hyperfine structure, and zero-field splitting of NV centers in diamond — WOLFGANG KÖRNER¹, •REYHANEH GHASSEMIZADEH¹, DANIEL URBAN¹, and CHRISTIAN ELSÄSSER^{1,2} — ¹Fraunhofer Institute for Mechanics of Materials IWM, Wöhlerstr. 11, 79108 Freiburg, Germany — ²University of Freiburg, Freiburg Materials Research Center (FMF), Stefan-Meier-Straße 21, 79104 Freiburg, Germany

We present a density functional theory analysis of the negatively charged nitrogen-vacancy (NV⁻) defect complex in diamond located in the vicinity of (111)- or (100)-oriented surfaces with mixed (N,H)-terminations [1]. We assess the stability and electronic properties of the NV⁻ center and study their dependence on the H:N ratio of the surface termination. The formation energy, the electronic density of states, the hyperfine structure and zero-field splitting parameters of an NV⁻ center are analyzed as function of its distance and orientation to the surface. We find stable NV⁻ centers with bulk-like properties at distances of at least ~ 8 Å from the surface provided that the surface termination consists of at least 25% substitutional nitrogen atoms. The studied surface terminations have a minor effect on the ground state whereas the NV orientation has major effects. Our results show that axial NV centers near a flat 100% N-terminated (111) surface are the optimal choice for NV-based quantum sensing applications as they are the least influenced by the proximity of the surface.

HL 36.2 Thu 15:15 H36

Quantum optimal control for conveyor-mode single-electron shuttling in Si/SiGe — •ALESSANDRO DAVID¹, VEIT LANGROCK², JULIAN D. TESKE³, LARS R. SCHREIBER³, HENDRIK BLUHM³, TOMMASO CALARCO¹, and FELIX MOTZOI¹ — ¹Institute of Quantum Control (PGI-8), Forschungszentrum Jülich, Germany — ²Institute of Theoretical Nanoelectronics (PGI-2), Forschungszentrum Jülich, Germany — ³JARA-FIT Institute of Quantum Information, Forschungszentrum Jülich and RWTH Aachen, Germany

An electron shuttling device is a promising candidate for the scalability of spinqubits quantum computers. We consider a gated Si/SiGe quantum well capable of shuttling electrons smoothly by a translating confining potential (conveyormode). Dephasing coupling with valley degree of freedom and geometry of the quantum well dictate a maximum shuttling speed to keep the electron state adiabatically in the ground state and avoid excitation of the valley state. In this work we use the position of the electron as a control parameter and we optimise the trajectory of the electron to show how the electron can be shuttled faster and with lower infidelity compared to the adiabatic regime.

**Optimizing Diamonds for the Electrical Readout of Nitrogen-Vacancy Centers in Diamond** — •LINA MARIA TODENHAGEN, HAMZA OUERFELLI, and MARTIN STEFAN BRANDT — Walter Schottky Institut, Technische Universität München, Garching

The nitrogen-vacancy (NV) center in diamond is one of the most attractive quantum systems used in practical applications. Owing to its exceptionally stable spin state, it can be easily initialized, manipulated and read out even at room temperature. However, the widely used optical readout (ODMR) of the NV center is not easily miniaturized, since it requires an extensive optical setup. Alternatively, we can directly read out the spins electrically by generating a spin-dependent photocurrent (EDMR). However, compared to the traditional optical readout, EDMR of NV centers has been investigated in much less detail up to now.

The present work addresses the optimization of the diamond host material for the electrical readout and compares the results to the optical analogue. The tor quantum dots (QDs) are bright sources of coherent single-photons, and their optical two-level transition can be coupled to mechanical motion via deformation potential coupling.

Here, we present a membrane-design resonator: a cantilever with a fundamental in-plane mode at 3.1 MHz with a quality factor as high as 22'000. The membrane design hosts a heterostructure diode for stabilising the QD's charge state. This results in narrow optical linewidths and a high mechanical sensitivity. We probe the Brownian motion at low temperature, 4 K, of the mechanical resonator via the resonance fluorescence from a single quantum dot. The mechanical noise imprinted on the QD's photons is extracted via an autocorrelation measurement. A single photon coupling strength of around 100 kHz is estimated. The in-plane mechanical motion probed here, together with the membrane design, allows a translation to higher frequencies using phononic-crystal resonators for which operation in the resolved-sideband regime becomes viable.

Location: H36

investigated substrates cover type IIa CVD diamonds as well as type Ib HPHT diamonds, both in their as-grown state and after different post-treatments, including electron irradiation and annealing. We focus on the effects of other defects such as substitutional nitrogen present in the samples on the spin-dependent photocurrent and the achievable contrast. Our results indicate that the choice of diamond material is a lot more critical for EDMR than for ODMR and may serve as a guideline for the further development of highly integrated NV sensors based on electrical readout.

HL 36.4 Thu 15:45 H36 Superconducting single-photon detectors made of NbTiN using a novel method to characterize the timing jitter — •LUCIO ZUGLIANI¹, RAS-MUS FLASCHMANN¹, STEFAN STROHAUER², CHRISTIAN SCHMID¹, FABIAN WIETSCHORKE¹, STEFANIE GROTOWSKI², SVEN ERNST², SIMONE SPEDICATO², MIRCO METZ¹, BJÖRN JONAS¹, JONATHAN FINLEY², and KAI MÜLLER¹ — ¹Walter Schottky Institute and Department for Electrical and Computer Engineering, Technical University of Munich, Germany — ²Walter Schottky Institute and Physics Department, Technical University of Munich, Germany

In recent years, superconducting single-photon detectors (SSPDs) have raised tremendous attention as a key technology for optical quantum processing and faint light detection. With their unparalleled performances to detect single photons, further investigation of these detectors is of high interest [1, 2].

Here, we present our recent progress on NbTiN SSPDs measured at 4.5K. We discuss our approaches to improve the most important figures of merit (dark count rate, dead time, timing jitter, efficiency) including an optimization of the quality of the superconducting NbTiN films and the integration of the detector in a broad-band cavity.

In particular, we focus on the impact of the substrate material on the resulting parameters such as the detected voltage pulse. We investigate the characteristic of pulse height, rise time and timing jitter, finding a relation between the timing jitter and the pulse properties.

Focused ion beam implantation and luminescence of erbium ions in semiconductor nanostructures — •CHRISTIAN DÜPUTELL¹, PATRICK LINDNER², VAR-VARA FOTEINOU³, YUJIAO LI⁴, JÖRG DEBUS², ARNE LUDWIG¹, and ANDREAS D. WIECK¹ — ¹Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum — ²Experimentelle Physik 2, TU Dortmund — ³RUBION, Ruhr-Universität Bochum — ⁴ZGH, Ruhr-Universität Bochum

We report on focused ion beam (FIB) implantation of erbium ions in semiconductor nanostructures. Semiconductor nanostructures have attracted a lot of attention due to their unique optical, electrical and mechanical properties. Focused ion beam is an elegant method to tune these specific properties. This contribution lines out the implantation processes and the methods used to characterize the samples after implantation. Erbium is implanted in various semiconductor nanostructures in its 3+ state using an alloy liquid metal ion source. Furthermore, a sputter cathode source is used to implant erbium(III) oxide. Implantation is done at room temperature as well as at elevated temperatures to reduce radiation damage. The implanted ion distribution is simulated by SRIM and measured by atom probe tomography. After the implantation, the samples are annealed under nitrogen gas using a rapid thermal annealing technique. Photoluminescence measurements on erbium luminescence are carried out at cryogenic temperatures (10 K) as a function of the annealing and implantation parameters. The quality of the samples is then rated according to emission intensity of the important telecom-C-band wavelength of 1.54  $\mu$ m.

Searching for signatures of magnetism and induced superconductivity in magnetic topological insulator-superconductor hybrid devices — •Max Vassen-Carl, Michael Schleenvoigt, Benedikt Frohn, Detlev GRÜTZMACHER, and PETER SCHÜFFELGEN — Peter Grünberg Institute 9, Forschungszentrum Jülich GmbH, 52425 Jülich, Germany

Topological materials harbor great possibilities for the future of quantum computation. In theory, when quasi-1D topological isolators (TIs) are coupled to superconductors localized Majorana zero modes (MZM) arise at the end of the quasi-1D hybrid structure. However, quasi-1D TIs require a certain in-plane magnetic field, which depends on the cross-section area of the TI, to retrieve the topological properties lost by confinement. Deviations of said TI cross-section change the penetrating flux and can lead to additional opening and closing of the topological gap, creating unwanted MZMs. One possible solution is to integrate magnetism directly into the TI, creating so-called magnetic topological insulators (MTIs), which retain their topological properties even when confined. In this work Chromium is used to magnetically dope (BixSb1-x)2Te3, by means of MBE. First, ex-situ fabricated MTI-Nb Josephson Junctions (JJ) showed no supercurrent, but instead an increase of resistance for low bias voltages. To gain further insights on the interplay between SC and MTI a new sample layout was designed which allows for Josephson and Hall bar measurements in one device. In order to obtain highest S-MTI interface quality those hybrid devices are fully fabricated under UHV conditions.

#### HL 36.7 Thu 16:45 H36

Coherent interactions between confined fluids of light and GHz-phonons — •ALEXANDER KUZNETSOV, KLAUS BIERMANN, and PAULO SANTOS — Paul-Drude-Institut für Festkörperelektronik in Forschungsverbund Berlin, e. V., Berlin, Germany

Microcavity exciton-polaritons are at the heart of an emerging field of polaromechanics, which studies coupling between polariton and mechanical degrees of freedom and promises unit quantum cooperativity. One challenge is to reach the regime of coherent interactions, when the polariton decoherence rate is smaller than mechanical frequency.

We reached this milestone by coupling polariton fluids of light (macroscopic quantum state) to GHz phonons. High-resolution optical spectroscopy revealed ns-long coherence time reaching  $\tau = 2ns$ . Monochromatic  $\Omega_M = 7GHz$  phonons were injected into a trap using acoustic transducers. Since  $1/\tau < \Omega_M$ , the interaction resulted in the appearance of well-resolved phonon sidebands in the emission – an optical frequency comb. We demonstrated tuning of the sidebands by the phonon amplitude, which was controlled by the radio-frequency power applied to the transducer.

The demonstrated coherent polaromechanical device is a building block for a bi-directional interface between microwave and optical domains, atomic clocks, and is useful to study rich physics of sideband cooling and amplification.

Thermal characterization of semiconductor membranes by Raman thermometry — •ISABELL HÜLLEN¹, MAHMOUD ELHAJHASAN¹, WILKEN SEEMANN¹, MARKUS R. WAGNER², and GORDON J. CALLSEN¹ — ¹Institut für Festkörperphysik, Universität Bremen, Germany — ²Institut für Festkörperphysik, Technische Universität Berlin, Germany

Photonic structures like nanolasers are often based on freestanding semiconductor membranes comprising hole lattices. As a result, a high number of interfaces limits the thermal conductivity and consequently the overall device performance under high injection conditions. Thus, it remains an open task to correlate the thermal and optical characterization of photonic membranes often based on III-V semiconductors. In this contribution we follow a careful step-by-step approach to attest the suitability of Raman thermometry (RT) for a precise determination of the thermal conductivity  $\kappa$ . First, we analyse a well-studied bulk material like Ge to not only extract  $\kappa$ , but also to assess underlying errors and experimental limitations. Consequently, the RT technique is applied to Ge membranes, in herence times enables the development of hybrid nanophotonic devices incorporating the advantages of both systems. GaAs/AlGaAs QDs based on droplet etching and nanohole infilling exhibit tunable, well-defined optical properties, with emission typically reported at around 780nm. Silicon-vacancy (SiV) centers in diamond show long coherence times and strong interactions with single photons via their zero phonon line (ZPL) at around 737 nm. Here we report the first quantum dot containing material emitting nonclassical light that matches the SiV ZPL. Careful adjustments of the GaAs thickness in the QDs lead to a narrow wavelength distribution (736.2 ± 1.7 nm) and small exciton fine structures (7.0 ± 4.6 eV). Polarization entangled photons are generated via the biexciton-exciton cascade decay with a fidelity of 0.727 ± 0.092. High single photon purity is maintained from 4 K (g⁽²⁾(0)= 0.07 ± 0.02) up to 80 K (g⁽²⁾(0)= 0.11 ± 0.01), therefore, paving the way towards cost-efficient applications in quantum repeaters and quantum memories.

HL 36.9 Thu 17:15 H36 Electric field-induced exciton darkening and fine structure vanishing in GAAs/AlGaAs coneshell quantum structures — •GEOFFREY PIRARD¹ and GABRIEL BESTER^{1,2} — ¹Physical Chemistry and Physics Departments, University of Hamburg, Luruper Chaussee 149, D-22761 Hamburg, Germany — ²The Hamburg Centre for Ultrafast Imaging, University of Hamburg, Luruper Chaussee, 149, D-22761 Hamburg, Germany

Electronic and optical properties of coneshell quantum structures (CSQS) are investigated via a combination of the empirical pseudopotential and the configuration interaction methods. It is found that the application of a vertical electric field onto CSQS can provoke a darkening of the exciton bright doublet accompanied by the suppression ot its fine structure. The existence of such a four-fold degenerate exciton state finds its origins in the carriers' localization: one type of carrier is strongly confined at the bottom of the nanostructure whereas its counterpart is pulled apart in such a way that its probability density acquires a delocalized ring-like nature. The separation between carriers' wave functions leads to a vanishing exchange interaction and reduces the values of the direct Coulomb integrals, giving rise to a tunable long-lived degenerate dark exciton. These properties make the CSQS promising candidates to construct the building blocks of quantum memories.

Bright InAs quantum dot based single-photon sources at telecom wavelengths — •MONICA PENGERLA¹, ALKAALES MOHANAD², RANBIR KAUR², JAN DONGES¹, LUCAS BREMER¹, JOHANNES SCHALL¹, SVEN RODT¹, MOHAMED BENYOUCEF², and STEPHAN REITZENSTEIN¹ — ¹Institut für Festkörperphysik, Technische Universität Berlin, Hardenbergstraße 36, D-10623 — ²Institute of Nanostructure Technologies and Analytics (INA), Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Heinrich-Plett-Str. 40, 34132 Kassel, Germany

Quantum dot (QD) based single-photon sources are key elements of photonic quantum networks. Most interesting are sources emitting at telecom wavelengths to enable long distance quantum communication. Here, we report on deterministically fabricated single-photon sources based on InAs QDs grown on InP substrate. Numerical simulations of such QD heterostructures with back-side distributed Bragg reflector and reveal photon extraction efficiency exceeding 50% when integration the QD into mesa or circular Bragg grating structures. The numerical designs are implemented by deterministic device processing using machine learning enhanced in-situ electron beam lithography. Micro-photoluminescence studies reveal the excellent optical and quantum optical properties of the fabricated quantum devices.

#### Location: H34

preparation of the subsequent thermal characterization of photonic membranes. Here, we characterize a 250-nm-thick c-plane GaN membrane, which forms the basis for state-of-the-art nanobeam lasers. RT reveals that  $\kappa$  is reduced by up to one order of magnitude in comparison to bulk values. The pronounced Photoluminescence signal of our GaN membrane directly enables an alternative optical and thermal characterization, which we link to RT, aiming to bridge optical and thermal material characterization.

HL 37.2 Thu 16:45 H34 **Can group IV alloys compete in thermoelectrics?** — •OLIVER KRAUSE¹, ADA CHIMENTI², OMAR CONCEPCIÓN¹, THORSTEN BRAZDA¹, STEFANO RODDARO², DETLEV GRÜTZMACHER¹, and DAN BUCA¹ — ¹Peter-Grünberg-Institute 9 (PGI-9), Forschungszentrum Jülich, 52428 Jülich, Germany — ²Dipartimento di Fisica "E. #### Semiconductor Physics Division (HL)

differences with a base at room temperature is of outmost interest. The figure of merit in thermoelectrics is *ZT*, indicating how suited a material is for thermoelectric applications. It can be optimized by reducing the thermal conductivity *k* and increasing the electrical conductivity  $\sigma$  of a material with a large Seebeck coefficient  $\alpha$ . Here, we investigate the potential of group-IV alloys GeSn and SiGeSn, a material system compatible to standard Si technology.

We present a study of *k* of crystalline GeSn alloys deposited by chemical vapor deposition. The differential  $3\omega$  technique was used to determine *k* electrically. Our preliminary data shows that *k* strongly decreases with increasing the Sn content, reaching values as low as  $5 \frac{W}{m \cdot K}$  at room temperature. The data are compared with previous reports of the same material using Raman thermometry. Using data of the electrical conductivity and modelling of Seeback coefficient, *ZT* values for both p and n type GeSn layers are calculated.

HL 37.3 Thu 17:00 H34 Anisotropy in the c-plane thermal conductivity of Gallium Nitride — •MAHMOUD ELHAJHASAN¹, ISABELL HÜLLEN¹, WILKEN SEEMANN¹, IAN ROUSSEAU², NICOLAS GRANDJEAN², and GORDON CALLSEN¹ — ¹Institute of Solid State Physics, University of Bremen, Germany —  $^2 {\rm Institute}$  of Solid State Physics, École Polytechnique Fédérale de Lausanne (EPFL), Switzerland

The thermal characterization of modern semiconductor membranes commonly employed for photonic devices like nanobeam lasers (1D) or photonic crystals (2D), often lacks spatial resolution and appropriate quantification. However exactly these two points are relevant for the detection of e.g., thermal anisotropies, heat spots, and interfaces providing thermal resitance.

In this contribution, Raman thermometry employing one laser beam (1LRT) is used to quantify the thermal conductivity  $\kappa$  of 250-nm-thick state-of-the-art, c-plane GaN membranes. The same membranes are then probed by two laser Raman thermometry (2LRT) to map the temperature distribution caused by a heating laser via a second probe laser. As a result,  $\kappa$  is determined for all inplane crystal directions. A particular thermal anisotropy is revealed in c-plane GaN via this direct thermal imaging technique with sub- $\mu$ m spatial resolution, which compares well to ab-initio calculations.

Consequently, we outline first potential routes towards thermal optimizations of photonic nanostructures.

Raman and X-ray photoemission study of thin films of binary and ternary semiconductor quantum dots — •OLEKSANDR SELYSHCHEV^{1,2}, VOLODYMYR DZHAGAN^{3,4}, and DIETRICH R.T. ZAHN^{1,2} — ¹Semiconductor Physics, TU Chemnitz, Germany — ²Center for Materials, Architectures, and Integration of Nanomembranes (MAIN), TU Chemnitz, Germany — ³Institute of Semiconductors Physics, NAS of Ukraine, Kyiv, Ukraine — ⁴Taras Shevchenko National University of Kyiv, Ukraine

Quantum dots (QDs) of ternary semiconductor chalcogenides MInS2 (M = Cu, Ag) attract attention as environment friendly alternatives to toxic cadmium and lead chalcogenides. Even though both ternary and binary QDs exhibit size dependent absorption and photoluminescence spectra, the properties of ternary compounds additionally depend on composition, variety of crystalline phases, and defects. Here, we present a comparative Raman and X-ray photoemission spectroscopic (XPS) study of thin films of binary CdS and ternary MInS2 QDs to examine their structural and electronic properties. Raman results show that MInS2 QDs co-exist in chalcopyrite and Cu-Au type phases. XPS study revealed indium-rich surface deviating from ideal stoichiometry. Auger parameters confirm metal ions in the expected oxidation states, while the boundary states of sulfur indicate surface passivation through the thiolate group of thioglycolate ligands. The ionization potentials of binary and ternary QDs are found to be the same as those for the bulk indicating that the bandgap increase is due to quantum confinement of electrons in the conduction band.

#### HL 39.2 Fri 9:45 H32

Collective Properties of CdSe-CdS giant-shell Quantum Dots — •YANNIC STÄCHELIN¹, ARTUR FELD¹, AGNES WEIMER¹, MICHAEL DEFFNER^{2,3}, SONJA KROHN⁴, JAN STEFFEN NIEHAUS⁴, and HOLGER LANGE^{1,3} — ¹Institut für Physikalische Chemie, Universität Hamburg, Hamburg, Germany — ²Institut für Anorganische und Angewandte Chemie, Universität Hamburg, Hamburg, Germany — ³The Hamburg Centre for Ultrafast Imaging, Hamburg, Germany — ⁴Fraunhofer IAP-CAN, Hamburg, Germany

CdSe-CdS core-giant-shell QDs are nowadays available with near-unity quantum yields, which makes them interesting candidates for lasing or display applications. Bright, high-PLQY QDs might also contribute to photonic quantum technologies as building blocks. QDs can realize deterministic photon-emitters and enable key quantum photonic resources and functionalities. Interaction of densely packed QDs can lead to collective phenomena like excitonic and photonic coupling, superfluorescence and enhanced quantum coherence. Incoherent dephasing processes may deteriorate the inherent quantum properties of QDs. We investigate dependencies of exciton formation in CdSe-CdS giant-shell QDs and interaction in dense ensembles of QDs via ultrafast THz and transient absorption spectroscopy. Polymer-micelles are used to produce dense ensembles containing a variable amount of QDs. In dense ensembles, we observe the onset of a collective dynamic depending on the excitation conditions, which are thus a means of controlling the dynamics.

HL 39.3 Fri 10:00 H32

**Excitonic fine structure of epitaxial Cd(Se,Te) on ZnTe type-II quantum dots** — •PETR KLENOVSKY^{1,2}, PIOTR BARANOWSKI³, and PIOTR WOJNAR³ — ¹Department of Condensed Matter Physics, Faculty of Science, Masaryk University, Kotlářská 267/2, 61137 Brno, Czech Republic — ²Czech Metrology Institute, Okružní 31, 63800 Brno, Czech Republic — ³Institute of Physics, Polish Academy of Sciences, Al Lotników 32/46, PL-02-668 Warsaw, Poland

The structure of the ground state exciton of Cd(Se,Te) quantum dots embedded in ZnTe matrix is studied experimentally using photoluminescence spectroscopy and theoretically using  $\mathbf{k}\cdot\mathbf{p}$  and configuration interaction methods. The experiments reveal a considerable reduction of fine-structure splitting energy of the exciton with increase of Se content in the dots. That effect is interpreted by theoretical calculations to originate due to the transition from spatially direct (type-I) to indirect (type-II) transition between electrons and holes in the dot induced by increase of Se. The trends predicted by the theory match those of the experimental results very well.

The theory identifies that the main mechanism causing elevated fine-structure energy in particular in type-I dots is due to the multipole expansion of the exchange interaction. Moreover, the theory reveals that for Se contents in the dot > 0.3, there exist also a peculiar type of confinement showing signatures of both type I and type II and which exhibits extraordinary properties, such as almost purely light hole character of exciton and toroidal shape of hole states.

garten 1A, D-30167 Hannover, Germany — ⁴Universität Tübingen, Institute of Physical and Theoretical Chemistry, Auf der Morgenstelle 18, D-72076 Tübingen, Germany

In the past few decades, the tunability and strong light-matter coupling in nanometer-sized colloidal systems promotes their potential use in novel applications such as quantum metrology, quantum imaging or quantum communication. Two-dimensional (2D) nanoplatelets (NPLs) have recently moved into focus due to their controllable photoluminescence properties. In this work, the optical properties of single colloidal 2D PbS NPLs are explored at cryogenic temperature (T=4 K). Stable and narrow-band excitonic emission of single PbS NPL near 1.8 eV is observed with linewidths down to 0.6 meV.The prominent exciton-phonon interaction are detected. The emission features a strongly polarized emission with a degree of polarization up to 77%. These findings denote the first observation of narrow-band polarized photoluminescence (PL) from 2D PbS nanoplatelets, which were believed to suffer from broad PL due to complex band-edge exciton states evolving from the 64-fold degeneracy in PbS.

Exciton recombination dynamics and polarization properties in CsPbI3 perovskite nanocrystals — •GANG QIANG¹, DMITRI R. YAKOVLEV^{1,2}, ELENA V. Shornikova¹, Danil O. Tolmachev¹, Mikhail A. Prosnikov³, Elena V. Kolobkova⁴, Peter C. M. Christianen³, and Manfred Bayer^{1,2} – ¹Experimentelle Physik 2, Technische Universität Dortmund, D-44221 Dortmund, Germany – ²St. Petersburg, Russia – ³High Field Magnet Laboratory (HFML-EMFL), Radboud University, 6525 ED Nijmegen, The Netherlands -⁴St. Petersburg, Russia

We synthesized CsPbI3 NCs in fluorophosphate glass matrix and investigated the optical properties at various temperatures down to 4.2 K and in external magnetic fields up to 30 T. Recombination dynamics demonstrate clearly twoexponential decay characteristic for exciton emission with the dark exciton as a ground state. An anomalous polarization properties is observed at low temperature (e.g. 4.2 K), i.e. with the increasing of magnetic field, the degree of circular polarization (DCP) increases smoothly, while at ~21 T a 'hump' shows up. Higher temperature blurs this behavior, and it can not be clearly observed at 20 K. Moreover, for the spin dynamics, at low temperature (4.2 K) and high magnetic field (> 8 T), after reaching the maximum, the time resolved DCP tends to decreases and slowly relaxes to at a constant level, which is quite different from the observations in III-V and II-VI NCs.

Time: Friday 9:30-11:45

HL 40.1 Fri 9:30 H33

Generation of intense sub-half-cycle terahertz pulses from spatially indirect interband transitions — •CHRISTIAN MEINEKE¹, MICHAEL PRAGER¹, JOhannes  ${\rm Hayes}^1,$  Qiannan  ${\rm Wen}^2,$  Lukas  ${\rm Kastner}^1,$  Dieter  ${\rm Schuh}^1,$  Kilian Fritsch³, Oleg Pronin³, Markus Stein⁴, Sangam Chatterjee⁴, Mackillo KIRA², RUPERT HUBER¹, and DOMINIQUE BOUGEARD¹ - ¹University of Regensburg, 93040 Regensburg - ²University of Michigan, Ann Arbor, Mi 48109 -³Helmut Schmidt University, 22043 Hamburg — ⁴Justus Liebig University, 35392 Giessen

Ultimately short phase-stable terahertz (THz) pulses form the bedrock of THz lightwave electronics, where the carrier field creates a transient bias to control electrons on sub-cycle time scales. Here, we introduce a fully scalable highrepetition-rate THz source generating intense phase-locked and strongly asymmetric sub-cycle field transients. The key idea is to engineer electronic wavefunctions in type-II aligned semiconductor quantum wells such that resonant interband photoexcitation induces an ultrafast charge separation over several nanometers even without any bias. Our detailed quantum mechanical analysis reveals that local charging dynamics lifts the spatial separation of electrons and holes, leading to an abrupt decrease of the dipole moment, generating one single pronounced positive field peak. The THz bandwidth is scalable up to the mid-infrared by reducing the pump pulse duration. The versatility of our emitter allows adjusting waveforms, spectra, and field strengths to many applications, such as ultrabroadband spectroscopy and femtosecond nanoscopy.

HL 40.2 Fri 9:45 H33 **Exploring mid-infrared transient gain in graphene** — •Kalliopi Mavridou^{1,2}, Angelika Seidl^{1,2}, Rakesh Rana¹, Alexej Pashkin¹, Manfred Helm^{1,2}, and Stephan Winnerl¹ — ¹Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstraße 400, Dresden 01328, Germany – ²Faculty of Physics and Center for Advancing Electronics Dresden, Technische Universität Dresden, Dresden 01062, Germany

In our study we employ a powerful method, namely a three-pulse pumpprobe technique, that was first suggested by Kim et al.¹, to explore the possibility to achieve transient gain photon energies below the optical phonon energy (~ 200 meV) in graphene. Intriguingly, this technique is not widely established and to our knowledge has never been used in the mid- or far-infrared spectral range. The principle behind this method relies on the effect of a strong prepump pulse of 1.55 eV photons, which can cause a transient population inversion at lower energies. This population inversion is evidenced by a sign flip of the mid-infrared (86 meV photon energy) pump-probe signal that is related to either absorption or stimulated emission of mid-infrared photons of the pump beam. We present the results on multilayer graphene obtained under various experimental configurations. Our findings shed light into the completion of rapid thermalization via Coulomb scattering and carrier cooling via optical phonons.

Elastic and inelastic exciton scattering in InGaAs multi-quantum wells •DANIEL ANDERS, MARKUS STEIN, and SANGAM CHATTERJEE — Institute of Experimental Physics I and Center for Materials Research (LAMA), Justus-Liebig-University Giessen, Heinrich-Buff-Ring 16, D-35392 Giessen, Germany The interaction of optically injected excitons amongst each other as well as with electrons is one of the most fundamental questions in semiconductor physics. In the past, scattering processes in semiconductors between charge carriers and excitons have been studied intensively using a wide variety of experimental methods, e.g., four-wave-mixing spectroscopy, time-resolved photoluminescence spectroscopy, or optical pump - optical probe spectroscopy. In contrast to the aforementioned methods optical pump - terahertz probe spectroscopy allows to distinguish between elastic and the destructive inelastic scattering processes of excitons. While the linewidth of the intraexcitonic resonance provides a measure for the total scattering rate of all scattering processes, the change of the intraexcitonic oscillator strength is only sensitive to inelastic scattering processes. In this work, we compare exciton-electron and exciton-exciton scattering and determine the respective contributions of elastic and inelastic scattering processes.

#### HL 40.4 Fri 10:15 H33

Highly superlinear terahertz photoconductance in GaAs quantum point contacts in the deep tunneling regime — •MAXIMILIAN OTTENEDER¹, MARCEL HILD¹, ZE-DON KVON^{2,3}, EKATERINA E. RODYAKINA^{2,3}, MIKHAIL M. GLAZOV⁴, and SERGEY D. GANICHEV^{1,5} — ¹Terahertz Center, University of Regensburg, 400 and 500 Regensburg, Germany — ²Novosibirsk, Russia — ³Novosibirsk, Russia — ⁴St. Petersburg, Russia — ⁵CENTERA, Institute of High Pressure Physics, Warsaw, Poland

A highly superlinear in radiation intensity photoconductance induced by continuous wave terahertz laser radiation with low intensities has been observed in quantum point contacts made of GaAs quantum wells operating in the deep tunneling regime. For very low values of the dark conductance  $G_{\text{dark}}/G_0 \approx 10^{-6}$ , with the conductance quantum  $G_0 = 2e^2/h$ , the photoconductance scales exponentially with radiation intensity and increases by almost four orders of magnitude at already 100 mW/cm². This effect is observed for a radiation electric field oriented along the source drain direction. We provide model considerations of the effect and attribute it to the variation of the tunneling barrier height by the radiation field due to local diffraction effects. We also demonstrate that cyclotron resonance due to an external magnetic field manifests itself in the photoconductance, completely suppressing the photoresponse.

HL 40.5 Fri 10:45 H33 Ultrafast subcycle dynamics of deep-strong light-matter coupling — •JOSHUA Mornhinweg¹, Maike Halbhuber¹, Laura Diebel¹, Viola Zeller¹, Josef RIEPL¹, CRISTIANO CIUTI², DOMINIQUE BOUGEARD¹, RUPERT HUBER², and Сня<br/>ıstoph Lange $^3-{}^1$ Universität Regensburg, Germany <br/>— 2 Université de Paris, France — ³TU Dortmund, Germany

Subcycle interactions of strong light fields and electric charges lead to multioctave spanning dynamics such as high-harmonic generation. In optical microcavities, even vacuum field fluctuations can drive non-perturbative light-matter coupling. Once the rate of energy exchange between the cavity and the matter mode becomes of the order of the carrier frequency of light, ultrastrong coupling (USC) emerges, and the profound modification of the vacuum ground state gives rise to novel phenomena such as cavity-mediated superconductivity. Here, we explore intriguing subcycle effects of USC including non-adiabatic dynamics occurring during quasi-instantaneous switch-off of the coupling, for which we observe sub-polariton-cycle polarization oscillations. Additionally, we drive USC with strong coherent THz fields to reveal nonlinear interactions between the polariton states, breaking the normal-mode approximation. Finally, we present deep-strong coupling (DSC) of multiple light and matter modes, creating a spectrum of Landau magneto-polaritons which covers 6 optical octaves, a coupling strength of  $\Omega_{\rm R}/\omega_c \approx 3.0$ , and a record virtual ground state population exceeding 1 photon. Our results open up new avenues for dynamically tailoring of USC and DSC on strongly subcycle timescales.

#### HL 40.6 Fri 11:15 H33

**Probing Free Electrons in InSb with Terahertz Shockwave Spectroscopy** – •PETER FISCHER, GABRIEL FITZKY, DAVIDE BOSSINI, ALFRED LEITENSTORFER, and RON TENNE — Department of Physics and Center for Applied Photonics, University of Konstanz, D-78457 Konstanz, Germany

The Auger process, a non-radiative three-particle recombination, is critical especially in narrow-band semiconductors where it sets a fundamental efficiency limit for optoelectronic applications. Since their characteristic response frequencies fall within a broadband interval in the terahertz and mid-infrared range, quantitative studies of the electron dynamics in these materials remain challenging. Here, we demonstrate a new pump-probe technique able to monitor the free carrier plasma by observing its signature in the transient terahertz reflectivity spectrum. A broadband terahertz source, providing at the same time maximum temporal resolution, emerges from slicing the electric-field transient on a subcycle time scale, effectively generating a shockwave. Applying this transient spectrum is the same time to the same time scale, effectively generating a shockwave.

sient to InSb after interband excitation, we find that the Auger-recombination coefficient increases by a factor of two from room temperature to 4.2 K. Furthermore, the importance of electron trapping to accurately model carrier dynamics is illustrated. Our approach exclusively targets the response of free charge carriers, disentangled from other contributions by e.g. bound excitons. Therefore, it offers a tool complementary to established time-resolved techniques.

## HL 40.7 Fri 11:30 H33

Nonlinear photocurrents induced by terahertz radiation in twisted bilayer graphene – •Stefan Hubmann¹, Philipp Soul¹, Giorgio di Battista², Marcel Hild¹, Kenji Watanabe³, Takashi Taniguchi³, Dmitri Efetov² and SERGEY GANICHEV¹ - ¹Terahertz Center, University of Regensburg, 93040 Regensburg, Germany - ²ICFO, Castelldefels, Barcelona 08860, Spain -³National Institute for Materials Science, 1-1 Namiki, Tsukuba 305-0044, Japan We report on the observation of nonlinear photocurrent and photoconductivity in twisted bilayer graphene (tBLG) with twist angles below 1°. We show that excitation of the tBLG bulk causes a photocurrent, whose sign and magnitude are controlled by the orientation of the radiation electric field and the photon helicity. The developed theory shows that the current is formed by asymmetric scattering in gyrotropic tBLG. For the observed photocurrents, we demonstrate the emergence of pronounced oscillations upon variation of the gate voltage, which correlate with the oscillations of the sample resistance. These photocurrent oscillations originate in interband transitions between a multitude of subbands in tBLG. Furthermore, at higher radiation intensities, we detected a nonlinear intensity dependence of bulk photogalvanic current and photoconductivity. These nonlinear photoresponses are caused by the interplay between interband, intersubband, and intraband transition. This interplay is controlled by the Fermi level position with respect to the Moiré subbands. We show that the photosignals saturate with rising intensity, while contributions from different transitions differ in their respective saturation behavior.

Understanding structure-to-property relationships for phonons and thermal transport in hydrogen-bonded organic semiconductors. - •LUKAS LEGEN-STEIN, LUKAS REICHT, TOMAS KAMENCEK, SANDRO WIESER, and EGBERT ZOJER - Institute of Solid State Physics, Graz University of Technology, Graz, Austria Research on organic semiconductors (OSC) has primarily focused on their (opto-)electronic properties. The understanding of phonons in these materials is, however, still rather poorly developed, despite their crucial role for charge and heat transport processes. Of central importance in this context are lattice phonons dominated by translations and rotations of entire molecules, which are coupled through non-covalent interactions. To elucidate how noncovalent bonding types such as H-bonding and  $\pi$ - $\pi$  interactions affect phonons in otherwise vdW-stacked OSCs, we simulate the phonon bands of crystalline quinacridone (QA), as a prototypical H-bonded OSC. Notably, QA forms polymorphs with fundamentally different crystal structures, which strongly impact the observed phonons. The obtained phonon bands show complex dispersions with avoided crossings and mode hybridisations due to a mixing of inter- and intra-molecular vibrations. The phonons are simulated combing the phonopy package with density-functional theory employing the FHI-aims and VASP codes. The calculated phonon band structures are also used for benchmarking on-the-fly trained machine learning force fields calculated with VASP, which are then employed for modelling thermal transport within the Green-Kubo formalism.

#### HL 41.2 Fri 9:45 H34

Regiochemistry of Donor-Dendrons Controls the Performance of TADF Dendrimer based OLEDs — •RISHABH SAXENA¹, DIANMING SUN², STAVROS ATHANASOPOULOS¹, ELI ZYSMAN-COLMAN², and ANNA KÖHLER¹ — ¹University of Bayreuth, Germany — ²University of St. Andrews, UK

The potential of dendrimers exhibiting thermally activated delayed fluorescence (TADF) as emitters in solution-processed organic light-emitting diodes (OLEDs) has to date not yet been realized. This in part is due to a poor understanding of the structure-property relationships in dendrimers where reports of detailed photophysical characterization and mechanism studies are lacking. In this study, we investigated dendrimers with multiple dendritic electron-donating moieties connected to a central electron-accepting core via a para- or a meta-phenylene bridge. Characterization of host-free OLEDs revealed the superiority of meta-dendrimers as compared to the already reported para-analogue. Photophysical investigations in the films showed that, although all the dendrimers possess similar singlet-triplet energy gap, normally implying similar reverse intersystem crossing (RISC) rate, better TADF properties are obtained for meta-dendrimers when compared to para-dendrimers. In this regard, what this study reveals is

that the reorganization energy can play an important role in enhancing RISC rate and that this can be modulated as a function of the regiochemistry of donor dendron about the acceptor. This is a heretofore unexploited strategy and can be used as a general chemical design principle, especially in the case of bulky dendrimers.

Light can carry two different kinds of angular momentum: spin angular momentum (SAM), which is associated with polarization, and orbital angular momentum (OAM), which occurs in light with spiral phase fronts. In recent years, it has been shown that rotational symmetry of a microcavity systems leads to an effective spin-orbit coupling of the SAM and the OAM of photons, resulting in new polariton eigenstates.

Here, we study helical Laguerre-Gaussian modes  $LG_{0\pm1}^{\sigma_{\pm}}$  formed in such systems. For a total angular momentum of J = 0, both eigenstates are radially and azimuthally polarized, respectively. Due to the spatial dependence of the linear polarization, we measure spin vortices for these modes. In contrast, the energetically degenerate modes with J = 2 exhibit opposite circular polarization and carry an optical OAM with opposite chirality. Accordingly, phase vortices with opposite sign were measured by polarization-dependent interference measurements.

Moreover, we show that the preservation of pump polarization allows selection of the optical OAM of  $\pm 1$ .

#### HL 41.4 Fri 10:15 H34

**Experimental and theoretical studies of the occupied density of states distribution of charge carriers at low temperatures in disordered organic semiconductors** — •ANDREI STANKEVYCH, RISHABH SAXENA, HEINZ BÄSSLER, ANDREY KADASHCHUK, and ANNA KÖHLER — Soft Matter Optoelectronics and Bavarian Polymer Institute (BPS), Universitätsstrasse 30, 95448 Bayreuth, Germany

The thermally-stimulated luminescence (TSL) technique has been applied to determine the width of density of state (DOS) distribution  $\sigma_{DOS}$  in pristine amorphous films of 18 common OLED materials. The high-temperature wing of the TSL curve in amorphous materials is an exact replica of the deeper portion of the DOS distribution and yields the effective DOS width. In addition, we measured the width of the TSL curves  $\sigma_{TSL}$  and found that it scales linearly with  $\sigma_{DOS}$  parameter, suggesting an existence of a universal ratio  $\sigma_{TSL} / \sigma_{DOS} \approx 2/3$  observed for a large set of organic materials. The low-temperature energy relaxation of photogenerated carriers within a Gaussian DOS implies a significant narrowing of the ODOS distribution. In order to gain a deeper insight into this effect, we performed extensive Monte- Carlo simulations of charge-carrier energetic relaxation process and found that such "spectral narrowing" effect is a genuine property of the hopping carrier relaxation at low temperature within a Gaussian DOS. Moreover, we found that spatial energy correlation effects, which are indeed present in organic media, must be considered for the quantitative description of experimental observations.

HL 41.5 Fri 10:30 H34

**Exploring the interplay of oriented molecules and device performance by post-annealing studies of organic light-emitting diodes** — •DINARA SAMIGUL-LINA, CHRISTIAN HÄNISCH, KARL SEBASTIAN SCHELLHAMMER, and SEBASTIAN REINEKE — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute of Applied Physics, Technische Universität Dresden, Germany

Organic light-emitting diodes (OLEDs) have been widely investigated in the last decades exploring strategies to enhance their performance. Nevertheless, a thorough understanding of the microscopic processes during the thin-film formation and morphology evolution is quite challenging and under debate in many facets. In this work, we present a comprehensive study of the influence of postannealing on the optoelectronic performance of OLEDs. In addition to standard characterisation techniques such as spectroscopy and electrical measurements, we use impedance spectroscopy in order to probe the change in polarisation of organic thin films depending on the annealing temperature. We show, how the orientation of permanent dipole moments (PDMs) in thin films can be manipulated by post-annealing and connect this to improved electrical performance. Moreover, angle-resolved emission spectra reveal the influence of heating on the orientation of the transition dipole moment (TDM) of emitting molecules. In such manner, the correlation between annealing temperature and orientation of PDMs and TDMs is studied while taking into consideration the optoelectronic properties of OLEDs.

# HL 42: 2D Materials 6 (joint session HL/CPP/DS)

Time: Friday 9:30-12:00

HL 42.1 Fri 9:30 H36

THz conductivity of nanograined Bi2Te3 pellets with varying Te doping — •Ahana Bhattacharya¹, JeongWoo Han¹, Sepideh Izadi², Sarah Salloum³, Stephan Schulz³, Gabi Schierning², and Martin Mittendorff¹ — ¹Universität Duisburg-Essen, Fakultät für Physik, 47057 Duisburg, Germany — ²Universität Bielefeld, Fakultät für Physik, 33615 Bielefeld, Germany — ³Universität Duisburg-Essen, Fakultät für Chemie, 45141 Essen, Germany

The topological insulator Bi2Te3 hosts surface states with a high carrier mobility as back scattering of charge carriers is suppressed due to the spin-momentum locking. While in large crystals the electronic properties are dominated by the bulk states, hot-pressed pellets of nanograined Bi2Te3 offer a high surface-tovolume ratio, which provides a platform to exploit the surface carriers even in extended samples. Here we employ THz time-domain spectroscopy to disentangle the contribution of surface and bulk carriers to the transport properties. Even at room temperature the THz reflection is determined by characteristic features of the high-mobility surface carriers, i.e. Drude conductivity but also plasmonic contributions. The latter are caused by confinement of the surface carriers due to the mechanical structure of the sample. Variations of the Te content allows to shift the Fermi energy and thus strongly influences the resulting THz spectra.

### HL 42.2 Fri 9:45 H36

**Direct growth of monolayer MoS2 on nanostructured silicon waveguides** — •A KUPPADAKKATH¹, E NAJAFIDEHAGHANI², Z GAN², A TUNIZ³, G NGO¹, H KNOPF¹, F LÖCHNER¹, F ABTAHI¹, T BUCHER^{1,5}, S SHRADHA¹, T KÄSEBIER¹, S PALOMBA³, N FELDE⁴, P PAUL¹, T ULLSPERGER¹, S SCHRÖDER⁴, A SZEGHALMI^{1,4}, T PERTSCH^{1,4}, I STAUDE^{1,5}, U ZEITNER^{1,4}, A GEORGE², A TURCHANIN², and F EILENBERGER¹ — ¹Institute of Applied Physics (FSU), Jena, Germany — ²Institute of Physical Chemistry (FSU), Jena, Germany — ³Sydney Nano, Camperdown, Australia — ⁴Fraunhofer IOF, Jena, Germany — ⁵Institute of Solid State Physics (FSU), Jena, Germany

We report for the first time the direct growth of Molybdenum disulfide (MoS2) monolayers on nanostructured silicon-on-insulator waveguides. Our results indicate the possibility of utilizing the Chemical Vapour Deposition (CVD) on nanostructured photonic devices in a scalable process. Direct growth of 2D material on nanostructures rectifies many drawbacks of the transfer-based approaches. We show that the van der Waals materials grow conformally across the curves, edges, and the silicon-SiO2 interface of the waveguide structure. Here, the waveguide structure used as a growth substrate is complex not just in terms of its geometry but also due to the two materials (Si and SiO2) involved. A transferfree method like this yields a novel approach for functionalizing nanostructured, integrated optical architectures with an optically active direct semiconductor.

#### HL 42.3 Fri 10:00 H36

Atomic layer deposition of ternary  $MoWS_2 - \cdot$ Christian Tessarek, Tim Grieb, Andreas Rosenauer, and Martin Eickhoff — Institut für Festkörperphysik, Universität Bremen

Two-dimensional (2D) monolayers of binary molybdenum disulfide (MoS₂) and tungsten disulfide (WS₂) belong to the transition metal dichalcogenide (TMDC) material family and are direct band gap semiconductors. The optical band gap of monolayer MoS₂ and WS₂ is ~1.9 and 2.0 eV, respectively. Ternary Mo_xW_{1-x}S₂ enables tuning of excitonic transition energy dependent on the concentration *x*.

Atomic layer deposition (ALD) is used to deposit  $MoWS_2$  in the whole composition range between pure  $MoS_2$  and  $WS_2$ . The concentration *x* is determined

Location: H36

by the frequency position of the  $A_{1g}$  Raman mode. The distribution of W and Mo atoms in the crystal lattice of MoWS₂ is studied by high resolution scanning transmission electron microscopy. Additional annealing is performed to improve structural and optical properties. Photoluminescence spectroscopy measurements show concentration dependent spectral position of A and B excitonic emission.

HL 42.4 Fri 10:15 H36

Epitaxial growth of post transition metal chalcogenides: From standard approaches to new capabilities — •EUGENIO ZALLO^{1,2}, MICHELE BISSOLO¹, MARCO DEMBECKI¹, GREGOR KOBLMÜLLER¹, and JONATHAN J. FINLEY¹ — ¹Walter-Schottky-Institut and Physik Department, Technische Universität München, Am Coulombwall 4, 85748, Garching, Germany — ²Paul-Drude-Institut für Festkoerperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Hausvogteiplatz 5-7, 10117, Berlin, Germany

Van der Waals (vdW) materials grown epitaxially are an urgent challenge for the development of scalable and high-crystalline-quality semiconductor films that can be exploited for novel device technologies. 2D materials "beyond graphene" have sparked immense interest in recent years, due to their excellent physical properties. Among them, post transition metal chalcogenides (PTMC,  $M=\{In,Ga\}$  and  $C=\{S,Se,Te\}$ ) are vdW semiconductor materials with extraordinary photoresponsivity, a quasi-direct gap with a Mexican hat valence band and promising thermoelectric properties but they suffer from fast layer oxidation. In this presentation, the molecular beam epitaxy (MBE) growth of large-area PTMC is demonstrated on 3D and 2D bonded substrates by means of encapsulation strategies and careful microscopic and spectroscopic characterizations supported by density functional theory calculations. In order to study the pristine information of air sensitive materials, we present a cutting edge UHV cluster tool for the synthesis of ultrapure 2D-PTMCs and their heterostructures. The potential directions will be described.

HL 42.5 Fri 10:30 H36

**Fabrication of Dielectric Mirrors and Microcavity Configurations for Light-Matter Coupling with Transition-Metal Dichalcogenides Heterostructures** — •CHIRAG PALEKAR¹, MANAN SHAH², FYNN KUNZE², PETER KLAR², STEPHAN REITZENSTEIN¹, and ARASH RAHIMI-IMAN² — ¹Institute of Solid State Physics, Technische Universität Berlin, D-10623, Germany. — ²I. Physikalisches Institut und Zentrum für Materialwissenschaften, Justus-Liebig Universität Gießen, D-35392, Germany

#### 15 min. break

HL 42.6 Fri 11:00 H36

Selective area growth of  $MoS_2$  via CVD on patterned GaN-AlO_x substrates — •SIMON WÖRLE, THERESA GRÜNLEITNER, ALEX HENNING, and IAN SHARP — Walter Schottky Institute and Physics Department, Technical University of Munich, Garching, Germany

Two-dimensional (2D) transition metal dichalcogenides have attracted considerable attention due to their unique optoelectronic properties. For the application of 2D materials in semiconductor devices, the controlled and scalable synthesis of high-quality 2D materials is critical.

Here, we demonstrate the selective area growth of  $MoS_2$  by chemical vapor deposition (CVD) on GaN substrates that were patterned with ultrathin aluminum oxide coatings created by low-temperature atomic layer deposition. Optical and scanning electron microscopy images show that mono- and few-layer

 $MoS_2$  flakes preferentially nucleate and grow directly on the (uncoated) GaN. Atomic force microscopy and Raman measurements further reveal the formation of triangular and star-like shaped multilayer  $MoS_2$  crystals at the interfaces between GaN and  $AlO_x$ . Moreover, the observed fixed orientation of the triangular  $MoS_2$  flakes with respect to the GaN substrate lattice indicates van der Waals epitaxy. By altering the CVD growth conditions, the density of deposited  $MoS_2$ flakes can be tuned, resulting in the growth of either isolated  $MoS_2$  nanosheets or continuous films, in the latter of which the individual flakes have coalesced.

The presented results mark an important step towards integrated  $MoS_2$  based heterostructures for semiconductor device applications.

#### HL 42.7 Fri 11:15 H36

Patterned growth of transition metal dichalcogenides monolayers and multilayers for electronic and optoelectronic device application — •SEUNG HEON HAN¹, ZIYANG GAN¹, EMAD NAJAFIDEHAGHANI¹, FATEMEH ABTAHI², CHRISTOF NEUMANN¹, JULIAN PICKER¹, TOBIAS VOGEL², UWE HÜBNER³, FALK EILENBERGER², ANTONY GEORGE¹, and ANDREY TURCHANIN¹ — ¹Institute of Physical Chemistry, Friedrich Schiller University Jena, Jena, Germany — ³Leibniz Institute of Photonic Technology (IPHT), Jena, Germany

We present a simple, large area, cost effective soft lithographic method for growth of high-quality two-dimensional transition metal dichalcogenides (TMDs). Initially, a liquid precursor (Na2MoO4 in aqueous solution) is patterned on the growth substrate using micro-molding in capillaries (MIMIC) technique. Subsequently, a chemical vapor deposition (CVD) step is employed to convert the precursor patterns to monolayer, few layers, or bulk TMDs, depending on the precursor concentration. The grown patterns were characterized using optical microscopy, atomic force microscopy, Raman spectroscopy, X-ray photoelectron spectroscopy, scanning electron microscopy, and photoluminescence spectroscopy to reveal their morphological, chemical, and optical characteristics. The applicability of the grown patterned TMDs were tested for application such as field effect transistors, photodetectors, and memtransistor devices.

#### HL 42.8 Fri 11:30 H36

**Conductive 2D MOFs in van-der-Waals heterostructures** — •JONAS PÖHLS¹, ZHIYONG WANG², RENHAO DONG², and THOMAS WEITZ¹ — ¹I. Physical Institute University of Göttingen, Göttingen, Germany — ²Technical University of Dresden, Dresden, Germany

In conventional three-dimentional (3D) Metal-Organic Frameworks (MOFs) the electric conductivity is limited by the large separation of the metal centers by the

organic ligands. Recent advantages in the synthesis of layered two-dimensional conjugated MOFs (2D c-MOFs) lead to a large improvement of the electronic properties, these materials allow a charge transfer along both interlayer ( $\pi$ - $\pi$ -stacking) and intralayer (basal plane) directions [1]. In order to elucidate the underlying charge transport mechanisms in the 2D c-MOFs, we perform electronic characterizations of the films implemented in field-effect transistors under varying conditions. In addition to the improved properties of the 2D c-MOFs themselves, their 2D nature make them also a promising candidate for the fabrication of van-der-Waals heterostructures with other 2D materials like graphene, which could give access to a variety of interaction-driven effects. We present first results on the charge transport of 2D c-MOFs down to the size of single crystals as well as implemented in van-der-Waals heterostructures.

#### HL 42.9 Fri 11:45 H36

**Controlled Encapsulation of Monolayer MoS2 with Ultrathin Aluminium Oxide for Tunnel Contacts** — •SERGEJ LEVASHOV, CHENJIANG QIAN, THERESA GRÜNLEITNER, JON J. FINLEY, ALEX HENNING, and IAN D. SHARP — Walter Shottky Institut, TUM, München, Deutschland

Two-dimensional (2D) semiconductors have unique optoelectronic properties that provide the opportunity to overcome current scaling and performance limits of semiconductor devices. To harness the full of potential of 2D materials, requires their seamless integration with bulk materials. In particular, contacting mono- and few-layer 2D semiconductors with metals is challenging since the deposition process may introduce defects impeding interfacial charge transport. Here we use low-temperature atomic layer deposition to encapsulate monolayer  $MoS_2$  with a van der Waals bonded and ultrathin aluminium oxide  $(AlO_x)$  layer. The 18 Å thin  $AlO_x$  coating introduces additional charge carriers (~5·10¹² cm⁻²), while it also protects monolayer MoS₂ from defect creation during metallization. Microscratching of the AlO_x adlayer by contact mode atomic force microscopy and subsequent spectroscopic analysis demonstrate the reversibility of the charge transfer doping effect, indicating weak interaction. Importantly, current voltage measurements yielded a two-fold reduction in the contact resistance for MoS₂ field-effect transistors contacted with AlO_x interlayer. Overall, this work demonstrates the beneficial effect of the AlO_x adlayer for improving 2D device contacts and provides a scalable route to the damage-free integration of 2D semiconductors.

#### Tutorial

KFM 1.1 Sun 16:00 H3

KFM 1.2 Sun 16:45 H3

**Domains and domain walls in functional ferroics** — •DENNIS MEIER — Department of Materials Science and Engineering, Norwegian University of Science and Technology — Center for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology, Trondheim, Norway

Ferroic materials with spontaneous magnetic or electric long-range order are a rich source for functional phenomena. Ferromagnets, for example, are used in hard discs and read heads, whereas ferroelectrics find application as capacitors, energy harvesters, and in tunnel junctions. The rich functionality of ferroic materials is closely linked to their domain structures and the responses of the domains to external stimuli.

In this tutorial, I will give an introduction to the fundamentals that underpin the domain formation in ferroics and discuss different microscopy techniques that allow for imaging electric and magnetic domains. Furthermore, we will talk about more exotic systems, such as improper ferroelectrics and multiferroics, where the interplay of coexisting order parameters gives rise to completely new domain and domain wall properties at the nanoscale. Open experimental challenges will be addressed, as well as future application and research opportunities.

#### Tutorial

Theory and simulations of ferroelectrics and related materials — •JORGE INIGUEZ — Luxembourg Institute of Science and Technology — University of Luxembourg

In this tutorial I will introduce the theoretical and simulation methods most frequently employed to investigate ferroelectrics and related materials (antiferroelectrics, multiferroics). I will start from the general electronic-structure methods that permit predictive calculations at the atomic scale, and introduce successive simplifications to eventually reach continuum field schemes that give us access to the mesoscale. I will illustrate the specificity and usefulness of the different approaches by presenting, for each of them, one or two classic examples of application. In passing, this will allow me to emphasize the key role that simulation has played in our field, and to touch upon interesting possibilities for application in energy-related problems.

Jorge Íñiguez's work on ferroelectrics and related materials is mainly funded by the Luxembourg National Research Fund, currently through projects FNR/C18/MS/12705883/REFOX/Gonzalez, INTER/NWO/20/15079143, and C21/MS/15799044.

 Atomic scale analysis of ferroic domain walls — •SHELLY CONROY — Department of Materials, London Centre of Nanotechnology, Imperial College London, United Kingdom

The dynamic interfaces of ferroic materials known as domain walls by-pass the static limitations of traditional nano-device designs. In contrast to heterointerfaces between different materials, domain walls can be created, moved and removed via an applied stimulus. By combining multiple ferroic properties such as electricity and magnetism, new multi-functional interactive device applications are possible. As these mobile walls can be atomically sharp, it is essential to have physical characterisation at this scale spatially and time-resolved. In this tutorial, I will give an introduction to electron microscopy techniques starting with how to identify domain patterns in the bulk samples, and the most appropriate electron microscopy techniques to use with increasing magnification, leading to pico-meter characterisation. We will discuss some of the most recent advances in electron microscopy characterisation methods for ferroelectrics such as visualising electric charge density at sub-angstrom resolution, and the benefits of coupling polarisation characterisation with electron energy loss spectroscopy band structure analysis. We will then talk about how one can probe multiferroic properties such as magnetic field, strain and phonon modes. As one of the most exciting aspects of ferroic domain walls is their mobility, the various in situ options to investigate their dynamics will be detailed.

# KFM 2: Focus Session: Defects and Interfaces in Multiferroics 1

The focus session is dedicated to advanced nano scale-characterization, property-engineering, and modelling methods of multiferroic materials focusing on defects and interfaces. Typical examples may include ferroic domain walls, microstructural levers, or strain effects. Further, applications in novel nanoelectronic devices and nano-related engineering concepts of macroscopic properties of multiferroics are of interest.

Chair: Dr. Marion Höfling (DTU Copenhagen)

Time: Monday 9:30-12:25

Invited TalkKFM 2.1Mon 9:30H5Domain-wall engineering in multiferroic materials — •GUILLAUME NATAF —<br/>GREMAN UMR7347, CNRS, University of Tours, INSA Centre Val de Loire,<br/>37000 Tours, France

Ferroelectric and ferroelastic domain walls are two-dimensional topological defects with thicknesses approaching the unit cell level that can move in response to an electric-field or an applied stress. They exhibit emergent functional properties, such as polarity in non-polar systems or electrical conductivity in otherwise insulating materials, and due their complex strain profiles they interact with phonons as 'defects' would.

In this talk I will: (1) Show how to characterize domain walls with optical techniques (polarized light optical microscopy, liquid crystal decoration, Raman spectroscopy); (2) Discuss how domain walls move in response to an electric field or an applied stress, through discrete impulsive jumps, indicators of avalanches on a broad range of scales; (3) Show that domain walls can be used to induce large thermal conductivity variations in materials.

KFM 2.2 Mon 10:00 H5

Engineering of improper ferroelectric vortex- and stripe-like domains in polycrystalline  $ErMnO_3 - \bullet$ Max HAAS, JAN SCHULTHEISS, and DENNIS MEIER - Norwegian University of Science and Technology (NTNU), 7034 Trondheim, Norway

The functionality and physical properties of ferroelectric materials are intimately coupled to their domain structure. An exciting recent discovery are topologically protected vortex domains in hexagonal manganites, which are of interest for different fields ranging from nanoelectronics to cosmology-related questions. A key characteristic of the domain structure is the vortex density, that can readily be tuned via the cooling rate across the ferroelectric phase transition.

Here, we explore the effect of cooling rate variations in combination with threedimensional spatial confinement in high-quality  $ErMnO_3$  polycrystals. Utilizing piezoresponse force microscopy, we demonstrate a propensity for the formation of stripe-like domains. Analogous to the vortex-like domains observed in  $ErMnO_3$  single crystals, we find that the periodicity of the stripe-like domains depends on the cooling rate through the Curie temperature. For cooling rates in the range of  $10^{-2}$  to  $10^1$  K/min, the periodicity of the stripe-domains increases

logarithmically. This scaling behavior is explained based on the interplay between cooling rate and long-ranging strain fields, offering new possibilities for the engineering of domains and domain walls in polycrystalline improper ferroelectrics.

KFM 2.3 Mon 10:20 H5 **Tuning multiferroic properties in hexagonal YMnO₃ by manipulation of the structural order** – •M. GIRALDO¹, H. SIM², A. SIMONOV¹, M. LILIENBLUM¹, A. SAMIR¹, E. GRADAUSKAITE¹, Y. HEO¹, M. ROSSELL³, M. TRASSIN¹, J.-G. PARK², TH. LOTTERMOSER¹, and M. FIEBIG¹ – ¹Department of Materials, ETH Zurich – ²Department of Physics and Astronomy, Seoul National University – ³Electron Microscopy Center, EMPA

We investigate the enhancement and suppression of the structural distortion (Q) in hexagonal YMnO3 upon substituting Mn by Al and Ga. We demonstrate its consequences on the electric and magnetic long-range order. We deploy various techniques for a systematic investigation. We observe a progressive decrease in the structural order. This behaviour is caused by the chemical pressure induced by the ionic size of Al and Mn. On the level of the ferroelectric domains, the suppression of the structural order manifests in a progressive size decrease upon increased Al concentration. We do not observe a domain size variation upon Ga substitution. Our experiments suggest that, surprisingly, the progressive reduction on the structural distortion is not directly proportional to a decrease in ferroelectric polarization. On the magnetic level, we find a progressive decrease of the ordering temperatures. This is due to the direct perturbation of the magnetic sublattices formed by the Mn³⁺ moments and the progressive dilution of the magnetic long-range order. By tracing changes in the inherent properties of these systems, we aim to broaden the understanding for new routes in the manipulation of ferroic properties in these compounds.

 $\begin{array}{l} {\color{black} \textbf{Strain-induced multiferroic ribbons in non-multiferroic phase of MnWO_4-} \\ \bullet \text{Lea FORSTER}^1, \text{SHINGO TOYODA}^2, \text{MANFRED FIEBIG}^{1,2}, \text{TAKA-HISA ARIMA}^{2,3}, \\ \text{YOSHINORI TOKURA}^{2,4,5}, \text{ and NAOKI OGAWA}^{2,5,6}- ^1\text{Deptartment of Materials}, \\ \text{ETH Zurich, Switzerland}- ^2\text{RIKEN CEMS, Saitama, Japan}- ^3\text{Department} \\ \text{of Advanced Materials Science, University of Tokyo, Kashiwa, Japan}- ^4\text{Tokyo} \\ \text{College, University of Tokyo, Tokyo, Japan}- ^5\text{Department of Applied Physics}, \\ \text{University of Tokyo, Tokyo, Japan}- ^6\text{PRESTO, JST, Kawaguchi, Japan} \end{array}$ 

Local structures, such as structural defects, interfaces, and domain walls have the potential to exhibit different physical properties than the bulk. The occurrence of magnetic and electric orders in a confined area may be of particular interest for technological applications, for example, to electrically control the magnetization in memory devices. However, probing local multiferroic structures is challenging caused by a lack of experimental techniques. In this study, we demonstrate a ribbon-shaped, spatially confined multiferroic phase in a nonmultiferroic environment in  $MnWO_4$ . We use optical second harmonic generation imaging to show that a multiferroic phase can be generated by local strain within a non-multiferroic bulk structure. Furthermore, we reveal within the confined multiferroic regions domains with different electric polarization directions and demonstrate deterministic writing of a multiferroic state by the application of strain.

Invited TalkKFM 2.5Mon 11:15H5Charged Higher Order Topologies in Room Temperature MagnetoelectricMultiferroic Thin Films — •SHELLY CONROY^{1,2}, KALANI MOORE², SINEADGRIFFIN³, LYNETTE KEENEY⁴, and EOGHAN O'CONNELL² — ¹Imperial CollegeLondon, London, United Kingdom — ²University of Limerick, Limerick, Ireland— ³Lawrence Berkeley National Laboratory, Berkeley, USA — ⁴Tyndall NationalInstitute, Cork, Ireland

Multiferroic topologies are an emerging solution for future low-power magnetic nanoelectronics due to their combined tuneable functionality and mobility. Here, we show that in addition to being magnetoelectric multiferroic at room temperature, thin film Aurivillius phase Bi6TixFeyMnzO18 is an ideal material platform for both domain wall and vortex topology based nanoelectronic devices. Utilising atomic resolution electron microscopy and atom probe tomography, we reveal the presence and structure of 180 type charged head-to-head and tail-to-tail domain walls passing throughout the thin film. Theoretical calculations confirm the sub-unit cell cation site preference and charged domain wall energetics for Bi6TixFeyMnzO18. Finally, we show that polar vortex type topologies also form at out-of-phase boundaries of stacking faults when internal strain and electrostatic energy gradients are altered. This study could pave the way for controlled polar vortex topology formation via strain engineering in other multiferroic thin films. Moreover, these results confirm the sub-unit-cell topological features play an important role in controlling the charge and spin state of Aurivillius phase films and other multiferroic heterostructures.

#### KFM 2.6 Mon 11:45 H5

X-ray investigation of a multiferroic YBaCuFeO₅ single crystal — •ARKADIY SIMONOV¹, MARISA MEDARDE², and RUGGERO FRISON³ — ¹ETH Zürich, Zürich, Switzerland — ²Paul Scherrer Institut (PSI), Willigen, Switzerland — ³University of Zürich, Zürich, Switzerland

Recent reports have shown that type-II multiferroic materials can be created using chemical disorder. Disorder frustrates magnetic interaction and induces a magnetic spiral state which breaks the inversion symmetry of the crystal [1]. Such a mechanism is robust since it involves only nearest-neighbor magnetic exchanges and can stabilize the spiral state almost up to room temperature in materials like YBaCuFeO₅. However, due to the complexity of characterizing and controlling chemical disorder, this mechanism is rarely used in practice to design novel multiferroic materials.

In this work we propose single-crystal x-ray diffuse scattering as a method for characterizing disorder. Using YBaCuFeO5 as our model system, we show that diffuse scattering can efficiently probe the local structure induced by chemical disorder. Moreover, when measured at sufficiently high resolution, diffuse scattering is also sensitive to the magnetic phase transition from antiferromagnetic to spiral state of the YBaCuFeO₅. This is unusual, and likely indicates that atomic relaxations induced by this transition are larger than the values observed in typical type-II multiferroics.

A phase-field model for ferroelectrics with local chemical defects — •DILSHOD DURDIEV¹, FRANK WENDLER¹, TAKAHIRO TSUZUKI², SHUJI OGATA², RYO KOBAYASHI², MASAYUKI URANAGASE², and HIKARU AZUMA² — ¹Friedrich-Alexander University Nuremberg-Erlangen, Fürth, Germany — ²Nagoya Institute of Technology, Nagoya, Japan

In this work, an electromechanical fully coupled phase-field model (PFM) is developed, based upon the approach [1], to study domain evolution and polarization switching under the combined influence of the mechanical and electrical loads and local chemical defects in a BaTiO₃ single crystal. The free energy density of the system includes the Landau potential, gradient, mechanical, piezo-electric and electrical energy, respectively. We apply a Fourier spectral method to solve the coupled constitutive equations. Molecular dynamics simulations with core-shell potentials are conducted to capture the domain wall dynamics including vacancies and cation-anion vacancy dipoles [2]. We develop procedures to obtain kinetic and energetic parameters of the PFM from these simulations. Scaling relations are applied to transfer local fields (of vacancies and aliovalent dopants) as well as local bond effects (from vacancies) from the micro- to the continuum scale.

**Small-Angle X-ray Scattering: Characterization of arbitrarily shaped nanoparticles using the Debye equation** — •JÉRÔME DEUMER¹, BRIAN RICHARD PAUW², SYLVIE MARGUET³, DIETER SKROBLIN¹, OLIVIER TACHÉ³, MICHAEL KRUMREY¹ und CHRISTIAN GOLLWITZER¹ — ¹Physikalisch-Technische Bundesanstalt, Abbestr. 2-12, 10587 Berlin — ²Federal Institute for Materials Research and Testing (BAM), Unter den Eichen 87, 12205 Berlin — ³Université Paris-Saclay, CEA, CNRS, NIMBE, 91191 Gif-sur-Yvette, France

We propose a versatile software package in the form of a Python extension, named CDEF (Computing Debye's scattering formula for Extraordinary Formfactors), to approximately calculate scattering profiles of arbitrarily shaped naLocation: H7

noparticles for small-angle X-ray scattering (SAXS). CDEF generates a quasirandomly distributed point cloud in the desired particle shape and then applies the open source software DEBYER for efficient evaluation of Debye's scattering formula to calculate the SAXS pattern. The usage of the software is demonstrated for the evaluation of scattering data of Au nanocubes with rounded edges, which were measured at the four-crystal monochromator beamline of PTB at the synchrotron radiation facility BESSY II in Berlin. Our implementation is fast enough to run on a single desktop computer and perform model fits within minutes. The accuracy of the method was analyzed by comparison with analytically known form factors. KFM 3.2 Mon 9:50 H7

Flat-field correction of highly-dynamic processes — •THEA ENGLER¹, JO-HANNES HAGEMANN¹, CHRISTIAN SCHROER¹, and MATHIAS TRABS² — ¹Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — ²Karlsruhe Institue of Technology KIT, Germany

Using hard coherent x-rays, as produced in PETRA III at DESY and in the European XFEL, objects with a size of  $\mu$ m to nm can be imaged with full-field phasecontrast imaging. With single-pulse imaging, specifically dynamic processes on the nanosecond-timescales can be investigated. A recorded single-pulse hologram of the object under investigation in a lens-less imaging setup is disturbed by illumination artifacts. The origin of these artifacts are aberrations in the optics, such as figure errors and surface roughness. For further analysis, the illumination artifacts have to be removed, which is achieved by a flat-field correction. Therefore, the x-ray image of the object of interest is divided by an empty-beam image. This approach assumes temporal stability of both illumination and object. In the case of XFEL experiments, the pulse-to-pulse fluctuations stemming from the SASE process violate this assumption. For the imaging conducted at PETRA III, in addition to vibrations in the beamline's optical components, the object itself incorporates dynamic movements. The common case of the flat-field correction can be improved by recording an empty-beam image-series. With principal component analysis (PCA) of the image series and a careful selection of the principal components, a synthetic flat-field can be reconstructed for each object-image.

#### KFM 3.3 Mon 10:10 H7

Formation and time dynamics of hydrogen-induced vacancies in nickel — •MAIK BUTTERLING¹, LUCA CHIARI², MASANORI FUJINAMI², MACIEJ OSKAR LIEDKE¹, ERIC HIRSCHMANN¹, AHMED GAMAL ATTALLAH¹, and ANDREAS WAGNER¹ — ¹Institute for Radiation Physics, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — ²Department of Applied Chemistry and Biotechnology, Chiba University, 1-33 Yayoi, Inage, Chiba 263-8522, Japan The formation of hydrogen-induced defects in nickel was investigated by positron annihilation lifetime spectroscopy and the time dynamics of those defects during room temperature aging was tracked with an unprecedented time resolution of the order of minutes using an ultrahigh-flux slow positron beam. Those measurements showed the formation of a large number of atomic vacan-

cies simply by hydrogen addition at room temperature. It could be proved that they were monovacancy-level defects and that hydrogen was trapped and bound to those vacancies during the hydrogen charge. Room temperature aging, i.e. below the stage III temperature in Ni, and the concomitant hydrogen desorption induced the agglomeration of those monovacancies into large vacancy clusters which remained even after all the hydrogen had desorbed and hydrides had disappeared. These results constitute the first empirical evidence that vacancyhydrogen complexes are induced in Ni only by hydrogen charging and demonstrate that hydrogen has a primary role in the formation and stabilization of vacancies even at room temperature.

Stereo X-Ray Microscopy: Seeing the nanocosm in 3D — •SINA RÖPER^{1,2}, KAROLINA STACHNIK², LUKAS GROTE², MATTIAS ÅSTRAND³, HANNA OHLIN³, MARTIN SEYRICH¹, SARAH-ALEXANDRA HUSSAK², THOMAS FRISK³, ANDREAS SCHROPP¹, ULRICH VOGT³, DOROTA KOZIEJ², and CHRISTIAN SCHROER^{1,2} — ¹Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — ²University of Hamburg, Hamburg, Germany — ³KTH Royal Institute of Technology, Stockholm, Sweden

Understanding the nucleation and growth mechanisms involved in the synthesis of nanomaterials is a key factor in determining their performance and functionality. In many cases, these processes are still not well understood in particular, due to the difficulty of observing them *in situ* or *operando*. Scanning hard X-ray microscopy offers the potential for *in situ* nanoimaging of complex chemical systems under relevant environmental conditions. However, standard X-ray to-mography relies on the rotation of the sample with respect to the X-ray beam. This is typically not possible for the synthesis of nanoparticles in solution, which requires an extended reaction cell.

We have developed a new stereoscopic X-ray imaging technique with improved depth resolution to overcome these challenges. By simultaneously illuminating the sample with two nanofocused X-rays at different angles, we increased the effective numerical aperture and improved the spatial resolution along the X-ray beam path. This provides a significant gain in depth-sensitivity in ptychography with multi-slicing and allows us to obtain 3D structural information from 2D scans.

KFM 6.1 Mon 11:05 H7 Sub-nm Control of Radioactive Isotope Incorporation at Surfaces and Interfaces using Ultra-Low Energy Ion Implantation: The ASPIC and ASCII Vacuum Chambers — •KOEN VAN STIPHOUT, LEONARD-ALEXANDER LIESKE,

terfaces using Ultra-Low Energy Ion Implantation: The ASPIC and ASCII Vacuum Chambers — •KOEN VAN STIPHOUT, LEONARD-ALEXANDER LIESKE, MANUEL AUGE, and HANS HOFSÄSS — Georg-August-Universität Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany

The use of radioactive tracer isotopes has a long history of providing unique insights into magnetic interactions, electric environments and crystal structures of materials at the atomic scale. Experimental techniques such as perturbed y - yangular correlations or emission Mössbauer spectroscopy require the incorporation of radioactive isotopes into the crystal lattice. However, as more research focuses on ever-smaller nano-scaled systems such as atomically thin 2D materials, precise and reproducible incorporation becomes challenging. One way of overcoming these difficulties is the introduction of ultra-low energy (ULE) ion implantation (10 - 100 eV), which enables sub-nm control of the implanted probe's location at the first few monolayers of the sample.

We present the refurbishment, design and application of two vacuum chambers that will soon be installed in the ISOLDE experimental hall of CERN: the *apparatus for surface physics and interfaces at CERN*(ASPIC), an experienced ultra-high vacuum chamber dedicated to surface characterization and modification, and the new *ASPIC's ion implantation* (ASCII) chamber, designed for ULE ion implantation of radioactive probes. Combined X-ray Raman Scattering Spectroscopy and X-Ray Diffraction on Shock-Compressed Vitreous SiO₂ — •LENA BUSSMANN¹, MIRKO ELBERS³, CHRISTIAN ALBERS², JOHANNES KAA², MARTIN SUNDERMANN⁴, HLYNUR GRETARSSON⁴, NICOLA THIERING², CHRISTIAN STERNEMANN², SINDY FUHRMANN¹, THOMAS SCHLOTHAUER¹, and GERHARD HEIDE¹ — ¹TU Bergakademie Freiberg, Institut für Glas und Glastechnologie/Institut für Mineralogie, D-09599 Freiberg — ²TU Dortmund, Fakultät Physik/DELTA, D-44221 Dortmund — ³Universität Potsdam, Institut für Geowissenschaften, D-14467 Potsdam-Golm — ⁴DESY, D-22609 Hamburg

Vitreous SiO₂ is a suitable model material for dynamic compression experiments: Many of its pressure-related properties are fairly well known, yet, several questions remain unsolved. Vitreous silica has been shock-compressed in the "Reiche Zeche" mine in Freiberg and investigated at the P01 beamline of PE-TRA III at DESY via X-ray Raman spectroscopy (XRS) and X-ray diffraction (XRD). XRS allows to classify the shock effects on a short scale, while XRD reflects the intermediate-range structure. Results are compared to crystalline SiO₂ modifications. The combination of both methods hence allows to analyse the samples in terms of the effective shock pressure achieved. Furthermore, time-resolved XRD acquisition revealed a structural 'relaxation' process in the shock compressed samples induced by the X-ray irradiation. This process is studied for different heat-treated glass samples as a function of time and temperature, and characterized by collating the XRD and XRS results.

# KFM 7: Focus Session: Defects and Interfaces in Multiferroics 2

The focus session is dedicated to advanced nano scale-characterization, property-engineering, and modelling methods of multiferroic materials focusing on defects and interfaces. Typical examples may include ferroic domain walls, microstructural levers, or strain effects. Further, applications in novel nanoelectronic devices and nano-related engineering concepts of macroscopic properties of multiferroics are of interest.

Organizers: Dr. Jan Schultheiß (Augsburg University, NTNU Trondheim) and Dr. Marion Höfling (DTU Copenhagen)

Chair: Dr. Jan Schultheiß (Augsburg University, NTNU Trondheim)

Time: Monday 15:00-17:25

Multiferroic materials are of interest for the coupling of different ferroic properties on the level of the domains. However, this coupling is not only limited to the bulk but concerns the domain walls too. Here, we show on the example of three different multiferroic systems, that the multi order-parameter coupling on the domain wall level leads to a wide variety of intrinsic domain wall phenomena. In (Dy,Tb)FeO₃, we demonstrate that the interaction of two independent magnetic sublattices gives rise to a polar, multiferroic domain wall in a non-multiferroic environment. The crosstalk of ferroelectricity, structural distortions and magnetic order in hex-ReMnO3 leads to spin rotations of 60°, 120° or 180° about the magnetic domain walls. Depending on the position of the magnetic domain walls with respect of the ferroelectric domain walls, these walls can exchange their rotational character. In the last example, we show that the interplay of two structural distortions in hybrid improper ferroelectrics induces head-to-head and tail-to-tail orientations of the polarization of adjacent ferroelectric domains. These examples illustrate the wide variety of domain wall phenomena thanks to (multi)ferroic coupling effects on the nanoscale.

#### KFM 7.2 Mon 15:30 H5

3D imaging of multiferroic (LuFeO₃)₉/(LuFe₂O₄)₁ superlattices by atom probe tomography — •KASPER HUNNESTAD¹, HENA DAS², CONSTANTINOS HATZOGLOU¹, MEGAN HOLTZ³, CHARLES BROOKS³, ANTONIUS T. J. HELVOORT¹, DARRELL SCHLOM^{3,4}, JULIA MUNDY⁵, and DENNIS MEIER¹ — ¹Norwegian University of Science and Technology, Norway — ²Tokyo Institute of Technology, Japan — ³Cornell University, USA — ⁴Kavli Institute at Cornell for Nanoscale Science, USA — ⁵Harvard University, USA

Oxide interfaces are a rich source for novel physical phenomena, ranging from interfacial superconductivity to unusual (multi-)ferroic effects. Over the last decade, significant progress has been made in both the understanding and engineering of oxide interfaces, propelled by the ongoing progress in the development of atomic-scale characterization techniques.

Here, we introduce atom probe tomography (APT) as versatile tool for studying oxide interfaces, investigating the 3D atomic-scale structure and chemical composition of multiferroic (LuFeO₃)₉/(LuFe₂O₄)₁ superlattices. Our APT measurements reveal a substantial accumulation of oxygen vacancies at the LuFe₂O₄ layers. Based on the data, we quantify the vacancy concentration and discuss their accumulation in relation to calculated defect formation energies

and the multiferroic domain structure. In general, this research establishes a new pathway for studying the interaction of interfaces and point defects in oxides, expanding related atomic-scale investigations into 3D.

Electric-field control of oxygen defects and local transport properties in ErMnO₃ — •JIALI HE¹, URSULA LUDACKA¹, DONALD M. EVANS¹, THEODOR S. HOLSTAD¹, ERIK D. ROEDE¹, KASPER A. HUNNESTAD¹, KON-STANTIN SHAPOVALOV², ZEWU YAN^{3,4}, EDITH BOURRET⁴, ANTONIUS T. J. VAN HELVOORT¹, SVERRE M. SELBACH¹, and DENNIS MEIER¹ — ¹NTNU Norwegian University of Science and Technology, Norway — ²Institute of Materials Science of Barcelona, Spain — ³ETH Zurich, Switzerland — ⁴Lawrence Berkeley National Laboratory, USA

The electronic properties of complex oxides can be tuned via oxygen defects, offering intriguing opportunities for controlling conductivity. Recently, anti-Frenkel defects moved into focus for minimally invasive property engineering, and their creation makes it possible to adjust the electronic properties without long-range ionic migration or stoichiometry changes. Here, we present a detailed analysis of the electric-field-driven formation and time-voltage-dependent evolution of anti-Frenkel defects in hexagonal ErMnO₃. By combining atomic force microscopy and scanning electron microscopy, we investigate the local electronic transport properties associated with the written defects, complemented by numerical simulations. The study reveals that oxygen interstitial - vacancy pairs can be split under an applied electric field. This splitting leads to spatially separated and well-defined vacancy- and interstitial-rich regions, forming a bipolar nanoscale junction. The results provide new insight into the electric-field-driven ionic migration in ErMnO₃ and defects physics in functional oxides.

Deep learning evaluation of conductive atomic force microscopy data — LORENZ GLÜCK^{1,2}, •MANUEL ZAHN^{1,3}, LUKAS PUNTIGAM¹, DONALD M. EVANS¹, SOMNATH GHARA¹, MICHAEL HEIDER², and STEPHAN KROHNS¹ — ¹Experimental Physics V, University of Augsburg, 86159 Augsburg — ²Organic Computing Group, University of Augsburg, 86159 Augsburg — ³Institut für Angewandte Physik, Technische Universität Dresden, 01069 Dresden

Machine learning has gained an enormous interest in the past decade to boost data evaluation in many fields of applied physics. For example, feature recognition in high dimensional datasets in scanning probe microscopy (SPM) can be improved and hidden effects resolved. However, the physical relevance of resolved features is normally still determined by humans.

In this work, we investigate if the regularization of a deep learning (DL) neuronal network, composed of long-short term memory and temporal convolu-

tional network based layers inside an autoencoder architecture, can be utilized to characterize physical significance. We do this on a conductive atomic force microscopy dataset, collected on ferroelectric GaV4S8, as the general properties have already been identified and there are emergent traits at the domain walls. The resolved features from the DL approach are compared to those derived from classical clustering algorithms and classically resolved local material properties. This set up is the first steps to automatic evaluation of physically significant properties in GaV4S8, and is expected to be applicable to other ferroelectric systems.

#### KFM 7.5 Mon 16:45 H5

**Oxygen off-stoichiometry and domain wall conductance in ErMnO**₃ — •LEONIE RICHARZ¹, JAN SCHULTHEISS¹, EDITH BOURRET^{2,3}, ZEWU YAN³, ANTONIUS T.J. VAN HELVOORT¹, and DENNIS MEIER¹ — ¹NTNU Norwegian University of Science and Technology, Trondheim, Norway — ²ETH Zurich, Switzerland — ³Lawrence Berkeley National Laboratory, Berkeley, CA, USA

Ferroelectric domain walls are natural interfaces, separating volumes with different orientation of the spontaneous polarization. Due to their symmetry, electrostatics, and strain, the walls can develop completely different electronic properties than the surrounding domains. In ferroelectric oxides, oxygen offstoichiometry is an additional versatile control parameter. This is reflected by the neutral ferroelectric domain walls in hexagonal manganites: Depending on the oxygen content, their conduction behavior varies from insulating to highly conducting.

In this work, we monitor the electronic transport properties at the domain walls as a function of temperature and oxygen partial pressure with nanoscale spatial resolution. Conductive atomic force microscopy measurements on high-quality  $ErMnO_3$  single crystals show anomalous conductance at the domain walls within the whole temperature range of 25 to 300°C. Furthermore, we find

that by annealing the sample in nitrogen, the domain wall conductance can be enhanced. Our results provide new insight into the impact of environmental parameters on the electronic domain wall properties. This is of interest for the development of atmospheric sensors, adding a new direction to the field of domain wall nanotechnology.

#### KFM 7.6 Mon 17:05 H5

Manipulation of improper ferroelectric domains in Gd₂(MoO₄)₃ using temperature, electric fields, and mechanical stress — •IVAN USHAKOV¹, THEODOR HOLSTAD¹, DIDIER PERRODIN², EDITH BOURRET², THOMAS TYBELL¹, and DENNIS MEIER¹ — ¹Norwegian University of Science and Technology (NTNU), Norway — ²Lawrence Berkeley National Laboratory, USA

In improper ferroelectrics, the spontaneous polarization arises as a biproduct of magnetic or structural order, promoting the formation of domains and domain walls with unusual electronic transport phenomena and scaling behavior.  $Gd_2(MOO_4)_3$  is a classical example of an improper ferroelectric material where a structural instability leads to the formation of a polar axis.

Here, we expand previous mesoscale microscopy studies of the domain structure to the nanoscale. By using piezoresponse force microscopy, we image the patterns of ferroelectric and structural anti-phase domains in  $Gd_2(MoO_4)_3$ . In addition to the established domain patterns, we resolve so far unexplored stripelike nanodomains with a periodicity of about 60 nm. Temperature-dependent measurements show that the nanodomains are stable up to 70°C. Furthermore, we demonstrate reversible switching of these nanodomains by local electric fields and their control via mechanical stress. Our findings provide new insight into the nanoscale domain-physics of  $Gd_2(MoO_4)_3$  and introduce novel opportunities for domain engineering in improper ferroelectrics.

In Situ Structural and Optical Characterization of Laser Recrystallization in an Ultrafast TEM — •Jаков Наден, Murat Sivis, and Claus Ropers — Max-Planck-Institute for Multidisciplinary Sciences, Göttingen, Germany

Surface-plasmon resonances (SPR) have gained increasing attention due to their widespread use in various scientific fields [1]. These resonantly excited collective free-electron oscillations are able to localize and enhance electromagnetic fields beyond the diffraction limit [2]. To this date, the fabrication of such structures with high optical quality remains challenging, since in general, bottom-up-approaches suffer from the poly-crystallinity of the metal which counteracts the plasmon propagation by damping at grain boundaries [3]. In this study, we created plasmonic nanodiscs by electron beam lithography (EBL) and subsequently performed in situ annealing with a pulsed laser source in an ultrafast transmission electron microscope (TEM). This method allows for live-tracking of the boundary migration and also for characterization of SPRs by photon-induced near-field electron microscopy (PINEM) [4]. Upon illumination, the number of grains reduces drastically leading to almost perfect mono-crystals while preserving the shape. Our approach combines the benefits of mono-crystalline plasmonics [5] with nanometrically precise positioning from EBL.

Impact of the stacking sequence on the stability of transition-metal diborides — •THOMAS LEINER¹, NIKOLA KOUTNÁ², PAUL H. MAYRHOFER², and DAVID HOLEC¹ — ¹Department of Materials Science, Montanuniversität Leoben, Austria — ²Institute of Materials Science and Technology, TU Wien, Austria

Transition-metal diborides are a very hard and brittle type of materials, which, among others, find their use as protective coatings, because of their excellent heat conductivity, oxidation stability and wear resistance.

The investigated diborides  $XB_2 X=(Cr, Hf, Mn, Mo, Nb, Re, Ta, Ti, V, Zr)$  occur in three different known stackings, the A-A-A-A stacking of e.g.  $TiB_2$ , the A-B-A-B stacking of ReB₂ and the A-B-B-A stacking of WB₂.

In this work, the impact of the stacking sequence on the stability of diborides is investigated via *ab initio* methods (VASP) and phonon analysis. The energy levels and the energy barriers for the different structures of the transition-metal diborides is calculated and evaluated. The stability of observed local and global energy minima are further investigated by assessing their phonon density of states and their phonon frequencies.

Predictions about a possible stability of certain stackings are made and the behaviour of different diborides was compared to each other.

Pressure-driven insulator-to-metal transition and superconductivity in one-dimensional transition-metal-trichalcogenide microstructures — •CHIN SHEN ONG¹, L. F. SHI^{2,3}, JIN-GUANG CHENG^{2,3}, IRINA GORLOVA⁴, SERGEY ZYBTSEV⁴, LINGYI AO⁵, JUNWEI HUANG⁵, HONGTAO YUAN⁵, RAMAN THIYAGARAJAN⁶, VADIM POKROVSKII⁴, OLLE ERIKSSON^{1,7}, and MAHMOUD ABDEL-HAFIEZ¹ — ¹Uppsala University, Uppsala, Sweden — ²Chinese Academy of Sciences, Beijing, China — ³University of Chinese Academy of Sciences, Beijing, China — ⁵Nanjing University, Nanjing, China. — ⁶Indian Institute of Technology Madras, Chennai, India — ⁷Örebro University, Örebro, Sweden

Transition metal trichalcogenides exhibit large tunability of nontrivial electronic states by modifying chemical composition, temperature, and pressure. Despite great interest in TMTCs, very little information exists on how their electronic properties change with compression. Here, we systematically investigate the high-pressure behavior of n-type semiconducting TiS3 of one-dimensional microstructural form. High-pressure electrical resistance measurements up to 98 GPa identify an exotic sequence of transitions from being a semiconductor to insulator, then metal and finally, a hitherto undiscovered superconducting phase at pressures above 70 GPa. The experimental results are supported by first-principles theoretical calculations.

**Impact of point defects on the ferroelectric phase diagram: a molecular dynamics study on the defect arrangements** — •SHENG-HAN TENG and ANNA GRÜNEBOHM — Interdisciplinary Centre for Advanced Materials Simulation (ICAMS) and Center for Interface-Dominated High Performance Materials (ZGH), Ruhr-University Bochum, Germany

Ferroelectric perovskites usually host imperfections and defects that affect their functional properties. Aging and fatigue are often related to the redistribution of these defects [1-3]. Microscopic insights are therefore needed to better apply these materials to different applications. In this study, we use the first-principle based effective Hamiltonian method [4] to screen the impact of distribution and agglomeration of point defects on the phase diagrams of BaTiO₃-based materials. With this approach, we can simulate up to  $10^6$  unit cells and efficiently investigate different defect arrangements. We find that the local fields induced by the defect dipoles play a key role in ferroelectric phase stability and the optimization of functional properties.

Strain-Induced Collapse of Landau Levels in TaAs — •YANG-JUN  $LEE^{1,2,3}$ , CHEOL-HWAN PARK^{1,2,3}, and MARIA A.H VOZMEDIANO⁴ — ¹Center for Correlated Electron Systems, Institute for Basic Science, Seoul 08826, Korea — ²Department of Physics and Astronomy, Seoul National University, Seoul 08826, Korea — ³Center for Theoretical Physics, Seoul National University, Seoul 08826, Korea — ⁴Instituto de Ciencia de Materiales de Madrid, CSIC, Cantoblanco, Madrid 28049, Spain

A Weyl semimetal, which has a topologically protected conic electronic structure, hosts interesting phenomena such as Fermi arc surface states and chiral anomaly. Recently, the deformation-driven pseudo gauge fields in strained Weyl semimetals have received attention. Among such examples is the collapse of strain-induced Landau levels in Weyl semimetal. In this study, we establish the theory for the effect of strain-induced gauge fields on realistic Weyl semimetals, and based on first-principles calculations, we investigate the conditions on the external strain for the collapse of Landau levels in TaAs.

KFM 8.6 Mon 16:55 H7 Hidden order in ferroelectric oxide thin films — •JOOHEE BANG¹, NIVES STRKALJ², MARTIN SAROTT¹, MORGAN TRASSIN¹, and THOMAS WEBER¹ — ¹Department of Materials Science, ETH Zurich, Zurich, Switzerland — ²Department of Materials Science and Metallurgy, Cambridge University, Cambridge, United Kingdom Nontrivial polar topologies such as flux-closure, vortex-antivortex pair, and skyrmions in ferroelectric thin films have recently garnered much interest as they have implications for the creation of new states of matter and hold promise for alternative device configurations for microelectronics [1]. These observations called for an in-depth structural investigation of the material as the polarization states such as orientation and domain architecture define the macroscopic ferroelectric properties in ferroelectric thin films. In fact, characterization of local order in such films using noninvasive probes is important as it not only allows access to the polarization states in the bulk, but also tracks structural local order. Here, we present a newly discovered local order state on ferroelectric lead titanate and dielectric strontium titanate superlattices from a comprehensive reciprocal space investigation analyzed with three-dimensional delta pair distribution function (3D- $\Delta$ PDF) method [2]. The structural analysis was performed by collecting a complete three-dimensional diffuse X-ray scattering data, which, to the best of our knowledge, was used for the first time to study local order in single-crystalline thin films.

Prize TalkKFM 10.1Tue 9:30H5Einfluss des Sauerstoffgehalts auf das Koerzitivfeld für die Polarisationsum-<br/>schaltung in HfO2 aus der Dichtefunktionaltheorie — •LUIS AZEVEDO ANTU-<br/>NES — Hochschule für angewandte Wissenschaften München — Laureate of the<br/>Georg-Simon-Ohm-Prize 2022

Die fortschreitende Miniaturisierung in der Mikroelektronik stößt beim Thema Energieeffizienz zunehmend an ihre Grenzen. Der Grund sind die Speicherund Schaltkonzepte, welche auf dem Schalten von elektrischen Strömen basieren. Einen Ausweg könnte hier der ferroelektrische Feldeffekt-Transistor (Fe-FET) bieten, welcher stromsparend und ohne Kondensator viel besser skalierbar ist. Mit dem vor 15 Jahren in einem Industrielabor in Dresden gefundenen ferroelektrischen HfO2 und ZrO2 gibt es ein Material, welches die Anforderungen bei sehr kleinen Bauelementen zu erfüllen scheint. Die Fluorit-struktur basierte ferroelektrische Phase des HfO2 weist im Vergleich zu den Perowskit basierten Ferroelektrika jedoch ein höheres Koerzitivfeld auf, welches die Zuverlässigkeit einschränkt. Derzeit wird der Einfluss von Dotierstoffen sowie von Sauerstoff auf die Eigenschaften des Koerzitivfeldes und weiterer Eigenschaften untersucht. In dem Vortrag wird über First-Principle-Berechnungen dieser Eigenschaften berichtet, welches Übergangszustände in den kristallinen Materialien betrachtet. Die Ergebnisse führen zu einem grundlegenden Verständnis von Sauerstoffdefekten auf die Bindungsstruktur und weiterführend auf das Koerzitivfeld. Die Ergebnisse werden mit experimentell gemessenen Koerzitivfeldern verglichen.

 Negative capacitance and voltage amplification in ferroelectric heterostructures — •JORGE INIGUEZ — Luxembourg Institute of Science and technology — University of Luxembourg

My group is interested in the behavior of ferroelectric materials that present nontrivial polar orders (vortexes, skyrmions) and properties (chirality, negative capacitance) in situations of reduced dimensionality (ultra-thin layers or films) and/or subject to suitable electrostatic boundary conditions. In this talk I will review our most recent theoretical results for one of the model systems in the field, the PbTiO₃/SrTiO₃ ferroelectric/dielectric superlattices where many of the above effects were first demonstrated. In particular, I will discuss the negative-capacitance response of such materials, with an emphasis on the attendant voltage amplification. I will show that this anomalous behavior is actually quite frequent, occurring in regular multi-domain structures as well as in novel topological states. Further, I will explain its atomistic underpinnings and show how it can be optimized (to obtain voltage amplifications beyond x10) if the polar layers are tuned to display an incipient ferroelectric state.

Most of the work done in collaboration with M. Graf and H. Aramberri (postdocs at the Luxembourg Institute of Science and Technolgoy) and funded by the Luxembourg National Research Fund through Grants IN-TER/RCUK/18/12601980 and C18/MS/12705883/REFOX. Other key contributors include P. Zubko (UC London), J. Junquera (U. Cantabria), R. Ramesh (UC Berkeley), etc.

#### Topical Talk

Advanced Phase-field Simulation of Ferroelectrics and Antiferroelectrics — •BAI-XIANG XU — Division Mechanics of Functional Materials, Institute of Materials Science, TU Darmstadt

Featured by high power density and high cyclic stability, ferroelectric (FE) and antiferroelectric (AFE) perovskites are distinct type of materials for energy storage and conversion particularly in pulse power equipment, miniaturized electronic devices and electronic control system in electric vehicles. The key issue is to increase the energy storage density, which is strongly related to ferroelectric domain structure in the materials and its interaction with defects.

In this talk I will present advanced phase-field simulations on the domain scale of such energy materials. In the first part, by combining phase-field simulations with dislocation mechanics and driving force theory (Zhou et al. IJSS

KFM 10.3 Tue 10:30 H5

Location: S053

2021; Höfling et al. Science, 2021), I will show simulation results and mechanistic understanding on domain wall-dislocation interaction in mechanically hardened ferroelectrics and its impact on properties. In the second part, a high order gradient phase-field model for antiferroelectrics will be presented (Liu and Xu, Script Mat. 2020). It enables simulations of the newly observed incommensurate modulations of (anti-)ferroelectric polarization configuration, which goes beyond the capability of the established models like the Kittel sublattice model. Simulations on the domain structure, hysteresis, and temperature induced FE-AFE phase transition will be shown, along with the comparison to experimental results.

#### 15 min. break

SmFeO3 is an antiferromagnet with a canted spin structure. We analyzed the basic magnetic properties of monocrystalline SmFeO3 samples through magnetic measurements and micromagnetic simulations. The measurements of the temperature dependent magnetization confirm a spin reorientation at 181°C. Hysteresis properties were found to depend on the magnetic history. We observed exchange bias at room temperature whereby the bias field is sensitive on and increases with the field which is applied after field cooling. Using the double sublattice weak ferromagnetic model we derived effective intrinsic material properties for micromagnetic simulations. The simulations show the existence of metastable multidomain states. In SmFeO3 ferroelectricity is believed to arise from antiferromagnetic domain walls. In a phenomenological model, in which the electric polarization arises from the noncollinear magnetization distribution in the domain walls, the average electric polarization is directly proportional to the total number of domain walls. We show how the number of antiferromagnetic domain walls and the electric polarization changes with the applied magnetic field.

A first-principles study of electronic properties of lead iron niobate — •MADHURA MARATHE¹, ANNA GRUNEBOHM², DORU LUPASCU³, and VLADIMIR SHVARTSMAN³ — ¹Department of Physics and Astronomy, Uppsala University, 75120 Uppsala, Sweden. — ²Interdisciplinary Center for Advanced Materials Simulations (ICAMS), Ruhr-University Bochum, 44801 Bochum, Germany — ³Institute for Materials Science and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, 45141 Essen, Germany

Efficient and cost-effective photovoltaic devices require materials which have optimal band gaps for absorption in the visible spectrum. Several ferroelectric perovskite materials have been investigated for their photovoltaic performance, but have too large band gaps. One promising candidate is multiferroic lead iron niobate  $Pb(Fe,Nb)O_3$  (PFN) which has a narrower band gap [1].

We study the electronic and magnetic properties of PFN using density functional theory calculations. We explore how magnetic ordering and structure (ground-state rhombohedral versus high temperature cubic phases) influence the electronic structure and can thus be used to improve material performance. KFM 10.6 Tue 12:05 H5

Lead-free Barium Zirconium Titanate-Based Ceramics for Energy Storage — •Eva Kröll, Vladimir Shvartsman, and Doru Lupascu — Institute for Materials Science and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Universitätsstr. 15, 45141 Essen, Germany

The growing world population and new technical developments request advanced energy storage systems which offer long life time, high power and energy densities. Relaxor ferroelectrics promise to provide these requirements for new energy storage systems due to their high dielectric permittivity and low hysteresis losses. In this work we added bismuth compounds, Bi(Zn_{2/3}Nb_{1/3})O₃ and Bi $(Zn_{2/3}Ta_{1/3})O_3$ , to the ferroelectric barium zirconium titanate to induce a relaxor state. The heterovalent substitution at the A- and B-sites interrupts the long-range ferroelectric order. Concurrently, Bi³⁺ and Nb⁵⁺ as ferro active ions improve the polarizability of the materials. The addition of Ta⁵⁺ should increase the breakdown strength of the ceramic which is crucial to withstand high electric fields and to increase the stored energy density. We used X-ray diffraction for the phase characterization and scanning electron microscopy for the microstructure analysis. The dielectric spectroscopy and polarization measurement show that small amounts of 1.5 mol% BZNb and BZTa induce relaxor behavior in  $Ba(Ti_{0.85}Zr_{0.15})O_3$ . With increasing content of dopants, the polarization loops become linear. The samples with 2 mol% BZNb and BZTa show the highest energy storage performance with 0.417 J/cm³ and 0.423 J/cm³ at 100 kV/cm, respectively.

HRTEM study of nanoparticle precipitation in additively manufactured 1.2709 maraging steel — •ANNA BENEDIKTOVÁ¹, DAGMAR JANDOVÁ¹, JIŘÍ BENEDIKT², ROSTISLAV MEDLÍN¹, and JÁN MINÁR¹ — ¹New Technologies - Research Center, University of West Bohemia, Pilsen, Czech Republic — ²Faculty of Applied Sciences, University of West Bohemia, Pilsen, Czech Republic

Maraging steels are known for their excellent properties, such as high strength and toughness, which are mainly due to the precipitation of intermetallic compounds during heat treatment. Up to now, mainly precipitation hardening from a temperature of about 500  $^{\circ}$ C has been studied, however, the hardening effect begins to show clearly at lower temperatures, even from 250  $^{\circ}$ C.

The HRTEM study was performed on maraging steel samples without tempering as well as after tempering at 350 °C and 490 °C, and the results were compared with simulations. Besides other relatively coarse precipitates, a high density of globular coherent nanoparticles with a superlattice was found in samples tempered at 350 °C. While the sample tempered at 490 °C contained slightly larger globular and rod-shaped Ni3Mo particles.

KFM 11.2 Tue 9:50 H7 Tuning local structure in Prussian Blue Analogues — •Yevheniia Kholina

and Arkadiy Simonov — ETH Zurich, Switzerland Prussian Blue analogues,  $M[M'(CN)_6]_{1-x}$ ,  $mH_2O$ , which we abbreviate here as M[M'] (M and M'=transition metal ions), is a diverse family of cyanide materials, which is intensely investigated for its potential application for hydrogen storage, as catalysts and as electrode materials. Applications that require efficient mass transport utilize the ability of the structure to accommodate a large number of M'(CN)₆ vacancies, which create a highly connected porous network. It was theoretically shown that the connectivity and the accessible volume of such a network depend on the local structure[1]. Therefore, to optimize mass transport properties not only the number of vacancies but also their distribution must Location: H7

be precisely controlled. In this work we show how to tune the local structure of Mn[Co] Prussian Blue analogues grown in gel by varying the crystallization parameters: the type of gel, the crystallization temperature, the concentration of reactants, and the concentration of chelating agents. We probe the defect distribution by single-crystal x-ray diffuse scattering, which allows quantitative characterization of the local structure. All of the above-mentioned parameters allow smooth continuous control of diffuse scattering and thus of the local order in Mn[Co] crystals.

#### KFM 11.3 Tue 10:10 H7

Electronically driven anharmonicities in low-energy lattice models: Affordable molecular dynamics of charge-density-wave systems — ARNE SCHOBERT¹, •JAN BERGES¹, MICHAEL SENTEF², MARIANA ROSSI², ERIK VAN LOON³, SERGEY BRENER⁴, and TIM WEHLING⁴ — ¹University of Bremen, Bremen, Germany — ²Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — ³Lund University, Lund, Sweden — ⁴University of Hamburg, Hamburg, Germany

Charge-density waves (CDWs) occupy an important position in the phase diagram of low- dimensional systems such as the transition metal dichalcogenide monolayers. Although a CDW can often be identified already from the undistorted structure in linear response, anharmonic effects are eventually responsible for the stabilization of the distorted phase and its precise properties. To study the mechanisms responsible for the anharmonicity, we build an ab-initio lowenergy lattice model, which reproduces Born-Oppenheimer potential surfaces from density-functional-theory (DFT). The ab-initio low-energy lattice model is used for molecular dynamics in the CDW phase of 1H-TaS2. KFM 11.4 Tue 10:30 H7

**Ab Initio Thermodynamics for Surface Motifs of the M1 Selective Oxidation Catalyst** — •K. NAM¹, Y. LEE¹, L. MASLIUK², T. LUNKENBEIN², A. TRUNSCHKE², C. SCHEURER¹, and K. REUTER¹ — ¹Theory Dept., Fritz-Haber-Institut der MPG, Berlin — ²Inorganic Chemistry Dept., Fritz-Haber-Institut der MPG, Berlin

The activity and selectivity of heterogeneous catalysts can be altered noticeably by small changes in different factors such as bulk composition, dopants, defects, reaction conditions, etc. The effects of these factors are furthermore interrelated in non-trivial ways. As an important first step to rationally disentangle them, we here aim to understand their influences on the local atomic-scale structural motifs offered by the catalyst. Specifically, we do this for the M1 structural modification of  $(Mo,V)O_x$  and  $(Mo,V,Te,Nb)O_x$  as an active catalyst for the oxidative dehydrogenation reaction of ethane to ethylene.

The large primitive cell of this M1 catalyst challenges a detailed study by means of predictive-quality first-principles calculations. To this end, we deconstruct the primitive cell into 'rod-like structures' of surface motifs with various oxygen content, faithfully modeling reported data from electron microscopy [1]. *Ab initio* thermodynamics then allows us to explore the effect of varying reaction conditions on the stability of these motifs and thus on M1 catalyst surfaces. Exploiting the data thus generated to train a machine-learn potential we can specifically rationalize the influence of vanadium and niobium doping on the active surface structure.

# KFM 14: Ferroics – Domains and Domain Walls 1

Chair: Dr. Donald Evans (Augsburg University)

Time: Wednesday 9:30–12:05

Ferroelectric domain walls, which can be written, tuned or erased, are being considered as functional building blocks for nanoelectronics. Especially, conducting domain walls are of high interest to achieve this functionality. To date, the origin for increased conductivity in ferroelectrics domain walls has been typically attributed to the formation of screening charges driven by polar discontinuities.

Here, we establish that for the template system, the lacunar spinel  $GaV_4S_8$ also strain can enhance the conductivity of specific domain walls. This system exhibits ferroelectric domain pattern below a Jahn-Teller transition at 42K. At this temperature a change in its crystal structure can result in mechanical stress at domain walls. Piezoresponse force microscopy revealed an interesting ferroelectric pattern. Each ferroelectric domain can be identified by structural considerations to be one of the four possible polar direction. In case of domain walls between structural incompatible domains measurements with conductive atomic force microscopy show strongly enhanced conductivity denoting an additional twist highly conductive domain walls. Further, spatially resolved IV spectroscopy enable the investigation of the underlying conductivity mechanism at the tip-sample interface.

In-situ tracking of the evolution of polarization during the growth of layeredferroelectric Aurivillius phases — •IPEK EFE, ELZBIETA GRADAUSKAITE, MAN-FRED FIEBIG, and MORGAN TRASSIN — Department of Materials, ETH Zürich, Switzerland

The highly anisotropic nature of layered oxides is key to exotic functionalities such as superconductivity, magnetoresistance, and ferroelectricity, which are promising for applications. However, their integration in epitaxial design is chalRaman spectroscopic structure analysis of colloidal semiconductor coreshell quantum dots for the achievement of near-unity quantum efficiency — •SANDRA HINZ^{1,2}, SONJA KROHN^{2,3}, HANNES VAN AVERMAET⁴, ZEGER HENS⁴, JAN STEFFEN NIEHAUS³, JANINA MAULTZSCH¹, and HOLGER LANGE² — ¹Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — ²Institute of Physical Chemistry, University of Hamburg, Hamburg, Germany — ³Fraunhofer IPA - Center for Applied Nano-Technology CAN, Hamburg, Germany — ⁴Physics and Chemistry of Nanostructures, Ghent University, Ghent, Belgium State of the art applications of quantum dots (QDs) require near-unity photolu-

State of the art applications of quantum dots (QDs) require near-unity photoluminescence quantum yield (PLQY). This demand is rarely achieved and therefore the synthesis process is under constant optimization and nanocrystals consisting of a core with one or more shells of different materials are paving the way to achieve high PLQY. As those components have diverse lattice parameters, the induction of strain within the QDs is inevitable. Recently, we applied Raman spectroscopy for in depth structure characterization and a strain minimization approach to optimize the synthesis of InP/ZnSe/ZnS QDs towards near-unity PLQY. A similar effect plays a role in CdSe/CdS QDs when aiming for high PLQY. In these QDs, the formation of an alloyed interface between the CdSe core and CdS shell is assumed. By Raman spectroscopy, we are able to monitor the formation of these alloyed domains for different QD parameters and correlate it with the PLQY.

lenging due to the complexity of the unit cell, which makes precise monitoring of the growth a necessity. Here, we directly access the polarization dynamics of the model system Aurivillius Bi₅FeTi₃O₁₅ films during the epitaxial growth using in-situ optical second harmonic generation (ISHG). We identify an oscillating intensity of the ISHG signal during two-dimensional layer-by-layer growth. We correlate these oscillations with the periodical evolution of the polarization of ferroelectric film dictated by the chemistry of the planes in the unit-cell, which consists of alternating positively charged fluorite-like (Bi₂O₂)²⁺ layer and negatively charged (Bi₃FeTi₃O₁₃)²⁻ perovskite blocks. In combination with reflection high-energy electron diffraction, we show how polarization of the films consistently switches from an out-of-plane orientation during the perovskite blocks growth, to a fully-in-plane orientation with the completion of the unit-cell termination and the (Bi₂O₂)²⁺ capping. Our findings reveal previously hidden polarization dynamics during the epitaxial design and bring new insights in the sub-unit cell control of layered oxide films properties for the development of energy efficient oxide electronics.

**Continuous polarization control at nanoscopic dimensions** — •MARTIN F. SAROTT¹, MARTA D. ROSSELL², MANFRED FIEBIG¹, and MORGAN TRASSIN¹ — ¹Department of Materials, ETH Zurich, Switzerland — ²Electron Microscopy Center, Empa Swiss Federal Laboratories for Materials Science and Technology, Switzerland

The switchable bistable polarization in ferroelectrics allows for the binary control of optical, electronic, and catalytic properties. Going beyond the limitation of a binary remanent polarization holds great promise for emerging neuromorphic concepts. Here, we demonstrate that we can arbitrarily set the magnitude of the remanent ferroelectric polarization at the nanoscale in epitaxial  $PbZr_{0.52}Ti_{0.48}O_3$  thin films with a single DC bias. By approaching the PZT morphotropic phase boundary, we achieve a high degree of control over this unusually susceptible system via epitaxial strain. We employ this to accomplish the formation of decoupled nanometric 180° domains with a broad coercive field dis-

KFM 11.5 Tue 10:50 H7

tribution. Using in-situ optical second harmonic generation and X-ray diffraction, we study the emergence of the nanoscopic domain configuration. We then use piezoresponse force microscopy to demonstrate the ability to locally and reversibly modulate the remanent polarization *continuously* between depolarized and saturated, while preserving the nanoscopic length scale of the domains. We highlight the technological relevance of nanoscale non-binary polarization switching, by showing (i) the voltage-controlled tunability of the nonlinear optical response and (ii) the quasi-continuous tunability of the tunnel electroresistance in ferroelectric tunnel junctions.

KFM 14.4 Wed 10:30 H5

Impact of strontium on domain wall mobility in barium titanate — •ARIS DIMOU¹, PIERRE HIREL², and ANNA GRÜNEBOHM¹ — ¹Ruhr-Uni. Bochum, Interdisciplinary Centre for Advanced Materials Simulation (ICAMS), Bochum, Germany — ²Univ. Lille, Unité Matériaux et Transformations (UMET), Lille, France

Solid solutions of barium-strontium titanate are widely used, environmentally friendly ferroelectric materials that are important for a plethora of applications [1,2]. The presence of domain walls are known to change the properties of a material, and its mobility is of key interest in contemporary electronic devices [3]. Surprisingly little attention has so far been paid to the impact of Sr on the domain wall mobility in barium titanate.

Here we present a microscopic study on the case of Sr inclusions in barium titanate. Our simulations reveal an increase in the activation energy for domain wall movement at the Sr inclusion. Suggesting that a thin Sr plane is enough to pin the domain wall.

Stability of enhanced domain wall conductivity in single-crystalline lithium niobate — •AHMED SAMIR LOTFY^{1,2}, MANUEL ZAHN¹, MICHAEL RÜSING¹, and LUKAS ENG¹ — ¹Institute of Applied Physics, Technische Universität Dresden, Dresden, Germany — ²Department of materials, ETH Zürich, Zürich, Switzerland

Domain-wall conductivity (DWC) in ferroelectrics has emerged as a key functionality for developing nanoelectronic devices. In this regard, lithium niobate (LNO) is a promising candidate as previous studies have shown the capability to significantly enhance its DWC by making use of head-to-head and tail-totail DW configurations, and DW inclination angles under voltage treatments. However, understanding of the temporal and temperature-dependent stability of the enhanced DWC is lacking, limiting further steps of device implementation. For this, we performed a series of conductive atomic force microscopy and macroscopic electrometer measurements on single crystalline LNO samples. We show a characteristic conductance trend during voltage-induced enhancement which provides insights into the temporal stability of DWC. Moreover, our temperature-dependent measurements between 100 K and 300 K reveal the transport mechanism along the walls, pointing to the role of bound polarons. This is confirmed by the calculation of the activation energy. These results provide key insights into the stability of DWC in LNO for applications in practical devices.

KFM 14.6 Wed 11:25 H5

Electron scattering signatures of ferroelectric domains — •URSULA LUDACKA¹, JIALI HE¹, EMIL FRANG CHRISTIANSEN¹, SHUYU QIN², ZEWU YAN3^{3,4}, EDITH BOURRET⁴, ANTONIUS VAN HELVOORT¹, JOSHUA AGAR², and DENNIS MEIER¹ — ¹NTNU Norwegian University of Science and Technology, Trondheim, Norway — ²Department of Materials Science and Engineering, Lehigh University, Bethlehem, PA 18015, USA — ³ETH Zurich, Zurich, Switzerland — ⁴Lawrence Berkeley National Laboratory, Berkeley, USA

The emergence of ferroelectricity originates from polar displacements of lattice atoms, connotating a one-to-one correlation between electronic and structural properties at the atomic level. An established approach that allows for determining associated structural variations is scanning electron diffraction (SED). In SED, a focused electron beam is scanned over the specimen, probing diffracted electrons at each position of the raster scan. The corresponding patterns represent unique fingerprints of the probed areas, containing structural information. We demonstrate the potential and opportunities of this innovative 4D-STEM approach using improper ferroelectric ErMnO₃, an ideal model system as its basic ferroelectric properties and atomic-scale structure are well understood. In the ferroelectric state, the Er ions exhibit characteristic up-up-down and downdown-up patterns, corresponding to ferroelectric 180° domains with positive and negative polarization, respectively. These shifts cause different Bragg scattering conditions for the electrons and, hence, specific diffraction patterns that we utilize for domain imaging assisted by machine learning algorithms.

Domain walls are topological defects which emerge spontaneously in ferroelectrics [1]. At charged domain walls (CDW), free charge from the bulk is promoted to the conduction band through a band-bending mechanism, to compensate their local bound charge [2]. This creates highly conductive embedded mobile 2D nanosheets, suitable for nanoelectronics related applications [2]. Oxygen vacancies are believed to play a role in helping CDW overcome their strong electrostatic interaction. In this work [3], by means of density functional theory calculations in BaTiO₃ we clarify the screening mechanism of CDW charge in both pristine and oxygen vacancy aided cases, and we propose that, beyond the commonly accepted view of oxygen vacancies as CDW stabilizers, they can actually ignite the formation of CDW. We explain the experimentally observed difference in electronic conductivity of the positively and negatively charged CDW in BaTiO₃, as well as the generic prevalence of CDW in ferroelectrics. Such a vacancy driven CDW formation implies that specific charged domain wall configurations may be realized by bottom-up design.

# KFM 15: Materials for Energy Storage (joint session KFM/CPP)

Chair: Prof. Dr. Theo Scherer (KIT, Karlsruhe)

Time: Wednesday 9:30-12:05

KFM 15.1 Wed 9:30 H7

**Hybrid CuCo2O4 nanosheets as binder-free supercapacitor electrodes** — •ZIDONG WANG^{1,2}, YUDE WANG², HUAPING ZHAO¹, and YONG LEI¹ — ¹Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany — ²School of Materials and Energy, Yunnan University, 6500504 Kunming, Peoples Republic of China

CuCo2O4 is one kind of pseudocapacitive materials and it has a high theoretical capacitance, but it suffers from poor electrical conductivity. In this work, CuCo2O4 nanosheets were directly grown on a conductive skeleton to significantly enhance the conductivity and at the same time reduce the agglomeration of CuCo2O4 nanosheets. In addition, the hybrid nanosheet structures also expand the interface and provide more active electrochemical sites, facilitating kinetic processes and electrochemical reactions. The as-prepared CuCo2O4 nanosheets on a conductive skeleton were studied as binder-free electrode and exhibited outstanding electrochemical performance with the specific capacitance of 1595 F g*1 at a current density of 1 A g*1 and 85.1% capacitance retention after Location: H7

4600 cycles. These results indicated that hybrid CuCo2O4 nanosheets has great application potential as binderfree electrode in supercapacitors.

KFM 15.2 Wed 9:50 H7

Investigation of K-ion Intercalation and Conversion in Layer Transiton Metal Disulfide anode: The case of MoS2 and WS2 — •YULIAN DONG, HUAPING ZHAO, and YONG LEI — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany Two-dimensional transition metal dichalcogenides (2D-TMDs) have a unique layered structure characterized by weak interlayer van der Waals interaction and strong in-plane covalent bonding. The structure allows the intercalation of guest species in the interlayer space, which shows impressive properties in potassiumion batteries (PIBs). Thus, various 2D TMDs, including sulfides (MoS2, SnS2, WS2) and selenide (MoSe2 and VSe2), have been studied as potential anode materials for PIBs. This work compares the intercalation and conversion of K in MoS2 and WS2. Intercalation and conversion process is observed during potassium in MoS2 in a voltage range of 3.0-0.5V and 0.5-0.01V, respectively. By controlling cut-off voltage, the investigation demonstrated high capacities derived from the conversion, but it destroys the 2D diffusion pathways leading to an unstable cycling span. While the K+ storage in WS2 is governed by the intercalation reaction rather than the conversion reaction. It exhibited a low capacity decay rate at both low and high current densities as well as great rate capability.

#### KFM 15.3 Wed 10:10 H7

Elucidation of the Pore Formation Mechanism in Hard-Carbon Microspheres — •MARTIN WORTMANN¹, WALDEMAR KEIL², MICHAEL WESTPHAL¹, ELISE DIESTELHORST³, JAN BIEDINGER¹, BENNET BROCKHAGEN³, GÜNTER REISS¹, CLAUDIA SCHMIDT², KLAUS SATTLER⁴, and NATALIE FRESE¹ — ¹Bielefeld University, Bielefeld, Germany — ²Paderborn University, Paderborn, Germany — ³Bielefeld University of Applied Sciences, Bielefeld, Germany — ⁴University of Hawaii, Honolulu, USA

Micro-spherical hydrochar can be carbonized by pyrolysis to produce hardcarbon microspheres with excellent electrochemical properties for the application as anode material in batteries. In this contribution, a temperature-resolved study of the chemical and morphological evolution of saccharide-derived hydrochar during pyrolysis up to 1000°C is presented. By combining a wide range of characterization methods all aspects of the structural transition are examined. The chemical processes occurring both in the bulk and at the surface of the carbon spheres are shown to affect the transition from an amorphous-polymeric to a nanocrystalline carbon-structure. The study focuses on the pore formation mechanism, which is driven by the aggregation of nanometer-sized oxygen-rich clusters at the sphere surface, which disintegrate in a narrow temperature range, leaving behind a mesoporous structure. The revealed molecular mechanisms provide key insights into the pyrolysis of carbonaceous materials.

#### KFM 15.4 Wed 10:30 H7

Hydrogenation of Pd nanoparticles at the nanoscale with in-situ TEM — •SVETLANA KORNEYCHUK^{1,2}, STEFAN WAGNER¹, GEORGIAN MELINTE², DARIUS ROHLEDER³, PHILIPP VANA³, and ASTRID PUNDT¹ — ¹IAM-WK, Karlsruhe Institute of Technology, Karlsruhe, Germany — ²INT, Karlsruhe Institute of Technology, Karlsruhe, Germany — ³Institute of Physical Chemistry Georg-August-University Göttingen, Göttingen, Germany

Palladium-based nanomaterials play an important role in hydrogen technology. Extreme affinity of palladium to hydrogen is very attractive for various applications. Besides catalysis, Pd nanoparticles can assist in hydrogen delivery into other materials for hydrogen storage through a spill-over process. Pd-based materials are also used as hydrogen purification membranes and hydrogen detectors. The hydrogenation and dehydrogenation process of Pd nanoparticles is hence of high interest in the applications mentioned above. Nanoscale systems reveal significant thermodynamic deviations from the bulk due to higher surface to volume ratio, absence of grain boundaries, different behavior of defects and mechanical stress. In this work, we investigate the behavior of Pd nanoparticles and formation of PdHx in real time with in-situ H2-gas TEM. Many applications require operation at elevated temperatures. With the special gas holder from Protochips it is possible to reach pressures up to 1 atmosphere and study the particles at elevated temperatures with the limit of 1000°C. We can observe the local phase change at different temperatures and pressures with the help of spectroscopic and diffraction techniques at the nanoscale.

KFM 15.5 Wed 11:05 H7

Mild-temperature solution-assisted encapsulation of phosphorus into ZIF-8 derived porous carbon as lithium-ion battery anode — •CHENGZHAN YAN¹, SHUN WANG², and YONG LEI¹ — ¹Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany. — ²Key Laboratory of Carbon Materials of Zhejiang Province, Institute of Materials and Industrial Technologies, Wenzhou University, Wenzhou, Zhejiang, 325027, China.

The high theoretical capacity of red phosphorus (RP) makes it a promising anode material for lithium-ion batteries (LIBs). However, the large volume change of RP during charging/discharging imposes an adverse effect on the cyclability, and the rate performance suffers from its low conductivity. Herein, a facile solution-based strategy is proposed to incorporate phosphorus into the pores of MOF-derived carbon hosts under a mild temperature. With this method, the blocky RP is etched into the form of polyphosphides anions (PP, mainly P5-), making it easily diffuse into the pores of porous carbon hosts. Especially, the indelible crystalline surface phosphorus could be effectively avoided, which is generated in the conventional vapor condensation encapsulation method. Moreover, highly-conductive ZIF-8 derived carbon hosts with any pore smaller than 3 nm are efficient for loading PP and these pores can well alleviate the volume change. Finally, the composite of phosphorus encapsulated into ZIF-8 derived porous carbon exhibits a significantly improved electrochemical performance as LIBs anode.

#### KFM 15.6 Wed 11:25 H7

Study on Li Ion Diffusion in  $\text{Li}_x V_2 O_5$  using First Principle Calculations and Kinetic Monte Carlo Simulations — •FABIAN DIETRICH¹, ED-UARDO CISTERNAS¹, MARCELO PASINETTI², and GONZALO DOS SANTOS^{2,3} — ¹Universidad de La Frontera, Temuco, Chile — ²Universidad Nacional de San Luis, CONICET, San Luis, Argentina — ³Universidad de Mendoza, Mendoza, Argentina

We study the Li diffusion in  ${\rm Li}_x {\rm V}_2 {\rm O}_5$  (0 <  $x \le 1$ ) - a potential cathode material for Lithium ion batteries. Different diffusion pathways in this material in dependence on the Li ion concentration are investigated by applying first-principles calculations. The results are used to obtain the corresponding diffusion coefficients by employing two complementary methodologies: Kinetic Monte Carlo (KMC) simulations and a statistical thermodynamics approach. The KMC simulations for two different crystal planes give new evidence that the diffusion coefficients show a temperature dependence obeying the Arrhenius' Law. The necessity of the consideration of concentration-dependent barrier heights in the KMC simulations are demonstrated by looking at the significant changes of the concentration-dependence of the diffusion coefficients. The simulated diffusion coefficients of the combined approach show a good quantitative agreement with experimental data reported previously.

#### KFM 15.7 Wed 11:45 H7

NMR studies of sintering effects on the lithium ion dynamics in  $Li_{1.5}Al_{0.5}Ti_{1.5}(PO_4)_3 - \bullet$ PHILIPP SEIPEL¹, EDDA WINTER¹, MICHAEL VOGEL¹, TATIANA ZINKEVICH², SYLVIO INDRIS², BAMBAR DAVASSUREN³, and FRANK TIETZ³ - ¹AG Vogel, Institute for Condensed Matter Physics, Technische Universität Darmstadt, Germany - ²Karlsruhe Institut of Technology, IAM-ESS, Karlsruhe, Germany - ³Forschungszentrum Jülich GmbH, IEK-1, Jülich, Germany

Various NMR methods are combined to study the structure and dynamics of Li_{1.5}Al_{0.5}Ti_{1.5}(PO₄)₃ samples, which were obtained from sintering at various temperatures between 650 °C and 900 °C and show high bulk conductivities up to 5 mS/cm. We use  7 Li NMR to study the transport mechanism in these glass ceramics [1]. Analysis of ⁷Li spin-lattice relaxation and line-shape changes indicates the existence of two species of lithium ions with clearly distinguishable jump dynamics, which can be attributed to crystalline and amorphous sample regions. An increase of the sintering temperature leads to higher fractions of the fast lithium species with respect to the slow one, but hardly affects the jump dynamics in either of the phases. ⁷Li field-gradient diffusometry reveals that the long-range ion migration is limited by the sample regions featuring slow transport. The high spatial resolution available from the high static field gradients of our setup allows us to observe also the lithium ion diffusion inside the small (< 100 nm) LATP crystallites, yielding a high self-diffusion coefficient of D=2 x 10⁻¹² m²/s at room temperature. [1]Winter et al., ZPCH, DOI:10.1515/zpch-2021-3109

Time: Wednesday 9:30-12:30

See HL 18 for details of this session.

# KFM 17: Focus Session: Surfaces and Interfaces of (Incipient) Ferroelectrics (joint session O/KFM)

Ferroelectricity is a property of materials that allows spontaneous, switchable electric polarization. Recently, many surface-related applications have been proposed where ferroelectric or incipient-ferroelectric materials exhibit superior properties. These include catalysis, electron-hole separation in light harvesting, unique electronic properties such as a negative capacitance in heterostructures of ferroelectric materials, to name just a few. While (incipient) ferroelectrics clearly perform well in the aforementioned applications, there is very limited fundamental understanding of the processes involved on the surfaces of these materials.

Organizers: Martin Setvin (Charles University, Prague), Chiara Gattinoni (London South Bank University), and Michele Reticcioli (University of Vienna)

Time: Wednesday 15:00-18:30

See O 44 for details of this session.

# KFM 18: Focus Session: Diamond and related dielectric materials

This focus session contains basic diamond research due to optical and dielectric properties for applications in low and high power electronics. High frequency and high microwave power applications are discussed. The use of diamond material in GHz up to THz range is the main purpose of this session.

Organizer: Prof. Dr. Theo Scherer (KIT, Karlsruhe)

Time: Wednesday 15:00–16:50

#### Invited Talk

KFM 18.1 Wed 15:00 H5 Deep understanding of advanced optical and dielectric materials for fusion diagnostic applications — •ANATOLI I. POPOV¹, E KOTOMIN¹, V KUZOVKOV¹, A LUSHCHIK², and THEO A SCHERER³ - ¹Institute of Solid State Physics, University of Latvia, 8 Kengaraga str., LV-1063 Riga, Latvia — ²Institute of Physics, University of Tartu, W. Ostwald Str. 1, 50411, Tartu, Estonia — ³Karlsruhe Institute of Technology, Hermann-von-Helmholtz-Platz 1, D-76344 Eggenstein-Leopoldshafen, Germany

In this talk, I will give a short overview of the most interesting results obtained in the framework of two EUROfusion Enabling Research projects - Advanced experimental and theoretical analysis of defect evolution and structural disordering in optical and dielectric materials for fusion applications (AETA) (2019-2020) and Investigation of defects and disorder in nonirradiated and irradiated Doped Diamond and Related Materials for fusion diagnostic applications (DDRM) Theoretical and Experimental analysis (2021-2023).

In a series of joint works by ISSP UL (Latvia), UT (Estonia), and KIT (Germany), radiation damage of some promising functional materials (Al2O3, MgAl2O4, SiO2, and diamond) from the priority list of the EUROfusion consortium was studied under neutron, proton, heavy-ion. Their optical, dielectric, vibrational & magnetic properties were carefully studied. Based on this study, we developed new theoretical methods able to evaluate and predict some important properties of these materials as well as their radiation damage evolution under extreme reactor conditions.

# KFM 18.2 Wed 15:30 H5

Physics of natural and artificial diamond gemstones — •THEO SCHERER — Karlsruhe Institut of Technology (KIT-IAM-AWP)

Diamond gemstones were very well appreciated in the antique world. Independent on the purpose of jewelry, diamond is a crystalline solid state material with excellent physical and chemical properties as a high Young modulus or a very high thermal conductivity. By doping the material with boron, electrical conductivity can be observed. This is important for electronic devices. In this talk the wide range of production of gemstones and technical applications like high frequency high power microwave transmission diamond windows for nuclear fusion power plants will be presented. Different diamond classifications, cuts and colors by impurities will be shown. A comparison of natural diamonds and artificial produces ones are topic of the discussion.

#### KFM 18.3 Wed 15:50 H5

Basic considerations for fracture toughness measurements of MPA CVD diamond to be used in nuclear fusion - • GAETANO AIELLO, THEO SCHERER, ANDREAS MEIER, SABINE SCHRECK, and DIRK STRAUSS - Karlsruhe Institute of Technology, Institute for Applied Materials, D-76344 Eggenstein-Leopoldshafen, Germany

In nuclear fusion, Microwave Plasma Assisted (MPA) Chemical Vapour Deposition (CVD) polycrystalline diamond is the only material allowing for transmission of high power microwave beams (1-2 MW) in long-pulse gyrotron operations. The reason lies in the combination of extraordinary thermal, mechanical and optical properties of diamond, which is used in the shape of disks having thickness of 1 to 2 mm for windows. Being diamond a brittle material, failure to fracture is the main failure mode. Accordingly, an appropriate mechanical characterization is required as diamond plays a major safety role in fusion machines. Due to limited body of work in literature, fracture toughness measurements have to be first carried out for this material and then a design criterion for structural integrity assessment has to be applied. In this work, the preliminary activities aiming to define the optimum experimental measurement method of fracture toughness for thin diamond samples are shown and discussed. An outlook to the next steps is also given.

#### KFM 18.4 Wed 16:10 H5

Development diamond based Kinetic Inductance Detectors  $- \bullet$ FRANCESCO MAZZOCCHI, DIRK STRAUSS, and THEO SCHERER - Karlsruhe Institute Of Technology

Kinetic Inductance Detectors (KIDs) have proven themselves as a very versatile cryogenic detector technology capable of applications in various fields due to their flexibility of design, sensibility and ease of production. We have recently proposed a polarization sensitive Lumped Elements KID as sensor for an innovative polarimetric diagnostics based on quantum cascade lasers (QCL) for application in the nuclear fusion. Each detector unit is composed by 4 pixels arranged at the vertices of a square, each pixels being sensible to only one polarization direction. The current system is based on niobium nitride (NbN) superconductor over High Resistivity Silicon (HRSi) substrate. Such material delivers good performances but its relatively high dielectric constant and loss tangent lead to increased substrate losses. Using a transparent substrate may improve this aspect and also the radiation resistance of such devices. Diamond is the substrate of choice, being a material already widely studied and used in the fusion environment as high power microwave window, due to its outstanding optical and mechanical performances. In this work we present the preliminary design study for a diamond based Kinetic Inductance Detector and subsequent characterization measurements of the first prototypes.

#### KFM 18.5 Wed 16:30 H5 Characterization of - A survey of electrical and dielectric properties - •THEO SCHERER — Karlsruhe Institute of Technology (KIT-IAM-AWP)

p-Boron-doped polycrystalline CVD diamond samples were produced and delivered by the German company Diamond Materials in Freiburg (Germany). In a first step, main properties of this candidates for diagnostic and/or heating windows in future nuclear fusion reactors were investigated. By a special measurement technique, it was possible to determine the Boron doping concentration in Diamond by measurement of the resistive properties by using the van der Pauw method. So prepared, an irradiation campaign with neutrons and/or heavy ions on these samples will follow. The second material investigated, was r-plane single crystalline sapphire. For the first characterization the dielectric properties of a 3*-wafer in dependency of the frequency in a FABRY-PEROT resonator setup was performed. Also, this is the preparation for the next irradiation experiments in this project.

Phase Field Simulations of the Dipolar Interaction in Hexagonal Manganites — •AARON MERLIN MÜLLER, AMADÉ BORTIS, MANFRED FIEBIG, and THOMAS LOTTERMOSER — Department of Materials, ETH Zurich, 8093 Zurich, Switzerland

We introduce a phase-field method that allows simulation of dipolar interaction in thin-film hexagonal manganites and investigate its effect on the unconventional ferroelectric vortex domain pattern of the material. Dipolar interactions are assumed to have negligible influence because of the improper nature of the ferroelectric order. Hence, dipolar interactions are commonly neglected when modeling such systems. Efficiently incorporating dipolar interactions of out-ofplane-oriented dipoles in phase-field methods is challenging as they represent a nonlocal Coulomb contribution to the free energy. In addition, the Coulomb interaction of a polarization field diverges at zero distance, unlike for atomistic dipole models. In our work, we show that including the dipolar interaction in the phase-field method results in more regular shaped domains in comparison to simulations that ignore the dipolar interaction, with lower variance in domain size. The ferroelectric domains of our revised approach resemble the experimentally observed patterns more closely. Hence, our work gives insights on the often neglected effects of dipolar interaction and the resulting depolarizing field on ferroelectric domains in an important class of improper ferroelectric materials.

#### KFM 19.2 Wed 15:20 H7

**Dynamics of the electrocaloric effect in ferroelectric materials** — •JAN FIS-CHER, DANIEL HÄGELE, and JÖRG RUDOLPH — Ruhr-Universität Bochum, Faculty of Physics and Astronomy, Experimental Physics VI (AG), Germany The electrocaloric effect (ECE) in ferroelectrics is a promising candidate for energy efficient cooling technologies. The ECE leads to a reversible adiabatic temperature change  $\Delta T$  of a ferroelectric material upon a change of an external electric field. The reliable determination of the adiabatic  $\Delta T$  is, however, experi-

mentally challenging and most studies use either indirect methods which are prone to artifacts, or comparably slow direct methods. The dynamics of the ECE

has therefore not been systematically studied so far. Here, we introduce a direct

and contactless method to study the full dynamics  $\Delta T(t)$  of the ECE with  $\mu K$  temperature resolution and  $\mu s$  temporal resolution via the infrared emission of the sample. The simultaneous recording of transients for  $\Delta T(t)$ , applied electric field E(t), and induced polarization P(t) gives the opportunity to correlate the caloric properties with the dielectric properties thus opening perspectives for a fundamental understanding of the ECE also in complex materials like relaxor ferroelectrics. Our techniques allows also for high-frequency measurements as needed for adiabatic measurements in thin films.^{1,2} We will discuss several examples ranging from bulk materials to thin films.

KFM 19.3 Wed 15:40 H7

Interfacial Stabilization of Homochiral Ferroelectric Domain Walls in BiFeO₃ – •ELZBIETA GRADAUSKAITE¹, QUINTIN N. MEIER², NATASCHA GRAY¹, MARCO CAMPANINI³, MARTA D. ROSSELL³, MANFRED FIEBIG¹, and MORGAN TRASSIN¹ – ¹Department of Materials, ETH Zurich, Switzerland – ²CEA Grenoble, LITEN, Grenoble, France – ³Electron Microscopy Center, Empa, Switzerland

Chirality is a concept central to all molecular interactions in biological systems. In the last decade its importance was also highlighted in condensed-matter physics, where spin textures at the homochiral ferromagnetic domain walls were shown to enable their deterministic current-driven motion. Nevertheless, only a few reports on polar chirality exist to this date, prompting increased research efforts on this important issue. Here, we report the stabilization of net chirality in BiFeO₃ ferroelectric films grown on a fully in-plane-polarized ferroelectric layer of the Aurivillius phase. By introducing an in-plane-polarized epitaxial buffer we create polarization continuity and provide a symmetry breaking at the interface with the out-of-plane polarized BiFeO₃. Scanning probe microscopy uncovers the stabilization of conceptually novel 251° domain walls in BiFeO₃. Their unusual chirality is likely associated with the ferroelectric analog to the Dzyaloshinskii-Moriya interaction in magnets. Thus, we demonstrate a simple design combining perpendicular polar anisotropies for the effective stabilization of homochiral textures in ferroelectric thin films.

Ferroelectric properties of  $(Na_{0.5}Bi_{0.5})TiO_3$ -BaTiO_3 perovskite ceramics modified by LiF additives — •SOBHAN M. FATHABAD¹, VLADIMIR V. SHVARTSMAN¹, EKATERINA D. POLITOVA², GALINA M. KALEVA², and DORU C. LUPASCU1¹ — ¹Institute for Materials Science and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg Essen, Essen, Germany — ²Moscow

The system of  $(\rm Na_{0.5}\rm Bi_{0.5})\rm TiO_3$ -BaTiO_3 solid solutions has attracted considerable interest due to its promising electromechanical, electrocaloric, and energy storage properties. In this work, the effect of LiF additive on the ferroelectric properties of  $0.8(\rm Na_{0.5}\rm Bi_{0.5})\rm TiO_3$ -0.2BaTiO_3 ceramics is investigated. The samples were prepared by the conventional solid state synthesis technology. The LiF content varied from 0 to 15 mol

#### KFM 25.2 Thu 15:00 P2

Strain and defect location in the cross-section of laterally aligned SnO2 NWs — •JASMIN-CLARA BÜRGER, SEBASTIAN GUTSCH, and MARGIT ZACHARIAS — Laboratory for Nanotechnology, Department of Microsystems Engineering - IMTEK, University of Freiburg, Georges-Köhler-Allee 103, 79110 Freiburg, Germany

The 1D structure and the high surface-to-volume ratio of SnO2 nanowire-based devices allow for high sensitivities in gas- and biosensing. By their self-alignment towards the substrate edge and by the self-alignment of the SnO2 nanowire crystal lattice towards the atomic arrangement on the substrate surface[1], laterally aligned SnO2 NWs are superior to freestanding NWs as a basic structure for a single-NW-based sensor. However, up to now, only little is known about their crystal quality compared to the excellent material quality of freestanding NWs. Hence, here, laterally aligned SnO2 NWs on r-plane sapphire substrates were grown by the vapor-liquid-solid mechanism and morphologically analyzed by scanning electron microscopy. By focused-ion beam preparation, cross-sectional TEM lamellas of the laterally aligned SnO2 NWs on r-plane sapphire were prepared. For analysis of the NW defect density, post-processed strain maps were computed of atomically resolved TEM images. The theoretical background for the experimentally observed location of the lowest strain density close to the substrate-NW interface and the highest defect density close to the NW surface will be discussed.

#### KFM 25.3 Thu 15:00 P2

Influence of sulfur doping on the creation yield of near-surface nitrogen vacancy centers and their charge state ratio — •SVEN GRAUS¹, ULRICH KÖHLER¹, TOBIAS LÜHMANN², and JAN MEIJER² — ¹Lehrstuhl für Experimentalphysik IV, Ruhr-Universität Bochum — ²Felix-Bloch-Institut für Festkörperphysik, Angewandte Quantensysteme, Universität Leipzig

The negative charge state of nitrogen vacancy (NV) centers presents an extremely attractive candidate for a number of applications in quantum information technology and magnetometry. However, the implantation of near-surface NV centers shows a low yield and they have the tendency to convert into the neutral charge state. Recently, a significant increase in the creation yield of negative NV centers in the bulk of the diamond has been achieved by prior local doping of sulfur. We report on the in-situ implantation of sulfur and subsequent nitrogen implantation at energies of up to 5 keV while the sample is heated to temperatures of up to ~800  $^{\circ}$ C under UHV conditions. Our setup presents a unique method for the implantation of near surface NV centers in small laboratories. First results on how these parameters influence the creation yield of negative NV centers close to the surface are presented.

#### KFM 25.4 Thu 15:00 P2

Improved thermoelectric properties of SnSe through forming a phase employing metavalent bonding — •NAN LIN, YUAN YU, OANA COJOCARU-MIREDIN, and MATTHIAS WUTTIG — I.Physikalisches Institut IA, RWTH Aachen, Sommerfeldstraße 14, 52074 Aachen, Germany

SnSe only shows high ZT values above 750 K when the structure transforms from the asymmetrical Pnma phase to the higher symmetrical Cmcm phase. As a typical IV-VI compound bonded by p-state electrons, the Cmcm phase SnSe with an improved symmetry is expected to show the same chemical bonding with other rock-salt IV-VI compounds, which could be responsible for its excellent thermoelectric performance. Yet, it is challenging to stabilize the Cmcm phase at room temperature to characterize the bonding indicators. We successfully obtained the high-symmetry rock-salt SnSe phase by growing (SnSe)0.67(AgSbTe2)0.33, (SnSe)0.67(AgBiSe2)0.33, and (SnSe)0.67(AgSbSe2)0.5 alloys in a Bridgman oven. All cubic SnSe alloys show a unique portfolio of properties including a high optical dielectric constant, a large Born effective charge, and abnormal bond-breaking behavior in laser-assisted atom probe tomography. All these characteristics are indicative of

Location: P2

the metavalent bonding mechanism while are not found in the pristine SnSe. Concomitantly, zT increases from near 0.1 for the Pnma SnSe to about 1.0 for all the Fm-3m SnSe phases. Our work demonstrates that metavalent bonding could be the origin of many special properties of SnSe including the excellent thermoelectric performance.

#### KFM 25.5 Thu 15:00 P2

Real space texture analysis using the 3D pair distribution function on a Pt thin film — •SANI Y. HAROUNA-MAYER^{1,2}, ZIZHOU GONG³, MARTIN V. ZIMMERMANN⁴, ANN-CHRISTIN DIPPEL⁴, SIMON J.L. BILLINGE², and DOROTA KOZIEJ^{1,2} — ¹Institute for Nanostructure and Solid-State Physics, Center for Hybrid Nanostructures (CHyN), University of Hamburg, Hamburg, Germany — ²The Hamburg Center for Ultrafast Imaging, Hamburg, Germany — ³Department of Applied Physics and Applied Mathematics, Columbia University, New York, USA — ⁴Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany

An approach is described for studying texture in nanostructured materials. It is demonstrated on a fiber textured polycrystalline Pt thin film. The approach uses 3D PDF methods to reconstruct the orientation distribution function (ODF) of the powder crystallites from a set of diffraction patterns taken at different tilt angles of the substrate with respect to the incident beam directly from the 3D PDF of the sample. A real space equivalent of the reciprocal space pole figure is defined in terms of interatomic vectors in the PDF and computed for various interatomic vectors in the Pt film. Further, it is shown how a valid isotropic PDF may be obtained from a weighted average over the tilt series. Finally, we describe an open source Python software package, FouriGUI, that may be used to help in studies of texture from 3D PDF data in general.

#### KFM 25.6 Thu 15:00 P2

An X-ray diffraction studies on AlCrVY(O)N thin films. — •ERIC SCHNEIDER¹, MICHAEL PAULUS¹, NELSON FILIPE LOPES DIAS¹, DAVID KOKALJ², DOMINIC STANGIER², and WOLFGANG TILLMANN² — ¹Fakultät Physik/DELTA TU Dortmund University, 44221 Dortmund, Germany — ²Institute of Materials Engineering, Dortmund, Germany

The aim of this project is to gain a fundamental understanding of the dependence between deposition parameters, layer structure and oxidation behavior of AlCrVY(O)N coatings. For this purpose, the coating systems were deposited on a WC-Co composite substrate by DC sputtering and high-energy pulse magnetron sputtering (HiPIMS). In addition to this, individual process parameters such as BIAS voltage and substrate temperature are varied to determine their influence on the thin films structure. For the investigation of the samples we used synchrotron radiation at beamline BL9 of the synchrotron radiation source DELTA (Dortmund, Germany) to perform XRD measurements. The samples were heated in an heating cell to temperatures up to 1000°C to study their oxidation behavior. Depending on the process parameters, different oxidation behaviour and residual stresses present in the samples were observed. We thank DELTA for providing synchrotron radiation. This work was supported by the DFG via TO 169/21-1.

Hydrostatic high-pressure cells for X-ray scattering applications — •KEVIN LEHNINGER¹, CHRISTIAN STERNEMANN¹, MICHAEL PAULUS¹, BRID-GET MURPHY¹, METIN TOLAN¹, and LUTZ FELDMANN² — ¹Fakultät Physik/DELTA TU Dortmund, 44221 Dortmund, Deutschland — ²Fakultät Physik/Konstruktionsbüro TU Dortmund, 44221 Dortmund, Deutschland

Small angle and wide angle X-ray scattering (SAXS/WAXS) at moderate pressures are of increasing relevance for the study of e.g. protein denaturation and stimuli responsive materials, respectively. One of the experimental challenges here is the precise pressure control in the pressure range up to 10 kbar while separating the sample volume from the pressure transmitting medium. For this purpose, we present two dedicated hydrostatic high pressure cells designed for use at beamlines BL2 and BL9 of the DELTA synchrotron radiation source that use water for pressure transmission. The WAXS cell with an opening angle of 60 degrees allows a sample volume with a cross-sectional area of one square millimeter that can be exposed to a maximum pressure of 5000 bar. The sample volume is enclosed in a flexible capillary tube which is placed between two diamond windows and can have a maximum diameter of 1.5 mm. The SAXS cell can be operated up to a pressure of 10000 bar providing an opening angle 20 degrees. Here the sample volume is contained in a cylinder sealed by polyimide film which is screwed into the high pressure cell by a slide system.

Entwicklung von Herstellungsverfahren für koordinatenbasierte 3D Mikro-Standarts — •CELINA HELLMICH¹, SEBASTIAN BÜTEFISCH¹, THOMAS WEIMANN¹, STEFANIE KROKER^{1,2} und MATTHIAS HEMMLEB³ — ¹Physikalisch-Technische Bundesanstalt Braunschweig, Bundesallee 100, 38116 Braunschweig, Deutschland — ²Technische Universität Braunschweig, Institut für Halbleitertechnik, LENA Laboratory for Emerging Nanometrology, Hans-Sommer-Str. 66, 38106 Braunschweig, Deutschland — ³point electronic GmbH Erich-Neuß-Weg 15 D-06120 Halle (Saale) Deutschland

3D-Normale vereinen die Eigenschaften der üblichen Normale und die Kalibrierfaktoren für alle Achsen und die Kopplungsfaktoren zwischen ihnen können in einem Mess- und Auswertungsschritt ermittelt werden können. Mit diesem alternativen Kalibrieransatz können geometrische Verlagerungen über 3D-Referenzstrukturen mit bekannten Objektkoordinaten bestimmt werden. Die derzeit verwendeten 3D-Normale werden mit FIB hergestellt. Jedes Normal ist daher eine kostenintensive Sonderanfertigung, die zudem eine zeitaufwändige Kalibrierung erfordert. Daher sollen waferbasierte Maskenprozesse zur Herstellung von 3D-Standarts entwickelt werden, mit denen viele Strukturen reproduzierbar hergestellt und an das jeweilige zu kalibrierende Gerät angepasst werden können. Erste Ergebnisse wurden durch den schrittweisen Aufbau von Siliziumoxidschichten in Kombination mit einem Trockenätzverfahren erzielt. Auf diese Weise können zweistufige Pyramidenstrukturen hergestellt werden, auf die der Marker für die Kalibrierung mit Hilfe von Lift-off aufgebracht werden kann.

#### KFM 25.9 Thu 15:00 P2

**The Relation between Electrocaloric Effect and Non-Collinear Electric Fields:** A Coarse-Grained Case Study of BaTiO₃ — •LAN-TIEN HSU^{1,2}, FRANK WENDLER¹, and ANNA GRÜNEBOHM² — ¹Institute of Materials Simulation (WW8), Friedrich-Alexander University of Erlangen-Nürnberg, Dr.-Mack-Str. 77, 90762 Fürth, Germany — ²Interdisciplinary Centre for Advanced Materials Simulation (ICAMS) and Center for Interface-Dominated High Performance Materials (ZGH), Ruhr-University Bochum, Universitätsstr 150, 44801 Bochum, Germany

Ferroelectric perovskites are promising candidates for future electrocaloric cooling devices due to their adiabatic temperature changes in varying external electric fields. [1,2] Recently, the origin of the inverse electrocaloric effect (ECE) has been discussed. [2,3,4] In this work, we do coarse-grained molecular dynamic simulation using feram [5] to explore the phase stability and caloric responses of BaTiO₃ over a wide temperature range including fields in low-symmetry directions. We observe large inverse ECEs close to high-symmetry directions where the applied fields stabilize phases outside the zero-field coexistence temperature range. We believe this finding can provide general insights into the anisotropic nature of the ECE of ferroelectric perovskites.

#### KFM 25.10 Thu 15:00 P2

Dielectric loss measurements of CVD diamond disks for ITER windows — •SABINE SCHRECK¹, GAETANO AIELLO¹, PABLO ESTEBANEZ², ANDREAS MEIER¹, DIRK STRAUSS¹, and THEO SCHERER¹ — ¹Karlsruhe Institute of Technology, Institute for Applied Materials, Hermann-von-Helmholtz-Platz 1, 76344 Eggenstein-Leopoldshafen, Germany — ²F4E, Josep Pla 2, Torres Diagonal Litoral B3, 08019 Barcelona, Spain

Diamond disks manufactured by chemical vapor deposition (CVD) are essential elements of windows of the Electron Cyclotron Heating and Current Drive systems of fusion reactors like ITER. Diamond is selected as window material because of its high mechanical stability, high thermal conductivity and low dielectric loss. Only diamond disks with a low loss tangent guarantee a high transmission, i.e. a low absorption of microwave power in the disk. The latter results in moderate window temperatures and therefore in low thermal stresses. Hence, the measurement of the loss tangent is essential for the qualification of diamond disks for high-power windows. Dedicated measurement facilities (Fabry-Perot resonators) at KIT allow a high resolution measurement of the loss tangent at the disk centre (spherical set-up) as well as a mapping over the disk area to estimate its homogeneity (hemispherical set-up). Within a contract between F4E and KIT more than 60 diamond disks (D=70mm, t=1.11mm) produced similarly by MPA-CVD need to be qualified for their application in the ITER EC-system. The development of a dedicated test plan as well as initial results for the first disks delivered to KIT will be presented.

X-ray emission spectroscopy at DELTA — •NICOLA THIERING, CHRISTIAN AL-BERS, ROBIN SAKROWSKI, MICHAEL PAULUS, METIN TOLAN, and CHRISTIAN STERNEMANN — Fakultät Physik/DELTA, Technische Universität Dortmund, D-44221 Dortmund, Germany

The analysis of the electronic and structural properties of transition metals is of enormous importance for a variety of research fields and applications. At beam-

line BL2 of the DELTA synchrotron radiation source (Dortmund, Germany) we used a hardened white beam of a bending magnet for efficient excitation to conduct X-ray emission spectroscopy experiments. The emission spectra were measured using a von Hámos spectrometer equipped with four cylindrically bent analyzer crystals in combination with a Pilatus 100K area detector. In order to demonstrate the capabilities of this setup, we present K $\alpha$ , K $\beta$ , and valence-to-core spectra of selected transition-metal bearing compounds.

#### KFM 25.12 Thu 15:00 P2

Phase retrieval for X-ray in-line holographic imaging: beyond the homogeneous object assumption — •JENS LUCHT¹, SIMON HUHN¹, LEON MERTEN LOHSE^{1,2}, and TIM SALDITT¹ — ¹Institut für Röntgenphysik, Universität Göttingen — ²Deutsches Elektronen-Synchrotron DESY

X-ray lensless near-field holographic imaging offers high resolution 3d imaging with spatial resolution down to the nanometer scale with wide applicability in biomedical imaging and material sciences. To access quantitative images, phase retrieval has to be performed on the recorded Fresnel diffraction patterns. This constitutes an ill-posed inverse problem where several reconstruction methods have been developed. For high resolution synchrotron experiments, computationally efficient algorithms are needed. Widely employed is the computationally efficient contrast transfer function (CTF) method proposed by P. Cloetens two decades ago [P. Cloetens et al., Appl. Phys. Lett. 75, 2912 (1999)], besides more demanding nonlinear Fresnel propagation based methods. The CTF relies upon linearization of the Fresnel propagation. Notwithstanding its tremendous success, CTF-based methods often assume a homogeneous or low absorbing object as prior. We propose a CTF-based scheme that could relax these restriction to applicability while keeping reconstruction stability and computational requirements comparable. First experiments indicate very promising results.

#### KFM 25.13 Thu 15:00 P2

X-ray emission setup to study electronic structure of iron bearing compounds in situ at high pressure and high temperature — •NICOLA THIERING¹, CHRISTIAN ALBERS¹, ROBIN SAKROWSKI¹, MAX WILKE², JOHANNES KAA^{1,4}, HLYNUR GRETARSSON^{3,5}, MARTIN SUNDERMANN^{3,5}, METIN TOLAN^{1,6}, and CHRISTIAN STERNEMANN¹ — ¹Fakultät Physik/DELTA, Technische Universität Dortmund, Dortmund, Germany — ²Institut für Geowissenschaften, Universität Potsdam, Potsdam, Germany — ³Deutsches-Elektronen-Synchrotron DESY, Hamburg, Germany — ⁴European XFEL, Schenefeld, Germany — ⁵Max Planck Institute for Chemical Physics of Solids, Dresden, Germany — ⁶Universität Göttingen, Göttingen, Germany

The determination of iron-bearing compounds' electronic structure under high pressure and temperature (HPHT) conditions is pivotal to understand the chemistry, physics and dynamics of the Earth's interior [1]. We present a setup for investigating the electronic structure of such compounds *in situ* at HPHT up to 80 GPa and 3000 K, achieved by using diamond anvils cells in combination with a double-sided laser heating setup [2,3] using (resonant) X-ray emission spectroscopy ((R)XES) and show results for  $\alpha$ -Fe₂O₃ and FeCO₃. (R)XES spectra were acquired utilizing a wavelength-dispersive von Hámos spectrometer in combination with a Pilatus 100K area detector [4] at PETRA III. [1] B. Orcutt et al. Deep Carbon (2019) [2] C. # X-ray off-axis holography using iterative phase retrieval and waveguide beam splitters — •PAUL MEYER and TIM SALDITT — Institute for X-ray Physics, Georg August University of Göttingen, Germany

Propagation based phase contrast imaging (PB-PCI) with hard X-rays has become a powerful technique to study weakly absorbing specimen. Iterative algorithms can for example make single cells in a hydrated environment visible by retrieving the phase shift induced by the sample [1].

As image contrast in PB-PCI data arises from phase curvature, the reconstruction of low-frequency signals is challenging. In practice, it often requires support constraints on the sample. This problem does not arise with off-axis holography. Here, information of the phase image is extracted through interference with an additional reference beam that can for example be generated by a beamsplitting waveguide [2].

We observed that introducing such a reference beam in simulations for PB-PCI accelerates convergence and improves accuracy of the iterative phase retrieval (RAAR). We aim to transfer the observed advantage to the practical application of off-axis holography at synchrotron imaging facilities.

Hierarchically Porous Carbon Derived from the Activation of Waste Chestnut Shells as High Performance Electrode Materials for Supercapacitor -•PING HONG^{1,2}, YUDE WANG², HUAPING ZHAO¹, and YONG LEI¹ — ¹Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany — ²School of Materials Science and Engineering, Yunnan University, Kunming, People's Republic of China 3D hierarchical porous carbon consisting of micropores, mesopores and macropores was successfully prepared through the activation of chestnut shell with potassium bicarbonate (KHCO3). The influence of KHCO3/chestnut shell ratio on the textural properties was carefully investigated. By optimizing the amount of KHCO3, 3D hierarchical porous carbon with high specific pore surface area (2298 m2 g-1) and high total pore volume (1.51 cm3 g-1) were achieved. When applying the as-prepared 3D hierarchical porous carbon as electrode materials for supercapacitors, a high specific electric capacity of 387 F g-1 was reached at a current density of 2 A g-1. The remarkable electrochemical performances are mainly attributed to the hierarchical porous structure with the high specific surface area and the eminent total pore volume. It suggests that this hierarchical porous carbon prepared by activated by using KHCO3 would have more promising foreground in the field of energy storage.

#### KFM 25.16 Thu 15:00 P2

Ni-SnO2 nanopore arrays as potassium-ion battery anodes – •Mo  $_{\rm SHA,}$ HUAPING ZHAO, and YONG LEI — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Sodium-ion batteries (SIBs) represent an effective energy storage technology with potentially lower material costs than lithium-ion batteries. Here, we show the electrochemical performance of SIBs with electrode design at the nanoscale. Highly ordered three-dimensional (3D) selfsupported Ni-TiO2 nanopore arrays (NiNPA@TiO2) with highly oriented nanoporous structures are fabricated using nanoimprited AAO templating technique and applied as nanostructured anodes for SIBs applications. Their large specific surface area can ensure a high capacity, and their highly oriented and stable nanoporous structure can facilitate ion transport. The NiNPA@TiO2 nanoarrays delivered a reversible capacity of 240 mAh g-1 after 100 cycles at the current density of 50 mAh g-1 and were able to retain a capacity of 105 mAh g-1 at the current density as high as 5 A g-1. Their large active sites, high ion accessibility, fast electron transport, and excellent electrode integrity were shown as great merits to obtain the presented electrochemical performance. Not limited to the SIBs electrodes, the highly ordered 3D heterostructured nanoarrays as a promising electrode design for other electrochemical energy conversion and storage devices.

#### KFM 25.17 Thu 15:00 P2

Enhanced efficiency of graphene-silicon Schottky junction solar cell through inverted pyramid arrays texturation — •JIAJIA QIU^{1,2}, HUAPING ZHAO¹, WEN-HUI MA², and YONG  $LEI^1 - {}^1$ Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany — ²State Key Laboratory of Complex Nonferrous Metal Resources Clean Utilization, Kunming University of Science and Technology, Kunming 650093, China

Nanostructures of silicon are gradually becoming hot candidate due to outstanding capability for trapping light and improving conversion efficiency of solar cell. In this work, silicon nanowires (SiNWs) and silicon inverted pyramid arrays (Si-IPs) were introduced on surface of graphene-silicon (Gr-Si) solar cell through silver and copper-catalyzed chemical etching, respectively. The effects of SiNWs and SiIPs on carrier lifetime, optical properties and efficiency of Gr-SiNWs and Gr-SiIPs solar cells were systematically analyzed. The results show that the inverted pyramid arrays have more excellent ability for balancing antireflectance loss and surface area enlargement. The power conversion efficiency (PCE) and carrier lifetime of Gr-SiIPs devices respectively increase by 62% and 34% by comparing with that of Gr-SiNWs solar cells. Finally, the Gr-SiIPs cell with PCE of 5.63% was successfully achieved through nitric acid doping. This work proposes a new strategy to introduce the inverted pyramid arrays for improving the performance of Gr-Si solar cells.

#### KFM 25.18 Thu 15:00 P2

Structural behavior of delithiated Li_xNi_{0.8}Co_{0.15}Al_{0.05}O₂ (0<x<1) battery **cathodes** — •TOBIAS HÖLDERLE^{1,2}, PETER MÜLLER-BUSCHBAUM^{1,2}, and ANA-TOLIY SENYSHYN² — ¹Lehrstuhl für funktionelle Materialien, Technische Universität München, Garching, Germany — ²Heinz Maier-Leibnitz Zentrum (MLZ), Technische Universität München, Garching, Germany

The development of portable electronic devices up to electric vehicles powered with lithium-ion batteries led to an increased demand for lithium-ion batteries with higher capacities, energy/power densities, and cycling life. One of the most encouraging and state of the art commercial cathode materials are mixed lithium Ni, Co, Al metal oxides, e.g. in the form of high nickel content LiNi_{0.8}Co_{0.15}Al_{0.05}O₂ (NCA) cathodes possessing high energy and power densities at lower costs. Besides advantages, NCA materials possess several essential drawbacks. For example, NCA cathode materials are known to suffer from poor

thermal stability, pronounced capacity as well as power density fading, and antisite disorder in NCA materials [1]. In the current contribution, a systematic exsitu neutron powder diffraction study on differently electrochemically delithiated NCA cathode materials is presented. A set of structural parameters was obtained using full-profile Rietveld refinement. The lithium occupations reflect the increasing state-of-charge whilst the occupations of transition metals do not change, indicating the absence of antisite defects (cation mixing) in the NCA material. [1] C. Xu, P. J. Reeves, Q. Jacquet and C. P. Grey, Adv. Energy Mater., 11, 2003404 (2021).

#### KFM 25.19 Thu 15:00 P2

Dense binary Fe-Cu sites promoting CO2 utilization to enable highlyreversible hybrid Na-CO2 battery - •CHANGFAN Xu - Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany - School of Metallurgy and Environment, Central South University, Changsha 410083, China — Faculty of Metallurgical and Energy Engineering, Kunming University of Science and Technology, Kunming 650093, China

A well-defined morphology of nitrogen-rich graphitic carbon framework with dense bimetallic active sites (Fe-Cu-N-C) was facilely prepared by introducing Fe3+ and Cu2+ to regulate in-situ grown carbon nanotubes as an advanced catalyst toward hybrid Na-CO2 batteries. Through metal content-tuning and carbon architecture-altering, the Fe-Cu-N-C was proved to be dramatically more effective than Cu-N-C and Fe-N-C. As the cathodic catalyst of a hybrid Na-CO2 battery, Fe-Cu-N-C can facilitate the fast evolution and degradation of flocculent discharge products and achieve an excellent long-term cyclability up to 1550 cycles (over 600 h). The outstanding performance is attributed to the cross-linked conductive framework affording a highway for accelerating electron transport and Na+/CO2 diffusion. Besides, the synergistic effects among defect-rich interfaces, Fe/Fe3C nanocrystals, Fe-Nx, and Cu-Nx sites derived from nitrogen doping enhance the catalytic activity. The possible growth and decomposition mechanisms of NaHCO3 products were also presented and discussed.

#### KFM 25.20 Thu 15:00 P2

Dynamics of lithium-distribution in 18650-type LFP|C lithium-ion batteries during electrochemical cycling — •DOMINIK PETZ^{1,2}, PETER MÜLLER-BUSCHBAUM^{1,2}, and ANATOLIY SENYSHYN¹ – ¹Heinz Maier-Leibnitz Zentrum (MLZ), Garching, Germany – ²Lehrstuhl für Funktionelle Materialien, Technische Universität München, Garching, Germany

The electrochemical cycling of lithium-ion batteries is characterized by an active transport of lithium ions and electrons, which are exchanged between the cathode and anode materials. Ionic exchange influences structural and chemical properties of electrode materials, which, in turn, affects electrode dimensions and geometry, current density, temperature, pressure, reaction rate, etc. Such parameters are in general neither uniformly nor statically distributed and therefore serve as stabilizing factor for heterogeneous states in lithium-ion batteries, which are typically reflected in the lithium concentration distribution in the electrodes. In most of the studies reported in literature, the lithium distribution has typically been examined in static equilibrium (e.g. in fully charged state), neglecting the evolution of the distribution under real charging conditions like the influence of C-rates, etc.

In this work the evolution of the lithium-ion distribution in the graphite anode was investigated in-operando by spatially-resolved neutron powder diffraction. Neutron data were supplemented by diffraction studies with high-energy photons. The occurrence of lithium inhomogeneities on different length scales was observed and will be presented in the current contribution.

 $\label{eq:KFM25.21} KFM 25.21 \ \ Thu \ 15:00 \ \ P2 \\ \textbf{Strong electron-phonon coupling in $EuPd_2Si_2 - \bullet$Mai Ye$^1, Mark Joachim}$ GRAF VON WESTARP¹, SOFIA-MICHAELA SOULIOU¹, MARIUS PETERS², ROBERT MÖLLER², KRISTIN KLIEMT², CORNELIUS KRELLNER², and MATTHIEU LE TACON¹ — ¹Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, 76021 Karlsruhe, Germany -²Institute of Physics, Goethe-University Frankfurt, 60438 Frankfurt am Main, Germany

Mixed-valence metal EuPd₂Si₂ exhibits a valence transition from Eu²⁺ to Eu³⁺ with the crossover temperature T_v around 140 K [Jpn. J. Appl. Phys. 50 (2011) 05FD03]. On cooling, the tetragonal crystal symmetry is unchanged, with the a-axis length decreasing and the c-axis length essentially unchanging [arXiv:2203.05136]. We study the phonon modes of this material by Raman spectroscopy to explore the effect of valence transition and electron-phonon coupling. The Raman-active A1g phonon mode shows Fano-type asymmetric lineshape, indicating interaction between the phonon mode and underlying continuum of electronic excitations. This mode also exhibits large frequency hardening on cooling: the frequency at 25 K is around 30% larger than that at 300 K. Such a large frequency change cannot be solely explained by the change of lattice parameters, which is only 2%, and points to the role played by electronphonon interaction. Moreover, the frequency and linewidth of other Ramanactive phonon modes show anomalies at  $T_v$ . We also present Raman spectra of  $EuPd_2(Si_{0.94}Ge_{0.06})_2$  for comparison.

## Sessions

MA 1.1-1.1	Sun	16:00-17:30	H1	Tutorial: Careers in Science (joint session MA/TUT)
MA 2.1–2.4	Mon	9:30-10:30	H37	Magnetic Imaging Techniques
MA 3.1-3.3	Mon	9:30-10:15	H43	Spin-Dependent Phenomena in 2D
MA 4.1-4.4	Mon	9:30-10:30	H47	Disordered Magnetic Materials
MA 5.1-5.4	Mon	9:30-10:30	H48	Magnetic Instrumentation and Characterization
MA 6.1-6.4	Mon	11:00-12:00	H37	Complex Magnetic Oxides
MA 7.1–7.4	Mon	11:00-12:00	H43	Magnetic Relaxation and Gilbert Damping
MA 8.1-8.12	Mon	15:00-18:00	H37	Ultrafast Magnetization Effects 1
MA 9.1-9.4	Mon	15:00-17:00	H43	INNOMAG e.V. Prizes 2022 (Diplom-/Master and Ph.D. Thesis)
MA 10.1-10.6	Mon	15:00-16:45	H47	Non-Skyrmionic Magnetic Textures
MA 11.1–11.8	Mon	15:00-17:00	H48	Computational Magnetism 1
MA 12.1-12.12	Tue	9:30-12:45	H37	Skyrmions 1 (joint session MA/KFM)
MA 13.1-13.12	Tue	9:30-12:30	H43	Magnonics 1
MA 14.1-14.9	Tue	9:30-12:00	H47	Cooperative Phenomena: Spin Structures and Magnetic Phase Transitions
MA 15.1-15.8	Tue	9:30-11:30	H48	Computational Magnetism 2
MA 16.1-16.11	Tue	15:00-17:45	H37	Frustrated Magnets
MA 17.1–17.4	Tue	15:00-17:00	H43	PhD Focus Session: The Hitchhiker's Guide to Spin Phenomena at the Space and
				Time Limit
MA 18.1-18.9	Tue	15:00-17:15	H47	Spintronics
MA 19.1-19.64	Tue	17:30-20:00	P2	Poster 1
MA 20.1-20.7	Wed	9:30-13:00	H37	Focus Session: Revealing Multidimensional Spin Textures and their Dynamics via
				X-rays and Electrons
MA 21.1-21.11	Wed	9:30-12:15	H43	Terahertz Spintronics

MA 22.1–22.9	Wed	9:30-11:45	H47	Thin Films: Magnetic Coupling Phenomena / Exchange Bias / Magnetic Anisotropy
MA 23.1-23.5	Wed	9:30-10:45	H48	Magnetic Domain Walls
MA 24.1-24.12	Wed	15:00-18:00	H37	Spin Transport and Orbitronics, Spin-Hall Effects
MA 25.1-25.8	Wed	15:00-17:00	H43	Ultrafast Magnetization Effects 2
MA 26.1-26.4	Wed	15:00-16:00	H48	Molecular Magnetism
MA 27.1-27.13	Thu	9:30-12:45	H37	Skyrmions 2 (joint session MA/KFM)
MA 28.1-28.13	Thu	9:30-12:45	H43	Magnonics 2
MA 29.1-29.9	Thu	9:30-11:45	H47	Caloric Effects in Magnetic Materials
MA 30.1-30.8	Thu	9:30-11:30	H48	Surface Magnetism
MA 31.1-31.10	Thu	15:00-17:45	H37	Topological Insulators (joint session MA/KFM)
MA 32.1-32.8	Thu	15:00-17:00	H43	Bulk Materials: Soft and Hard Permanent Magnets
MA 33.1-33.7	Thu	15:00-16:45	H47	Multiferroics and Magnetoelectric Coupling (joint session MA/KFM)
MA 34.1-34.7	Thu	15:00-16:45	H48	Functional Antiferromagnetism
MA 35.1-35.76	Thu	16:00-18:00	P4	Poster 2
MA 36	Thu	18:00-19:00	H37	Members' Assembly
MA 37.1-37.13	Fri	9:30-12:45	H37	Skyrmions 3 (joint session MA/KFM)
MA 38.1-38.7	Fri	9:30-11:15	H43	Electron Theory of Magnetism and Correlations
MA 39.1-39.6	Fri	9:30-11:00	H47	Magnetic Particles / Clusters
MA 40.1-40.5	Fri	9:30-10:45	H48	Weyl Semimetals
MA 41.1-41.5	Fri	11:30-12:45	H47	Micro- and Nanostructured Magnetic Materials
MA 42.1-42.5	Fri	11:30-12:45	H48	Magnetic Heuslers

# Members' Assembly of the Magnetism Division

Thursday 18:00-19:00 H37

## Sessions

- Invited Talks, Tutorials, Contributed Talks, and Posters -

## MA 1: Tutorial: Careers in Science (joint session MA/TUT)

Time: Sunday 16:00-17:30

#### Tutorial

MA 1.1 Sun 16:00 H1

#### **Careers in science: "To boldly go where no one has gone before"** — •MANFRED FIEBIG — Department of Materials, ETH Zurich

What does it take to do a career in science and become a university professor? An obvious answer is: you have to do outstanding research. But just doing great science plays a surprisingly small part — and what defines scientific work as outstanding anyway? Then, you also need to communicate your findings well. The best result is worth little if you present it in an awful talk or manuscript. You also need to be "good with people", may these be your students or your colleagues. Even luck can play an important role in a successful scientific career, but is very important to distinguish luck from "luck". I will refer to all these points and analyze what "being lucky" has actually to do with luck. I will present a list of points that I consider essential for a prosperous start into a scientific career. Some of these points are surprisingly unnoticed, so following them may put you ahead of the crowd.

Questions and discussion

## MA 2: Magnetic Imaging Techniques

Time: Monday 9:30-10:30

#### MA 2.1 Mon 9:30 H37

High resolution magnetic imaging with holography-aided phase retrieval – •RICCARDO BATTISTELLI¹, SERGEY ZAYKO², MICHAEL SCHNEIDER³, CHRISTIAN M. GÜNTHER⁴, KATHINKA GERLINGER³, DANIEL METTERNICH¹, LISA-MARIE KERN³, KAI LITZIUS⁵, STEFAN EISEBITT^{3,4}, BASTIAN PFAU³, and FELIX BÜTTNER¹ – ¹Helmholtz-Zentrum Berlin, Berlin, Germany – ²University of Göttingen, Göttingen, Germany – ³Max Born Institute, Berlin, Germany – ⁴Technische Universität Berlin, Berlin, Germany – ⁵Max-Planck-Institut für Intelligente Systeme, Stuttgart, Germany

In the fields of magnetism and spintronics, magnetic multilayers continue to thrive as pivotal structures to functionalize magnetic interactions and to engineer complex non-trivial spin textures. Despite the intense research on this topic, relatively little is known about 3D magnetic textures in multilayers and their interaction with local defects, despite the expected richer physics and potential in information technologies. The experimental challenges of studying such systems can be met by merging Fourier Transform Holography with phase retrieval algorithms for coherent diffractive imaging, obtaining high throughput, high resolution and high contrast images of magnetic materials. Here we present 5 nm resolution X-ray images of magnetic multilayers in which the presence of 3D magnetic defects can be inferred thanks to the high sensitivity of the technique. The interaction of magnetic domains with these defects favors the presence of domain walls, reducing the average domain size with respect to the pristine material.

#### MA 2.2 Mon 9:45 H37

Using electron microscopic methods to evaluate the magnetic proximity effect — •DANIELA RAMERMANN^{1,3}, INGA ENNEN¹, DOMINIK GRAULICH¹, TREVOR ALMEIDA², STEPHEN MCVITIE², BJÖRN BÜKER¹, TIMO KUSCHEL¹, and ANDREAS HÜTTEN¹ — ¹Universität Bielefeld, Dünne Schichten und Physik der Nanostrukturen, Universitätsstr. 25, 33615 Bielefeld, Germany — ²University of Glasgow, School of Physics and Astronomy, Glasgow G12 8QQ, UK — ³Max Planck Institute for Chemical Energy Conversion, Stiftstraße 34-36, 45470 Mülheim an der Ruhr

Magnetic proximity effects are part of spintronic, superconducting, excitonic and topological phenomena which can induce desired or parasitic effects in measurements and devices. They are induced by a ferromagnet in a layer of a material close to the Stoner criterion in proximity to the ferromagnet. Usually magnetic proximity effects are studied by X-ray techniques. Modern analytical electron microscopy can be used to analyse the same underlying effects as well as electronic structure properties of materials. Therefore, it can be used to investigate the proximity effect in thin film systems.

As a model system a V/Fe thin film sample has been chosen. The techniques of electron energy loss magnetic chiral dichroism (EMCD) and differential phase contrast (DPC) have been used in combination. EMCD is used to show the presence of a magnetic moment on the material and DPC to locate the magnetic induction with high accuracy. Thus, we were able to observe a magnetic proximity effect of about 1.5 nm in V, which is in agreement with X-Ray measurements.

MA 2.3 Mon 10:00 H37

Location: H37

Coherent Correlation Imaging: Resolving fluctuating states of matter — •CHRISTOPHER KLOSE¹, FELIX BÜTTNER^{2,3,4}, WEN HU³, CLAUDIO MAZZOLI³, KAI LITZIUS², RICCARDO BATTISTELLI⁴, IVAN LEMESH², JASON M. BARTELL², MANTAO HUANG², CHRISTIAN M. GÜNTHER⁵, MICHAEL SCHNEIDER¹, ANDI BARBOUR³, STUART B. WILKINS³, GEOFFREY S.D. BEACH², STEFAN EISEBITT^{1,5}, and BASTIAN PFAU¹ — ¹Max Born Institute, Berlin — ²Massachusetts Institute of Technology, Cambridge, MA, USA — ³National Synchrotron Light Source II, Upton, NY, USA — ⁴Helmholtz-Zentrum Berlin — ⁵Technische Universität Berlin

Fluctuations and stochastic transitions are ubiquitous in nanometer-scale systems, especially in the presence of disorder. However, their direct observation has so far been impeded by a seemingly fundamental, signal-limited compromise between spatial and temporal resolution.

Here, we develop coherent correlation imaging (CCI) — a high-resolution, full-field imaging technique that realizes multi-shot, time-resolved imaging of stochastic processes. The key of CCI is the classification of camera frames that correspond to the same physical state by combining a correlation-based similarity metric with powerful classification algorithm developed for genome research.

We apply CCI to study previously inaccessible magnetic fluctuations in a highly degenerate magnetic stripe domain state with nanometer-scale resolution. The spatiotemporal imaging reveals the transition network between the states and details of the magnetic pinning landscape which have been inaccessible so far.

#### MA 2.4 Mon 10:15 H37

Charge State Instabilities of shallow Nitrogen-Vacancy Centers in Diamond at Cryogenic Ultra-High-Vacuum Conditions — DOMENICO PAONE^{1,2,5}, •Toni Hache^{1,5}, Jeffrey N. Neethirajan^{1,2,5}, Dinesh Pinto^{1,3}, Andrej Denisenko², Rainer Stöhr², Péter Udvarhelyi⁴, Ádám Gali⁴, Aparajita Singha¹, Jörg Wrachtrup^{1,2}, and Klaus Kern^{1,3} — ¹Max Planck Institute for Solid State Research —  $^2 \rm 3rd$  Institute of Physics and Research Center SCoPE, University of Stuttgart — ³Institute de Physique, École Polytechnique Fédérale de Lausanne — ⁴Wigner Research Centre for Physics, Institute for Solid State Physics and Optics, Hungarian Academy of Sciences — ⁵Equal contribution. Nitrogen-vacancy (NV) centers in diamond have attracted an immense interest for non-invasive magnetic imaging and quantum sensing. All NV based magnetic sensing protocols rely on the negative charge state of this quantum sensor (NV⁻). In this work we demonstrate dramatic charge state conversions within individual NV centers at cryogenic (4.7 K) and  $2 \cdot 10^{-10}$  mbar ultra-high-vacuum (UHV) conditions. The NV centers are characterized based on autocorrelation measurements, ODMR contrast and emission spectra. Under these extreme conditions, each of these measurements indicate a significant decrease of the relative occupancy of the NV⁻ charge state. Furthermore, we note a slight recovery of the NV⁻ charge state by dosing water (H₂O) on top of the diamond surface under UHV conditions. These results indicate that controlled surface treatments are essential for implementing NV center based quantum sensing protocols at cryogenic-UHV conditions.

Location: H1

## MA 3: Spin-Dependent Phenomena in 2D

## MA 3.1 Mon 9:30 H43

Noncollinear magnetism in a monolayer of two-dimensional  $CrTe_2$  — •NIHAD ABUAWWAD^{1,2}, MANUEL DOS SANTOS DIAS^{2,1}, HAZEM ABUSARA³, and SAMIR LOUNIS^{1,2} — ¹Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich & JARA, 52425 Jülich, Germany — ²Faculty of Physics, University of Duisburg-Essen, 47053 Duisburg, Germany — ³Department of Physics, Birzeit University, PO Box 14, Birzeit, Palestine

The discovery of two-dimensional (2D) van der Waals magnets opened unprecedented opportunities for the fundamental exploration of magnetism in quantum materials. Recently, thin CrTe₂ films were demonstrated to be ferromagnetic up to room temperature, with an intriguing dependence of the easy axis on the thickness of the material [1,2]. Using first principles, we show that the chargedensity waves characterizing a single CrTe₂ give rise to spiral magnetism through the emergence of the Dzyaloshinskii-Moriya interaction (DMI). Utilizing atomistic spin dynamics, we perform a detailed investigation of the complex magnetic properties pertaining to this 2D material impacted by the presence of various types of charge density waves. Also, we study the electronic and magnetic properties of heterostructures consisting of a single CrTe₂ monolayer interfaced with either Graphene or hBN.

#### MA 3.2 Mon 9:45 H43

**Electric-field control of the DMI in magnetic heterostructures** — •DONYA MAZHJOO, GUSTAV BIHLMAYER, and STEFAN BLÜGEL — Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich, Germany The use of external electric fields can extend the exploration of spintronic devices with a tunable Dzyaloshinskii-Moriya interaction (DMI) by allowing control of the interfacial DMI. Moreover, the magnetocrystalline anisotropy energy (MAE) changes as function of electric field intensity. By using density functional theory as implemented in the FLEUR-code [1], we investigated the electric field effects on graphene (Gr) covered Co/Pt(111) heterostructures. Experiments show evidence of a sizable DMI at the Gr/Co interface which partially compensates

#### Location: H43

Monday

the spin-orbit coupling induced DMI at the Co/Pt interface [2], which could make these structures susceptible to electric fields. To stimulate their influence, we sandwiched the film between two electrodes of opposite polarity. The self-consistent spin-spiral calculations were performed with these changed bound-ary conditions and spin-orbit effects were included in first order perturbation theory for the DMI and self-consistently for the MAE. We demonstrate that external fields lead to modulation of the spin-orbit induced quantities that allow a tuning of properties like domain wall widths or skyrmion radii. Support from the FLAG-ERA JTC 2019 grant SOgraphMEM is gratefully acknowledged. [1] https://www.flapw.de

MA 3.3 Mon 10:00 H43 Spinon induced drag in quantum spin liquid heterostructures — •RAFFAELE MAZZILLI¹, ALEX LEVCHENKO², and ELIO KOENIG¹ — ¹Max-Planck-Institut für Festkörperforschung, 70569 Stuttgart, Germany — ²Department of Physics,

University of Wisconsin-Madison, Madison, Wisconsin 53706, USA Several quantum spin liquid candidate materials, such as  $\alpha RuCl_3$  and 1T-TaSe₂, are exfoliable, so that it is possible to investigate 2D samples which avoid the manifestation of bulk properties that might disrupt the quantum spin liquid phase. In this phase the material is a Mott insulator and therefore it is impenetrable to direct electric probes such as charge currents. Despite this, in this work we propose an experimental setup that will allow to use non-local electrical probes to gain information on the transport properties of a gapless quantum spin liquid. The proposed setup is a spinon induced drag experiment, that consists in interfacing two metallic films separated by a layer of a quantum spin liquid. A current is injected in one of the two layers (active layer) and a voltage is measured on the second (passive) metallic film. The overall momentum transfer mechanism is a two-step process mediated by the Kondo interaction between the local moments in the quantum spin liquid and the spins of the electrons. We calculate, both for a U(1) and a  $Z_2$  spin liquids, the drag resistivity in the framework of the linearized quantum Boltzmann equation derived from the Keldysh formalism. In this framework the three layers are out of thermodynamic equilibrium. We further confront the results obtained with the equilibrium case and with the results of standard Coulomb drag.

## MA 4: Disordered Magnetic Materials

Time: Monday 9:30-10:30

## MA 4.1 Mon 9:30 H47

Destruction of long-range magnetic order in the Cu₂GaBO₅ ludwigite in a magnetic field — A. KULBAKOV¹, R. SARKAR¹, O. JANSON², S. DENGRE¹, E. M. MOSHKINA³, P. Y. PORTNICHENKO¹, H. LUETKENS⁴, F. YOKAICHIYA⁵, A. S. SUKHANOV^{1,6}, R. M. EREMINA⁷, A. SCHNEIDEWIND⁸, H.-H. KLAUSS¹, A. KORSHUNOV⁹, and •D. S. INOSOV¹ — ¹TU Dresden, Germany — ²IFW Dresden, Germany — ³Krasnoyarsk, Russia — ⁴PSI, Villigen, Switzerland — ⁵HZB, Berlin, Germany — ⁶MPI CPfS, Dresden, Germany — ⁷Kazan, Russia — ⁸JCNS @ MLZ, Forschungszentrum Jülich, Germany — ⁹ESRF, Grenoble, France

The quantum spin system  $Cu_2GaBO_5$  with the ludwigite structure consists of a structurally ordered  $Cu^{2+}$  sublattice interpenetrated by a disordered sublattice with a random site occupation by magnetic  $Cu^{2+}$  and nonmagnetic  $Ga^{3+}$ . In zero magnetic field, antiferromagnetic long-range order with the propagation vector  $q_m = (0.45, 0, 0.7)$  sets in below  $T_N = 4.1$  K, corresponding to a complex noncollinear structure with a large magnetic unit cell. Gapless spin dynamics in the form of a diffuse quasielastic peak is evidenced by neutron scattering. Remarkably, a magnetic field of ~1 T destroys the static long-range order, which is manifested in the gradual broadening of magnetic Bragg peaks. Such a crossover to a spin-glass regime may result from orphan spins on the structurally disordered magnetic sublattice, which are polarized in magnetic field and act as a tuning knob for field-controlled magnetic disorder. For details, see Phys. Rev. B **103**, 024447 (2021).

#### MA 4.2 Mon 9:45 H47

**Transport properties of FeAl under ion irradiation** — •SERHII SOROKIN¹, GREGOR HLAWACEK¹, SHADAB ANWAR¹, JOÃO SALGADO-CABAÇO¹, RICHARD BOUCHER², KAY POTZGER¹, JÜRGEN FASSBENDER¹, JÜRGEN LINDNER¹, and RANTEJ BALI¹ — ¹Institute of Ion Beam Physics and Materials Research, HZDR, Dresden, Germany — ²Institute for Materials Science, TU Dresden, Germany In  $Fe_{60}Al_{40}$  ion irradiation can be used to control the saturation magnetization ( $M_s$ ) due to the gradual transition from paramagnetic (ordered B2-phase) to ferromagnetic (disordered A2-phase) as a function of ion fluence. The corresponding changes to the transport properties occurring during this phase transition are lesser known. Here we track the variation of electronic transport properties in parallel with gradual ion irradiation. A sample is inserted into a He/Ne-ion microscope on top of a permanent magnet and contacted with feedthrough probes to enable step-wise measurements during  $Ne^+$ -irradiation. The variation of the resistance and the Hall voltage are tracked as a function of the  $Ne^+$ -fluence, as the ordered B2 structure transforms into a disordered A2 structure. Peaks in the electrical resistance and the Hall voltage are observed corresponding to the existence of a partial B2/A2 state, thereby hinting at the important role of the induced ferromagnetic clusters and their distribution on the transport properties. The state of disorder is reversible by annealing with higher electric current.

Project funded by the DFG - 322462997 (BA 5656/1-2 | WE-2623/14-2).

## MA 4.3 Mon 10:00 H47

Location: H47

Magnetostructural phase transition in  $Fe_{60}V_{40}$  alloy thin films — •MD SHADAB ANWAR^{1,2}, HAMZA CANSEVER¹, BENNY BOEHM³, RUDOLFO GALLARDO⁵, RENÉ HÜBNER¹, SHENGQIANG ZHOU¹, ULRICH KENTSCH¹, BENEDIKT EGGERT⁴, SIMON RAULS⁴, HEIKO WENDE⁴, KAY POTZGER¹, JÜRGEN FASSBENDER¹, KILIAN LENZ¹, JÜRGEN LINDNER¹, OLAV HELLWIG^{1,3}, and RANTEJ BALI¹ — ¹HZDR, Germany — ²TU Dresden, Germany — ³TU Chemnitz, Germany — ⁴UDE Duisburg, Germany — ⁵UTF Santa María, Chile Ferromagnetism can be induced in non-ferromagnetic alloys such as B2  $Fe_{50}Rh_{50}[2]$  through lattice disordering. Here we study a

re₆₀Al₄₀[1] and B2 Fe₅₀Rn₅₀[2] through lattice disordering. Here we study a magnetostructural transition in Fe₆₀V₄₀ thin films using ion-irradiation. We show that the as-grown films possess an M_s of 17 kA/m and irradiation with 25 keV Ne⁺-ions at a fluence of 5 x 10¹⁵ions/cm² leads to an increase of M_s to ~ 750 kA/m. A structural short-range order is observed in the as-grown films that transforms to A2 phase via ion-irradiation. Mössbauer spectroscopy and Ferromagnetic Resonance have been applied to track the variation of local magnetic ordering and dynamic behaviour respectively.

Financial support by DFG grants BA 5656/1-2 and WE 2623/14-2 is acknowledged.

[1]Ehrler, J.et al., New J. Phys., 22,073004(2020) [2]Eggert, B.et al., RSC Adv., 10,14386(2020) MA 4.4 Mon 10:15 H47

Understanding the ion induced reordering of amorphous  $Fe_{60}V_{40}$  thin films - •Simon Rauls¹, Benedikt Eggert¹, Shadab Anwar², Damian Günzing¹ Philipp Klassen¹, Alexander Herman¹, Rantej Bali², and Heiko Wende¹ ⁻¹Faculty of Physics and CENIDE, University of Duisburg-Essen — ²Interface Magnetism, Helmholtz-Zentrum Dresden-Rossendorf

For efficient spintronic devices, magnetic materials possessing both low moment and low Gilbert damping are highly demanded [1]. In this field, binary alloys consisting of Fe and easily polarizable elements like V are promising candidates, as they are reported to have a Gilbert damping parameter of  $\alpha \sim 0.001$  which is about one order of magnitude lower as compared to the much-used permalloy [2]. Additionally, FeV can be grown as amorphous, paramagnetic thin films

Time: Monday 9:30-10:30

MA 5.1 Mon 9:30 H48 Cubic magneto-optic Kerr effect in Ni(111) thin films with and with-

out twinning — •MAIK GAERNER¹, ROBIN SILBER², TOBIAS PETERS¹, JAROSLAV HAMRLE³, and TIMO KUSCHEL¹ - ¹Bielefeld University, Germany ²IT4Innovations, VŠB - Technical University of Ostrava, Czech Republic — ³Charles University, Prague, Czech Republic

In most studies utilizing the magneto-optic Kerr effect (MOKE), the detected change of polarized light upon reflection from a magnetized sample is supposed to be proportional to the magnetization M. However, MOKE signatures quadratic in *M* have also been identified and utilized, e.g., to sense the structural order in Heusler compounds [1].

In our study, we employ the eight-directional method [2] to separate different MOKE contributions in Ni(111) thin films. We observe a strong anisotropic longitudinal MOKE contribution of third order in *M* which we attribute to a cubic magneto-optic tensor proportional to  $M^3$  [3]. We further show that the angular dependence of cubic MOKE (CMOKE) is affected by the amount of structural domain twinning (two structural (111) phases with  $60^{\circ}$  in-plane rotation) in the sample [3]. Our detailed study on CMOKE for two selected photon energies will open up new opportunities for CMOKE applications with sensitivity to twinning properties of thin films, e.g. CMOKE spectroscopy and microscopy or time-resolved CMOKE.

MA 5.2 Mon 9:45 H48

A cryogen-free 10T asymmetric neutron scattering magnet with 50mm sample space and temperature range from 300mK to 375K - •TOM RITMAN-MEER, MARC SAVEY-BENNETT, and ROGER MITCHELL — Cryogenic Ltd, 6 Acton Park Estate, The Vale, London, W3 7QE, United Kingdom

Cryogenic Ltd has built and delivered a Cryogen-Free ring-separated magnet for polarised neutron scattering experiments with 10T central field and integral VTI cooled from a single 1.8W cryocooler.

The magnet has a novel dual power-supply control unit to provide an asymmetric field when required, allowing the twin requirements of minimal depolarisation and maximum homogeneity to be managed. The magnet consists of inner and outer pairs which are separately controlled to minimise the impact of the asymmetry. The zero field point can be shifted by up to 20mm from the central plane.

The system has a sample space of 50mm diameter, housed within a closedcycle refrigeration system, offering a temperature controlled environment of 1.5K-375K. Sample exchange is into an inner *static column* eliminating the risk of accidental blockage.

The system includes a specially designed helium-3 insert with >40mm working space inside an aluminium IVC of just 1mm thick allowing continuous operation at 280mK for 76 hours within the main VTI space. Total aluminium in

which reorder to the A2 structure upon ion irradiation. This can be exploited in such a way that ferromagnetic nanostructures can be written into the paramagnetic template in a single ion irradiation step using focussed ion beams or broad ion beams with masks.

Using Mössbauer spectroscopy and EXAFS, we will provide further insights into the reordering mechanics of amorphous  $\mathrm{Fe}_{60}\mathrm{V}_{40}$  thin films by comparing the evolution of short range order and the hyperfine fields across the ion irradiationand annealing-induced phase transition.

Funding by the Deutsche Forschungsgemeinschaft (DFG) - 322462997 (BA5656/1-2 WE 2623/14-2) is acknowledged.

## MA 5: Magnetic Instrumentation and Characterization

Location: H48

the beam path is limited to just 15mm (sample to outer wall).

The system also includes an automated z-axis and rotation manipulator stage for both the He-3 unit and standard sample probes.

MA 5.3 Mon 10:00 H48

Detection of nanowire vibrations with a co-resonantly coupled cantilever system — •Maneesha Sharma, Aniruddha Sathzadharma Prasad, Bernd BÜCHNER, and THOMAS MÜHL — Leibniz Institute for Solid State and Materials Research, IFW Dresden, Germany

Nanowires can constitute the basis for high-sensitivity sensing of masses and magnetic properties of nanoparticles. We report a novel and efficient vet simple method for detecting nanowire flexural vibrations. In this work we present a co-resonantly coupled cantilever system consisting of a microcantilever and a nanocantilever. Achieving co-resonance involves matching the resonance frequencies of the individual systems. It allows us to measure the coupled system*s eigenmodes at the microcantilever. In the co-resonant state weak force gradients acting at the nanowire end have a considerable impact on the eigenmodes of the coupled system and thus can be easily sensed at the microcantilever.

We analyze mechanical properties of the nanowire subsystem and of the coupled system by exploiting thermally induced fluctuations which are measured by recording time-resolved secondary electron signals when using an electron beam and, in case of the microcantilever, by optical laser deflection. Finally, we discuss applications of the coupled cantilever sensor for high-sensitivity magnetometry.

A Ti/Pt/Co Multilayer Stack for Transfer Function Based Magnetic Force Mi**croscopy Calibrations** — •BAHA SAKAR¹, SIBYLLE SIEVERS¹, OSMAN ÖZTÜRK², and HANS WERNER SCHUMACHER¹ — ¹Physikalisch-Technische Bundesanstalt, Braunschweig, Germany — ²Gebze Technical University, Kocaeli, Turkey

Magnetic force microscopy (MFM) is a widespread technique for imaging magnetic structures with a resolution of some 10 nanometers. MFM can be calibrated to obtain quantitative (qMFM) spatially resolved magnetization data in units of A/m by determining the calibrated point spread function of the instrument, its instrument calibration function (ICF), from a measurement of a wellknown reference sample. Beyond quantifying the MFM data, a deconvolution of the MFM image data with the ICF also corrects the smearing caused by the finite width of the MFM tip stray field distribution. However, the quality of the calibration depends critically on the calculability of the magnetization distribution of the reference sample. Here, we discuss a Ti/Pt/Co multilayer stack that shows a stripe domain pattern as a suitable reference material. A precise control of the fabrication process, combined with a characterization of the sample micromagnetic parameters, allows reliable calculation of the sample*s magnetic stray field, proven by a very good agreement between micromagnetic simulations and qMFM measurements. A calibrated qMFM measurement using the Ti/Pt/Co stack as a reference sample is shown and validated, and the application area for quantitative MFM measurements calibrated with the Ti/Pt/Co stack is discussed.

The microscopic mechanism driving colossal magneto-resistance (CMR) remains controversial. In La_{1.2}Sr_{1.8}Mn₂O₇, CMR is most pronounced at its insu-

Location: H37

lator to ferromagnetic-metal transition at  $T_c = 120$  K. In this compound, initial ARPES studies revealed the abrupt formation of quasi-particles having a strong mass renormalization below  $T_c$ , subsequently interpreted as the condensation of localized polarons into a coherent polaronic liquid. Yet, conflicting results showing finite quasi particle spectral weight above  $T_c$  cast doubt on this scenario. Here we use resonant inelastic X-ray scattering (RIXS) to investigate this controversy. In contrast to ARPES which measures the single particle spectral function, RIXS probes collective excitations directly and is thus especially suitable for the investigation of charge-lattice coupled phenomena. In this presentation, I will discuss the RIXS signatures of polarons in La_{1.2}Sr_{1.8}Mn₂O₇.

Magneto-optic Kerr effect in ferromagnetic manganite multilayers - •Jörg SCHÖPF, PAUL H.M. VAN LOOSDRECHT, and IONELA LINDFORS-VREJOIU - Universität zu Köln, II. Physikalisches Institut, Zülpicherstr. 77, 50937 Köln (DE) Magnetic functional oxide epitaxial thin films and heterostructures offer a rich variety of physical properties due to lattice mismatch induced strain, interfacial effects and interlayer coupling between different ferromagnetic (FM) layers. The magneto-optic Kerr effect (MOKE) can be used as an indirect probe of the magnetization of a sample. The MOKE of a material is wavelength dependent, and is non-monotonic in the vicinity of MO-active transitions, where the Kerr rotation can change sign and even vanish at particular wavelengths. Knowledge of the wavelength dependence can help to distinguish the contributions of different FM layers within a multilayer to the total measured Kerr effect. Here we present a study on the MOKE of a heterostructure of 10% Ru-doped La0.7Sr0.3MnO3 (LSMRO), where the layers are of different thickness (30 nm bottom layer and a 10 nm top layer), and separated by a NdNiO3 spacer. We found that the measured Kerr hysteresis loops of the heterostructure have an anomalous shape originating from a different sense of rotation of the MOKE from the different LSMRO layers. This can readily be described by Kerr-loops measured on reference samples using the additivity of the MOKE in multilayer systems.

MA 6.3 Mon 11:30 H37

**Strain-induced ferromagnetism in LaCoO3 thin film** — •FARZIN ABADIZA-MAN, MICHAL KIABA, and ADAM DUBROKA — Department of Condensed Matter Physics, Faculty of Science, Masaryk University, Kotlářská 2, 611 37 Brno, Czech Republic. Ellipsometry measurements were performed on unstrained, tensile strained, and compressive strained LaCoO3 thin films. Only the tensile strained sample shows ferromagnetism, which has a Currie temperature of about 85 K. Using the differential optical conductivity,  $\delta\sigma_1 = \sigma_1(T) - \sigma_1(T = 7K)$ , we find that in the tensile strain sample, while the spectral weight  $N_{eff} = 2mV/\pi e^2 \int \sigma_1(\omega)$ ,  $d\omega$  below 3.5 eV decreases with decreasing temperature in the paramagnetic phase, it starts increasing in the ferromagnetic phase below the transition temperature. This is the first time that the ferromagnetism in this material is observed via optical measurements, and we interpret the results as stabilization of the high-spin state in the ferromagnetic phase associated with transition of spectral weight from higher to lower energy region.

#### MA 6.4 Mon 11:45 H37

Spin-Orbit Excitations in a Strongly Correlated 4d-Metal Studied by Resonant Inelastic X-ray Scattering — •VALENTIN ZIMMERMANN¹, DENIZ WONG², CHRISTIAN SCHULZ², MACIEJ BARTKOWIAK², KLAUS HABICHT², ARVIND YOGI³, MASAHIKO ISOBE¹, LICHEN WANG¹, MATTEO MINOLA¹, GINIYAT KHALLIULIN¹, BERNHARD KEIMER¹, and MATTHIAS HEPTING¹ — ¹Max-Planck-Institute for Solid State Research, Stuttgart, Germany — ²Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany — ³UGC-DAE-Consortium for Scientific Research, Indore, India

Spin-orbit coupling (SOC) is an important player determining the electronic and magnetic properties of 4*d* and 5*d* transition metal oxides. The 5*d* compound Sr₂IrO₄ is an antiferromagnetic Mott insulator, where SOC leads to a splitting of the t_{2g} manifold into bands with effective total angular momentum J_{eff} = 3/2 and 1/2. This electronic structure gives rise to low-energy excitations with excitonic character, which were recently studied by resonant inelastic X-ray scattering (RIXS) and assigned to the transition of holes across the spin-orbit split states. Here, we use RIXS at the oxygen K-edge to investigate the isovalent 4*d* compound Sr₂RhO₄, which is a paramagnetic, strongly correlated metal. We observe similar spin-orbit excitons as in Sr₂IrO₄, however, on a smaller energy scale and with a distinct dispersion, which we attribute to a reduced SOC strength and the metallic ground state, respectively. In addition, we explore whether the solid-solution Sr₂Rh_{1-x}Ir_xO₄ is a viable platform to tune the effective strength of SOC.

Strong photon-magnon-coupling between superconducting niobium lumped-element-resonators and micron sized magnets — •PHILIPP GEYER¹, PHILIP TREMPLER¹, KARL HEIMRICH¹, and GEORG SCHMIDT^{1,2} — ¹1Institut für Physik, Martin-Luther-Universität Halle-Wittenberg, Von-Danckelmann-Platz 3, 06120 Halle (Saale), Germany — ²2Interdisziplinäres Zentrum für Material-wissenschaften, Martin-Luther-Universität Halle-Wittenberg, Nanotechnikum Weinberg, 06120 Halle (Saale), Germany

Since quantum computing plays a more and more important role in information technology hybrid quantum magnonics emerge as a promising research field. Here, the coupling between different quantum states like microwave photons and magnons at cryonic temperatures is in focus [1]. We investigate the coupling between superconducting niobium Lumped-Element-Resonators and thin micronsized magnetic structures. Therefore, we use the magnetic material permalloy and yttrium-iron-garnet (YIG). Permalloy was structured by optical lithography and grown by argon-ion sputtering at room-temperature. YIG was grown as free standing structure [2] or commercial LPE film and further processed and placed on the cavity by focused-ion-beam technique. We detect strong coupling as avoided crossing in the transmission related S-Parameter measured by a vector-network-analyzer. For validation of our experimental results, we perform electromagnetic simulations with CST Studio Suite and micromagnetic simulations with MuMax3. [1] H. Huebl et.Al. Phys. Rev. Lett. 111, 127003 (2013) [2] P. Trempler et. Al. Appl. Phys. Lett. 117, 232401 (2020)

Coupling magnetic and acoustic excitations enables novel functionalities for magnonic devices. We explore broadband ferromagnetic resonance (FMR) in

### Location: H43

a  $Y_3Fe_5O_{12}$  film on a  $Gd_3Ga_5O_{12}$  substrate. At low frequencies, the Kittel mode hybridizes with standing ultrasound waves that form across the layer stack resulting in a characteristic modification of the magnetic susceptibility. At higher frequencies, the individual phonon resonance overlap, leading to a permanent emission of phonons and thus an enhanced relaxation of the FMR. The broadband frequency dependence of the magnetoelastic coupling and thus the phonon pumping follows theoretical predictions. We additionally find substantial magnon-phonon coupling of a perpendicular standing spin wave mode. This evidences the importance of the mode overlap between the acoustic and magnetic modes and thus paves the way to tailoring the magnetoelastic mode coupling.

Gilbert damping in the real-space KKR method — BALÁZS NAGYFALUSI¹, LÁSZLÓ SZUNYOGH², and •KRISZTIÁN PALOTÁS^{1,2} — ¹Wigner Research Center for Physics, Budapest, Hungary — ²Institute of Physics, Budapest University of Technology and Economics, Budapest, Hungary

The ab-initio determination of Gilbert damping parameters is an important issue for accurate atomistic spin dynamics calculations. Going beyond presently available methods of calculating the Gilbert damping scalar parameter in bulk materials, we implemented the torque-torque correlation formula [1] into the realspace Korringa-Kohn-Rostoker (KKR) method [2] using the Budapest SKKR code to be able to treat chemically inhomogeneous systems. This enables the abinitio determination of spatially resolved on-site and non-local Gilbert damping tensors [3] in atomic nanostructures. After performing extensive tests for metallic bulk materials to identify the relevant parameter settings of the calculations, we show some examples of inhomogeneous Gilbert damping results in various metallic atomic (nano-)structures.

Spectrally resolved spin dynamics of 3d transition metals in EUV T-MOKE – •HENRIKE PROBST¹, CHRISTINA MÖLLER¹, MARIANA BREDE¹, MAREN SCHUMACHER¹, KAREN STROH¹, MARCEL REUTZEL¹, G. S. MATTHIJS JANSEN¹, SANGEETA SHARMA², DANIEL STEIL¹, and STEFAN MATHIAS¹ – ¹I. Physikalisches Institut, University of Göttingen – ²Max-Born-Institute for Non-linear Optics and Short Pulse Spectroscopy, Berlin

Light in the extreme ultraviolet (EUV) range has found increasing application in the field of magneto-optical spectroscopy. It allows to get new insights in light-matter interaction processes, as EUV spectroscopy provides the potential to investigate energy- and element-resolved spin dynamics [1-2].

Here, we carry out a comprehensive study of spectrally resolved spin dynamics of the 3d transition metals Co, Fe and Ni using EUV transverse magneto-optical Kerr spectroscopy (T-MOKE) [3]. Covering the *M*-edges in the 30-72 eV energy window, this allows to resolve spin dynamics at specific energies around the Fermi-level. We discuss different processes leading to energy dependent changes in the magnetic asymmetry at early times after the optical excitation, i.e. charge excitation and band renormalization.

MA 8.2 Mon 15:15 H37

Ultrafast element- and depth-resolved magnetization dynamics probed by transverse magneto-optical Kerr effect spectroscopy in the soft x-ray range — •MARTIN HENNECKE¹, DANIEL SCHICK¹, THEMISTOKLIS SIDIROPOULOS¹, FELIX WILLEMS¹, ANKE HEILMANN¹, MARTIN BOCK¹, LUTZ EHRENTRAUT¹, DIETER ENGEL¹, PIET HESSING¹, BASTIAN PFAU¹, MARTIN SCHMIDBAUER², ANDREAS FURCHNER^{3,4}, MATTHIAS SCHNUERER¹, CLEMENS VON KORFF SCHMISING¹, and STEFAN EISEBITT^{1,5} — ¹Max-Born-Institut, Berlin, Germany — ²Leibniz-Institut für Kristallzüchtung, Berlin, Germany — ³Helmholtz-Zentrum Berlin, Berlin, Germany — ⁴Leibniz-Institut für Analytische Wissenschaften, Berlin, Germany — ⁵IOAP, Technische Universität Berlin, Berlin, Germany

Understanding the light-driven spin dynamics occurring at buried interfaces of complex magnetic heterostructures as used in today's opto-spintronics applications requires direct experimental access to the nonlocal magnetic order on sub-ps time scales. Here, we report on broadband time- and angle-resolved transverse magneto-optical Kerr effect spectroscopy probing the Gd N_{5,4} resonance ( $\approx$ 150 eV) of a ferrimagnetic GdFe nanostructure with fs soft x-ray pulses provided by a laboratory-scale light source based on high-harmonic generation. Employing a pump-probe technique, we follow the fs laser-induced demagnetization of the GdFe layer. Analyzing the fs time-resolved spectra via magnetic scattering simulations allows a quantitative determination of the transient magnetization depth profiles evolving within the magnetic film due to strongly layer-dependent photoexcitation.

#### MA 8.3 Mon 15:30 H37

Table-top X-ray magnetic circular dichroism at the Fe L edges — •MARTIN BORCHERT^{1,2}, DANIEL SCHICK¹, CLEMENS V. KORFF SCHMISING¹, DENNY SOMMER¹, DIETER ENGEL¹, BASTIAN PFAU¹, and STEFAN EISEBITT^{1,2} — ¹Max-Born-Institut, Berlin — ²TU Berlin

Time-resolved X-ray magnetic circular dichroism (XMCD) is a powerful tool to directly probe the element-specific magnetization in multi-component heterostructures.

Due to the lack of laboratory-scale light sources with sufficient brightness and control over the light's polarization, static and time-resolved XMCD studies in the higher soft X-ray photon energy range have so far been limited to large-scale facilities such as synchrotrons and free-electron lasers.

Here, we present first XMCD spectroscopy data recorded at the Fe  $L_{3,2}$  resonances employing a laboratory-scale soft X-ray source utilizing a magnetic thinfilm polarizer to circularly polarize the soft X-rays from the continuous, broadbe Ohmic; that is, if one assumes the bath spectral density to be linear in frequency. Real baths, however, can be Ohmic only at low frequencies and, as we will argue, the baths' high-frequency modes induce magnetization inertia. Explicitly, we show for a macrospin coupled linearly to a bath of harmonic oscillators (Caldeira-Leggett model) that the low-frequency bath modes (if Ohmic) lead to Gilbert damping while the high-frequency bath modes universally lead to macrospin inertia. We expect our results to give new insights into recent experiments on magnetization nutation. But our results might prove to be relevant in general, as they indicate that a Gilbert-damping term should always be accompanied by a term accounting for bath-induced spin inertia.

Location: H37 band (50–1500 eV) emission of a laser-driven plasma source with <10 ps pulse duration. A reflection zone plate (RZP) is used as the single optical element to collect, disperse and focus the full spectrum across the Fe L edges through a thin-film sample, to which an external magnetic field can be applied to observe

the resulting asymmetry spectrum, as well as hysteresis loops. Utilizing different RZPs, this setup enables the first laboratory-based whitelight XMCD spectroscopy with picosecond time resolution, covering the full spectrum of the magnetically relevant resonances from the transition metal Mand L edges up to the rare earth M edges.

#### MA 8.4 Mon 15:45 H37

Temperature dependence of spin interaction parameters in two-sublattice ferrimagnets — •Levente Rózsa¹, Severin Selzer¹, Niklas Windbacher¹, ULRICH NOWAK¹, and UNAI ATXITIA² — ¹University of Konstanz, Konstanz, Germany — ²Instituto de Ciencia de Materiales de Madrid, Madrid, Spain

Ferrimagnets consist of two antiferromagnetically coupled sublattices with different magnetic moments, thereby possessing a finite magnetization like ferromagnets. The ferrimagnet magnetite has been known since ancient times, yet ferrimagnets continue to attract research interest in various areas of spintronics from magnons to skyrmions. The properties of ferrimagnets may be tuned between those of ferromagnets and antiferromagnets by changing the temperature. Therefore, determining the temperature dependence of model parameters of ferrimagnets is essential for their accurate description.

Here we present an analytical method for describing the temperature dependence of spin interactions in ferrimagnets, based on Callen's Green's function formalism [1]. The temperature dependence of the Heisenberg and Dzyaloshinsky-Moriya interactions, as well as of the anisotropy terms are derived and compared to known expressions in ferromagnets [2,3]. The role of spin correlations is highlighted in reduced dimensions. The results are compared to numerical simulations of the magnon frequencies and of reversal times of nanoparticles.

MA 8.5 Mon 16:00 H37

**Electron-Magnon Scattering Dynamics in a two-band Stoner Model** — •FÉLIX DUSABIRANE, KAI LECKRON, SANJAY ASHOK, BÄRBEL RETHFELD, and HANS CHRISTIAN SCHNEIDER — Physics Department & Research Center OPTIMAS, University of Kaiserslautern, Germany

We use a microscopic model to study carrier dynamics in ferromagnets due to electron-magnon scattering on ultrafast timescales. We employ a simple model band structure (Stoner model), for which the electron magnon-interaction is formally obtained as coupling to a Heisenberg spin system in the Hamiltonian. We compute the dynamics of momentum resolved electron and magnon distributions due to electron-magnon and statically screened electron-electron scattering, which are treated at the level of Boltzmann scattering integrals. We find that electron-magnon scattering leads to a pronounced non-equilibrium for magnon modes that couple directly to Stoner transitions. The spin-flip scattering with electrons results in a transient electron spin polarization, which is similar for excitations either within the minority or the majority band. The influence of model parameters such as band filling and exchange coupling strengths will be discussed.

Ultrafast optical generation of antiferromagnetic spin texture — •SUMIT GHOSH^{1,2}, STEFAN BLÜGEL¹, and YURIY MOKROUSOV^{1,2} — ¹PGI1, Forschungszentrum Jülich, Germany. — ²Institute of Physics, Johannes Gutenberg-University Mainz, Germany.

We present here an unified picture of ultrafast manipulation of collinear antiferromagnetic order by combining both electronic and magnetic degrees of freedom via a hybrid quantum classical evolution scheme. Our approach allows us to probe slow magnetic relaxation for several picoseconds with a sub-femtosecond resolution and thus allows us to identify the emergent interactions driving the formation of nontrivial textures which remains hidden from classical magnetisation dynamics. In case of a one dimensional spin chain this mechanism can lead to the formation of spin spirals [1] where the induces chirality can be tuned with the laser parameter. In case of two dimensional antiferromagnets this mechanism can lead to more exotic outcome - generation of a texture and anti-texture which can survive for 100ps [2] and is fairly robust against impurity. Our results thus opens new possibilities to generate higher order nontrivial magnetic texture with ultrafast laser.

Polarized phonons carry the missing angular momentum in femtosecond demagnetization — •HANNAH LANGE¹, MARTIN EVERS¹, ANDREAS DONGES¹, SONJA TAUCHERT^{1,2}, MIKHAIL VOLKOV^{1,2}, PETER BAUM^{1,2}, and UL-RICH NOWAK¹ — ¹University of Konstanz, Fachbereich Physik, 78464 Konstanz — ²LMU Munich, Am Coulombwall 1, 85748 Garching

When a thin nickel film is subjected to ultrashort laser pulses, it can lose its magnetic order almost completely on within hundreds of femtoseconds. This phenomenon offers opportunities for rapid information processing or ultrafast spintronics. However, a crucial question has remained elusive: Where is the angular momentum transferred to in such short time? Here we use molecular dynamics simulations to investigate the role of phonon angular momentum. When exciting a rotational lattice motion which carries the amount of angular momentum corresponding to the demagnetization, we observe an anisotropy of the atoms' velocities which violates the equipartition theorem. When calculating the corresponding electron diffraction pattern, this results in an anisotropy of normally equivalent Bragg spots. This is in line with ultrafast electron diffraction which show an almost instantaneous, long-lasting, non-equilibrium population of phonons. Theory and experiment hence indicate the formation of polarized phonons that take up the missing angular momentum [1] before the onset of a macroscopic Einstein-de Haas rotation [2].

**Does the orbital angular momentum of light affect ultrafast demagnetization?** — •EVA PRINZ¹, BENJAMIN STADTMÜLLER^{1,2}, and MARTIN AESCHLIMANN¹ — ¹Department of Physics and Research Center OPTIMAS, TU Kaiserslautern, Germany — ²Institute of Physics, Johannes Gutenberg University Mainz. Germany

Optical fields can carry an orbital angular momentum (OAM) in helical beams with an azimuthal phase dependence. Since its discovery in 1992 [1], there has been a variety of applications of light with additional OAM, such as quantum entanglement, micro manipulation, communication, and microscopy [2].

Our research is focused on exploring the potential effects of the OAM of light on laser-induced ultrafast demagnetization. In this field, the question of how the angular momentum is conserved during spin-flips is not fully answered. Pumping the system with photons carrying OAM offers the potential to provide new insights, not only into the dissipation of angular momentum in the material but also into the interaction of photonic OAM with matter in general.

We investigate ultrafast demagnetization of ferromagnetic thin films induced by OAM light with time-resolved magneto-optic Kerr-effect measurements. We observed peculiar demagnetization dynamics that have so far not been observed for light without OAM.

#### MA 8.9 Mon 17:00 H37

**Role of diffusive transport in ultrafast demagnetization dynamics** — •SANJAY ASHOK, SEBASTIAN T. WEBER, CHRISTOPHER SEIBEL, JOHAN BRIONES, and BÄR-BEL RETHFELD — Fachbereich Physik and OPTIMAS Research Center, TU Kaiserslautern, Kaiserslautern, Germany

Ultrafast demagnetization dynamics in thick metallic magnetic films is greatly influenced by transport processes. In this contribution we present the space-resolved magnetization dynamics in a thick Nickel film induced by a femtosecond laser pulse [3]. Starting from the thermodynamic  $\mu$ T-model [1], we explicitly include diffusive heat transport, spin-resolved charge transport, as well as Seebeck and Peltier effects.

Our results show that the spatial dependence of maximal magnitude of quenching is induced by a depth-dependent energy deposition and is only moderately equilibrated by transport processes. We reveal a stronger influence of transport on the time of quenching which becomes nearly independent of depth [3]. Additionally, we present the influence of pump-wavelength [2] on spatially resolved magnetization dynamics.

Spin fluctuations around a reorientation transition in  $Sm_{0.7}Er_{0.3}FeO_3$ — •Julius Schlegel¹, Martin Evers¹, Tobias Dannegger¹, Andreas Donges¹, Marvin Weiss¹, Takayuki Kurihara², Sebastian T.B. Goennenwein¹, and Ulrich Nowak¹ — ¹Department of Physics, University of Konstanz — ²ISSP, University of Tokyo

The competition between thermal fluctuations, spin-spin interactions and magnetic anisotropies can lead to various magnetic phase transitions. For example the antiferromagnetic orthoferrite  $Sm_{0.7}Er_{0.3}FeO_3$  undergoes a reorientation transition at approximately room temperature. On the basis of an atomistic spin model and the LANDAU-LIFSHITZ-GILBERT equation of motion we numerically calculate the time evolution of the magnetization around the reorientation transition on a timescale from picoseconds up to one nanosecond and investigate the thermal fluctuations of the magnetization. By FOURIER-transforming the time dependent magnetization we find that the spectra of the noise are temperature dependent and change significantly while going through the reorientation. We also observe several resonances in the spectra. By means of analytical calculations based on linear spin wave theory these peaks can be assigned to the different modes of a model with four sublattices.

Finally, these results are compared to current experimental data from spin noise measurements.

MA 8.11 Mon 17:30 H37

Ultrafast spin dynamics: complementing theoretical analyses by quantum state measures — FRANZISKA ZIOLKOWSKI, •OLIVER BUSCH, JÜRGEN HENK, and INGRID MERTIG — Institut für Physik, Martin-Luther-Universität, D-06099 Halle

In theoretical studies of ultrafast spin dynamics, one usually analyses and discusses observables — such as magnetization. On top of this, quantum state (QS) measures defined for density matrices may provide additional valuable insights into the dynamics [1].

We report on a study on QS measures that complement simulations of ultrafast spin dynamics [2]. For a Co/Cu heterostructure which is excited by a femtosecond laser pulse and coupled to a bosonic heat bath, we discuss the time dependence of QS measures, in particular distances in Hilbert space and degree of purity in the density matrix [3].

We identify observables and modifications of the investigated system to which both the distance and the purity measures are in particular sensitive: the polarization of the laser pulse and the composition of the sample. In contrast, temperature and photon energy affect the QS measures mildly. Our study shows that QS measures are complementary and beneficial quantities for spin dynamics simulations.

Tuning all-optical magnetization switching efficiency by laser pulse wavelength variation — •MARCEL KOHLMANN¹, LUCAS VOLLROTH¹, KRISTÝNA HOVOŘAKOVÁ², EVA SCHMORANZEROVÁ², ROBIN JOHN¹, DENISE HINZKE⁴, PETER OPPENEER³, ULRICH NOWAK⁴, MARKUS MÜNZENBERG¹, and JAKOB WALOWSKI¹ — ¹Greifswald University, Greifswald, Germany — ²Charles University, Prague, Czech Republic — ³Uppsala University, Uppsala, Sweden — ⁴Konstanz University, Konstanz, Germany

Heat-assisted magnetic recording (HAMR) presents a promising candidate for high data density devices. Leaving investigation of magnetization manipulation a topic of interest for research and development. We study all-optical helicitydependent switching of FePt granular HAMR media[2] as an alternative writing mechanism. The latest perception of interaction of heating and ultra fast excitation suggests the contribution of magnetic dichroism and the inverse Faraday effect as interchanging driving forces behind the magnetization reversal. The switching rates for individual FePt nano particles from ab-initio calculations of the inverse Faraday effect and magnetic dichroism induced heating provide a model to describe the switching as a stochastic process. We extend the study to wavelength dependent switching experiments from 800 nm up to 1550 nm for all-optical writing experiments on FePt granular media evaluating the writing efficiency.

We greatly acknowledge the DFG funding within the project "Fundamental aspects of all-optical single pulse switching in nanometer-sized magnetic storage media.

## MA 9: INNOMAG e.V. Prizes 2022 (Diplom-/Master and Ph.D. Thesis)

Die Arbeitsgemeinschaft Magnetismus der DPG hat einen Dissertationspreis und einen einen Diplom-/Masterpreis ausgeschrieben, welche auf der Tagung der DPG 2022 in Regensburg vergeben werden. Ziel der Preise ist die Anerkennung herausragender Forschung im Rahmen einer Diplom-/Masterarbeit beziehungsweise einer Promotion und deren exzellente Vermittlung in Wort und Schrift. Im Rahmen dieser Sitzung tragen die besten der für ihre an einer deutschen Hochschule durchgeführten Diplom-/Masterarbeit beziehungsweise Dissertation Nominierten vor. Im direkten Anschluss entscheidet das Preiskommittee über den Gewinner des INNOMAG e.V. Diplom/Master-Preises und des Dissertationspreises 2022. Talks will be given in English!

Time: Monday 15:00-17:00

## MA 9.1 Mon 15:00 H43

Magnetoelastic coupling and uniaxial pressure dependencies in the honeycomb quantum magnets  $CrI_3$  and  $Na_2Co_2TeO_6 - \bullet JAN ARNETH^1$ , MAR-TIN JONAK¹, MAHMOUD ABDEL-HAFIE2², KWANG-YONG CHOI³, and RÜDIGER KLINGELER¹ — ¹Kirchhoff-Institute for Physics, Heidelberg University, Germany -  $^{2}\mathrm{Dep.}$  of Physics and Astronomy, Uppsala University, Sweden -³Dep. of Physics, Sungkyunkwan University, Republic of Korea

Due to their layered structure, competing magnetic interactions, and magnetic anisotropy, quasi-2D honeycomb systems are promising quantum materials featuring fundamentally and technologically relevant phenomena. Often, relevant materials are at the verge of the desired properties, and strain has been proven to be a tuning parameter. Strain engineering of the critical temperature in 2D ferromagnetic semiconductors such as CrI₃ [1] towards room temperature or driving the quantum magnet Na₂Co₂TeO₆ into the Kitaev spin-liquid phase are illustrative examples. The precise determination of uniaxial strain effects is hence a mandatory step towards new applications and phenomena. We report dilatometric studies on the honeycomb quantum magnets CrI₃ and Na₂Co₂TeO₆ at low temperatures and high magnetic fields. Our data enable us to quantify magnetoelastic coupling and the uniaxial pressure dependencies of the respective ordering temperatures. Additionally, the magnetic phase diagrams are constructed, including structural response of the surface phase in CrI₃ and signatures of competing degrees of freedom in Na₂Co₂TeO₆.

#### MA 9.2 Mon 15:20 H43

Magnetisation dynamics in epitaxial Co₂Mn-based Heusler thin films with ultralow damping for thicknesses below 50 nm - •ANNA M. FRIEDEL^{1,2}, CLAUDIA DE  $MELO^2$ , VICTOR PALIN^{2,3}, SÉBASTIEN PETIT-WATELOT², STÉPHANE ANDRIEU², and PHILIPP PIRRO¹ — ¹Fachbereich Physik and Landesforschungszentrum OPTIMAS, Technische Universität Kaiserslautern, Kaiserslautern, Germany — ²Institut Jean Lamour, UMR CNRS 7198, Université de Lorraine, Nancy, France — ³Synchrotron SOLEIL-CNRS, L'Orme des Merisiers, Gif-sur-Yvette, France

For future applications of magnetisation dynamics, materials with low Gilbert damping are indispensable. Co2Mn-based Heusler compounds are considered excellent candidates as they combine high saturation magnetisation, high Curie temperature, half-metallicity and ultralow Gilbert damping, especially when grown epitaxially with decent control over stoichiometry to ensure the desired chemical ordering [1]. However, downscaling towards microstructures is a challenge in which the fabrication of high-quality ultrathin films with consistent excellent properties is a crucial step. We succeeded in the epitaxial growth of high-quality Co₂MnSi Heusler films in the thickness range of 4-44 nm for all of which the half-metallicity was confirmed [2]. Consequently, an ultralow Gilbert damping was obtained for the whole series reaching down to  $7.8 \times 10^{-4}$  for the 8 nm film. Coupling effects and magnetisation dynamics in heterostructures are currently under investigation.

△E-Effect Magnetic Field Sensors — •BENJAMIN SPETZLER, ELIZAVETA GOL-UBEVA, PATRICK WIEGAND, ROBERT RIEGER, JEFFREY MCCORD, and FRANZ FAUPEL — Kiel University, Kiel, Germany

Many conceivable biomedical and diagnostic applications require the detection of small-amplitude and low-frequency magnetic fields. Against this background, we investigate a magnetometer concept based on the magnetoelastic  $\Delta E$  effect. The  $\Delta E$  effect causes the resonance frequency of a magnetoelastic resonator to detune in the presence of a magnetic field, which can be read out electrically with an additional piezoelectric phase. Various microelectromechanical resonators are experimentally analyzed in terms of the  $\Delta E$  effect and signal-and-noise response, and models are developed and extended where necessary to identify current limitations. Although a large  $\Delta E$  effect is confirmed in the shear modulus, the sensitivity of classical cantilever resonators does not benefit from this effect. An approach utilizing surface acoustic shear waves provides a solution and can detect small signals over a large bandwidth. Comprehensive analyses of the quality factor and piezoelectric material parameters indicate methods to increase sensitivity and signal-to-noise ratio significantly. The latter is currently limited by the loss of the magnetic material. First exchange-biased  $\Delta E$ -effect sensors pave the way for compact setups and arrays with a large number of sensor elements. The insights gained lead to a new resonator and processing concept that can circumvent several previous limitations with prospects for sensor improvements in the future.

High-contrast mapping of atomic-scale spin-textures — •LUCAS SCHNEIDER, PHILIP BECK, JENS WIEBE, and ROLAND WIESENDANGER - Department of Physics, University of Hamburg, D-20355 Hamburg, Germany

A scanning tunneling microscope (STM) with a magnetic tip that has a sufficiently strong spin polarization can be used to map the sample's spin structure down to the atomic scale [1] but usually lacks the possibility to absolutely determine the value of the sample's spin polarization. Magnetic impurities in superconducting materials give rise to pairs of perfectly, i.e., 100%, spin-polarized subgap resonances. In this talk, I will present a method exploiting this effect by functionalizing the apex of a superconducting Nb STM tip with such impurity states [2]. These tips can be used to probe the spin polarization of atommanipulated Mn nanomagnets on a Nb(110) surface. By comparison with spinpolarized STM measurements of the same nanomagnets using conventional Cr bulk tips, we demonstrate an extraordinary spin sensitivity and the possibility to measure the sample's spin-polarization values close to the Fermi level quantitatively with the new functionalized probes.

## MA 10: Non-Skyrmionic Magnetic Textures

Time: Monday 15:00-16:45

#### Invited Talk

MA 10.1 Mon 15:00 H47 Magnetic vortices: into the third dimension - •SEBASTIAN GLIGA - Swiss Light Source, Paul Scherrer Institute, 5232 Villigen PSI, Switzerland

Vortices are familiar phenomena in fluids and gases. In ferromagnets, they are naturally forming flux-closure states characterized by a curling of the magnetization around a very stable and narrow core. Over the past decades, vortex structures have been extensively studied in laterally confined thin-film elements owing to their rich dynamics [1].

Recently, non-destructive imaging of three-dimensional magnetic structures at the nanoscale has become possible. Using hard X-ray tomography [2], we

have uncovered three-dimensional structures forming closed vortex loops in a bulk magnet. Based on magnetic vorticity (a quantity analogous to hydrodynamic vorticity), we identified these configurations as magnetic vortex rings [3]. In contrast to theoretical predictions, the observed vortex rings exist as static configurations, rather than purely dynamic states.

Our results open possibilities for further studies of complex three-dimensional solitons.

MA 10.2 Mon 15:30 H47 High-Resolution Magnetic Imaging of Surface Magnetic Textures in Synthetic Antiferromagnets Using SEMPA — •MONA BHUKTA, TAKAAKI DOHI, M-A. SYSKAKI, ROBERT FRÖMTER, and MATHIAS KLÄUI — Institut für Physik, Iohannes Gutanberg Universität Maing Staudiogerung 7 Meing Cermany

Johannes Gutenberg-Universität Mainz, Staudingerweg 7, Mainz, Germany Magnetic skyrmions[1] are twisted spin configurations, which shows a nonzero skyrmion Hall angle when driven by current due to their topological nature[2], which is detrimental for applications. Skyrmions in synthetic antiferromagnet(SAFs), could suppress this effect owing to an overall zero topological charge. Recent observations of skyrmions in SAFs have opened the possibility for using skyrmions as a candidate for logic operations, data storage devices[3]. Here, we investigate different, more exotic spin textures in a SAF consisting of (CoFeB/Ir/CoFeB)n by using scanning electron microscopy with polarization analysis (SEMPA). The unique feature of SEMPA is especially effective on a SAFs enabling us to investigate the topological spin textures even in a fully compensated composition. We report high-resolved vortex-antivortex pairs in the SAF that are stable at zero magnetic fields and room temperature. Micromagnetic simulations of the investigated SAF stacks have been carried out to understand the way stabilize for these exotic spin textures as well as to explore the possible emergence of three-dimensional (3D) spin structures in the SAF multilayer system. #### MA 10.3 Mon 15:45 H47

Effects of static magnetic fields in antiferromagnetic ring-shaped spin chains — •YELYZAVETA A. BORYSENKO^{1,2,3}, DENIS D. SHEKA¹, JÜRGEN FASSBENDER², JEROEN VAN DEN BRINK³, DENYS MAKAROV², and OLEKSANDR V. PYLYPOVSKY1^{2,4} — ¹Taras Shevchenko National University of Kyiv, Kyiv, Ukraine — ²Helmholtz-Zentrum Dresden-Rossendorf e.V., Dresden, Germany — ³IFW Dresden, Dresden, Germany — ⁴Kyiv Academic University, Kyiv, Ukraine While antiferromagnets with the easy axis of anisotropy are considered to be ro-

bust against external magnetic fields of a moderate strength, strong-field-driven spin reorientations provide an insight into subtle properties of the material usually hidden by the high symmetry of the ground state. Here, we address theoretically the effects of curvature in the curvilinear antiferromagnetic achiral anisotropic ring-shaped spin chains in strong magnetic fields. We identify the geometry-driven helimagnetic phase transition above the spin-flop field between the vortex and onion states. The spin-flop transition is of the first- or secondorder depending on the ring curvature, which is influenced by the geometryinduced Dzyaloshinskii–Moriya interaction. Inhomogeneity of the Néel vector distribution in spin-flop phase generates weakly ferromagnetic response, which lies in the plane perpendicular to the applied magnetic field. Our findings provide an understanding of complex responses of curvilinear antiferromagnets on magnetic fields and allow further experimental study of geometrical effects relying on spin-chain-based nanomagnets.

Screw dislocations in chiral magnets — •MARIA AZHAR¹, VOLODYMYR KRAVCHUK^{1,2}, and MARKUS GARST¹ — ¹Karlsruhe Institute of Technology, Germany — ²Bogolyubov Institute for Theoretical Physics of National Academy of Sciences of Ukraine, Kyiv, Ukraine

The Dyzaloshinskii-Moriya interaction stabilizes helimagnetic order in cubic chiral magnets for a large range of temperatures and applied magnetic field. In

#### Monday

this helimagnetic phase the magnetization varies only along the helix axis, that is aligned with the applied field, giving rise to a one-dimensional periodic magnetic texture. This texture shares many similarities with generic lamellar order like cholesteric liquid crystals, for example, it possesses disclination and dislocation defects [1]. Here, we investigate both analytically and numerically screw dislocations of helimagnetic order. Whereas the far-field of these defects is universal, we find that various core structures can be realized even for the same Burgers vector of the screw dislocation. In particular, we identify screw dislocations with smooth magnetic core structures, that close to the transition to the field-polarized phase continuously connect either to vortices of the XY-order parameter or to skyrmion strings. In addition, close to zero fields we find singular core structure comprising a chain of Bloch points with alternating topological charge [2].

MA 10.5 Mon 16:15 H47

Chiral response of spin spiral states as the origin of chiral transport fingerprints of spin textures — •JONATHAN  $KIPP^{1,2}$ , FABIAN  $LUX^3$ , and YURIY MOKROUSOV^{2,3} — ¹Department of Physics, RWTH Aachen University, 52056 Aachen, Germany — ²Peter Gr\"unberg Institut and Institute for Advanced Simulation, Forschungszentrum J\"ulich and JARA, 52425 J\"ulich, Germany — ³Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Germany

To extend the commonly accepted yet simplifying and approximate picture of transport effects taking place in systems with spatially varying magnetization such as skyrmions, domain walls and multi-q states, it is important to understand the transport properties of the homochiral spin-spiral states, which are building blocks for these more advanced textures of different nature and dimensionality. In this work, by referring to phenomenological symmetry arguments based on gradient expansion and explicit calculations within the Kubo framework, we study transport properties of various types of spin-spirals in a two-dimensional model with strong spin-orbit interaction. Specifically, we focus on the contributions to the magnetoconductivity, planar Hall effect and anomalous Hall effect, which are sensitive to the sense of chirality of the spiral states. In particular, we analyze the emergence, symmetry, and microscopic properties of the result-ing chiral magnetoconductivity, chiral planar Hall effect and chiral Hall effect in terms of spin-spiral propagation direction, cone angle, spiral pitch and disorder strength.

 $MA \ 10.6$  Mon 16:30 H47 Single-crystal growth and low temperature properties of  $ErB_2 - \bullet$ CHRISTOPH RESCH¹, ANDREAS BAUER¹, GEORG BENKA², and CHRISTIAN PFLEIDERER¹ - ¹TU München Physik-Department, 85748 Garching, Germany - ²Kiutra GmbH, 81369 München, Germany

Single crystals of the hexagonal rare-earth diboride ErB₂ were synthesized by means of the self-adjusted flux travelling solvent optical floating zone technique and metallurgically characterized. The magnetic phase diagram of single crystalline ErB₂ was inferred from measurements of the specific heat, the magnetissation, the ac susceptibility, and the electrical transport for fields applied along major crystallographic axes. We find behavior characteristic of an easy-plane antiferromagnet below  $T_{\rm N}$  = 14 K. For magnetic fields applied along the hard out-of-plane axis we observe a spin-flip transition at  $B_{\rm N}$  = 12 T. Most notably, the Hall resistivity below  $T_{\rm N}$  for fields applied along the hard axis exhibits a large anomalous contribution that does not scale with the uniform magnetization. Possible origins include spin-chirality mechanisms and large Berry curvatures associated with a canted spin structure, or more exotic types of magnetic order.

## MA 11: Computational Magnetism 1

Time: Monday 15:00-17:00

MA 11.1 Mon 15:00 H48

**Monte Carlo modeling of magnetic crystals from graphical input** — MICHAEL GIGER, •AMADÉ BORTIS, MANFRED FIEBIG, and THOMAS LOTTERMOSER — Department of Materials, ETH Zurich

Magnetism in crystals can be described by a spin Hamiltonian which contains all the magnetic interactions between spins. The resulting magnetic properties of the material, like the spin-ordering or the critical behavior, can be derived from Monte Carlo simulations. The correct and efficient implementation of such a Hamiltonian into a computer program for the simulation is error-prone and time-consuming. Here, we present a tool where the magnetic interactions can be defined by connecting atoms in a three-dimensional visualization of a crystal. Our software then automatically generates an efficient code for the Monte Carlo simulations. All simulation parameters can be set in a graphical user interface. We will showcase our software by reproducing the magnetic order in the protoLocation: H48

typical antiferromagnet  $\rm Cr_2O_3$  as an example. Our tool thus makes Monte Carlo simulations of complex spin systems more accessible to non-specialist users.

MA 11.2 Mon 15:15 H48

AiiDA-UppASD: Automatic workflow engine for high-throughput mag-netic simulations and machine learning — •QICHEN XU^{1,2,3}, JONATHAN CHICO⁴, MANUEL PEREIRO², DANNY THONIG⁵, ERIK SJÖQVIST², OLLE ERIKSSON², ANDERS BERGMAN², and ANNA DELIN^{1,3} — ¹KTH Royal Institute of Technology, Stockholm,Sweden — ²Uppsala University, Uppsala, Sweden — ³Swedish e-Science Research Center, Stockholm,Sweden — ⁴Sandvik Coromant, Stockholm, Sweden — ⁵Örebro University,Örebro,Sweden

The ever-raising theoretical peak performance and accessibility of supercomputer resources bring automated simulations to a more important position for studies of magnetic materials properties. Recently, Huber et al. developed the

AiiDA framework. In order to perform high-throughput atomic spin dynamics (ASD) simulations and take advantage of AiiDA platform and its build-in DFT plugins, we introduce the AiiDA-UppASD plugin which allows users to access to the majority of the functionalities of the UppASD code within the AiiDA framework via a Python package. In addition, several robust built-in workflows are also provided for managing ASD simulations, handling possible errors, and providing common modular workchains. With these workflows, complex tasks like high-throughput simulations of magnetodynamic properties as well as the determination of spin-wave excitation spectra and magnetic phase diagrams can be performed in a very efficient manner. Meanwhile, a machine learning (ML) prepared data generation workflow is also designed in order to offer ASD-related databases for the ML community to benchmark and develop methods.

MA 11.3 Mon 15:30 H48 Calculation of magnetic properties using Green's functions in the LAPW basis — •HENNING JANSSEN^{1,2}, STEFAN BLÜGEL¹, GUSTAV BIHLMAYER¹, and ALEXANDER SHICK³ – ¹Forschungszentrum Jülich, Jülich, Germany – ²RWTH, Aachen, Germany — ³Czech Academy of Sciences, Prague, Czech Republic

Green's functions are a powerful tool for understanding responses and interactions, including the magnetic properties, in materials.

A method for calculating Green's functions utilizing the Kramers-Kronig transformation is presented. The implementation of this method in the linearized augmented plane-wave basis, as implemented in the Fleur code [1], is especially suited for orbitals mainly localized inside the Muffin-tin regions around the atoms. These Green's functions are used to calculate magnetic properties including the Heisenberg exchange constants J_{ij} or the Dzyaloshinskii-Moriya Interaction (DMI) using force-theorem methods [2] and non-collinear torques. Results for these calculations are shown for bulk systems of iron and Co/Pt films.

The authors gratefully acknowledge the computing time granted by the JARA Vergabegremium and provided on the JARA Partition part of the supercomputer CLAIX at RWTH Aachen University.

MA 11.4 Mon 15:45 H48

Ab initio study of exchange interactions at planar defects of crystal lattices - •Martin Zelený¹, Monika Všianská², Denis Ledue³, Renaud Patte³ MIROSLAV ČERNÝ⁴, LADISLAV STRAKA⁵, and OLEG HECZKO⁵ — ¹Institute of Materials Science and Engineering, Faculty of Mechanical Engineering, Brno University of Technology, Brno, Czech Republic — ²Department of Chemistry, Faculty of Science, Masaryk University, Brno, Czech Republic - ³Normandie Université, UNIROUEN, INSA Rouen, CNRS, GPM, Saint Étienne du Rouvray, France $-\,^4$ Central European Institute of Technology, Brno University of Technology, Czech Republic — ⁵FZU - Institute of Physics of the Czech Academy of Sciences, Czech Republic

Planar defects play an important role in crystalline magnetic materials, because they serve as obstacles to magnetic domain wall motion. Atomistic description of the magnetic properties requires knowledge of exchange interaction parameters  $J_{ij}$  between two atomic sites. These parameters can be found in literature for many bulk magnetic materials. However, very little is known about  $J_{ii}$  in the vicinity of planar defects where the symmetry of crystal lattice is reduced and atoms have different chemical environment. We provide deep analysis of  $J_{ij}$ obtained from ab initio calculations in the vicinity of the clean  $\Sigma 5(310)$  grain boundary in bcc Fe as well as grain boundary with segregated P impurities. We analyze also  $J_{ij}$  parameters in the vicinity of twin boundaries and antiphase boundaries in Ni2MnGa magnetic shape memory alloys. Our results show strong influence of planar defects on exchange interactions.

#### MA 11.5 Mon 16:00 H48

Computationally Driven Evaluation of Magnetocrystalline Anisotropy — •Simone Köcher^{1,2} and Stefano Sanvito¹ — ¹School of Physics / CRANN, Trinity College Dublin, Ireland — ²IEK-9 - Fundamental Electrochemistry, Forschungszentrum Jülich, Germany

Custom-tailored magnetic materials are a crucial component in numerous modern technologies. The experimental search for new high-performance magnets can profit considerably from guidance by computational screening approaches, which however depend on reliable first-principle methods for calculating the key physical properties which underlie the magnetism of the material. One of them is the magnetocrystalline anisotropy (MCA), which contributes to the magnetic hardness.

For the well-studied X(acac)₃ (X = transition metal) coordination complexes we specifically explore and compare different methods for calculating the MCA: the finite energy difference approach (force theorem) within periodic boundary conditions and all-electron, full-potential perturbative approaches ranging from PT2 on PBE DFT to CASSCF-PT2 and NEVPT2. We explicitly study the influence of cluster geometry and various computational parameters at different levels of theory. Finally, we address the challenges involved in high-throughput MCA calculations for material screening applications.

#### MA 11.6 Mon 16:15 H48

Functional RG for Rydberg Array Spin Hamiltonians — •BENEDIKT SCHNEI-DER - Physics Department, Arnold Sommerfeld Center for Theoretical Physics, and Center for NanoScience, Ludwig Maximilian University Munich, 80333, Germany

Rydberg-Atom arrays are a versatile platform to simulate strongly correlated phenomena from spin liquids to lattice gauge theories. We develop a functional renormalization group approach based on Kitaev's pseudo-Majorana spin representation that produces quantitative accurate results for Rydberg array Hamiltonians at finite temperature. A special feature of our approach is that implementation of infinite lattices with long-range interactions and complicated lattice geometries is straightforward.

MA 11.7 Mon 16:30 H48 Hubbard interactions in 2D magnetic FePS₃ and CrI₃ - •FATEMEH  $\mathsf{Haddadi}^1, \ \mathsf{Edward} \ \mathsf{Linscott}^1, \ \mathsf{Marco} \ \mathsf{Gibertini}^2, \ \mathsf{Iurii} \ \mathsf{Timrov}^1, \ \mathsf{and}$ NICOLA ${\rm MARZARI}^1-{}^1{\rm THEOS}$  and MARVELL, EPFL, Lausanne, Switzerland ²University of Modena and Reggio Emilia, Modena, Italy

Hubbard-corrected density-functional theory has proven to be successful in addressing self-interaction errors in 3D magnetic materials. However, the effectiveness of this approach for magnetic 2D materials has remained elusive. Here, we use PBEsol+U and its extensions to investigate the electronic, structural, and vibrational properties of two 2D magnets: antiferromagnetic FePS3 and ferromagnetic CrI₃. Hubbard parameters are computed from first-principles using density-functional perturbation theory (DFPT) [PRB 98, 085127 (2018)], thus avoiding any empiricism. First, we show that for FePS3 the Hubbard corrections are crucial for obtaining the experimentally observed insulating state with the correct crystal symmetry. While empirical U can lead to instabilities, the Hubbard parameters from DFPT stabilize the ground state. We show that Hubbardcorrected vibrational frequencies are in good agreement with Raman experiments. Finally, we discuss 2D CrI₃, and the requirements it elicits in correcting separately the majority and minority bands.

MA 11.8 Mon 16:45 H48

Magnetism in strongly correlated twisted bilayers from first principles -•ADITYA PUTATUNDA and SERGEY ARTYUKHIN — Italian Institute of Technology, Genova, Italy

Twisted bilayer structures of van der Waals materials attract experimental and theoretical interest because of easy single layer exfoliation and processing and a variety of correlated states.1,2 Magnetic twisted bilayers hosting skyrmions have recently been demonstrated.3 Within first-principles approach, large supercells and tight convergence are required to compute magnetic interactions. Here we combine DFT and model simulations of Wannier function based tight-binding Hamiltonian to study the states in the twisted bilayer of CrI3.

## MA 12: Skyrmions 1 (joint session MA/KFM)

Time: Tuesday 9:30-12:45

#### Invited Talk

MA 12.1 Tue 9:30 H37 Topological spin structures at surfaces — • STEFAN HEINZE — Institute of Theoretical Physics and Astrophysics, University of Kiel, Germany

Magnetic skyrmions are of great interest for future applications ranging from data storage to neuromorphic computing [1]. Fundamental insight into the properties of skyrmions and the underlying microscopic interactions can be obtained by studying them at surfaces [2,3]. Here, I will discuss the stabilization, creation, and annihilation mechanisms of nanoscale topological spin structures based on density functional theory and atomistic spin simulations [4-8]. A novel

skyrmion annihilation mechanism, the Chimera collapse [4], is presented which has been confirmed by direct comparison with scanning tunneling microscopy (STM) experiments [5]. It is further shown that skyrmion stability can be tuned via applied electric fields [6] allowing writing and deleting of skyrmions. Higherorder exchange interactions (HOI) beyond Heisenberg exchange also play a role since they can stabilize skyrmion lattices [2] as well as isolated skyrmions or antiskyrmions [7]. Unexpectedly, HOI can induce not only non-collinear but also collinear two-dimensional multi-Q states observed via spin-polarized STM [8].

MA 12.2 Tue 10:00 H37

**Controlling Magnetic Skyrmion Nucleation and Motion** – •LISA-MARIE KERN¹, VICTOR DEINHART^{1,4}, KATHINKA GERLINGER¹, MICHAEL SCHNEIDER¹, DIETER ENGEL¹, CHRISTIAN GÜNTHER^{2,3}, KATJA HÖFLICH^{4,5}, RICCARDO BATISTELLI⁴, DANIEL METTERNICH⁴, FELIX BÜTTNER⁴, BASTIAN PFAU¹, and STEFAN EISEBITT^{1,3} – ¹Max-Born-Institut, Berlin, Germany – ²Zentraleinrichtung für Elektronenmikroskopie (ZELMI), Technische Universität, Berlin, Germany – ³Institut für Optik und Atomare Physik, Technische Universität, Berlin, Germany – ⁴Helmholtz Zentrum für Materialien und Energie, Berlin, Germany – ⁵Ferdinand-Braun-Institut, Berlin, Germany Magnetic skyrmions are topological quasiparticles, stabilized in out-of-plane magnetized multilayers. Great advances have been reported in generating, annihilating and shifting skyrmions via spin-orbit torque from spin-polarized cur-

rents. Optical nucleation with single laser pulses offers a possibly faster and more energy-efficient alternative. While the underlying mechanisms of the nucleation are different, both methods suffer from a certain stochasticity in the spatial distribution of the skyrmions nucleated. However, in view of scientific and practical applications, a controllable localization of the skyrmion's nucleation site is typically required. Nanopatterning of a tailored magnetic anisotropy landscape using He+-ions provides a promising platform for enhanced control of skyrmions in thin films. Based on this technique, we have recently demonstrated reproducible skyrmion nucleation and motion - a prerequisite for any fundamental or applied research on topological structures.

#### MA 12.3 Tue 10:15 H37

**Current-Induced H-Shaped Skyrmion Creation and Their Dynamics in the Helical Phase** – •ROSS KNAPMAN^{1,4}, DAVI R RODRIGUES², JAN MASELL³, and KARIN EVERSCHOR-SITTE^{4,5} – ¹Institute of Physics, Johannes Gutenberg University Mainz, 55128 Mainz, Germany – ²Department of Electrical and Information Engineering, Politecnico di Bari, 70126 Bari, Italy – ³RIKEN Center for Emergent Matter Science (CEMS), Wako 351-0198, Japan – ⁴Faculty of Physics, University of Duisburg-Essen, 47057 Duisburg, Germany – ⁵Center for Nanointegration Duisburg-Essen, University of Duisburg-Essen, 47057 Duisburg, Germany

A potential application of magnetic skyrmions is in racetrack memory devices. [1] While efforts have often been concentrated on the use of ferromagnetic and antiferromagnetic racetracks, previous work has suggested that the use of helimagnets could be more effective. [2] Here, the helices provide a means to naturally confine the skyrmions to quasi-1D channels, mitigating the skyrmion Hall effect. They additionally allow for high-speed skyrmion motion. Moreover, inspired by previous works which demonstrated electric-current-controlled skyrmion injection at magnetic impurities, [3] we propose a method of creating skyrmions in a helical background. MA 12.4 Tue 10:30 H37

Skyrmion automotion in confined geometries for applications — •KILIAN LEUTNER¹, THOMAS BRIAN WINKLER¹, HANS FANGOHR^{2,3}, and MATHIAS KLÄUI¹ — ¹Johannes Gutenberg University, Institute for Physics, Staudinger Weg 7, 55128 Mainz, Germany — ²Max-Planck Institute for the Structure and Dynamics of Matter, Luruper Chaussee 149, 22761 Hamburg, Germany. — ³University of Southampton, SO17 1BJ, Southampton, United Kingdom

Magnetic skyrmions are promising candidates for energy-efficient applications due to their quasi-particle nature and their topological stabilization. We present here a new concept for a multi-turn sensor-counter based on skyrmions. The skyrmion-boundary force in confined geometries leads with the topologydependent dynamics to the effect of automotion in certain cases. Automotion describes the movement of magnetic structures without the supply of external energy. For our case, we describe and investigate this effect with micromagnetic simulations and the coarse-grained Thiele equation. Automotion has already been demonstrated for domain walls [1], but is not well explored in skyrmionic systems yet.

MA 12.5 Tue 10:45 H37 Walking Skyrmions — •Alla Bezvershenko and Achim Rosch — Institute

for Theoretical Physics, University of Cologne, 50937 Cologne, Germany We study the pinning - unpinning transition of the skyrmion lattice in bulk MnSi under applying a slowly oscillating transverse magnetic field. We model the system using an elastic model for skyrmion strings in the presence of pinning forces. With this effective model we show that the presence of a transverse magnetic

field reduces the critical current density needed to depin the skyrmion lattice,

reaching zero at the critical magnetic field value. Further, the complete phase diagram of this model will be discussed. Below the threshold amplitude, the skyrmion lines stay fully pinned. Upon increasing the amplitude, a so-called "walking" phase starts, where the skyrmion lines start to unpin. If in this phase a sufficiently large electric current is being applied, the skyrmion lattice starts to move. Obtained results are compared to the experimental data on the transverse susceptibility measurements for this system.

MA 12.6 Tue 11:00 H37

Small-angle neutron scattering of kinetically driven skyrmion lattice motion — •DENIS METTUS¹, ALFONSO CHACON¹, ANDREAS BAUER¹, SEBASTIAN MÜLBAUER², and CHRISTIAN PFLEIDERER¹ — ¹Physik-Department, Technische Universität München, D-85748 Garching, Germany — ²Heinz Maier-Leibnitz Zentrum (MLZ), Technische Universität München, Garching, Germany

Skyrmions are topologically non-trivial spin textures that exhibit an exceptionally efficient coupling to spin currents, notably spin-polarized charge currents and magnon currents as observed in MnSi, FeGe, and Cu₂OSeO₃. This raises the question for the microscopic mechanisms that control the pinning of the skyrmion lattice, and how they depend on the topology, electronic structure, and disorder. We report neutron scattering measurements of kinetically driven skyrmion lattice unpinning and motion by means of Time-Involved Small Angle Neutron scattering Experiment (TISANE). In our study we examined the unpinning process under changing field orientation for different materials including the metallic systems  $Mn_{1-x}Fe_xSi$  and the insulator  $Cu_2OSeO_3$ . We discuss our results in the light of methodological aspects of the TISANE technique and recent theoretical predictions of walking skyrmions.

MA 12.7 Tue 11:15 H37

Spin Wave Driven Skyrmions in Antiferromagnets — • MICHAEL LAU¹, WOLF-GANG HÄUSLER², and MICHAEL THORWART¹ – ¹I. Institut für Theoretische Physik, Universität Hamburg — ²Institute of Physics, University of Augsburg In a two-dimensional lattice of antiferromagnetically coupled classical magnetic moments of unit length it is theoretically possible to stabilize Skyrmions when appropriately adjusting the Dzyaloshinskii-Moriya interaction (DMI) and a uniaxial anisotropy. We present simulations on a discrete lattice which reveal that these Skyrmions can be moved by spin waves injected at one edge of the lattice. It is known that in ferromagnets spin waves are scattered by Skyrmions, imposing a driving force on them. In antiferromagnets, we find similar scattering of spin waves by Skyrmions, exerting a net driving force. However, contrary to ferromagnets, the driving force acts in the direction of spin wave propagation and the Skyrmion accelerates like a classical particle with finite mass, as typically found for antiferromagnetic solitons. Additionally, we exploit the fact that antiferromagnetic spin waves can appear left- or right handed and study the impact of spin waves of different polarizations on the Skyrmion. It turns out that chirality, frequency and amplitude of the spin waves all significantly influence the Skyrmion motion.

MA 12.8 Tue 11:30 H37

**Skyrmion lattice dynamics** — •DANIEL SCHICK, MARKUS WEISSENHOFER, LEV-ENTE RÓZSA, and ULRICH NOWAK — Universität Konstanz, Konstanz, Germany We investigate the movement of skyrmions in lattices by performing molecular dynamics simulations based on the Thiele equation [1], using different effective skyrmion-skyrmion interactions. We compare mean-square displacement and the dynamical orientational correlation function  $g_6(t)$  for different values of damping  $\alpha$  and different topological charges and find the topological charge to change the effect of damping on the examined quantities. Furthermore, we find that for finite topological charge, the mean-square displacement in low-density skyrmion lattices increases compared to free diffusion. By comparing to trivial topology, we can demonstrate the increase in mean-square displacement to be the result of the gyrocoupling of skyrmions.

MA 12.9 Tue 11:45 H37

Skyrmion Pinning Energetics in Thin Film Systems — RAPHAEL GRUBER¹, JAKUB ZÁZVORKA¹, •MAARTEN A. BREMS¹, DAVI R. RODRIGUES¹, TAKAAKI DOHI¹, NICO KERBER¹, BORIS SENG¹, MEHRAN VAFAEE-KHANJANI¹, KARIN EVERSCHOR-SITTE², PETER VIRNAU¹, and MATHIAS KLÄUI¹ — ¹Institute of Physics, Johannes Gutenberg-Universität Mainz, 55099 Mainz, Germany — ²CENIDE, University of Duisburg-Essen, 47057 Duisburg, Germany

Magnetic skyrmions in thin films have been shown to exhibit thermal diffusion, making them a promising system for applications in probabilistic computing [1] as well as Brownian computing [2]. In such applications, pinning effects are of crucial importance as the pinning strength is often comparable to thermal excitations and thus impacts the operation of skyrmion-based devices. Using thermal skyrmion dynamics, we characterize the pinning in a sample and ascertain the spatially resolved energy landscape [3]. To understand the mechanism of pinning, we image the skyrmion is pinned at its boundary (domain wall) and not as previously considered at its core. As a consequence, we find that the size-

dependence follows from different favorable overlaps of the skyrmion boundary with the pinning regions, which is supported by micromagnetic simulations. This allows us to switch pinning sites on and off by small tuning of external fields. [1] J. Zázvorka et al., Nat. Nanotechnol. 14, 658 (2019). [2] M. A. Brems et al., Appl. Phys. Lett. 119, 132405 (2021). [3] R. Gruber et al., under review (2021).

MA 12.10 Tue 12:00 H37

Coexistence of topologically distinct spin textures — •BÖRGE GÖBEL¹, JA-GANNATH JENA², STUART PARKIN², and INGRID MERTIG¹ — ¹Institut für Physik, Martin-Luther-Universität Halle-Wittenberg — ²Max-Planck-Institut für Mikrostrukturphysik, Halle

Over the last decade, the field of skyrmionics has attracted great research interest, as skyrmions (small, whirl-like spin textures) possess a topologically-induced stability that allows to consider them as the carriers of information in future data storage devices. However, due to their integer topological charge there are two major shortcomings of skyrmion-based racetrack storages: The skyrmions do not move parallel to a current and multiple skyrmions attract and repell each other.

A solution to these problems is the utilization of alternative magnetic nanoobjects that go beyond conventional skyrmions; see review [1]. In this talk, we show via simulations, Lorentz transmission electron microscopy measurements [2,3] and Hall transport measurements [4] that skyrmions, antiskyrmion and topologically trivial bubbles [5] can coexist in Heusler materials. They can even appear fractionally near the sample's edges [6]. We propose an advanced version of the racetrack storage device based on these results.

[1] BG et al. Physics Reports 895, 1-28 (2021), [2] Jena, BG et al. Nat. Com. 11, 1115 (2020), [3] Jena, BG et al. Science Advances 6, eabc0723 (2020), [4] Sivakumar, BG et al. ACS Nano 14, 13463 (2020), [5] BG et al. PRAppl. 15, 064052 (2021), [6] Jena, BG et al. Nat. Com. 13, 2348 (2022)

Several skyrmionic magnetic systems have been discovered since the first observation of skyrmions in a B20 compound MnSi. Only a few of them host not just

magnetism but also ferroelectricity and prominent examples are lacunar spinels  $GaV_4S_8$  and  $GaV_4Se_8$ . These bulk systems are rather unique, because they host Neel skyrmions, which are otherwise only observed in metallic multilayers. Detailed description of magnetic phenomena in the multiferroic spinels is challenging for theory due to correlations within the  $V_4$  clusters.

We study the role of the magnetic state of these clusters and electronic correlations for the Heisenberg and Dzyaloshinskii-Moriya interactions in V- and Mo-based lacunar spinels. The character of magnetic interactions is discussed in relation to the crystal symmetry and electronic properties derived from the V₄ molecular orbitals. Based on micromagnetic simulations, we determine the role of different interactions for the formation of magnetic textures.

Systematic identification and assessment of topological spin textures via saddle point searches — •HENDRIK SCHRAUTZER^{1,2}, GRZEGORZ KWIATKOWSKI¹, HANNES JÓNSSON¹, PAVEL F. BESSARAB^{1,3}, and STEFAN HEINZE² — ¹University of Iceland, Reykjavik, Iceland — ²Christian-Albrechts-University, Kiel, Germany — ³Linnaeus University, Kalmar, Sweden

Magnetic systems hosting topological textures such as skyrmions have been of great technological and fundamental interest in recent years. The growing zoo [1] of co-existing meta-stable states makes investigation of such systems challenging. Here, we present a methodology combining global optimization based on recursive traversing between energy minima via saddle points on the energy surface [2,3], and harmonic transition state theory. The methodology provides a systematic approach to predict previously unknown metastable states, identify their lifetime at a given temperature and compute kinetics of their mutual transformations. We apply the method to the widely studied Pd/Fe/Ir(111) skyrmionic system, parametrized using density functional theory, and predict a variety of new transition mechanisms and spin textures including skyrmions with chiral kinks [1], which have been unknown so far in this system.

Topology induced spin-wave modes in curved surfaces — •MICHAEL VOGEL¹, TIM MEWES², and CLAUDIA MEWES² — ¹Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Kassel, Germany — ²Department of Physics and Astronomy, University of Alabama, Tuscaloosa, USA

Extending the research of magnetization dynamics from planar two-dimensional structures into the third dimension [1] promises rich physics from theoretically predicted fast domain wall velocities beyond the walker breakdown [2] to Cherenkov-like effects for magnons[3]. Here we investigate the effects of curvature in soft-magnetic hemispheres by means of micromagnetic simulation. The resonant spin-wave spectrum is calculated for different geometries and the power-spectral density is evaluated. The interplay of the local curvature and the external field gives rise to new spin-wave modes at relatively high frequencies located a the edge of the three-dimensional objects.

### MA 13.2 Tue 9:45 H43

**Propagating Spin-Wave Spectroscopy Studies in a Millikelvin Temperature Environment** — •DAVID SCHMOLL, SEBASTIAN KNAUER, ROSTYSLAV SERHA, QI WANG, and ANDRII CHUMAK — University of Vienna, Faculty of Physics, Boltzmanngasse 5, A-1090 Vienna, Austria

Technological advancements in the access to millikelvin temperatures, combined with high-frequency microwave technology, allow first steps towards the investigation of individual magnons, as the corresponding quasi-particles of spin waves, in the field of quantum magnonics. Such experiments require millikelvin base temperatures, to ensure a thermal magnon-free system. We measured spin-wave propagation for external bias magnetic fields in the range of 300 mT to -300 mT at room temperature and at a base temperature of 45 mK. The results were obtained in a cryogenic propagating spin-wave spectroscopy setup, comprising a dilution refrigerator, a 9-1-1 T vector magnet, and a 65 GHz-rated VNA mea-

surement system. The spin-wave transmission was measured in a 70 mm  $\times$  2 mm  $\times$  5.65  $\mu$ m yttrium-iron-garnet (YIG) film on a 500  $\mu$ m-thick gadolinium-gallium-garnet (GGG) substrate in the Magnetostatic Surface Spin-Wave Configuration (MSSW), using a microstrip antenna PCB. The demonstration of spin-wave propagation at cryogenic temperatures, provides the technical capabilities and the platform for future investigations of individual magnons. Moreover, direct optical access to the dilution refrigerator allows millikelvin experiments in the field of hybrid opto-magnonic quantum systems.

MA 13.3 Tue 10:00 H43 Finite-element micromagnetic modeling of spin-wave propagation with the open-source package TetraX — •LUKAS KÖRBER^{1,2}, GWEN-DOLYN QUASEBARTH^{1,2}, ALEXANDER HEMPEL^{1,2}, ANDREAS OTTO², JÜRGEN FASSBENDER^{1,2}, and ATTILA KÁKAY¹ — ¹Helmholtz-Zentrum Dresden -Rossendorf, Dresden Germany — ²Fakultät Physik, Technische Universität Dresden

We present a finite-element-method (FEM) dynamic-matrix approach to efficiently calculate the dispersion and spatial mode profiles of spin waves propagating in waveguides with arbitrary cross section, where the equilibrium magnetization is invariant along the propagation direction. This is achieved by solving numerically a linearized version of the equation of motion of the magnetization only in a single cross section of the waveguide at hand. To compute the dipolar field, we present an extension of the well-known Fredkin-Koehler method to plane waves. The presented dynamic-matrix approach is implemented within our recently published open-source micromagnetic modeling package TetraX [1] which aims to provide user friendly and versatile FEM workflows for the magnonics community (not only for magnonics community, but FEM simulations in general), covering several classes of sample geometries and, in the near future, also antiferromagnets. As a brief introduction, this talk will include a short live-demo of TetraX.

Magnons in antiferromagnets: tools for transport and processing of information — •OLENA GOMONAY — 1Institute of Physics, Johannes Gutenberg University Mainz, Staudingerweg 7, 55128 Mainz, Germany

Magnonics as a concept of information processing with magnon spins is a promising alternative to spintronics, which manipulates electron-mediated spin currents. Magnons in antiferromagnets have further advantages of high limiting velocities and long propagation length compared to their ferromagnetic counterparts. Moreover, magnon currents in antiferromagnets, in contrast to ferromagnets, can carry both spin orientations and thus can be used for manipulation of the magnetic states. In my talk I discuss different aspects of magnonmediated transport in antiferromagnets and possible applications to information processing. I compare two mechanisms of the nonlocal spin transport observed in easy-plane and easy-axis antiferromagnets via spin-polarised eigenmodes and via magnon birefringence. Magnon birefringence effect can be also observed in the multidomain antiferromagnets with the pronounced magnetostriction. Interaction of magnons in such a case results in a paramagnetic downconversion and resonance excitation of different magnon modes. I show further how the spin-polarised magnons can be used for manipulation of the magnetic states in multilayered films.

A bifold theoretical approach to spin transport in 2D easy axis and easy plane antiferromagnets — •Verena Breнм and Alireza Qaiumzadeн — QuSpin, NTNU Trondheim, Norway

Due to their terahertz excitation spectrum and the absence of stray fields, antiferromagnetic insulators are great candidates for magnonic applications [1].

We model an antiferromagnet with homogenous DMI inspired by hematite  $\alpha$ -Fe₂O₃, that undergoes two phase transitions: For very low temperatures, there is no magnetization as the Néel vector lies in the plane, which corresponds to an easy axis anisotropy. At the Morin temperature, the Néel vector rotates out of plane, leading to a finite DMI-induced magnetization with the system being in an easy plane phase, until at the Néel temperature magnetic order is lost. Spin transport measurements across the Morin temperature [2] are exciting, since the magnonic modes show an anisotropy-dependent polarization [3], which has an impact on the transported angular momentum [4].

In this talk, we demonstrate both analytically and numerically (micromagnetic simulations [5]), how the magnon polarization impacts the spin transport signal across the Morin transition, in connection to Néel vector dynamics and dispersion relation analysis.

**Employing magnons for generating multi-qubit entangled states for quantum error correction** — IDA SKOGVOLL¹, JONAS LIDAL¹, JEROEN DANON¹, and •AKASHDEEP KAMRA^{2,1} — ¹Center for Quantum Spintronics, Norwegian University of Science and Technology, Trondheim, Norway — ²Condensed Matter Physics Center (IFIMAC) and Departamento de Física Teórica de la Materia Condensada, Universidad Autónoma de Madrid, Madrid, Spain

The ongoing rapid progress towards quantum technologies relies on new hybrid platforms optimized for specific quantum computation and communication tasks, and researchers are striving to achieve such platforms. We study theoretically a spin qubit exchange-coupled to an anisotropic ferromagnet that hosts magnons with a controllable degree of intrinsic squeezing. We find this system to physically realize the quantum Rabi model from the isotropic to the Jaynes-Cummings limit with coupling strengths that can reach the deep-strong regime. We demonstrate that the composite nature of the squeezed magnon enables concurrent excitation of three spin qubits coupled to the same magnet. Thus, three qubit Greenberger-Horne-Zeilinger and related states needed for implementing Shor's quantum error-correction code can be robustly generated. Our analysis highlights some unique advantages offered by this hybrid platform, and we hope that it will motivate corresponding experimental efforts.

## MA 13.7 Tue 11:00 H43

Long-range quantum entanglement between two distant ferromagnets mediated by dipol-dipol interaction — •DENNIS WUHRER, NIKLAS ROHLING, and WOLFGANG BELZIG — Universität Konstanz, D-78457 Konstanz, Germany Recently the quantum states of an antiferromagnet in the spin wave approximation have been identified as two-mode squeezed sublattice-magnon states. The massive sublattice entanglement leads to a non-trivial structure of the two-mode squeezed vacuum in the magnetic Brillouin Zone.

Further the entanglement in synthetic antiferromagnets became of interest. It can be tuned by an applied magnetic field, but an extraction of squeezing pa-

rameters is difficult. In this talk we regard a system consisting of two distant 2D ferromagnets coupled via dipol-dipol interaction. The Bogoliubov transformation will be interpreted in terms of inter-/intra-layer squeezing and hybridisation parameters. Using the logarithmic negativity we derive an analytic formula to quantify the degree of entanglement for which we investigate the distance dependence due to the long-range interaction. Using the distance and an external field the entanglement can be manipulated from zero to large values and maintained over large distances. The prospect to transfer massive entanglement over large distances is discussed.

 ⁴Faculty of Physics, University of Vienna, A-1090 Vienna, Austria

Generally, magnon Bose-Einstein condensation (BEC) is achieved by increasing the particle density. Previously, it was shown that the rapid cooling of yttriumiron garnet/Pt nanostructures, preheated by an electric current passed through the Pt layer, leads to an imbalance between the magnon and the phonon system. Consequently, magnon BEC is triggered by the excess of magnons.

We report on the additional contribution of the spin Hall effect (SHE), generating a spin current in the Pt layer. Depending on the orientation of the electric current and the applied field, the SHE injects or annihilates magnons. We find that the SHE contribution prevents or promotes the rapid-cooling induced magnon BEC, changing the BEC threshold by -8% to +6% depending on the current polarity. These results demonstrate a new method for controlling macroscopic quantum states and pave the way for its application in spintronic devices.

#### MA 13.9 Tue 11:30 H43

Confinement of Bose-Einstein magnon condensates in adjustable complex magnetization landscapes — •MATTHIAS R. SCHWEIZER, ALEXANDER J.E. KREIL, GEORG VON FREYMANN, ALEXANDER A. SERGA, and BURKARD HILLE-BRANDS — Fachbereich Physik and Landesforschungszentrum OPTIMAS, TU Kaiserslautern, Kaiserslautern, Germany

We demonstrate the capability to control a room-temperature magnon Bose-Einstein condensate (BEC) by spatial modulation of the saturation magnetization. We use laser heating in combination with a phase-based wavefront modulation technique to create adjustable temperature patterns in an yttrium-irongarnet film. The increase in temperature leads to a decrease of the local saturation magnetization and in turn to the modification of the corresponding BEC frequency. Over time, a phase accumulation between different BEC-areas arizes, leading to phase-driven magnon supercurrents.

The BEC is created by microwave parametric pumping and probed by Brillouin light scattering spectroscopy. We observe a strong magnon accumulation effect caused by magnon supercurrents for several distances between heated regions. This accumulation effect manifests in the confinement of the magnon BEC, which exhibits an enhanced lifetime due to the continuous influx of magnons. The experimental results are supported by a numerical model, based on the hydrodynamic approximation of the Gross–Pitaevskii equation.

### MA 13.10 Tue 11:45 H43

New magnetostatic modes in biaxial magnets — •YUE SUN^{1,2}, CHANG-MIN LEE², LINDA YE³, SHINGO TOYODA^{1,2}, VERONIKA SUNKO^{1,2}, JOSEPH CHECKELSKY⁴, and JOSEPH ORENSTEIN^{1,2} — ¹University of California, Berkeley, Berkeley, California, USA — ²Lawrence Berkeley National Laboratory, Berkeley, California, USA — ³Stanford University, Stanford, California, USA — ⁴Massachusetts Institute of Technology, Cambridge, Massachusetts, USA

Easy-plane antiferromagnets have been demonstrated to have long-distance magnon propagation and flexible control of ultrafast magnetic dynamics. However, exact XY systems are rare, and it is common to have a small in-plane crystalline easy-axis, which leads to the great interest in biaxial magnets. Spin superfluidity has been predicted in biaxial antiferromagnet in an applied magnetic field. Here, we discover new magnetostatic modes in both biaxial ferromagnet and antiferromagnet, where the interesting biaxial anisotropy opens new ranges for magnon frequency. We observe the new magnetostatic modes in biaxial ferromagnet Fe₃Sn₂, and the prediction of the magnetostatic modes in biaxial antiferromagnet matches with the experimental observations in CrSBr. Comparing to the spin wave induced by the exchange interaction, the magnetostatic modes dominate in the long wavelength limit and offer a unique possibility to observe magnon Bose-Einstein condensation in biaxial antiferromagnet.

## MA 13.11 Tue 12:00 H43

Features of magnon spectra in conductive altermagnet: ab initio calculations — •Alberto Marmodoro¹, Ondřej Šipr^{1,2}, and Tomas Jungwirth¹ —¹Institute of Physics (FZU) of the Czech Academy of Sciences, Prague, Czech Republic —  2 New Technologies Research Centre, University of West Bohemia, Pilsen, Czech Republic

Altermagnets [1] are materials with zero net magnetization, alike traditional antiferromagnets, as well as a characteristic alternation of spin polarization for the electronic structure in reciprocal space, due to the relative orientation for anisotropic crystal field effects on different magnetic sublattices in direct space. This may have significant implications for possible spintronics and nanoelectronics applications. We report on ongoing work for the ab initio study of transverse magnon excitations in the case of the conducting, colinear antiferromagnetic altermagnet material RuO2

Beating Fabry-Pérot interference pattern in a magnonic scattering junction in the graphene quantum Hall ferromagnet - •JONATHAN ATTEIA^{1,2} FRANÇOIS PARMENTIER³, PREDEN ROULLEAU³, and MARK-OLIVER GOERBIG² Faculty of Physics, University of Duisburg-Essen, 47057 Duisburg, Germany - ²Laboratoire de Physique des Solides, Université Paris Saclay, CNRS UMR 8502, F-91405 Orsay Cedex, France – ³SPEC, CEA, CNRS, Université Paris-Saclay, CEA Saclay, F-91191 Gif sur Yvette Cedex, France

At filling factor  $v = 0, \pm 1$ , the ground state of graphene is a particular SU(4) ferromagnet which hosts a rich phase diagram along with several spin, pseudospin or "entanglement" magnon modes. Motivated by recent experiments, we study a v = -1|0| - 1 Fabry-Pérot magnonic junction. If the ground state at v = 0is spin polarized, there exist two spin modes which interfere and create a beating pattern, while pseudospin modes are reflected. The same scenario occurs for pseudospin magnon if the v = 0 ground state is pseudospin polarized. The observation of such an interference pattern would provide information on the low-energy anisotropies and thus on the ground state.

## MA 14: Cooperative Phenomena: Spin Structures and Magnetic Phase Transitions

Time: Tuesday 9:30-12:00

### **Invited Talk**

MA 14.1 Tue 9:30 H47 Overriding universality of ferromagnetic phase transitions through nanoscale materials design — •ANDREAS BERGER — CIC nanoGUNE BRTA, E-20018 San Sebastian, Spain

In recent years, significant interest has developed in magnetic thin films, in which the exchange coupling strength is ferromagnetic everywhere, but locally varying by means of nano-scale materials design. This interest is associated with the fact that such designed materials profiles translate into strongly varying magnetization states down to the 1-2 nm length scale, which is somewhat surprising, given that ferromagnetism is a collective phenomenon [1]. Correspondingly, such exchange-graded magnetic materials have shown themselves to be a very efficient way of modifying magnetic properties of otherwise rather conventional materials [1]. The most impressive result is hereby the possibility to tune critical exponents, in particular the magnetization onset exponent  $\beta$  in an extremely wide parameter range, which represents a unique way to override the universality usually associated with phase transitions of ferromagnets [2]. The same approach also enabled a complete separation of the temperature dependent onset of ferromagnetism at the Curie temperature from the onset of hysteresis, even in anisotropic materials [3], and it allowed for an enhancement of magnetocaloric properties [4]. Thus, exchange-graded materials are an extremely promising way to design the thermal evolution of magnetic properties and adapt it to device requirements. [1] Phys. Rev. B 98, 064404 (2018); [2] Phys. Rev. Lett. 127, 147201 (2021); [3] Phys. Rev. Appl. 16, 034038 (2021); [4] J. Phys. D 54, 304003 (2021).

Poisson-Dirichlet distributions and weakly first-order spin-nematic phase transitions — •NILS CACI¹, PETER MÜHLBACHER², DANIEL UELTSCHI², and STEFAN WESSEL¹ — ¹RWTH Aachen University, Aachen, Germany — ²University of Warwick, Coventry, United Kingdom

Weakly first-order transitions, i.e. discontinuous phase transitions with very large correlation lengths, have become a vivid subject in condensed matter research and beyond in recent years. Therefore, establishing quantum systems in which weakly first order phase transitions can be robustly demonstrated is of great interest. We present a quantitative characterization of generic weakly first-order thermal phase transitions out of planar spin-nematic states in threedimensional spin-one quantum magnets, based on calculations using Poisson-Dirichlet distributions (PD) within a universal loop model formulation, combined with large-scale quantum Monte Carlo calculations. In contrast to earlier claims, the thermal melting of the nematic state is not continuous, instead we identify a weakly first-order transition. Furthermore, we obtain exact results for the order parameter distribution and cumulant ratios at the melting transition. Our findings establish the thermal melting of planar spin-nematic states as a generic platform for quantitative approaches to weakly first-order phase transitions in quantum systems with a continuous SU(2) internal symmetry.

#### MA 14.3 Tue 10:15 H47

Derivation of Spin Hamiltonian by Algebraic Methods - •HIROSHI KATSUMOTO¹, FABIAN LUX^{1,2}, YURIY MOKROUSOV^{1,2}, and Stefan Blügel¹ ¹Peter Grünberg Institute and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — ²Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Germany

Complex magnetism is known to emerge from competing Heisenberg interactions and higher-order spin interactions [1]. In addition, previously unknown interactions such as the Chiral-Chiral interaction due to topological orbital magnetism turn also out to be essential to explain the magnetic properties [2]. HowLocation: H47

ever, a method for uniquely deriving spin Hamiltonians that captures the spin interactions of a given system has not yet been established. In this presentation, we give rigorous spin Hamiltonians for isotropic spin interactions for a given total localized spin S and the number of magnetic sites. The derivation of the spin Hamiltonian is based on the algebraic structure that the spin operators follow for arbitrary spin magnitude. By organizing the algebraic structure obeyed by the general spin operators, we discuss the construction of the exact spin Hamiltonian and the higher-order terms of interactions, especially for the cases S = 1/2and 1.

Ab initio approach to compute magnetic Gibbs free energies and phase transitions using magnetically constrained supercells - •EDUARDO MENdive Tapla^{1,2,3}, Nicolas Essing¹, Rudolf Zeller¹, Stefan Blügel¹, Jörg Neugebauer², and Tilmann Hickel² — ¹Forschungszentrum Jülich and JARA, 52425 Jülich, Germany-  $^2 \rm Max-Planck-Institut$  für Eisenforschung, 40237 Düsseldorf, Germany-  $^3 \rm Universitat$  de Barcelona, D-08028 Barcelona, Spain

We present a first-principles approach for the computation of the magnetic Gibbs free energy of materials using magnetically constrained supercell calculations [1]. Our approach, based on an adiabatic approximation for the local moment orientations [2], describes magnetic phase transitions and how electronic and magnetovolume mechanisms generate a discontinuous (first-order) character. Results obtained for bcc Fe and the triangular antiferromagnetic state of Mn₃AN (A = Ga, Ni) [3] will be presented and used to explain their negative volume expansion and the first-order nature observed experimentally. The performance of two different density functional theory codes, the Vienna Ab Initio Simulation package (VASP) and the linear-scaling KKR-nano code suitable for thousands of atoms (https://jukkr.fz-juelich.de), will be shown.

spin-reorientation in CuCr2S4 from muSR — •ELAHEH SADROLLAHI¹, JOCHEN LITTERST², LILIAN PRODAN^{3,4}, VLADIMIR TSURKAN^{3,4}, and ALOIS LOIDL³ -¹Institut für Festkörper- und Materialphysik, Technische Universität Dresden, Germany — ²Institut für Physik der kondensierten Materie, Technische Universität Braunschweig, Germany —  3 Institute of Physics, University of Augsburg, 86135 Augsburg, Germany —  4 Institute of Applied Physics, MD 2028, Chisinau, Republic of Moldova

Muon Spin Relaxation and Rotation (muSR) experiments have been performed on the thio spinel CuCr2S4 for further clarifying the long-standing controversy regarding its electronic and magnetic states [1,2]. Long regarded as ferromagnet (Tc=378 K) with magnetic moments residing only on Cr, CuCr2S4 is nowadays considered a ferrimagnetic with small magnetic moments on the Cu sites [3]. In addition to the transition at Tc, our muSR data reveal transitions around 50 K and 100 K with changes in spontaneous rotation signals and in relaxation behaviour. There is a close resemblance between these muSR results with those found for Fe1-xCuxCr2S4 with high Cu concentrations [4]. We interpret the transitions with spin re-orientations and will discuss the Jahn-Teller effect as a possible reason.[1] F. K. Lotgering et al., J. Phys. Chem. Solids 30, 799 (1969) and Solid State Commun. 2, 55 (1964). [2] J. B. Goodenough, Solid State Commun. 5, 577 (1967) and J. Phys. Chem. Solids 30, 261 (1969).[3] A. Kimura et al., Phys. Rev. #### MA 14.6 Tue 11:00 H47

identification of a new hidden-order phase in the magnetic phase diagram of  $Ce_3Pd_{20}Si_6 - \bullet F. MAZZA^1$ , P. Y. PORTNICHENKO², P. STEFFENS³, M. BOEHM³, E. S. CHOI⁴, M. NIKOLO⁵, S. PASCHEN¹, and D. S. INOSOV² - ¹TU Wien, Austria - ²TU Dresden, Germany - ³ILL, Grenoble, France - ⁴Florida State University, Tallahassee, USA - ⁵St. Louis University, USA

Magnetically hidden order is a hypernym for electronic ordering phenomena whose microscopic symmetry cannot be revealed with conventional neutron or x-ray diffraction. In a handful of *f*-electron systems, the ordering of odd-rank multipoles leads to order parameters with a vanishing neutron cross-section. Among them, Ce₃Pd₂₀Si₆ is known for its unique phase diagram exhibiting two distinct multipolar-ordered ground states (phases II and II'), separated by a fielddriven quantum phase transition. Using torque magnetometry at subkelvin temperatures, here we find another phase transition at higher fields above 12 T, which appears only for low-symmetry magnetic field directions. While the order parameter remains unknown, this discovery renders  $\mathrm{Ce}_3\mathrm{Pd}_{20}\mathrm{Si}_6$  the first known material with two metamultipolar phase transitions. They are both clearly manifested in the magnetic-field dependence of the field-induced (111) Bragg intensities measured with neutron scattering for **B** || [112]. Furthermore, the magnetic excitation spectrum suggests that the new phase II'' may have a different propagation vector in the vicinity of  $\mathbf{Q} = (010)$ , revealed by the minimum in the dispersion representing the Goldstone mode of this hidden-order phase.

Magnetic and thermodynamic properties of van-der-Waals CuCrP₂S₆ — •Kranthi Kumar Bestha^{1,2}, Laura Teresa Corredor Bohorquez¹, Vilmos Kocsis¹, Sebastian Selter¹, Saicharan Aswartham¹, Bernd Buechner^{1,2}, and Anja U. B. Wolter¹ — ¹Institute for Solid State Research, Leibniz IFW Dresden, 01069, Dresden, Germany — ²Institute of Solid State and Materials Physics and Wuerzburg-Dresden Cluster of Excellence ct.qmat, Technical University Dresden, 01062 Dresden, Germany

Two-dimensional van-der-Waals materials with intrinsic multiferroic properties are advantageous over 3D multiferroic materials for next generation nanoscale magnetic and electric devices. CuCrP₂S₆ is a quasi-2D vdW multiferroic candidate with magnetic and ferroelectric polarization arising from Cr and Cu sublattices, respectively. CuCrP₂S₆ exhibits intralayer ferromagnetic and interlayer antiferromagnetic interactions. M(T) and Cp(T) on single crystal CuCrP₂S₆ reveal antiferromagnetic interactions below the ordering temperature and short-range ferromagnetic correlations above  $T_N$ . Magnetic fields applied in the abplane exhibit a spin-flop transition at a relatively small magnetic field of 4.3 kOe with weak anisotropy in the ab-plane. For a clear understanding of the magnetic anisotropy of this material, in-plane and out-of-plane angular-dependent

dc magnetic studies were performed. Different symmetries are observed for both the in- and out-of-plane angular-dependent data. Our results are summarized in H-T phase diagrams for different main directions.

Probing magneto-elastic coupling in the quasi-2D van der Waals ferromagnet  $Cr_2Ge_2Te_6$  — •LAURA T. CORREDOR¹, BASTIAN RUBRECHT^{1,2}, TAKAHIRO SAKURAI³, HITOSHI OHTA⁴, ALEXEY ALFONSOV¹, SEBASTIAN SELTER¹, SAICHARAN ASWARTHAM¹, VLADISLAV KATAEV¹, ANJA U. B. WOLTER¹, and BERND BÜCHNER⁵ — ¹Institute for Solid State Research, Leibniz IFW Dresden, 01069 Dresden, Germany — ²Institute for Solid State and Materials Physics, TU Dresden, 01062 Dresden, Germany — ³Research Facility Center for Science and Technology, Kobe University, Kobe 657-8501, Japan — ⁴Molecular Photoscience Research Center, Kobe University, Nada, Kobe 657-8501 Japan — ⁵Institute of Solid State and Materials Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, 01062 Dresden, Germany

The first 2D uniaxial ferromagnetic semiconductor  $Cr_2Ge_2Te_6$  -with a layered structure-is promising for exciting new applications such as ultra-compact spin-tronics or magnonic devices, which need 2D long-range magnetic order as crucial feature. Since magnetocrystalline anisotropy is essential for the stabilization of magnetic order in 2D spin systems, the possibility to control it via a tunable external parameter-such as pressure or strain- can provide useful hints for the engineering of magneto-electric heterostructures with strained architectures. With this motivation, magnetization and ferromagnetic resonance (FMR) experiments under hydrostatic pressure on  $Cr_2Ge_2Te_6$  single crystals were performed. Insights on the magneto-elastic coupling and magnetic interactions with the increase of pressure are discussed.

MA 14.9 Tue 11:45 H47 Spin structure of Frenkel excitons on Cu²⁺-ions in the antiferromagnet  $CuB_2O_4$  revealed by magneto-absorption spectroscopy - •Dennis Kudlacık¹, Natalia E. Kopteva¹, Dimitri R. Yakovlev¹, Mikhail V. EREMIN³, ALEXEY R. NURMUKHAMETOV³, MANFRED BAYER¹, and ROMAN V. PISAREV² — ¹Experimentelle Physik 2, Technische Universität Dortmund, 44221 Dortmund, Germany — ²St. Petersburg, Russia — ³Kazan, Russia Frenkel excitons in magnetic insulators have attracted considerable interest in recent years as they allow the migration or transmission of a localized excitation. We have investigated this property which is reflected in the Davydov splitting of the exciton in the antiferromagnet copper metaborate,  $CuB_2O_4$  [1]. This magnetic insulator consists of two weakly interacting sublattices of Cu²⁺ ions. Below the Neel temperature of  $T_N = 21$  K its magnetic structure is dominated by the antiferromagnetic order of the 4b sublattice which comprises 4 Cu²⁺ ions twice degenerate in spin resulting in the formation of 8 collective charge-spin Frenkel-Davydov excitations. From a comparison of the experimental data with the results of the theoretical model we define the parameters of Frenkel exciton states, determine the electron-energy transfer between antiferromagnetically coupled copper spins as well as the anisotropic Cu²⁺ g-factors of ground and excited states.

An *ab initio* study of temperature effects on the optical and magneto-optical properties of ferromagnetic BCC Fe — •KISUNG KANG, DAVID G. CAHILL, and ANDRÉ SCHLEIFE — Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign, Urbana, Illinois 61801, USA

This work investigates the temperature-dependent optical properties of ferromagnetic BCC Fe in terms of electron, lattice, and magnetic temperatures. With the supercell approach, lattice and magnetic temperature is portrayed by the perturbed atomic and magnetic structures at finite temperature. In imaginary optical conductivity spectra at finite temperature, a large signal at low energy range is induced by phonon and magnon-assisted intraband transitions. We identify that this surging signal originates from the change of the dipole transition matrix elements. Magnetic temperature provokes a unique spectral change which is a redshift of the peak near 2.8 eV in the imaginary optical conductivity spectrum. From band unfolding analysis, it turns out that thermal demagnetization induces the reduction of exchange splitting in the electronic band structure, leading to the electron excitation with a smaller energy transition and explaining the peak redshifting. **Illinois MRSEC NSF DMR-1720633 Kisung Kang's present address: The NOMAD laboratory, Fritz-Haber-Institut der Max-Placnk-Gesellschaft, Faradayweg 4-6, 14195 Berlin, Germany Location: H48

An ab-initio parameterised spin model of hematite — •TOBIAS DANNEGGER¹, ANDRÁS DEÁK², SHUBHANKAR DAS³, E. F. GALINDEZ RUALES³, EUNCHONG BAEK³, MATHIAS KLÄUI³, LÁSZLÓ SZUNYOGH^{2,4}, and ULRICH NOWAK¹ — ¹Department of Physics, University of Konstanz — ²Department of Theoretical Physics, Institute of Physics, Budapest University of Technology and Economics ³

-  3 Institute of Physics, Johannes Gutenberg University Mainz-  4 MTA-BME Condensed Matter Research Group, Budapest University of Technology and Economics

The canted antiferromagnetic insulator hematite, known for motivating the theory of the Dzyaloshinskii–Moriya interaction [1, 2] as well as the first description of the Morin transition [3], is of interest in modern antiferromagnetic spintronics because of its long-distance spin transport properties [4]. We present an abinitio parameterised atomistic spin model of hematite that accurately reproduces its magnetic properties and phase transitions, and shows how dipole-dipole interactions play an important role in determining the transition between the antiferromagnetic and weak ferromagnetic phase. We compare our model's predictions with extensive experimental measurements on a hematite single crystal and find good quantitative agreement across a wide range of temperatures.

## MA 15.3 Tue 10:00 H48

The pyrochlore s = 1/2 Heisenberg antiferromagnet at finite temperature — •ROBIN SCHÄFER¹, IMRE HAGYMÁSI^{1,2}, RODERICH MOESSNER¹, and DAVID LUITZ¹ — ¹Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — ²Strongly Correlated Systems *Lendület* Research Group, Budapest, Hungary

We use state-of-the-art computational methods to investigate a frustrated threedimensional quantum spin liquid candidate, the pyrochlore s = 1/2 antiferromagnet at finite temperature.

Using a systematic cluster expansion based on tetrahedra, including clusters up to 25 lattice sites with nontrivial hexagonal and octagonal loops, we gain access to various thermodynamic properties in the thermodynamic limit at finite temperature. We found a pronounced maximum in the specific heat at T = 0.57J that is stable across finite size clusters and converged in the series expansion. At  $T \approx 0.25J$  (the limit of convergence of our method), the residual entropy per spin is 0.47 $k_{\rm B} \log(2)$ , which is relatively large compared to other frustrated models at this temperature.

The generality of this algorithm allows us to investigate realistic compounds: Using recent experimental data on the dipolar-octopolar pyrochlore  $Ce_2Zr_2O_7$ , we were able to determine possible regions for the exchange parameters which give an accurate description of the high temperature regime.

#### MA 15.4 Tue 10:15 H48

Stabilisation of external-magnetic-field-induced magnetisation switching with respect to thermal fluctuations — •GRZEGOR J. KWIATKOWSKI¹, MOHAMMAD H. A. BADARNEH¹, and PAVEL F. BESSARAB^{1,2} — ¹Science Institute of the University of Iceland, Reykjavík, Iceland — ²Department of Physics and Electrical Engineering, Linnaeus University, Kalmar, Sweden

As magnetic memory devices are the cornerstone of data storage, rapid global growth of information transfer creates a pressing need for faster and more energy-efficient memory devices. One of the important directions of research is focused on optimizing the magnetization switching protocols [1,2] showing that both the amplitude of the external pulse as well as the switching time can be significantly reduced in comparison to currently used ones. Before those ideas are implemented one needs to test reliability of the designed optimal pulses when thermal fluctuations are present.

We present the effect of thermal fluctuations on the success rate of magnetization switching induced by an optimized external magnetic field pulse [1]. Furthermore, using perturbation theory and direct numerical simulations we systematically study how to increase the probability of switching by modifying the external pulse depending on the system parameters, temperature and chosen switching time.

**Energy-efficient control of magnetization reversal in nanoparticles** — •MOHAMAMD BADARNEH¹, GRZEGORZ KWIATKOWSKI¹, and PAVEL BESSARAB^{1,2} — ¹Science Institute of the University of Iceland, 107 Reykjavik, Iceland — ²Department of Physics and Electrical Engineering, Linnaeus University, Kalmar, Sweden

Control of magnetization switching is of critical importance for the development of novel technologies based on magnetic materials. Here we identify by means of optimal control theory energy-efficient protocols for magnetization switching in nanoparticles with uniaxial and biaxial anisotropy [1]. Optimal control paths minimizing the energy cost of magnetization reversal are calculated as functions of the switching time and materials properties, and used to derive energy-efficient switching pulses of external magnetic field. Hard-axis anisotropy reduces the minimum energy cost of magnetization switching due to activation of the internal torque in the desired switching direction. Analytical estimates quantifying this effect are obtained based on the perturbation theory. The optimal switching time providing a tradeoff between fast switching and energy efficiency is obtained. The energy cost of switching and the energy barrier between the stable states can be tuned independently in a biaxial nanomagnet. This provides a solution for the dilemma between energy-efficient writability and good thermal stability of magnetic memory elements. This work was funded by the Icelandic Research Fund (Grant No. 217813-052). [1] G.J. Kwiatkowski et al., Phys. Rev. Lett. 126, 177206 (2021).

Exchange striction from first principles: how electron-phonon coupling modifies magnetic exchange — •RYOTA ONO and SERGEY ARTYUKHIN — Italian Institute of Technology, Via Morego, 30, 16163 Genoa, Italy

Electron-phonon coupling refers to interactions between electrons and lattice distortions. We investigate how such coupling affects interactions between spins in solids. Ionic displacements from equilibrium positions modify overlap integrals between magnetic ions and ligands and thus modulate magnetic exchange. By extracting the self-consistent potential in the first-order in ionic displacements within the Born-Oppenheimer approximation, we obtain a general formula of the change in the one-electron Hamiltonian (electron-phonon coupling). The realistic electron-phonon coupling parameters entering a model Hamiltonian are accessible thorough the constrained density functional perturbation theory [1]. Using the obtained parameters, we construct a multiband Hubbard-like model. Finally, realistic magnetic interactions are obtained through Anderson's superexchange theory.

MA 15.7 Tue 11:00 H48

**First principles theory of electron-magnon scattering and the spin polarized electron energy loss spectroscopy** — •SEBASTIAN PAISCHER¹, PAWEL BUCZEK², MIKHAIL KATSNELSON³, and ARTHUR ERNST¹ — ¹JKU Linz — ²HAW Hamburg — ³Radboud University Nijmegen

Magnetic solids constitute a very important class of materials as they are extensively used in everyday life and are essential to many new technologies currently under development. In spite of their high relevance, some of the basic properties, like the interaction between electronic and magnetic degrees of freedom still remain a mystery. It leads to spin dependent lifetimes of electronic states and inelastic electron transport to name but a few. In our current study we investigate the impact of magnetic excitations on the electronic spectrum of solids as well as the scattering of high energy electrons with magnetic materials to formulate an ab initio theory for the spin polarized electron energy loss spectroscopy (SPEELS). Our approach is formulated in the framework of the formally exact many body GW theory. The novelty in our approach is that quantities from linear response time dependent density functional theory (LRTDDFT) calculations will be used to approximate an effective interaction between electrons and magnons. As our LRTDDFT calculations are based upon the Korringa-Kohn-Rostocker method, bulk systems as well as complex geometries can be accounted for. In this presentation, we sketch the theoretical basis of the electron-magnon scattering as well as the SPEELS theory and show several results.

The Complex Magnetic Structure and Giant Topological Hall Conductivity in Kagome Metal YnMn₆Sn₆ — •HAO WANG¹, STEFAN BLÜGEL¹, and YURIY MOKROUSOV^{1,2} — ¹Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, Jülich, Germany — ²Institute of Physics, Johannes Gutenberg University Mainz, Mainz, Germany.

The discovery of topological Kagome magnets attracts enormous research interest in recent years. The typical band structure of a Kagome lattice includes a flat band and a Dirac point. The high localized electrons induced strong manybody interactions in the flat bands and the linear dispersion of the Dirac point could lead to many intriguing physical phenomena, such as the quantum anomalous Hall effects, superconductivity, and the non-Fermi liquid behavior. Furthermore, the relationship between the complex noncolinear magnetic structures and band topology of the Kagome magnets also deserves further exploration. In this work, using first-principles calculation and spin Hamiltonian analysis, we investigated the complex magnetic structures, phase transition, and topological Hall conductivity of the Kagome metal YMn6Sn6. We confirm that the ground state of this material is a double flat-spiral structure, and we demonstrate the important role of thermal fluctuation in the origin of the giant Hall conductivity. This work provides a platform to understand the complex magnetic structure and topological properties of Kagome magnets for future spintronic devices.

MA 16.4 Tue 15:45 H37

**An Exact Chiral Amorphous Spin Liquid** — •PERU D'ORNELLAS¹, TOM HODSON¹, GINO CASSELLA¹, JOHANNES KNOLLE^{1,2,3}, and WILLIAN NATORI⁴ — ¹Blackett Laboratory, Imperial College London, London SW7 2AZ, United Kingdom — ²Department of Physics TQM, Technische Universität München, James-Franck-Straße 1, D-85748 Garching, Germany — ³Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany — ⁴Institut Laue-Langevin, BP 156, 41 Avenue des Martyrs, 38042 Grenoble Cedex 9, France

The conventional wisdom has been that amorphous lattice structure would provide an obstacle to the formation of a long-range entangled ground states because of the inherent geometric disorder. Recently, symmetry protected topological phases have been proposed in non-interacting amorphous systems, raising the question of whether it is possible to construct a topologically ordered quantum many-body phase on an amorphous lattice. Here we provide such an example. We extend the Kitaev honeycomb Hamiltonian to amorphous lattices, constructed using the Voronoi method on a set of random points. The resulting model retains its exact solubility, displaying Abelian as well as a non-Abelian quantum spin liquid phases. However, the presence of plaquettes with an odd number of sides leads to a spontaneous breaking of time reversal symmetry, opening a gap in the non-Abelian phase. Furthermore, we show that the system undergoes a finite-temperature phase transition to a conducting thermal metal state. Possible experimental realisations in metal-organic frameworks are discussed.

## MA 16.5 Tue 16:00 H37

Hole Spectral Function of a Chiral Spin Liquid in the Triangular Lattice Hubbard Model — •WILHELM KADOW^{1,2}, LAURENS VANDERSTRAETEN³, and MICHAEL KNAP^{1,2} — ¹Department of Physics, Technical University of Munich, 85748 Garching, Germany — ²Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 München, Germany — ³Department of Physics and Astronomy, Ghent University, B-9000 Ghent, Belgium

Quantum spin liquids are fascinating phases of matter, hosting fractionalized spin excitations and unconventional long-range quantum entanglement. These exotic properties, however, also render their experimental characterization challenging and finding ways to diagnose quantum spin liquids is therefore a pertinent challenge. Here, we numerically compute the spectral function of a single hole doped into the half- filled Hubbard model on the triangular lattice using techniques based on matrix product states. At half filling the system has been proposed to realize a chiral spin liquid at intermediate interaction strength, surrounded by a magnetically ordered phase at strong interactions and a supercon-

ducting/metallic phase at weak interactions. We find that the spectra of these phases exhibit distinct signatures. By developing appropriate parton mean-field descriptions, we gain insight into the relevant low energy features. Our results suggest that the hole spectral function, as measured by Angle-Resolved Photoemission Spectroscopy (ARPES), provides a useful tool to characterize quantum spin liquids.

#### MA 16.6 Tue 16:15 H37

The nature of visons in the perturbed ferromagnetic and antiferromagnetic Kitaev honeycomb models — CHUAN CHEN¹ and •INTI SODEMANN VILLADIEGO^{2,3} — ¹Institute for Advanced Study, Tsinghua University, 100084 Beijing, China — ²Institut für Theoretische Physik, Universität Leipzig, 04103 Leipzig, Germany — ³Max-Planck Institute for the Physics of Complex Systems, 01187 Dresden, Germany

The Kitaev honeycomb model hosts a fascinating fractionalized state of matter that features emergent Majorana fermions and a vison particle that carries the flux of an emergent gauge field. In the exactly solvable limit, these visons are static, but perturbations can induce their motion.

We show that the nature of the vison motion is sharply distinct in the ferromagnetic vs the anti-ferromagnetic Kitaev models. Namely, in the ferromagnetic model the vison has a trivial non-projective translational symmetry, whereas in the anti-ferromagnetic Kitaev model it has a projective translational symmetry with pi-flux per unit cell. The visons of the FM case have zero Berry curvature, and no associated intrinsic contribution to the Thermal Hall effect. In contrast, in the AFM case and under a Zeeman perturbing field, there are two gapped vison bands with opposite Chern numbers and an associated intrinsic vison contribution to the Thermal Hall effect. We will comment on other results in the literature that are in disagreement with ours (arXiv:2109.00250, 2021) and discuss the potential connections of our findings to the physics of the spin liquid candidate alpha-RuCl_3.

 $\label{eq:main_matrix} MA 16.7 \ \mbox{Tue 16:30} \ \mbox{H37} \\ \mbox{Magnetism in a distorted kagome lattice: the case of Y-kapellasite} $-$ ALEKSANDAR RAZPOPOV^1, MAX HERRING^2, FRANCESCO FERARRI¹, IGOR MAZIN³, ROSER VALENTI¹, HARALD JESCHKE⁴, and JOHANNES REUTHER² $-$ ^1 Goethe University, Frankfurt, Germany $-$ ^2 Free University of Berlin, Berlin, Germany $-$ ^3 George Mason University, Washington DC, United States $-$ ^4 Okayama University, Okayama, Japan $-$ ^1 Context Context$ 

Compounds like the well-known Herbertsmithite are examples of the ideal spin-1/2 antiferromagnetic (AFM) kagome lattice which has one of the most interesting magnetic phase diagrams. However, while the perfect AFM kagome lattice has been extensively investigated, less is known about distorted kagome lattices.

Here we focus on an unexplored distorted spin-1/2 kagome lattice with three symmetry-inequivalent nearest-neighbor AFM Heisenberg couplings. The recently synthesized Y-kapellasite  $Y_3Cu_9(OH)_{19}Cl_8$  is a realization of such a distorted lattice. First, we analyse the classical magnetic phase diagram using analytical arguments and numerical methods, and find a rich classical phase diagram with a Q=0 magnetic phase, Q=(1/3,1/3) non-collinear coplanar magnetic phases and a classical spin liquid regime. In a second step we estimate the effective magnetic Heisenberg Hamiltonian by total-energy mapping analysis within the FPLO framework. Using the extracted Heisenberg Hamiltonian we predict Y-kapellasite to be localized in the Q=(1/3,1/3) phase which is stable after inclusion of quantum effects.

Thermodynamic and magnetic properties of the rare-earth delafossite  $NaGdS_2 - J$ USTUS GRUMBACH¹, MATHIAS DOERR¹, ELLEN HAEUSSLER², and SERGEY GRANOVSKY¹ - ¹Institut für Festkörper- und Materialphysik, Technische Universität Dresden, 01062 Dresden, Germany. - ²Fakultät für Chemie und Lebensmittelchemie, Technische Universität Dresden, 01062 Dresden, Germany Rare-earth delafossites are materials containing ideal triangular magnetic planes which are frustrated. Due to their properties, rare-earth delafossites are promising candidates for a QSL ground state. In recent years, research has focused on  $S = \frac{1}{2}$  delafossites where either QSL or AFM ground states occur, with transitions in the mK range (e.g. [1] vs. [2]).

Now a number of new measurements have been made on NaGdS₂ single crystals with the pure spin moment  $J = S = \frac{7}{2}$  of the Gd³⁺ magnetic ion. Measurements of several thermodynamic and magnetic properties were performed on very small samples (size ~  $\mu$ m) down to 40 mK. Essential physical data could be extracted which consistently show a magnetic ordered AFM ground state below ~200 mK.

## MA 16.9 Tue 17:00 H37

Single crystal study of the magnetic phase diagrams in  $BaCo_2(PO_4)_2 - \bullet XIAO$ Wang¹, Rohit Sharma¹, Petra Becker-Bohatý², Ladislav Bohatý², and Тномаs Lorenz¹ — ¹II. Physikalisches Institut, Universität zu Köln, Zülpicher Straße 77, Köln, Germany — ²Abteilung Kristallographie, Institut für Geologie und Mineralogie, Universität zu Köln, Zülpicher Straße 49b, Köln, Germany The study of the Kitaev materials has been an active area in the past decades, mainly motivated by their novel physical properties such as topological order, exotic excitations and potential application for quantum computing. Motived by recent theoretical proposals that Kitaev model might be realized in 3d transitionmetal compounds, we have successfully synthesized single crystal samples of  $BaCo_2(PO_4)_2$ . Our work on the high-quality  $BaCo_2(PO_4)_2$  sample unveils a sharp phase transition at ~3.5K which signals the evolution of antiferromagnetic long-range order in zero magnetic field. Such a transition is not observed in previous studies on polycrystalline  $BaCo_2(PO_4)_2$  [3], while for a  $T_N = 5.4$  K is reported for  $BaCo_2(AsO_4)_2$  [4]. Here we present a comprehensive study of the magnetic phase transitions by magnetization, specific heat and thermal expansion measurements and construct the magnetic phase diagram of BaCo₂(PO₄)₂. This work is funded by the DFG via CRC 1238 Projects A02 and B01.

MA 16.10 Tue 17:15 H37 **Resonant X-ray and neutron investigation of the double perovskite Nd_2ZnIrO_6** — •FABIAN STIER, MAREIN RAHN, and JOCHEN GECK — Institut für Material- und Festkörperphysik, TU Dresden, Deutschland We present a study of the magnetic order in the double perovskite Nd_2ZnIrO6 as a function of temperature and magnetic field. This material contains Ir with a formal valence of 4+, which is is very often described in terms of localized j=1/2 states. The magnetism of such j=1/2 states has attracted much attention, especially in relation to the possible formation of quantum spin liquids in actual materials. In order to elucidate the magnetism of the Nd 4f- and the Ir 5d-electrons in Nd2ZnIrO6, we performed resonant magnetic x-ray scattering and neutron powder diffraction. Below T_N=15 K we observe magnetic order with propagation vector (0.5 0.5 0) and moments in the ab plane. The temperature dependence reveals the Ir moment as the driving force of the magnetic ordering below T_N. Applying a magnetic field along the crystallographic a-direction at T=5K causes a metamagnetic transition to a phase with a propagation vector (0 0 0). Interestingly, applying the magnetic field along the crystallographic c-direction shows a linear field dependence.

MA 16.11 Tue 17:30 H37 Pressure induced multicritical behaviour in a kagome ferromagnet — •ARVIND MAURYA — Max Planck Institute for Solid State Research, Heisenbergstrasse 1, 70569 Stuttgart, Germany

We report high quality single crystal growth of ferromagnetURhSn, crystallizing in ZrNiAl- type hexagonal structure in which the magnetic U-atoms form potentially frustrated quasi-kagome two-dimensional net. Our measurements of electrical transport under hydrostatic pressures up to 11 GPa reveals two bicritical points concurrent at  $P_{\rm C}$  = 6.25 GPa corresponding to its successive double phase transitions ( $T_{\rm O}$  = 54 K,  $T_{\rm C}$  = 18 K at ambient). Rermakably, the intermediate phase remains hidden as local probes like neutron scattering and Mössbauer spectra do not capture any new feature across the  $T_{\rm O}$ . Our low temperature resistivity data under pressure points out a Fermi surface reconstruction across the  $P_{\rm C}$ , corresponding to an unconventional class of quantum phase transition involving multicritical points. This picture is further ascertained by gradual development of -lnT behavior in 5f-derived electrical resistivity and appearance of  $T^{5/3}$  dependence in the pressure induced phase.

## MA 17: PhD Focus Session: The Hitchhiker's Guide to Spin Phenomena at the Space and Time Limit

The growing hunger of society for fast data storage and processing, together with the end of Moore's law, demand the development of new technologies to implement smaller, faster and more power-efficient devices. Research in magnetic materials has shown the potential of spin-based devices in this regard. Pushing for 'More than Moore' devices, space and time limits need to be tackled. At the heart of this research are three fundamental operations: Control of magnetic order, spin transport and efficient monitoring of spin angular momentum in space and time. Topical clusters ranging from ferro- to antiferromagnets up to 2D materials, magnetic-organic interfaces and heterostructures are extensively studied. New materials and concepts are being developed rapidly which can appear very complex to someone new to the field. Young researchers often manage to get an overview of their own specific field but lack the big picture. For this reason, this PhD symposium will focus on talks in mostly tutorial-like style, yet will also include recent highlights. In addition, the symposium aims to exchange ideas and foster discussions on a broad range of spin phenomena.

Organizers: Yannic Behovits (Physics, Freie Universität Berlin and Fritz Haber Institute of the MPS), Mona Bhukta (Physics, Johannes Gutenberg University Mainz), Bikash Das Mohapatra (Physik, Martin-Luther-Universität Halle-Wittenberg), Oliver Gueckstock (Physics, Freie Universität Berlin and Fritz Haber Institute of the MPS), Hendrik Meer (Physics, Johannes Gutenberg University Mainz), Maximilian Paleschke (Physik, Martin-Luther-Universität Halle-Wittenberg), Eva S. Walther (Physics, Technische Universität Kaiserslautern).

Time: Tuesday 15:00-17:00

#### Invited Talk MA 17.1 Tue 15:00 H43 Ultimately fast, small and energy-efficient magnetism: fundamentals and prospects — •JOHAN MENTINK — Radboud University, Nijmegen, The Netherlands

Findings ways to switch between magnetically ordered states at the smallest possible length and time scale, while simultaneously dissipating the least amount of energy is a major challenge in magnetism. One of the most appealing routes to achieve this goal is by bringing a magnetic system strongly out of equilibrium, after which the dynamics is driven by exchange interaction, the strongest force in magnetism. Although this has been extensively discussed in ferrimagnetic systems, harnessing such exchange-driven dynamics in ferromagnets is fundamentally limited by angular momentum conservation. We will discuss basic models of magnetism that can be solved even under strongly nonequilibrium conditions and have been key to identify the mechanisms for ultrafast switching. We will exemplify this for chiral ferromagnets as studied by recent XFEL experiments. For this case, the nonequilibrium dynamics is driven by an additional antisymmetric exchange interaction, resulting in ultrafast nucleation of nanoscale magnetic skyrmions. This opens a new path for switching that is not only fast, but also can operate at the nanoscale. By comparing with the fundamental energy-speed limits for switching between physically distinct states, we will argue that such

exchange-driven dynamics can be key to achieve even faster, smaller and much more energy-efficient switching than demonstrated so far.

From spintronics at limiting temporal and spatial scales in antiferromagnets to an emerging altermagnetic phase — •TOMAS JUNGWIRTH — Institute of Physics, Czech Academy of Sciences and University of Nottingham, UK Magnetically ordered crystals are traditionally divided into two basic phases ferromagnetism and antiferromagnetism. In the first part of the talk, we will recall that the ferromagnetic order offers a range of phenomena and existing device applications, while the vanishing net magnetization in antiferromagnets is potentially favorable for temporal and spatial scalability of spintronic devices. In the second part of the talk we will move on to the recent predictions of instances of strong time-reversal symmetry breaking and spin splitting in electronic bands, typical of ferromagnetism, in crystals with antiparallel compensated magnetic order, typical of antiferromagnetism. This apparent fundamental conflict in magnetism is resolved by symmetry considerations that allow us to classify and describe a third basic magnetic phase. Its alternating spin polarizations in both crystal-structure real space and electronic-structure momentum space suggest a term altermagnetism. We will demonstrate that altermagnets combine merits of ferromagnets and antiferromagnets, that were regarded as principally incompatible, and have merits unparalleled in either of the two traditional basic magnetic phases. We will show that they underpin a development of a new avenue in spintronics based on strong non-relativistic spinconserving phenomena, without magnetization imposed scalability limitations, and with complex logic-in-memory functionalities.

## MA 17.3 Tue 16:00 H43

An electronic structure viewpoint on candidate van der Waals ferromagnets — •Phil King¹, Matt Watson¹, Brendan Edwards¹, Akhil Rajan¹, Jiagui Feng¹, Deep Biswas¹, Monica Ciomaga Hatnean², Amelia Hall², Geetha Balakrishnan², Giovani Vinai³, David Burn⁴, Thorsten Hesjedal⁵, Gerrit van der Laan⁴, Oliver Dowinton⁶, and Saeed Bahramy⁶ — ¹Univ. St Andrews — ²Univ. Warwick — ³Elettra synchrotron — ⁴Diamond Light Source — ⁵Univ. Oxford — ⁶Univ. Manchester

Control over materials thickness down to the single-atom scale has emerged as a powerful tuning parameter for manipulating both single-particle band structures and collective states of solids. Magnetism is a new frontier in the study of 2d materials. Here, I will show how direct measurement of the electronic structure using angle- resolved photoemission (ARPES) can lead to valuable insight not only into whether a 2d material exhibits long-range magnetic order, but also on its microscopic mechanisms. I will consider monolayer VSe₂, where a putative magnetic order is destabilised by the formation of a robust charge density wave,^{1,2} but can be re-established via proximity coupling;³ V_{1/3}NbS₂, where proximity coupling to the surface layer can lead to a modulation of spin-valley locking, and CrGeTe₃, an established van der Waals ferromagnet, where band structure measurements provide important microscopic insights even in a local

moment system.  4   1 Rajan et al., Phys. Rev. Materials 4 (2020) 014003;  2 Feng et al., Nano Lett. 18 (2018) 4493;  3 Vinai et al., Phys. Rev. B 101 (2020) 035404 ;  4 Watson et al., Phys. Rev. B 101 (2020) 205125.

Invited TalkMA 17.4Tue 16:30H43Nano-scale skyrmions and atomic-scale spin textures studied with STM —•KIRSTEN VON BERGMANN — Department of Physics, University of Hamburg,<br/>Germany

Non-collinear magnetic order arises due to the competition of different magnetic interactions. Often the dominant interaction is the isotropic pair-wise exchange between neighboring atomic magnetic moments. An additional sizable contribution from anisotropic exchange (Dzyaloshinskii-Moriya-Interaction) typically leads to spin spiral ground states in the absence of magnetic fields. In applied magnetic fields such systems can transition into skyrmion lattices or isolated skyrmions with diameters down to a few nanometers.

In zero magnetic field single skyrmions can arise as metastable states, stabilized by frustrated exchange interactions, which originate from competing nonnegligible exchange interaction to more distant magnetic moments [1]. Periodic two-dimensionally modulated magnetic states on the atomic scale can arise due to higher-order magnetic interactions. Such higher-order interactions can favor superpositions of spin spirals, so called multi-q states. Depending on the sample system atomic scale non-collinear magnetic lattices of different symmetry and size can form [2]. Higher-order interactions can also determine the type and width of domain walls in antiferromagnets [3].

## MA 18: Spintronics

Time: Tuesday 15:00-17:15

MA 18.1 Tue 15:00 H47

**Multilayer on-chip spintronic THz emitters** — •WOLFGANG HOPPE¹, MO-HAMED AMINE WAHADA², STUART S. P. PARKIN², and GEORG WOLTERSDORF¹ — ¹Institute of Physics, Martin Luther University Halle-Wittenberg, Von-Danckelmann-Platz 3, 06120 Halle, Germany — ²Max Planck Institute for Microstructure Physics, Weinberg 2, 06120 Halle, Germany

Nanometer thin ferromagnet/heavy metal bilayers illuminated by intense, short laser pulses have proven to be a reliable source for THz emission [1]. When integrated into a gold waveguide structure, the bilayer can be used as an on-chip source for ultrafast current pulses, ranging from the GHz to the THz regime [2]. One possible application is the switching of the magnetization of an adjacent magnetic layer [3]. A way to achieve the needed threshold current density is by increasing the amplitude of the current-pulses. This can be accomplished by stacking the bilayers, each separated by a thin MgO interlayer impeding the formation of any spin-currents in between the individual bilayers [4]. Here, the charge current in all bilayers can add, leading to an enhanced signal. We demonstrate an increase by a factor of three for the optimal stacking configuration. The multilayers are investigated by electro-optic sampling.

MA 18.2 Tue 15:15 H47

Ab initio studies of chiral crystals for generalized linear response transport and x-ray absorption spectroscopy — •ALBERTO MARMODORO¹, HUBERT EBERT², and ONDŘEJ ŠIPR^{1,3} — ¹Institute of Physics (FZU) of the Czech Academy of Sciences, Prague, Czech Republic — ²Department of Chemistry, Ludwig-Maximilians-University (LMU), Munich, Germany — ³New Technologies Research Centre, University of West Bohemia, Pilsen, Czech Republic

Materials with a chiral atomic arrangement exhibit specific electronic structure features [1]. The clock-wise or anti-clock-wise winding of sublattices has been associated with a radial spin texture of the Fermi surface in reciprocal space [2]. This provides interesting consequences for the response [3] to e.g. an applied electric field, for instance in terms of Edelstein effect and particularly its dependence on the sign of the perturbation. We report generalized linear response predictions [3] and theoretical x-ray spectroscopy cross-sections [4] for inorganic bulk crystals from first-principles studies performed within the frameworks of a spin-polarized relativistic Korringa, Kohn, Rostoker (SPRKKR) treatment.

MA 18.3 Tue 15:30 H47

Studying Spin Dynamics of Thin  $Cr_2Ge_2Te_6$ , using Superconducting Resonators — •Christoph W. Zollitsch¹, Safe Khan¹, Nam Vu Thanh Trung², Dimitrios Sagkovits¹, Ivan Verzhbitskiv², Goki Eda², and Hidekazu Kurebayashi¹ — ¹London Centre for Nanotechnology, University College London, London WC1H 0AH, United Kingdom — ²Department of Physics, National University of Singapore, 2 Science Drive 3, Singapore 117551

Two-dimensional van der Waals material systems gained an increased interest in the field of spintronics, as they can maintain ferromagnetic order even down to the few monolayer regime. These materials naturally permit device miniaturization. An ideal test bed for new spintronics applications in the 2D limit is the ferromagnetic semiconductor  $Cr_2Ge_2Te_6$ , where intrinsic ferromagnetism has been discovered for atomic bilayers [1].

We investigate the spin dynamics of thin exfoliated flakes (11 - 150 nm) of  $Cr_2Ge_2Te_6$ , using superconducting lumped element resonators made of NbN. The flakes are transferred directly on top of several superconducting resonator structures, featuring resonance frequencies from 12 GHz to 18 GHz. We perform ferromagnetic resonance (FMR) at a temperature of 1.8 K and can easily resolve the response from the flakes, even down to a thickness of 11 nm. With our multi-resonator approach, can confirm a Kittel FMR behaviour for the full thickness range. The FMR data can very well be described with bulk values of the magnetic parameters.

### MA 18.4 Tue 15:45 H47

Spin wave spectrum asymmetry from nonlocal chiral renormalization of gyromagnetic ratio — •IVAN ADO^{1,2} and MIKHAIL TITOV² — ¹Institute for Theoretical Physics, Utrecht University, 3584 CC Utrecht, The Netherlands — ²Institute for Molecules and Materials, Radboud University, 6525 AJ Nijmegen, The Netherlands

We present a new potential source of the spin wave spectrum asymmetry in metallic and semiconducting magnets. Such an asymmetry is often used to experimentally measure the Dzyaloshinskii-Moriya interaction (DMI) strength using Brillouin light scattering (BLS). We argue that there exists an additional contribution to the asymmetry that originates in coupling between magnetic moments and charge carriers. Moreover, this contribution is sensitive to electron scattering by impurities and depends on the parameters of the electron diffusive motion. We address the corresponding mechanism as "nonlocal chiral renormalization of gyromagnetic ratio". We analyze it both microscopically and using symmetry arguments, for a prototypical 2D metallic ferromagnet. The resulting contribution to the asymmetry scales quadratically with the scattering time and thus can be particularly strong in sufficiently clean systems. We suggest that experimental measurements of DMI by means of BLS may be inaccurate if one does not take this effect into account.

#### MA 18.5 Tue 16:00 H47

Influence of dusting layers on the magneto-ionic response of Ta/X/CoFeB/Y/MgO/HfO2 thin film stacks — •TANVI BHATNAGAR-SCHÖFFMANN¹, AURÉLIE SOLIGNAC², DJOUDI OURDANI³, ROHIT PACHAT¹, MARIA-ANDROMACHI SYSKAKI⁵, YVES ROUSSIGNÉ³, SHIMPEI ONO⁶, DAFINÉ RAVELOSONA⁴, JÜRGEN LANGER⁵, MOHAMED BELMEGUENAI³, and LIZA HER-RERA DIEZ¹ — ¹Centre de Nanosciences et de Nanotechnologies, CNRS, Université Paris-Saclay, 91120 Palaiseau, France — ²Université Paris-Saclay, CEA, CNRS, SPEC, 91191, Gif-sur-Yvette, France — ³Laboratoire des Sciences des Procédés et des Matériaux, CNRS-UPR 3407, Université Paris 13, Sorbonne Paris Cité, 93430 Villetaneuse, France — ⁴Spin-Ion Technologies, C2N, 10 Boulevard Thomas Gobert, 91120 Palaiseau, France — ⁵Singulus Technologies AG, Hanauer Landstrasse 103, 63796 Kahl am Main, Germany — ⁶Central Research Institute of Electric Power Industry, Yokosuka, Kanagawa 240-0196, Japan

Here,we present the room temperature magneto-ionic control of magnetic anisotropy, coercivity and DMI in Ta/X/CoFeB/Y/MgO/HfO2, where X and Y are dusting layers of heavy metal elements (Pt,W) sharing different interfaces with CoFeB. Dusting layers at the bottom interface (Y) can define a system locked in a PMA state allowing for a reversible magneto ionic control of coercivity, while samples with dusting layers at the top interface (X) can allow for a full and reversible spin-reorientation transition. The intercalation of dusting layers of heavy metal elements in Ta/CoFeB/MgO stacks has the potential to fine tune magnetic properties.

## MA 18.6 Tue 16:15 H47

Anisotropic magnetoresistance in systems with non-collinear magnetic order - • PHILIPP RITZINGER and KAREL VYBORNY — Institute of Physics of the Czech Academy of Sciences, Na Slovance 1999/2, 182 21 Prague 8, Czech Republic Since its discovery in 1857 by William Thomson, the anisotropic magnetoresistance (AMR) has been in focus of many theoretical studies seeking to understand the microscopic mechanisms of this effect. Most attention has been paid to ferromagnets (FMs) and recently, the scope of research on AMR is extended to include also antiferromagnets (AFMs). AMR can be due to anisotropic scattering (extrinsic) or an anisotropic Fermi surface (intrinsic). Here we focus on the latter, much less investigated intrinsic mechanism, which is achieved by considering non-collinear magnetic order inspired by real materials such as CrSe, delta-FeMn, Mn3Ge or RbFe(MoO4)2. We explore various types of lattices on toymodel level amongst which are trigonal, tetraedral or Kagome lattice. Magnetic moments can be arranged in many different ways on such lattices and seemingly small changes alter the Fermi surface symmetry, spin texture and transport properites. We have investigated systematically the influence of magnetic ordering on these properties which allows to predict general features of spin texture and transport by only considering the symmetry of the underlying system. As an example of these effects we have shown that AFM systems without spin-orbit coupling on Kagome lattices can develop anisotropy in the electric conductivity under applied in-plane magnetic field. This does not occur in FMs without spin-orbit coupling.

 rials Research, IFW Dresden, 01069 Dresden, Germany —  2 Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, 01062 Dresden, Germany —  3 Centro Atómico Bariloche and Instituto Balseiro, CNEA, 8400 Bariloche, Argentina —  4 Instituto de Nanociencia y Nanotecnología CNEA-CONICET, Argentina

Collinear antiferromagnetic (cAFM) materials can break the spin degeneracy in momentum space based on their magnetic symmetry, giving rise to the so called AFM-induced spin splitting. In this mechanism, spin splitting originates neither from a non-zero net magnetization (Zeeman effect) nor spin-orbit coupling (SOC) in noncentrosymmetric materials (Rashba-Dresselhaus effect), but from the magnetic symmetries. In this work, we performed a systematic analysis for 62 cAFM compounds and investigated the AFM-induced spin splitting without considering SOC. We established three measures to analyze the average spin splitting. Based on our measures, we identified the compounds with sizable spin splitting, such as  $CoF_2$  and  $FeSO_4F$ , and analyzed their electronic structure in detail. A similar analysis was performed for particular low-dimensional magnets, e.g.  $LiFe_2F_6$  and antiferromagnetic metals with spin splitting, e.g.  $RuO_2$ ,  $CrNb_4S_8$  and CrSb.

MA 18.8 Tue 16:45 H47

Superparamagnetic tunnel junctions for neuromorphic computing — •Leo Schnitzspan^{1,2}, Gerhard Jakob^{1,2}, and Mathias Kläui^{1,2} — ¹Institut für Physik, Johannes Gutenberg Universität Mainz — ²Max Planck Graduate Center, Mainz

Superparamagnetic tunnel junctions (SMTJ) are promising candidates for the implementation of neuromorphic computing. In a SMTJ, the magnetic free layer can switch its orientation induced by thermal activation, leading to a random two-level resistance fluctuation with relaxation times in the order of a few nanoseconds [1]. Their intrinsic stochastic behaviour and additional tunability by external magnetic fields, Spin Transfer Torques (STT) or Spin Orbit Torques (SOT) are key ingredients for low-energy artificial neurons in neural networks. Non-conventional computing, like inverse logic for integer factorization already has been demonstrated based on SMTJs[2]. Measurements of the characteristic stochastic switching behaviour are highlighted and the quality of randomness (according to NIST Statistical Test Suite) for a SMTJ as a potential true random number generator is evaluated. New possible implementation ideas of a stochastic neural network based on SMTJs are proposed and their efficiency is studied in detail.

MA 18.9 Tue 17:00 H47

Simulation of Polymer Spintronics — •Shih-Jye Sun — National University of Kaohsiung, Kaohsiung, Taiwan

We proposed a two-level model to simulate the spin-polarization current and the mobility in a field-effect transistor constructed by an antiferromagnetic-coupling polymer chain connected with the source, drain electrodes, and the oxide gate. This model is beyond the single-level model because of considering the inducing states in the polymer host by adding the magnetic functional side groups. We found that the double Coulombic excitations sensitively depend on the inducing states in the model significantly influencing the spin-polarization current and the mobility. Eventually, the workable organic spintronics can be realized based on our simulations.

Magnetic states in a nanocylinder of B20-type FeGe are studied using off-axis electron holography and micromagnetic simulations [1]. Considering the presence of a damaged layer on the surface of the nanocylinder, which results from focused ion beam milling during sample preparation, we achieved a quantita-

tive agreement between experimental and theoretical images. Remarkably, we identified one of the experimentally observed states as a dipole string composed of two Bloch points of opposite topological charge. 1. A.S. Savchenko et al., arXiv:2205.05753.

MA 19.2 Tue 17:30 P2

Imaging magnetization dynamics in ferromagnetic multilayer systems with Dzyaloshinskii-Moriya interaction, modified by local He+ irradiation — •ARNE VEREIJKEN¹, SAPIDA AKHUNDZADA¹, FLORIAN OTT¹, MAXWELL LI², TIM MEWES³, ARNO EHRESMANN¹, VINCENT SOKALSKI², and MICHAEL VOGEL¹ — ¹Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Kassel, Germany — ²Department of Materials Science and Engineering, Carnegie Mellon University, Pittsburgh, USA — ³Department of Physics and Astronomy, University of Alabama, Tuscaloosa, USA

The Dzyaloshinskii-Moriya interaction (DMI) is an asymmetric exchange interaction[1,2] promoting chiral coupling between spins, giving rise to robust, chiral, topological spin textures, e.g., skyrmions with outstanding properties for information storage and processing[3]. DMI may originate, e.g., from the interface between a ferromagnet and a heavy metal. Recently it has been demonstrated that the DMI at such interfaces can be tuned by irradiation with keV He+ ions[4]. In a systematic study, we investigated the influence of local He+ ion irradiation on the magnetization dynamics in a perpendicularly magnetized ferromagnetic/heavy metal multilayer system by high-resolution magneto-optical Kerrmicroscopy. Limits of skyrmion detection — •HAUKE LARS HEYEN¹, JAKOB WALOWSKI¹, MALTE RÖMER-STUMM², MARKUS MÜNZENBERG¹, and JEFFREY McCORD² — ¹Institut für Physik, Universität Greifswald, Felix-Hausdorff-Straße 6, 17489 Greifswald, Germany — ²Christian-Albrechts-Universität zu Kiel, Institute for Materials Science, Nanoscale Magnetic Materials and Magnetic Domains, 24143 Kiel, Germany

Skyrmion detection is an important feature for the implementation in storage media like e.g. racetrack memory. Kerr microscopy is well suited for the detection of skyrmions on the micrometer scale, but can not be miniaturised down to the nanometer scale. To compete with established storage media methods, miniaturisation of detection methods is essential. Magnetic tunnel junctions (MTJ) are a promising tool to detect small magnetisation changes.

The selected Ta/CoFeB/MgO material system allows to build MTJs integrated into tracks in which skyrmions can be generated and moved along using current pulses. This integration of MTJs into skyrmion racetracks remains challenging, even though they work fine independently. We employ Kerr microscopy to investigate the influence of MTJs on the skyrmion generation and propagation.

#### MA 19.4 Tue 17:30 P2

**Exchange- and Dzyaloshinskii-Moriya interactions in magnetic multilayers at surfaces** — •TIM DREVELOW, MARA GUTZEIT, and STEFAN HEINZE — Institute of Theoretical Physics and Astrophysics, University of Kiel, Leibnizstraße 15, 24098 Kiel, Germany

The coupling of magnetic skyrmions in synthetic antiferromagnets leads to a significant reduction of skyrmion Hall effect and therefore enhanced transports properies [1]. We investigate antiferromagnets based on Rh/Fe and Rh/Co bilayers on an Ir(111) surface, which have previously been grown on this surface [2,3]. With an additional magnetic layer of Fe or Co, we find that these systems realize a synthetic antiferromagnet as a potential host for magnetic skyrmions. Considerations on the symmetry of magnetic states in multilayer systems allow to compute both exchange and Dzyaloshinskii-Moriya interactions within and in between the magnetic layers with *ab initio* calculations using density functional theory.

#### MA 19.5 Tue 17:30 P2

High-resolution in-situ mapping of magnetization dynamics — •ARSHA THAMPI^{1,2}, FELIX LUCAS KERN¹, YEJIN LEE¹, DANIEL WOLF¹, ANDY THOMAS^{1,2}, and AXEL LUBR^{1,2} — ¹Leibniz IFW Dresden, D-01069 — ²Institute for Solid State and Materials Physics, TU Dresden, D-01069

Mapping of magnetization dynamics at the nanometer scale, which includes domain wall motion and also study on magnetic textures like skyrmions, is performed with time resolved measurements using transmission electron microscopy (TEM). On-chip microsized magnetic charged particle optical elements were developed for spatiotemporal electron beam modulation. The employed micro-coils with a diameter of about 80  $\mu$ m are combined with soft-magnetic cores and arranged as dipoles and quadrupoles. These micro-electromagnets can generate alternating magnetic fields of about ±100 mT up

to hundred MHz. They supply sufficiently large optical power and high-frequent beam manipulation to perform stroboscopic imaging. We discuss stroboscopic magnetization dynamics measurement employing either fast beam blanking or fast focusing. In order to study dynamics of magnetic structures, short electric pulses are applied by means of a sample holder that passes high frequencies. Current driven domain wall motion by spin torque effect is observed in a Nickel system by Lorentz TEM. The shift in domain walls is quantitatively analyzed depending on the current density and the heat deposited on the system. Highresolution mapping of magnetization dynamics can open the way to understand more on defects or pinning sites of domain wall.

#### MA 19.6 Tue 17:30 P2

Spin dynamics of skyrmion lattices in a chiral magnet resolved by microfocused Brillouin light scattering — PING CHE¹, •RICCARDO CIOLA², MARKUS Garst², Arnaud Magrez¹, Helmuth Berger¹, Thomas Schönenberger¹, Не<br/>NRIK Rønnow¹, and DIRK Grundler¹ — ¹École Polytechnique Fédérale de Lausanne, Lausanne (CH) -²Karlsruhe Institute of Technology, Karlsruhe (DE) Chiral magnets provide an innovative framework to study non-collinear spin textures and their associated magnetization dynamics. They include helical and conical magnetic textures that are spatially modulated with a wavevector  $k_h$ , as well as the topologically non-trivial skyrmion lattice (SkL) phase. So far, different techniques have been used to probe the magnetization dynamics of the latter SkL phase both in the small wavevector limit,  $k \ll k_h$ , as well as for  $k > k_h$ . Here, we show that Brillouin light scattering (BLS) is ideally suited to probe the complementary range of wavevectors  $k \leq k_h$ . We study both theoretically and experimentally BLS from bulk spin waves in the SkL phase of Cu2OSeO3. We provide parameter-free predictions for the BLS cross section and compute both the resonances and their spectral weight. The theoretical results are compared to BLS experiments in the backscattering geometry that probe magnons with a wavevector  $k = 48/\mu m < k_h = 105/\mu m$ . The clockwise, counterclockwise and breathing modes are clearly resolved. Due to the finite wavevector of the magnon excitations, finite spectral weight is theoretically predicted also for other resonances. Experimentally, at least one additional resonance can be identified.

#### MA 19.7 Tue 17:30 P2

Interplay of moderate magnetocrystalline anisotropies and skyrmion lattice order in  $\text{Fe}_{1-x}\text{Co}_x\text{Si} - \bullet$ DENIS METTUS¹, GRACE CAUSER¹, ALFONSO CHACON¹, ANDREAS BAUER¹, CHRISTIAN FRANZ¹, ANNA SOKOLOVA², SEBAS-TIAN MÜHLBAUER³, and CHRISTIAN PFLEIDERER¹ - ¹Physik-Department, Technische Universität München, D-85748 Garching, Germany - ²Australian Nuclear Science and Technology Organisation (ANSTO), Lucas Heights NSW 2234, Australia - ³Heinz Maier-Leibnitz Zentrum (MLZ), Technische Universität München, Garching, Germany

Cubic chiral magnets exhibit a universal magnetic phase diagram due to a hierarchy of energy scales comprising exchange interactions, Dzyaloshinsky-Moriya spin-orbit coupling and magnetocrystalline anisotropies (MCAs). In MnSi thermal Gaussian fluctuations stabilize a skyrmion lattice phase near  $T_c$  for all magnetic field orientations reflecting very weak MCAs [1,2]. In Cu₂OSeO₃, an additional skyrmion lattice phase stabilizes in the low temperature limit due to strong MCAs for magnetic field parallel  $\langle 100 \rangle$  [3]. We report a study of the interplay of moderate MCAs and disorder in Fe_{1-x}Co_xSi. Combining magnetometry and small-angle neutron scattering we observe a wide parameter range in which the effects of thermal fluctuations, MCAs and disorder stabilize skyrmion lattice order over an exceptionally wide parameter range depending on field orientation.

## MA 19.8 Tue 17:30 P2

Interactions between magnetic skyrmions — •László UDVARDI^{1,2} and Mátryás Török¹ — ¹Budapest University of Technology and Economics, Budapest Hungary — ²MTA-BME Condensed Matter Research Group, Budapest, Hungary

Recently magnetic skyrmions received considerable attention due to their potential in spintronic devices. Magnetic properties of skyrmions are often described by a classical Heisenberg model with tensorial couplings. We have developed a conjugate gradient method to find the local minima of the energy of a classical spin system. By analyzing the energy of an isolated skyrmion and of pair of skyrmions in the case of FePd bilayer on Ir(111) substrate¹ interactions can be derived as a function of the separation of the skyrmions. The knowledge of the pair interactions permits us to perform Monte Carlo simulations treating skyrmions as quasi particles.

**Realization of Shankar Skyrmions in magnetically frustrated platforms.** — •STEVEN SCHOENMAKER, RICARDO ZARZUELA, and JAIRO SINOVA — Johannes Gutenberg University, Mainz, Germany

Three-dimensional magnetic solitons are gathering momentum in the last few years due to their intrinsic complexity and their potential use in topological com-

puting and high-density memory storage. For instance, recent advances have led to the experimental observation of hopfions [1] and skyrmion strings [2] in collinear magnets. Shankar skyrmions [3], the condensed matter realization of skyrmions present in baryonic matter and of which magnetic skyrmions are a two-dimensional analog, can emerge in spin systems described by a SO(3)-order parameter, such as frustrated magnets (namely, magnetic systems with frustrated interactions dominated by isotropic exchange) [4]. Motivated by this possibility, we propose phenomenological and exactly solvable models for Shankar skyrmions in magnetically frustrated spintronic platforms and we also explore whether these topological textures form a crystal phase.

## MA 19.10 Tue 17:30 P2

Exploring the limitations of the micromagnetic framework with a stable Bloch point — •THOMAS BRIAN WINKLER¹, MARIJAN BEG², MARTIN LANG^{3,4}, MATHIAS KLÄUI¹, and HANS FANGOHR^{3,4} — ¹Institut für Physik, JGU Mainz — ²Department of Earth Science and Engineering, Imperial College London — ³Faculty of Engineering and Physical Sciences, University of Southampton — ⁴Max Planck Institute for the Structure and Dynamics of Matter Hamburg

Bloch points [1,2] are well-known magnetisation configurations that often occur in transient processes. However, recent simulations have shown that opposing chiralities of layers in a thin-film geometry can stabilise such magnetic Bloch points and make them equilibrium states [3], potentially opening the door towards Bloch point based spintronic applications [4]. An open question, from a methodological point of view, is whether the Heisenberg model approach (atomistic model) must be used to study such systems or if the – computationally more efficient – micromagnetic models can be used as well. In this work, we are investigating and comparing the energetics and dynamics of a stable Bloch point [3,4] obtained using both Heisenberg and micromagnetic approaches.

 $\begin{array}{ccc} MA \ 19.11 & Tue \ 17:30 & P2 \\ \textbf{Magnetocaloric effect in (La, Ce)(Fe, Si, Mn)_{13} with tunable, low transition \\ temperature - •M. \ STRASSHEIM^{1,2}, C. \ SALAZAR MEJIA^1, J. \ WOSNITZA^{1,2}, and T. \\ \ GOTTSCHALL^1 - ^1 Hochfeld-Magnetlabor \ Dresden (HLD-EMFL), HZDR, \ Dresden, \ Germany - ^2 \ Technische \ Universität \ Dresden, \ Dresden, \ Germany \\ \end{array}$ 

The La(Fe, Si)₁₃ family is one of the most promising group of magnetocaloric materials due to their overall good cost-benefit ratio in comparison to alloys based on scarce rare-earths such as Gd or Ho. By partly substituting La with Ce and Fe with Mn, the point of the metamagnetic transition can be tuned down to at least 40 K, while maintaining a rather sharp transition to enable a notable magnetocaloric effect. Tuning the magnetocaloric effect down to these temperatures opens up large-scale applications such as the magnetic liquefaction of hydrogen. In this work, we synthesized  $(La_{1-z}Ce_z)(Fe_{0.88-y}Mn_ySi_{0.12})_{13}$  with  $z = 0 \dots 0.4$ ,  $y = 0 \dots 0.04$  and determined the adiabatic temperature change in pulsed magnetic fields. For some samples, we calculated the magnetic entropy change using isothermal magnetization measurements.

## MA 19.12 Tue 17:30 P2

**Chemical Ordering and Phase Transition in all-d-metal Heusler alloy NiCoMnTi** — •DAVID KOCH¹, BENEDIKT BECKMANN¹, OLGA MIROSHKINA², NUNO M. FORTUNATO¹, MARKUS GRUNER², HONGBIN ZHANG¹, OLIVER GUTFLEISCH¹, and WOLFGANG DONNER¹ — ¹Institute of Material Science, Technical University of Darmstadt, 64287 Darmstadt Germany — ²Faculty of Physics and Center of Nanointegration, University of Duisburg-Essen, 47057 Duisburg Germany

Chemical ordering in NiMn-based Heusler alloys with magnetostructural phase transition is crucial for understanding the physics of the phase transition and is known for influencing the properties of the alloys. In the new field of all-d-metal Ni(Co)MnTi Heusler alloys, the experimental determination of chemical order is challenging due to the low difference in scattering power of the different elements. Here we report a combined approach of neutron and x-ray diffraction for an analysis of chemical order in Ni(Co)MnTi alloys and show that no Heusler-typical L21 order between Ti and Mn is present. Furthermore, Co and Ni atoms do not exhibit order among them; however, the martensitic phase transition and Curie temperature of Co containing samples can be shifted significantly by changing the degree of B2 order with a proper heat treatment. Using first-principles calculations, we reveal how the structural and magnetic sub-systems depend on the degree of B2 disorder. An outlook to further experiments on single crystals is given.

#### MA 19.13 Tue 17:30 P2

Simultaneous measurements of magnetocaloric materials in pulsed magnetic fields — •TINO GOTTSCHALL¹, EDUARD BYKOV^{1,2}, MARC STRASSHEIM¹, TIMO NIEHOFF^{1,2}, CATALINA SALAZAR-MEJIA¹, and JOCHEN WOSNITZA^{1,2} — ¹Dresden High Magnetic Field Laboratory (HLD-EMFL), HZDR, Dresden — ²Institut für Festkörper- und Materialphysik, TU Dresden, Germany

The direct determination of the adiabatic temperature change as a function of magnetic field and starting temperature is of central importance for a profound characterization of magnetocaloric materials. Recently, we developed a technique to measure the temperature change in pulsed magnetic fields directly and simultaneously also other properties such as strain and magnetization can be determined. In this work, we give an overview of the most recent results that have been obtained in pulsed fields at the Dresden High Magnetic Field Laboratory. This work was supported by HLD at HZDR, member of the European Magnetic Field Laboratory (EMFL) and the Helmholtz Association via the Helmholtz-RSF Joint Research Group Project No. HRSF-0045.

MA 19.14 Tue 17:30 P2

Tuning the magnetocaloric phase transition of  $La(Fe,Si)_{13}$  by rare earth doping — •JOHANNA LILL¹, BENEDIKT EGGERT¹, BENEDIKT BECKMANN², OLGA N. MIROSHKINA¹, ILIYA RADULOV², KONSTANTIN SKOKOV², JOSE R. LINARES MARDEGAN³, SONIA FRANCOUAL³, RICHARD BRAND¹, KATHARINA OLLEFS¹, MARKUS E. GRUNER¹, OLIVER GUTFLEISCH², and HEIKO WENDE¹ — ¹University of Duisburg-Essen, Duisburg, Germany — ²TU Darmstadt, Darmstadt, Germany — ³DESY, Hamburg, Germany

Magnetocaloric (MC) materials are promising environmentally friendly candidates to replace gas-compression refrigerants. There are many MC systems possessing a high MC effect by showing high adiabatic temperature or isothermal entropy changes, but goals are still to minimize hysteresis and to tune the phase transition (PT) temperature to room temperature (RT). Therefore, knowledge of electronic and magnetic interactions in different magnetic phases are essential, as these determine the PT properties. One promising MC material is  $La(Fe,Mn,Si)_{13}H$ , which has its PT temperature around RT after hydrogenation, stabilized by Mn-doping which increases thermal hysteresis. To tune its thermal hysteresis, we study the effect of rare earth doping in the (La,Ce,Nd)(Fe,Si)_{13} system and systematically investigate local electronic and magnetic properties in the different magnetic states utilizing e.g. XMCD and Mössbauer spectroscopy. With this study we present a deepened understanding of tuning local properties which may open new ways for tailoring hysteresis of MC materials. We acknowledge financial support from DFG through TRR270 HoMMage.

#### MA 19.15 Tue 17:30 P2

Insights into the magnetic structure of Mn-doped La(Fe,Si)₁₃ — •Benedikt Eggert¹, Johanna Lill¹, Olga N. Miroshkina¹, Konstantin Skokov¹, Katharina Ollefs¹, Markus E. Gruner¹, Oliver Gutfleisch², and Heiko Wende¹ — ¹Faculty of Physics and CENIDE, University of Duisburg-Essen — ²Functional Materials, TU Darmstadt

Magnetic cooling has the potential to replace conventional gas compression refrigeration. Here, materials such as FeRh, NiMn-based Heusler alloys or La(Fe,Si)13 exhibit a sizeable first-order magnetocaloric effect To further optimize the efficiency, it is necessary to tune the phase transition close to room temperature and reduce the thermal hysteresis. For La(Fe,Si)₁₃, it was shown that it is possible to tailor the phase transition towards room temperature by interstitial H-doping, while maintaining first-order character. In addition, Mn doping allows fine tuning of Tc to enlarge to temperature window of operation, inducing also second-order features. We discuss variations of the electronic and geometric structure in La(Fe,Si)13 with increasing Mn content by means of Mössbauer spectroscopy. Mössbauer measurements reveal a reduction of the Fe magnetic moment with increasing Mn concentration. A reduction and broadening of the hyperfine field distribution occurs for higher Mn-content, while in-field measurements indicate a non-colinear spin structure for high Mn-concentrations. We acknowledge the financial support through the Deutscheforschungsgemeinschaft wihtin the framework of the CRC/TRR270 HoMMage.

MA 19.16 Tue 17:30 P2

Thermally generated spin transport in Fe₃O₄/NiO/Pt trilayers — •JOHANNES DEMIR¹, STEFAN BECKER¹, PAULA BUNTE¹, LENNART SCHWAN², OLGA KUSCHEL³, JOACHIM WOLLSCHLÄGER³, and TIMO KUSCHEL¹ — ¹Bielefeld University, Germany — ²Bielefeld University of Applied Sciences, Germany — ³Osnabrück University, Germany

We investigate the spin Seebeck effect (SSE) in Fe₃O₄/NiO/Pt trilayers by varying the thickness of the antiferromagnetic NiO layer from 0 to 20 nm. Furthermore, we compare the SSE voltage normalized to the temperature difference to literature [1] and to the experimentally detected heatflux [2]. The Fe₃O₄/NiO bilayer is grown in situ by molecular-beam epitaxy, while the Pt layer is deposited ex situ by DC sputtering. We see an enhanced spin current signal in 0.5 and 1.1 nm NiO on 48 nm Fe₃O₄ for both normlizations. Moreover, we recognize a deviation from the simple exponential behaviour above 9.5 nm NiO thickness indicating a generation of spin current in NiO detectable for larger NiO thickness. Addi[1] L. Systematic variation of NiFe₂O₄ thin film lattice parameters by postannealing in oxygen atmosphere — •JULIAN STRASSBURGER, JAN BIEDINGER, OLIVER RITTER, TOBIAS PETERS, LUCA MARNITZ, KARSTEN ROTT, and TIMO KUSCHEL — Center for Spineletronic Materials and Devices, Bielefeld University, Germany

Nickel ferrite (NFO) is a ferrimagnetic insulator and a promising material for spin caloric applications [1,2,3]. In this study, twin samples of NFO thin films (45nm thick) were prepared on MgAl₂O₄ substrates by reactive DC magnetron sputter deposition. The samples were in-situ post-annealed in oxygen atmosphere at different temperatures. After cooling down to room temperature, one sample of each pair was capped by 3nm of Pt for future spin Seebeck effect studies. It was shown by x-ray diffraction analysis that the in-plane and out-of-plane lattice constants change systematically by varying the post-annealing temperature. A possible change of oxygen content in the samples was investigated by determining the unit cell volume and Possion's ratio from the lattice parameters as well as the optical band gap energy from optical spectroscopy data [4,5]. In a next step, the influence of systematically modified lattice parameters on thermally induced spin transport will be investigated.

The origin of S-shaped magnetizations and why the connection to toroidal moments is misleading — •DENNIS WESTERBECK, DANIEL PISTER, and JÜRGEN SCHNACK — Universität Bielefeld, D-33501 Bielefeld, Deutschland

Recent studies for toroidal molecules suggest a connection between low-lying toroidal states and an S-shaped magnetization [1]. We show that for theoretical models the S-shape neither is an evidence for a toroidal moment nor do all toroidal systems form S-shaped magnetizations [2]. Instead, the shape of magnetization curve is a result of a combination of strong anisotropies with spin-spin interactions blocking a spin flip for weak magnetic fields. The phenomenon also strongly depends on the spin quantum numbers. Toroidal moments even can be transformed to zero, if no additional anisotropic interactions between spins are taken into account.

X-ray absorption and differential reflectance spectroscopies of spin-crossover **molecules on HOPG** — •Jorge Torres¹, Sascha Ossinger², Sangeeta Thakur¹, Clara W.A. Trommer², Marcel Walter¹, Ivar Kumberg¹, Rahil Hosseinifar¹, Evangelos Golias¹, Sebastien Hadjadj¹, Jendrik Gördes¹, PIN-CHI LIU¹, CHEN LUO³, LALMINTHANG KIPGEN¹, TAUQIR SHINWARI¹, FLORIN RADU³, FELIX TUCZEK², and WOLFGANG KUCH¹ – ¹Freie Universität Berlin, Institut für Experimentalphysik, Berlin, Germany — ²Christian-Albrechts-Universität zu Kiel, Institut für Anorganische Chemie, Kiel, Germany ³Helmholtz-Zentrum Berlin für Materialien und Energie, Berlin, Germany In order to use visible light to observe the switching between the high spin (HS) and low spin (LS) state of a [Fe{H₂B(pzpy)pz}₂] [1] spin-crossover molecule (SCM), a sub-monolayer was deposited on highly oriented pyrolytic graphite (HOPG) and the sample temperature varied from 120 to 350 K. The difference in light reflection between the pristine HOPG and the SCM sub-monolayer was analyzed by differential reflectance spectroscopy (DRS). Furthermore, the total HS fraction obtained from X-ray absorption spectroscopy (XAS) at temperatures ranging from 10 to 350 K was compared to the DRS absorption spectra. A systematic absorption in the UV region shows that the intensity is proportional to the temperature. Here, the ligand-centered absorption is stronger than the metal-to-ligand charge transfer, making this SCM a promising candidate for optically switched storage devices at room temperature. [1] S. Ossinger, Inorg. Chem., 2020, 59, 7966-7979

#### MA 19.20 Tue 17:30 P2

**Spin-phonon interaction and tunnel splitting in single-molecule magnets** — •KILIAN IRLÄNDER¹, JÜRGEN SCHNACK¹, and HEINZ-JÜRGEN SCHMIDT² — ¹Fakultät für Physik, Universität Bielefeld, Postfach 100131, D-33501 Bielefeld, Germany — ²Fachbereich Physik, Universität Osnabrück, D-49069 Osnabrück, Germany

Quantum tunneling of the magnetization is a phenomenon that impedes the use of small anisotropic spin systems for storage purposes even at the lowest tem-

peratures. Phonons, usually considered for relaxation of the magnetization over the anisotropy barrier, also contribute to magnetization tunneling for integer spin quantum numbers. In this context, it is not viable to consider phonons perturbatively but to treat spins and phonons on the same footing by performing quantum calculations of a Hamiltonian where the single-ion anisotropy tensors are coupled to harmonic oscillators.

We demonstrate the ability of phonons to induce a tunnel splitting of the ground doublet which then reduces the required bistability due to Landau-Zener tunneling of the magnetization [1]. We also present the unexpected observation that certain spin-phonon Hamiltonians are robust against the opening of a tunneling gap, even for strong spin-phonon coupling. The key to understanding this phenomenon is provided by an underlying supersymmetry that involves both spin and phonon degrees of freedom [2].

MA 19.21 Tue 17:30 P2

⁵⁷Fe Mössbauer spectroscopy on FePcF₁₆ and its μ-Oxo dimer in catalysis reaction — •FELIX SEEWALD¹, FLORIAN PULS², HANS-JOACHIM KNÖLKER², and HANS-HENNING KLAUSS¹ — ¹Institute of Solid State and Materials Physics, TU Dresden, D-01069, Germany — ²Department Chemie, Technische Universität Dresden, Bergstraße 66, D-01069 Dresden, Germany

Iron-hexadecafluorophthalocyanine (FePcF₁₆) is used as an oxidation catalyst. Understanding its catalysis mechanism is part of current research. The Fe atom is square planar coordinated by four nitrogen atoms. Both FePcF₁₆ and its mu-Oxo dimer ([FePcF₁₆]₂O) are already identified as steps of the oxidation cycle.

The Mössbauer spectra of  $[FePcF_{16}]_2O$  can be described by two sites at room temperature, both exhibiting quadrupole splitting. A temperature dependent reversible transition between both sites can be observed. Below 30 K the onset of a magnetic hyperfine field is observed obtaining a value of  $B_{Hyp} = 48.77(12)$  T at 4.2 K.

The FePcF₁₆ spectra show one additional third site with a considerable quadrupole splitting and an electric field gradient largest principle component of  $V_{zz} = 154(2) \text{ V/Å}^2$ . This site stays paramagnetic down to 4.2 K.

First measurements of the frozen reaction solution unveil an additional fourth site in a characteristic Fe(II) charge and high spin (S=2) state. We will discuss the implications of these findings on the catalysis process.

#### MA 19.22 Tue 17:30 P2

Approaches towards observing toroidal magnetic moments in Dy-based molecular nanomagnets with Inelastic Neutron Scattering techniques. — •DENNY LAMON¹, JULIUS MUTSCHLER¹, THOMAS RUPPERT², CHRISTOPHER E. ANSON², ANNIE K. POWELL², and OLIVER WALDMANN¹ — ¹Physikalisches Institut, Universität Freiburg, Germany — ²Institut für anorganische Chemie, Universität Karlsruhe, KIT, Germany

Single-molecule toroics (SMT) have been a subject of increasing interest both for their fundamental physics properties and for the potential applications in quantum computers or information storage. In fact the associated vortex arrangement of magnetic moments leads to weaker dipolar interactions and to a lack of interaction with a possible external magnetic field. A particular class of these molecules, which incorporate a triangle of exchange coupled magnetic Dy ions, can support a toroidal magnetic moment; in this work a class of  $Me_2Dy_3$ molecules, there Me = Al, Cr, Fe, is investigated. The available experimental data for magnetic susceptibility and magnetization curves are fitted and simulated using full and effective Hamiltonian models in order to extract the model parameters, especially the tilt angles of the anisotropy axes. The inelastic neutron scattering spectra are simulated in order to develop experimental schemes for directly observing toroidal magnetic moments in SMTs.

#### MA 19.23 Tue 17:30 P2

Synthesis, optical and magnetic properties of Au-Fe3O4 nanohybrids — •TATIANA SMOLIAROVA, MARINA SPASOVA, ULF WIEDWALD, and MICHAEL FARLE — Faculty of Physics, University of Duisburg-Essen, Duisburg, 47057, Germany

Gold-magnetite nanohybrids composed of Fe3O4 and Au nanoparticles (NPs) have attracted large attention due to the evident advantages of Au nanoparticles such as unique biocompatibility, facile surface modification, and high catalytic properties. Herein, we report on the facile room-temperature synthesis approach for Au-Fe3O4 nanohybrids preparation and their optical and magnetic properties investigation.

Au-Fe3O4 nanohybrids were synthesized by chemical precipitation with a chemisorption process of Au nanoparticles (NPs) to the Fe3O4 surface using polyvinylpyrrolidone (PVP) coverage. Prepared NPs were studied by transmission electron microscopy (TEM), UV-vis spectroscopy and magnetometry. The obtained results seem to be the promising step for the core-shell Au-Fe3O4 NPs preparation, in the case of Au NPs will be considered as the seeds for the complete Au shell growth.

This work was supported by European Union*s Horizon 2020 research and innovation program under grant agreement No 857502 (MaNaCa).

Differential Phase Contrast and Lorentz microscopy — •JUDITH BÜNTE, BJÖRN BÜKER, DANIELA RAMERMANN, INGA ENNEN, and ANDREAS HÜTTEN — Universität Bielefeld, Dünne Schichten und Physik der Nanostrukturen, Universitätsstr. 25, 33615 Bielefeld, Germany

Differential Phase Contrast (DPC) and Lorentz microscopy are two well-known techniques for analyzing magnetic structures in the transmission electron microscope (TEM). The Lorentz force inside the magnetic domain of a specimen deflects the transmitted electron beam depending on the orientation of the corresponding magnetic field. This deflected beam then results in a different intensity distribution in the recorded image which can be analyzed. In this contribution we present DPC and Lorentz transmission electron microscope (LTEM) images of a specimen consisting of a CoFe membrane with structured holes. These different kinds of holes inside the magnetic material of the specimen yield interesting domain structures. The focus is on the analysis of these magnetic domain structure and the impact of changing external magnetic fields. For this, a hysteres is loop inside the TEM is recorded. Furthermore, the two different techniques are compared giving the possibility to confirm the resulting domain structure.

Kerr microscopy for all-optical helicity-dependent magnetization switching – •LUCAS VOLLROTH¹, MARCEL KOHLMANN¹, KRISTÝNA HOVOŘÁKOVÁ², EVA SCHMORANZEROVÁ², MARKUS MÜNZENBERG¹, and JAKOB WALOWSKI¹ – ¹Greifswald University, Greifswald, Germany – ²Charles University, Prague, Czech Republic

The ever growing demand for data storing capacities requires the development of high bit density data storage devices with fast read and write capabilities. New generation heat assisted magnetic recording devices (HAMR) emerging the market are promising candidates decreasing bit sizes. Simultaneously, the recording media based on nanometer sized FePt grains are suitable for other writing approaches like the all-optical helicity-dependent switching (AOHDS) [1]. We investigate this method for potential future applications of HAMR media. Wide field Kerr-microscopy is a well suited method to explore and analyze the outcome of our AOHDS experiments. We present a build from scratch and cost efficient Kerr microscope for the observation of magnetic domains. The setup can be implemented in pump-probe experiments to investigate magnetization changes after the deposition of ultrashort laser pulse energies in magnetic thin films. Besides measurements on hard drive media, the microscope can also be used for the observation of skyrions.

**Magnetic proximity effect in V uncovered by TEM techniques** — •INGA ENNEN¹, DANIELA RAMERMANN¹, DOMINIK GRAULICH¹, TREVOR ALMEIDA², STEPHEN MCVITIE², BJÖRN BÜKER¹, TIMO KUSCHEL¹, and ANDREAS HÜTTEN¹ — ¹Universität Bielefeld, Dünne Schichten und Physik der Nanostrukturen, Universitätsstr. 25, 33615 Bielefeld, Germany — ²University of Glasgow, School of Physics and Astronomy, Glasgow G12 8QQ, UK

Thin film structures consisting of magnetic and non-magnetic materials are of great technical interest, due to their special magnetic and electronic characteristics. These characteristics were influenced e.g. by the interface quality and the magnetic proximity effect. Here, the penetration depth of magnetism in nonmagnetic films adjacent to ferromagnetic layers is investigated, usually by employing X-ray techniques such as XRMR. In this contribution, we demonstrate the opportunities of modern transmission electron microscopy techniques for the investigation of the magnetic proximity effect in a V/Fe thin film system as a model sample. Here, a combination of magnetic differential phase contrast (DPC) and electron energy loss magnetic chiral dichroism (EMCD) has been employed. The basic idea is that DPC measures the presence of a magnetic induction into V and EMCD shows that there is a magnetic moment present. In this way, a magnetic proximity effect of about 1.5nm in V has been observed, which is in accordance to corresponding measurements with X-rays.

Imaging the coherent spin dynamics of nitrogen vacancies coupled to CrTe₂ at room temperature – •RICCARDO SILVIOLI¹, MARTIN SCHALK¹, KARINA HOUSKA¹, DOMINIK BUCHER², ZDENEK SOFER³, ANDREAS V. STIER¹, and Jonathan J. Finley¹ - ¹WSI, TUM - ²Chemie, TUM - ³UCT Prague Magnetic resonance imaging of coupled spin-systems is a technique capable of rendering highly accurate descriptions of magnetic fields even at room temperature, and is therefore lying at the heart of various applications in medicine, chemistry and physics. We present coherent wide-field imaging of a 100 x 100  $\mu m$ sized region of interest implanted with nitrogen vacancy centers (NVs) in diamond coupled to a 50 nm thick flake of the in-plane van der Waals ferromagnet CrTe₂. We can quantitatively probe the stray magnetic field of the material with the NVs' electron spin signal. First, we combine the nano-scale sample shapes measured by atomic force microscope with the magnetic resonance imaging data for accurate reconstruction of the sample's magnetization. We then map out the coherent dynamics of the colour centers coupled to the van der Waals ferromagnet using pixel-wise coherent Rabi and Ramsey imaging of the NV sensor layer. We find that the spin coherence of the ensemble is strictly correlated with the variation in the magnetic field generated by the sample. What results is an enhanced detection of the magnetic field where we describe its variation in three dimensions, improving the reconstruction of the magnetization. Finally, we infer the quantum dynamics using a neural network to speed up the convergence of the pixel-wise Hamiltonian fitting.

Ultrafast Lorentz microscopy with magnetic field excitation at microwave frequencies — JONATHAN TILMAN WEBER, NIKITA PORWAL, •ANDREAS WENDELN, MICHAEL WINKLHOFER, and SASCHA SCHÄFER — Carl von Ossietzky Universität, Oldenburg, Deutschland

Recent progress in the development of laser-driven, high brightness photocathodes offers a path to investigate magnetization dynamics with high spatial and temporal resolution, utilizing a Lorentz imaging approach in ultrafast transmission electron microscopy (UTEM) [1]. In particular, non-optical excitation schemes, such as current or field excitation provide pathways for a selective triggering of magnetic dynamics. Extending the available frequencies in such experiments [2], we developed a TEM sample holder based on a two-dimensional microwave cavity, with which we can excite ferromagnetic resonances in magnetic nanostructures. The microwave excitation signals are phase-locked to the nanolocalized photoemission of ultrashort electron pulses from a Schottky field emitter, using high harmonics of the amplified laser system as a master clock for their synthetization [3]. With this advanced excitation and measurement scheme we aim to image ferromagnetic resonance modes with high spatial and temporal resolution and to further establish ultrafast Lorentz microscopy as a powerful tool to characterize magnetization dynamics on the nanoscale.

Brownian reservoir computing realized using geometrically confined skyrmions — •KLAUS RAAB¹, MAARTEN A. BREMS¹, GRISCHA BENEKE¹, TAKAAKI DOHI¹, JAN ROTHÖRL¹, FABIAN KAMMERBAUER¹, JOHAN H. MENTINK², and MATHIAS KLÄUI^{1,3} — ¹Institut für Physik, Johannes Gutenberg-Universität Mainz, Staudingerweg 7, 55128 Mainz, Germany — ²Radboud University, Institute for Molecules and Materials, Heyendaalseweg 135, 6525 AJ Nijmegen, The Netherlands — ³Graduate School of Excellence Materials Science in Mainz, Staudingerweg 9, 55128 Mainz, Germany

We demonstrate experimentally [1] a conceptionally new approach for reservoir computing (RC), that leverages the thermally activated diffusive motion of magnetic skyrmions in a confined, triangular geometry. The combination of gated and thermal skyrmion motion of a single skyrmion already suffices to realize all Boolean logic gate operations including the non-linearly separable XOR operation that cannot be realized using a conventional single layer perceptron. An effective potential well created by the confinement allows for a natural, energy efficient reset mechanism enabled by the thermal fluctuations of the skyrmions. We show that the output training costs using linear regression are low and that our ultra-low power operation using current densities orders of magnitude smaller than used in existing spintronic reservoir computing demonstrations. Our concept can be easily extended by linking multiple confined geometries for scalable and low-energy reservoir computing. [1] K. Raab et al. Brownian reservoir computing with geometrically confined skyrmions - arXiv:2203.14720

#### MA 19.31 Tue 17:30 P2

**FD** micromagnetic solver for inverse-design magnonics — •ANDREY VORONOV¹, QI WANG¹, DIETER SUESS², ANDRII CHUMAK¹, and CLAAS ABERT² — ¹Nanomagnetism and Magnonics, Faculty of Physics, University of Vienna, Austria — ²Physics of Functional Materials, Faculty of Physics, Iniversity of Vienna, Austria

The idea of utilizing a collective excitation of the electron spin system in magnetic solids, so-called spin-waves, for data processing has been developing in recent

years. However, the design of complex data-processing units requires elaborate and complicated investigations.

Recently, the concept of inverse-design magnonics, in which any functionality can be specified first and a feedback-based computational algorithm is used to obtain the device design, has been demonstrated numerically [1]. The same algorithm was used to design a magnonic (de-)multiplexer, a nonlinear switch, and a circulator [1].

One of the next challenges for inverse design is the computation of universal Boolean logic gates NAND and NOR. However, such gates require increasing the complexity of the structure used in [1] and the combination of the MuMux3 simulations with the direct binary search algorithm (DBS) is no longer applicable. Here I report on the use of finite difference (FD) micromagnetic solver based on the Pytorch open source machine learning framework for inverse design. The proposed algorithm greatly facilitates the design of the applied devices and is a useful tool especially for spin-wave computing elements.

#### MA 19.32 Tue 17:30 P2

Efficiency and Comfort Optimization of Induction Hobs Trough Appropriate Materials Selection — •LENNART SCHWAN^{1,2}, SONJA SCHÖNING¹, and ANDREAS HÜTTEN² — ¹Bielefeld Institute for Applied Materials Research (BIFAM), Bielefeld University of Applied Sciences, Department of Engineering Sciences and Mathematics — ²Thin Films & Physics of Nanostructures Bielefeld University, Department of Physics

Inductive power transfer is nowadays a widely used technology, e.g. for inductive heating in industrial applications and household appliances like inductions hobs. An inductive heating system usually consists of a coil (transmitter) which is powered by an alternating current and a ferromagnetic material (receiver), for example a pot. The ferromagnetic material is heated by induced eddy currents and hysteresis losses Regarding to energy efficiency and comfort, it is desirable to minimize the parasitic losses which do not contribute to the heating of the cooking good and to homogenize the temperature distribution within the cooking container. As a future basis for the development of novel cooking containers, we use FEM simulations to investigate the influence of the material parameters of the ferromagnetic material on the efficiency and temperature distribution. In addition to the simulations, parts of the results are verified by experimental investigations.

Moments and multiplets in moiré materials: A pseudo-fermion functional renormalization group for spin-valley models — •LASSE GRESISTA, DOMINIK KIESE, and SIMON TREBST — Institute for Theoretical Physics, University of Cologne, Germany

The observation of strongly-correlated states in moiré systems has renewed the conceptual interest in magnetic systems with higher SU(4) spin symmetry, e.g. to describe Mott insulators where the local moments are coupled spin-valley degrees of freedom. In addition to possible geometrical or interaction induced frustration, the enhanced quantum fluctuations in these systems are expected to counteract the formation of magnetic order, making them prime candidates to host exotic quantum spin-valley or spin-orbital liquid ground states. A method that has demonstrated its potential to distinguish between magnetically ordered and disordered states, even in the presence of frustration and in three dimensions, is the pseudo-fermion function renormalization group (pf-FRG). In our work we generalize this method from conventional SU(2) spin models to very general spin-valley Hamiltonians, showing that it can indeed be applied to study the magnetic behavior of moiré materials. We present the quantum phase diagram of SU(2)^{spin}  $\otimes$  U(1)^{valley} symmetric spin-valley models relevant for the strong coupling description of trilayer graphene on hexagonal boron nitride (TG/h-BN) and twisted bilayer graphene (TBG).

#### MA 19.34 Tue 17:30 P2

Calculation of the temperature-dependent exchange stiffness from Domain Wall modelling — •FELIX SCHUG^{1,2}, NILS NEUGEBAUER^{2,3}, MICHAEL CZERNER^{1,2}, and CHRISTIAN HEILIGER^{1,2} — ¹Institute for Theoretical Physics, Justus Liebig University Giessen, Heinrich-Buff-Ring 16, 35392 Giessen, Germany — ²Center for Materials Research (LaMa), Justus Liebig University Giessen, Heinrich-Buff-Ring 16, 35392 Giessen, Germany — ³Institute of Experimental Physics I, Justus Liebig University Giessen, Heinrich-Buff-Ring 16, 35392 Giessen, Germany

Understanding the different influences on the macroscopic magnetic properties of a material at finite temperatures is of great interest from the theoretical point of view. As macroscopic magnetic properties, such as anisotropies or the exchange stiffness, are related to the quantum nature of electrons and thus to the most fundamental level of solids, the atomic level, atomistic modelling of a magnetic material may promote a more profound understanding of the microscopic processes. Performing the corresponding numerical simulations at various temperatures from 0 K to the Curie-temperature  $T_C$ , the temperature dependence of the associated macroscopic properties may be modelled. These modelled material parameters can then be used to simulate magnetic properties on the next higher hierarchy to the microscopic scale, leading to the so-called multi-scale modelling approach. Here the approach of simulating Bloch walls of a finite cobalt stripe at different temperatures is demonstrated to extract the macroscopic crystalline anisotropy constant  $K_C$  and the exchange stiffness parameter  $A_{exc}$ .

#### MA 19.35 Tue 17:30 P2

**Multiconfiguretional approch to XAS applied to Co- and Ni- doped magnetite** — •FELIX SORGENFREI¹, JOHANN SCHÖTT¹, M'EBAREK ALOUANI², PATRIK THUNSTRÖM¹, and OLLE ERIKSSON¹ — ¹Department of Physics and Astronomy, Uppsala University, Box-516, Uppsala SE-751 20 Sweden — ²Université de Strasbourg, IPCMS UMR 7504, 67034 Strasbourg, France

L-edge X-ray absorption spectroscopy (XAS) is an important tool to extract element-specific information about the electronic structure, magnetism and in particular electronic correlation effects. Ab initio calculations typically struggle to reproduce the 2p to 3d excitation, in particular for materials with strong electron correlations and significant core-hole effects. The combination of density functional theory and multiplet ligand field theory is applied to fill this gap. Here, parameters are calculated from first principles and used to construct a single-impurity Anderson model by projecting the local Hamiltonian and hybridization function onto the 3d states. In this talk, this method is applied to NiFe2O4, CoFe2O4 and Fe3O4. We find systematically good agreement with experiment for both XAS and XMCD spectra.

#### MA 19.36 Tue 17:30 P2

Finite-element dynamic-matrix approach for propagating spin waves: Extension to mono- and multilayers of arbitrary spacing and thickness – •ALEXANDER HEMPEL^{1,2}, LUKAS KÖRBER^{1,2}, ANDREAS OTTO², RODOLFO GALLARDO^{3,4}, YVES HENRY⁵, and ATTILA KÁKAY¹ – ¹Helmholtz-Zentrum Dresden - Rossendorf, Germany – ²Technische Universität Dresden, Germany – ³UTFSM, Chile – ⁴CEDENNA, Chile – ⁵IPCMS, France

Over the last few years micromagnetic simulations became an important tool in the field of magnonics. In a recent work Körber et al. [1] presented an efficient method to numerically determine the dispersion and the spatial mode profiles of spin-waves propagating in waveguides with arbitrary cross section, if the equilibrium magnetization is invariant along the propagation direction. In this work their finite-element dynamic-matrix approach is used as a starting point to develop a tool to investigate propagating spin waves in mono- and multilayers. This approach has the advantage, that the linearized equation of motion is solved in just a section of the layers, and has therefore a comparatively low numerical complexity. Nevertheless the dipolar interaction still requires special care and we show how an extension of the Fredkin-Koehler method can be used to handle this problem. As a validation of the method, which is implemented into the open source FEM micromagnetic package TetraX [2], we present a variety of simulation results and compare them with analytics and other numerical approaches.

**Predictive Design of Induction Coil Geometries using Neural Networks** — •SIMON BEKEMEIER¹, SVEN GEHLE¹, and CHRISTIAN SCHRÖDER^{1,2} — ¹Bielefeld Institute for Applied Materials Research (BIFAM), Computational Materials Science and Engineering (CMSE), Bielefeld University of Applied Sciences, Department of Engineering Sciences and Mathematics, Interaktion 1, 33619 Bielefeld, Germany — ²Faculty of Physics, Bielefeld University, Universitätsstraße 25, 33615 Bielefeld, Germany

Nowadays, inductive power transfer is an established technology with its most common application in induction hobs. Such appliances usually use planar coils with homogeneous winding distances. With regard to energy efficiency, comfort and electromagnetic compatibility it is desirable to start from an optimal magnetic field distribution and derive the necessary coil geometry from it.

Unknown, highly non-linear functional relations can be modelled using neural networks with relative ease. In this contribution, we use a deep convolutional auto-encoder to predict the relationship between coil geometries and the respective magnetic fields. To achieve this, the current-path and the coil's magnetic field are presented to the neural network in spatially discretized form. By using the current-path as input and the magnetic field as output, the neural net is trained to find coil geometries, which produce a desired magnetic field. In this contribution we present our results of predicted coil designs for magnetic fields, which require coil geometries ranging from simple linear wires to more complex spiral geometries.

#### MA 19.38 Tue 17:30 P2

**First-principles local interactions extracted from non-collinear magnetic states** — MIKLÓS SALÁNKI¹, BENDEGÚZ NYÁRI¹, ANDRÁS LÁSZLÓFFY², and •LÁSZLÓ SZUNYOGH¹ — ¹Department of Theoretical Physics, Budapest University of Technology and Economics, Hungary — ²Wigner Research Centre for Physics, Institute for Solid State Physics and Optics, Hungary

The local Dzyaloshinskii-Moriya interactions (DMI) derived from first principles in non-collinear magnetic configurations in the absence of spin-orbit cou-

pling [1] became recently the subject of an intense discussion [2,3,4]. On the one hand, the local DMI has been explained due to charge and spin currents emerging in non-collinear spin-configurations [1,3], on the other hand, it was shown to be a consequence of fourspin (or higher-order multispin) interactions [2].

As in Ref. [1] we perform calculations of the local interaction parameters for a Cr trimer on Au(111) in terms of the multiple scattering Green's function technique. We use two alternative formalisms that lead to different local parameters. We show that this ambiguity occurs due to longitudinal terms in the corresponding expressions. We find that the formalism based on the structural Green's-function matrices provides local interactions being consistent with a spin model including fourspin interactions calculated on the same basis.

Anomalous and spin Hall effect in chiral antiferromagnets  $Mn_3X$  (X=Ir, Sn, ...) — •OLIVER BUSCH, BÖRGE GÖBEL, and INGRID MERTIG — Institut für Physik, Martin-Luther-Universität, D-06099 Halle

Recently, large anomalous Hall effects (AHEs) have been measured in the noncollinear kagome antiferromagnets (AFMs)  $Mn_3Sn$  [1] and  $Mn_3Ge$  [2] and large spin Hall effects (SHEs) were predicted in such compensated  $Mn_3X$  systems [3].

We discuss the intrinsic contributions to both Hall effects of kagome AFMs via tight-binding calculations. We describe a microscopic mechanism for the occurrence of the AHE: within this model, spin-orbit coupling (SOC) is equivalent to an out-of-plane tilting of the magnetic texture [4]. Thus, the AHE can be interpreted as a topological Hall effect generated by the opening angle of the virtually tilted texture.

Besides, we find that the main contribution to the SHE in  $Mn_3X$  is a pure spin current originating from the non-collinear magnetic texture and it occurs even without SOC when the AHE is absent [5]. In addition to that, SOC gives rise to the AHE and reduces the SHE effectively which gives rise to spin-polarized currents.

Vertical Pt|Y₃Fe₅O₁₂|Pt heterostructures for magnon mediated magnetoresistance measurements — •PHILIPP SCHWENKE^{1,2}, MANUEL MÜLLER^{1,2}, ANDREAS HASLBERGER^{1,2}, STEPHAN GEPRÄGS¹, and RUDOLF GROSS^{1,2,3} — ¹Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany — ²Physik-Department, Technische Universität München, 85748 Garching, Germany — ³Munich Center for Quantum Science and Technology (MCQST), 80799 München, Germany

Spin currents and their generation (detection) via the (inverse) spin Hall effect in heavy metal (HM)|ferrimagnetic insulator (FMI) heterostructures gain increasing attention in the field of spintronics. In particular, spin current valves in HM|FMI|HM trilayers such as Pt|YIG|Pt heterostructures are of great interest to enable device miniaturization and the implementation of three-dimensional spintronic devices. In this work we optimize the fabrication of these vertical Pt|YIG|Pt heterostructures. We study the interface quality between Pt an YIG by performing angle dependent magnetoresistance measurements on the Pt layers. We observe a good top YIG|Pt interface quality and find an improvement of the bottom Pt|YIG interface by introducing a Ru buffer layer, which reduces the intermixing of Pt and YIG. Furthermore, we observe a finite magnon mediated magnetoresistance and spin Seebeck effect signal in our heterostructures demonstrating the possibility of HM|FMI trilayers as spin current valve devices.

#### MA 19.41 Tue 17:30 P2

Investigation of Quasipaticle Spin Transport in Superconductors/Ferrimagnet Heterostructures — •YUHAO SUN^{1,2}, MANUEL MÜLLER^{1,2}, JANINE GÜCKELHORN^{1,2}, MATTHIAS GRAMMER^{1,2}, HANS HUEBL^{1,2,3}, RUDOLF GROSS^{1,2,3}, and MATTHIAS ALTHAMMER^{1,2} — ¹Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — ²Physik-Department, Technische Universität München, Garching, Germany — ³Munich Center for Quantum Science and Technology, München, Germany

Magnon based spintronics is intensely researched as it enables alternative information processing schemes and additional functionalities compared to charge based counterparts. Recent studies suggest that the interplay of superconductivity and magnetism can enhance spin-related effects, such as the interfacial spin injection efficiency [1]. The present assumption is that magnetic excitation or magnons interact with the quasiparticles of the superconducting phase. To test this conjecture, we investigate magnon injection and transport using the ferrimagnetic insulator  $Y_3Fe_5O_{12}$  as magnetic system. In detail, we use a superconducting niobium nitride (NbN) strip as the detector. A heater structure on top of the NbN allows to apply thermal gradient. A spatially separated heavy metal platinum strip acts as the injector of thermal magnon spin-currents. We present temperature dependent data to access the influence of superconducting quasiparticles on our transport signal.

MA 19.42 Tue 17:30 P2

**Nonrelativistic spin currents in altermagnets** — •RODRIGO JAESCHKE-UBIERGO, LIBOR ŠMEJKAL, and JAIRO SINOVA — Institut für Physik, Johannes Gutenberg Universität Mainz, Germany

Altermagnetism has emerged recently as a third basic collinear magnetic phase [1], in addition to ferromagnets and antiferromagnets. Conventional antiferromagnets exhibit two sublattices with opposite magnetic moment related by translation or inversion. In altermagnets the magnetic sublattices are connected by a rotation or a mirror operation. The particular symmetry causes that altermagnets display time-reversal ( $\mathscr{T}$ ) symmetry breaking and spin split band structure even in absence of spin-orbit coupling [2].

In this work, we study the spin conductivity tensor in altermagnets by using spin group theory formalism [1]. We also use Kubo's linear response to calculate the spin conductivity tensor in all the altermagnetic spin point groups models. Additionally, we indentify and sort 200 altermagnetic candidates into spin conductivity tensor classes. We will discuss some spin point groups that allow for a transverse spin current in detail. This is the case of spin splitter current in RuO₂ [3,4], which is a nonrelativistic effect that conserves spin unlike in general magnetic spin Hall effect in noncollinear magnets. Moreover, the spin conductivity tensor is symmetric and  $\mathcal{T}$ -odd, which makes it different to the conventional spin Hall effect.

 Šmejkal, et al. arXiv preprint arXiv:2105.05820, 2021. [2] Šmejkal, et al. Sci.Adv 2020. [3] Gonzalez-Hernandez, et al. PRL 2021. [4] Šmejkal, et al. PRX 2022.

**Spin-orbit torques in ferromagnetic heterostructures** — •MISBAH YAQOOB¹, FABIAN KAMMERBAUER², VITALIY VASYUCHKA¹, GERHARD JAKOB², MATH-IAS KLÄUI², and MATHIAS WEILER¹ — ¹Fachbereich Physik and Landesforschungszentrum OPTIMAS, TU Kaiserslautern, Kaiserslautern, Germany — ²Institut für Physik, Johannes Gutenberg-Universität Mainz, Mainz, Germany

Spin-orbit torques (SOTs) can be used to electrically control the spin dynamics, while inverse SOTs enable the electrical detection of spin dynamics. Here, based on theoretical predictions [1], we study the spin-to-charge conversion in ferromagnetic materials with high spin-orbit interaction. In particular, we chose the perpendicular magnetic anisotropy (PMA) multilayers CoNi and CoPt. We investigate the spin dynamics and SOTs of corresponding purely metallic ferromagnetic thin film in-plane anisotropy (IPA) / PMA hybrid systems using an inductive technique based on vector network analysis [2].

We observe substantial damping-like SOTs generated in the PMA layers. The SOTs in CoNi/Cu/CoFeB are comparable to those observed in Pt/CoFeB [3] and Pt/NiFe [4] heterostructures using the same technique and similar layer thicknesses.

MA 19.44 Tue 17:30 P2 **Current-induced interlayer DMI in synthetic antiferromagnets** — •FABIAN KAMMERBAUER¹, WON-YOUNG CHOI¹, FREIMUTH FRANK², KYUJOON LEE³, ROBERT FRÖMTER¹, YURIY MOKROUSOV^{1,2}, and MATHIAS KLÄUI¹ — ¹Institute of Physics, Joahnnes Gutenberg University, Staudingerweg 7, 55128 Mainz, Germany — ²Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — ³Division of Vierberg Vierber

display and semiconductor physics, Korea University, Sejong-ro 2511, Sejong, Republic of Korea There is rising interest in 3D magnetism and magnetic textures, such as hop-

fions. Stabilizing 3D magnetics in the lateral direction textures, such as hop fions. Stabilizing 3D magnetic textures is in need of additional interactions favoring the canting of spins in the lateral direction. Layered synthetic antiferromagnets coupled by the symmetric interlayer exchange can additionally display an antisymmetric interlayer exchange, henceforth called interlayer DMI, which exerts such canting. Here, we report the effect of an electrical current on the antisymmetric interlayer DMI by employing anomalous Hall effect measurements with an additional applied in-plane field. In order to quantify the current dependence of the antisymmetric interlayer exchange interaction, an interlayer DMI field is introduced. Using a model of two superimposed cosine functions accounting for current-dependent and static contributions, we demonstrate that the current-dependent interlayer DMI field increases linearly with current and maximal along the direction of current flow. Thus, we demonstrate the possibility to control the interlayer DMI directly by electrical currents.

**Spin current transmission in LaSrMnO** / **NiO** / **Pt layers** — •EVANGELOS TH. PAPAIOANNOU¹, CAMILLO BALLANI¹, PHILIPP GEIER¹, PHILIP TREMPLER¹, CHRISTOPH HAUSER¹, OLENA GOMONAY², and GEORG SCHMIDT¹ — ¹Institute of Physics, Martin-Luther University Halle-Wittenberg, 06120 Halle, Germany — ²Institute of Physics, Johannes Gutenberg University Mainz, 55128 Mainz, Germany

We investigate the effect of spin pumping and inverse spin-Hall effect (ISHE) in trilayers composed of a ferromagnetic half-metal/ antiferromagnetic oxide/non-magnetic layer in the form of La0.7Sr0.3MnO3/ NiO (x nm) / Pt. The generated spin current is pumped through the antiferromagnetic NiO layer and is detected via ferromagnetic resonance and ISHE measurements at low temperatures down to 10K. We refine two competing mechanisms of spin transport whose contribution to spin transport and supremacy is temperature dependent. The mechanism arising from the direct exchange coupling between FM and AFM dominates below the blocking temperature, while the spin pumping mechanism dominates above the blocking temperature and shows to be more efficient spin current transport through NiO layers.

## MA 19.46 Tue 17:30 P2

**THz-2D Scanning Spectroscopy** — •FINN-FREDERIK STIEWE, TOBIAS KLEINKE, TRISTAN WINKEL, ULRIKE MARTENS, JAKOB WALOWSKI, CHRISTIAN DENKER, and MARKUS MÜNZENBERG — Institute of Physics, University Greifswald, Germany

THz-spectroscopy offers attractive imaging capabilities for scientific research, especially in life science. Its low photon energies lead to non-destructive interaction with matter In our study, we investigate THz-pulses generated by fs-laserexcitations in CoFeB/Pt heterostructures (STE), based on spin currents together with a LT-GaAs Auston switch as detector. The spatial resolution is tested by applying a 2D scanning technique with motorized stages allowing scanning steps in the sub-micrometer range. By applying an external magnetic field, the spin alignment in the CoFeB layer can be changed and the influence on the THz emission can be studied. For determining the spatial resolution, the STE is directly evaporated on a gold-test pattern separated by a several hundred nanometer thick insulating spacer layer. We observe a THz beam FWHM of 4.86 *0.37  $\mu m$  at 1 THz by using near-field imaging, which are in the dimension of the laser spot [1]. Our phase sensitive detection allows to image the magnetic alignment of the CoFeB layer. For this purpose, the STE*s are patterned in micrometer sized geometric shapes on a glass substrate and scanned by our 2D scanning technique. Due to its simplicity, our technical approach offers a large potential for wide-ranging applications. [1] F.-F. Stiewe et al., Appl. Phys. Lett. 120, 32406 (2022).

Spatially Resolved Terahertz Spectroscopy using Spintronic-Terahertz-Emitter — •Bruno Rosinus Serrano^{1,2}, Alex Chekhov^{1,2}, Yannic Behovits^{1,2}, and Tobias Kampfrath^{1,2} — ¹Freie Universität Berlin — ²Fritz-Haber-Institut Berlin

New efficient laser-driven sources provide high THz fields suitable for excitation of ultrafast spin dynamics in various materials. These intense THz pulses are often characterized with a use of infrared and THz cameras also known as focal plane arrays (FPA). Since the FPA output strongly depends on its spectral sensitivity, it is often important to know the transfer function of a given FPA in the corresponding THz range. Here, we develop a table-top technique, which allows one to separate and spatially resolve spectral contributions to the FPA image in the THz range. Our results indicate that the FPA sensitivity can be quite resonant at different frequencies.

Identification and characterization of plastics using THz-spectroscopy — •TOBIAS KLEINKE, FINN-FREDERIK LIETZOW, ULRIKE MARTENS, JAKOB WALOWSKI, and MARKUS MÜNZENBERG — Institute of Physics, University Greifswald, Germany

THz-spectroscopy is an attractive tool for scientific research, especially in life science, offering non-destructive interaction with matter due to its low photon energies [1]. Current research investigates the impact of plastic nanoparticles on cell tissue in several aspects, because those particles are highly abundant in the environment and also enter the human body potentially causing harmful interactions [2].

THz spectroscopy offers the opportunity to discover and study the influence of microplastics in living human cells. Our project aims to identify and characterize different types of plastics in the human body or even in cells. Therefore it is necessary to set up a database with THz-spectra of the most abundant polymers. We analyse transmission spectra of several plastics with a commercial THz spectrometer (bandwidth from 0.1 to 6 THz) and identified specific absorption peaks for the individual studied materials. Furthermore, by determining the refractive index and the absorption coefficient, specific polymers can be characterized and identified.

Spin-Hall-Angle measurements on magnetic heterostructures with bismuth alloys using THz-spectroscopy — •TRISTAN WINKEL¹, FINN-FREDERIK STIEWE¹, JAKOB WALOWSKI¹, CHRISTIAN DENKER², and MARKUS MÜNZENBERG¹ — ¹Institute of Physics, University Greifswald, Germany — ²EMCC DR. RASEK, Ebermannstadt, Deutschland

Spin Hall angle measurements are important for spin device design. THz spectroscopy provides effective means to measure spin Hall angles. In our study, we investigate THz pulses generated by fs laser excitations in magnetic heterostructures based on spin currents, together with an LT-GaAs Auston switch as a detector. The magnetic heterostructures consist of a CoFeB layer and a heavy metal layer such as bismuth alloys [1]. From the THz measurement, we can extrapolate the spin Hall angle of the heavy metal. The data is then used to build optimized spin Hall nano-oscillators for the fabrication of a neuromorphic computer chip [2]. Our technical approach offers great potential for wide-ranging applications due to its simplicity.

Formation and decay dynamics of the perpendicular standing spin-wave (PSSW) mode following the ultrafast demagnetization of an ultrathin permalloy film — •ANULEKHA DE¹, AKIRA LENTFART¹, LAURA SCHEUER¹, BENJAMIN STADTMÜLLER^{1,2}, PHILIPP PIRRO¹, GEORG VON FREYMANN^{1,3}, and MARTIN AESCHLIMANN¹ — ¹Department of Physics and Research Center OPTI-MAS, University of Kaiserslautern, Germany — ²Institute of Physics, Johannes Gutenberg University Mainz, Germany — ³Fraunhofer Institute for Industrial Mathematics ITWM

One of the most thoroughly explored spin-wave modes in ferromagnetic films is the perpendicular standing spin wave (PSSW) mode, the coherent excitation of which require nonuniform excitation or pinning of the magnetization. By tuning the film thickness, it is possible to shift this mode to the sub-THz regime due to the increased exchange contribution quantized over the thickness. Here, we demonstrate the formation of the first PSSW mode on the ps timescale following the optically induced ultrafast demagnetization of the thin Py film using fs-light pulses in an all-optical, time-resolved magneto-optical Kerr effect (tr-MOKE) technique. For the excitation of coherent spin waves using ultrashort laser pulses, the magnetization of the samples was canted in OOP direction with an external field. The observed time-dependent behavior of the first PSSW mode gives an insight into the role of spin waves during the ultrafast demagnetization and remagnetization process. This research was supported by the DFG through No. TRR 173-268565370 (B11).

Characterizing electro-optic terahertz analyzers using a polarizationtunable spintronic terahertz emitter — •GENARO BIERHANCE^{1,2}, OLIVER GUECKSTOCK^{1,2}, and TOBIAS KAMPFRATH^{1,2} — ¹Department of Physical Chemistry, Fritz Haber Institute of the Max Planck Society, 14195 Berlin, Germany — ²Department of Physics, Freie Universität Berlin, 14195 Berlin, Germany

One goal of current spintronics research is to push the speed of spin torques, transport and their detection to terahertz (THz) frequencies. Here, THz spectroscopy is a powerful tool that provides immediate access to the femtosecond time scales of spin dynamics. The toolbox of THz spectroscopy was recently extended by spintronic emitters (STEs), which provide efficient, spectrally broad and gapless emission in the THz frequency range.

Here, we show that the emitted THz field has a linear polarization with a high intensity purity. The polarization axis can easily be set by an external magnetic field. Subsequently, we use this property to quantify the capability of the electro-optic crystals ZnTe and GaP as THz polarization analyzers in the context of electro-optic THz detection. We find excellent performance with frequency-resolved intensity extinction ratios up to 40,000:1.

MA 19.52 Tue 17:30 P2

**Orbitronic influences on spintronic THz emitters** — •JULIEN SCHÄFER, LAURA SCHEUER, PHILIPP PIRRO, and BURKARD HILLEBRANDS — TU Kaiserslautern, Kaiserslautern, Deutschland

Magnetic / non-magnetic thin film bilayers were recently introduced as novel sources of THz radiation: A fs laser pulse generates a spin current in the ferromagnetic layer which diffuses into the non-magnetic layer. Usually, the non-magnetic layer is chosen to exhibit a high spin-orbit coupling in order to efficiently transform the spin current into a charge current via the inverse spin-Hall effect. The accelerated electrons of the transient charge current then emit a broadband radiation in the THz regime.

The orbital Hall effect is reported to be remarkably long-ranged in ferromagnets and to generate considerate spin-orbit torques on  $CuO_X/Pt$  interfaces [1]. Therefore, we investigated Co/Pt-emitters in various combinations with  $CuO_X$ 

MA 19.56 Tue 17:30 P2

and  $Al_2O_3$  as an insulator barrier to extract the influence of a potential inverse orbital Hall effect on the THz emission. The exploitation of the inverse orbital Hall effect opens new perspectives in terms of material choices for the next generation of spintronic THz emitters.

Enhancement of THz emission from Fe/L1₀-FePt/Pt spintronic emitters – •LAURA SCHEUER¹, MORITZ RUHWEDEL¹, DOMINIK SOKOLUK³, GARIK TOROSYAN⁴, MARCO RAHM³, BURKARD HILLEBRANDS¹, THOMAS KEHAGIAS², RENÉ BEIGANG¹, and EVANGELOS PAPAIOANNOU⁵ – ¹Department of Physics and Landesforschungszentrum OPTIMAS, TU Kaiserslautern, Kaiserslautern, Germany – ²Department of Physics, Aristotle University of Thessaloniki, Thessaloniki, Greece – ³Fachbereich Elektro-Informationstechnik and Landesforschungszentrum OPTIMAS, University of Kaiserslautern, Kaiserslautern, Germany – ⁴Photonic Center Kaiserslautern, Kaiserslautern, Germany – ⁵Institute for Physics, Martin-Luther University Halle Wittenberg, Halle, Germany

The development of thin film multilayers composed of a ferromagnetic metal (FM) layer and a non-magnetic metal (NM) layer as sources for THz emission opened a new direction in physics.

In this presentation we concentrate on the impact of the FM/NM interface on the THz emission. We intentionally modify the Fe/Pt interface by manipulating the Pt growth temperature to achieve the formation of an ordered  $L1_0$ -FePt alloy interlayer. Subsequently, we find a Fe/L1_0-FePt (2nm)/Pt configuration to be significantly superior to a Fe/Pt bilayer structure, regarding THz emission amplitude and bandwidth. Both can be controlled by the extent of alloying on either side of the interface [1].

[1] L. Scheuer et al.: THz emission from Fe/Pt spintronic emitters with  $L1_0$ -FePt alloyed interface, iScience, Volume 25, Issue 5, 2022

 $\begin{array}{ccc} MA \ 19.54 & Tue \ 17:30 & P2 \\ \textbf{Spectral characteristics of microstructured spintronic THz emitters} & \\ \bullet \text{Rieke von Seggern}^1, \text{Christopher Rathje}^1, \text{Leon Gräper}^1, \text{Jana Kredl}^2, \\ \text{Jakob Walowski}^2, \ \text{Markus Münzenberg}^2, \ \text{and Sascha Schäfer}^1 & \\ ^1\text{Institute of Physics, University of Oldenburg, Germany} & \\ & \\ & \\ \text{University of Greifswald, Germany} \end{array}$ 

The introduction of spintronic terahertz emitters (STE) opened up a new class of terahertz (THz) sources with useful properties for spectroscopy applications, such as an ultrabroad and gapless emission spectrum and high THz peak field strengths [1].

Here, a resonator-grafted STE bilayer (CoFeB/Pt) is illuminated by a focused optical excitation pulse (780-nm central wavelength, 70-fs pulse duration, 16-um FWHM spot size) to generate a micrometer-scale broadband THz source. The radiated THz field coupled to the adjacent resonator is recorded via electro-optic sampling, dependent on the excitation location. Remarkably, the emitted THz signal changes drastically due to the coupling of the local dipole to the microresonators [2]. The spectral influence of different resonator geometries is experimentally demonstrated, and the underlying physical mechanisms are discussed based on detailed numerical simulations of the phenomenon. Special emphasis is placed on the interplay between intrinsic resonator characteristics and angular THz emission distributions.

**Domain structure of few-layer Fe_3GeTe_2 microflakes** — •HONEY BOBAN¹, KEDA JIN², TOBIAS WICHMANN², ANNA MANDZIAK³, EWA MADEJ³, JOSE MAR-TINEZ CASTRO², VITALIY FEYER⁴, IULIA COJOCARIU⁴, DANIEL BARANOWSKI⁴, FELIX LUPKE², CLAUS MICHAEL SCHNEIDER¹, and LUKASZ PLUCINSKI¹ — ¹PGI-6, Forschungszentrum Juelich — ²PGI-3, Forschungszentrum Juelich — ³SOLARIS Centre, Krakow — ⁴Elettra Synchrotron, Trieste

 $Fe_3GeTe_2$  is a ferromagnetic 2D metal with a bulk transition temperature of 220K[1]. Monolayer FGT is inversion asymmetric, whereas in the bulk inversion symmetry is recovered because of the AB stacking. FGT exhibits stripe domain patterns with an average width of 140 nm at 110K[1]. Within each layer a combination of inversion asymmetry with ferromagnetism gives rise not only to a finite spin polarization but also to energy shifts of spectral features between K and K' momenta[2].

To study the spin polarized bands in FGT, we shall probe a single terrace with domain larger than the photon beamspot. We exfoliated FGT flakes of 4-5 monolayer thickness on graphite/Au/SiO₂ in a glovebox and encapsulated them with graphene, since thin FGT flakes degrade rapidly in ambient conditions[3]. Dichroic PEEM measurements on these flakes showed single domains of sizes up to 4 x 3  $\mu$ m, when cooled down to <100K. The thin flakes with 4 x 3  $\mu$ m single domain can be used to demonstrate the predicted asymmetries at the K and K' points.

**Exchange interactions in monolayers of the MnBi**₂ $Te_4$  family — •DONYA MAZHJOO, GUSTAV BIHLMAYER, and STEFAN BLÜGEL — Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich, D-52425 Jülich, Germany

Due to their novel properties, two-dimensional magnetic materials are highly desirable for spintronic applications. An interesting material is  $MnBi_2Te_4$  [1]. Of substantial interest is the relating of the intrinsically topological properties of  $MnBi_2Te_4$  and the magnetic interactions and the impact of the alteration of their chemical constitution. The question can be resolved by density functional theory (DFT), which enables the calculation of the magnetic interaction directly from the electronic structure.

By using the full-potential linearized augmented planewave method (FLAPW) as implemented in the FLEUR-code [2], we analyzed the exchange interaction in septuple layers of  $MnBi_2Te_4$  type. Mapping our results on the extended Heisenberg model, we disentangle different exchange interactions, spin-orbit coupling effects like the magnetocrystalline anisotropy, and higher-order interactions [3]. Also, applying an external electric field breaks the inversion symmetry and allows for a strong DMI that may lead to the realization of metastable topological magnetic structures [4].

Investigation of the surface structure of  $Y_3Fe_5O_{12}$  thin films by X-ray photoelectron spectroscopy and diffraction (XPS and XPD) — •THOMAS RUF¹, PHILIP TREMPLER², GEORG SCHMIDT², and REINHARD DENECKE¹ — ¹Wilhelm-Ostwald-Institut, Universität Leipzig — ²Institut für Physik, Martin-Luther-Universität Halle-Wittenberg

 $Y_3Fe_5O_{12}$  (YIG) is a ferrimagnetic and insulating material with low ferromagnetic resonance (FMR) linewidth and damping constant. High surface quality and complete epitaxial growth are important for YIG thin films. High-quality YIG thin films are good candidates for integrated magnonics and spin injection in YIG/metal bilayers.

XPD measurements for assignment of the surface structure of pulsed laser deposited, high quality and pseudomorphic YIG(100) on Gd₃Ga₅O₁₂(100) and YIG(111) on Gd₃Ga₅O₁₂(111) 50 nm thin films were conducted. XPS angular intensity anisotropies for high kinetic energy lines Y 3d ( $E_{kin} = 1329$  eV), Fe 3p ( $E_{kin} = 1430$  eV) and O 1s ( $E_{kin} = 957$  eV) of the thin films can be interpreted in the forward focusing regime as a bulk-like (SG Ia3d) surface structure. Simplifying the interpretation to forward focusing allows for interpretation as a real space scan. The normalized intensity for Y 3d and Fe 3p lies in the range of 0.85 to 1.2 and approx. 0.9 to 1.1 for O 1s. This confirms epitaxial coherence reaching to the film surface, as XPD effects are restricted to few atomic layers. The measured XPS quantification ratios of 1.1 and 1.2 for [Y]/[Fe], compared to nominally 0.6, can only be partly explained by those XPS angular intensity anisotropies.

MA 19.58 Tue 17:30 P2

Ti, V, Ta, Nb as a boron sink in crystalline CoFeB/ MgO/ CoFeB Magnetic Tunnel Junctions — •TOBIAS PETERS, LAILA BONDZIO, INGA ENNEN, and GÜN-TER REISS — Center for Spinelectronic Materials and Devices, University of Bielefeld, Germany

We investigated the tunnel magnetoresistance (TMR) in CoFeB/MgO/ CoFeB Magnetic Tunnel Junctions (MTJs) and studied the use of Ti, V, Ta and Nb as a boron getter during thermal annealing. Exchange bias MTJs were deposited by sputtering deposition. The basic TMR stack was modified by inserting an additional ultrathin layer into the CoFeB bottom electrode and changing the capping layer with the stated materials. TMR measurements have been performed for samples post-annealed at temperatures from 270°C to 420°C for 1h. The boron diffusion was observed via Electron Energy Loss Spectroscopy and Transmission Electron Microscopy. Nb-samples show the highest TMR for post-annealing temperatures smaller then 360°C. For higher temperatures we found even higher TMR for a Ta-sample. However, the insertion of Ta in the CoFeB electrode leads to a severe loss of pinning.

#### MA 19.59 Tue 17:30 P2

Magnetization dynamics in hybrid ferromagnetic / antiferromagnetic systems — •HASSAN AL-HAMDO¹, YARYNA LYTVYNENKO², GUTENBERG KENDZO¹, MISBAH YAQOOB¹, MORITZ RUHWEDEL¹, PHILIPP PIRRO¹, OLENA GOMONAY², VITALIY I. VASYUCHKA¹, MATHIAS KLÄUI², MARTIN JOURDAN², and MATHIAS WEILER¹ — ¹Fachbereich Physik and Landesforschungszentrum OPTI-MAS, Technische Universität Kaiserslautern, 67663 Kaiserslautern, Germany — ²Institute of Physics, Johannes Gutenberg-University Mainz, 55128 Mainz, Germany

While typical antiferromagnetic magnons are in the THz range at zero external magnetic field, ferromagnetic magnons are gapless. A ferromagnet/antiferromagnet bilayer is thus expected to host hybrid spin excitations. We study the magnetization dynamics of  $Mn_2Au/Ni_{80}Fe_{20}$  thin film bilayers. This system allows us to control the  $Mn_2Au$  Néel vector orientation with moderate external magnetic fields [1].  $Mn_2Au$  furthermore shows strong spin-orbit torque efficiency [2] making this system intriguing for all-electrical control of magnetization direction. By varying the thickness of Ni₈₀Fe₂₀, we investigated the effect of the  $Mn_2Au/Ni_{80}Fe_{20}$  interface on Ni₈₀Fe₂₀ spin dynamics. Broadband ferromagnetic resonance and Brillion light scattering experiments reveal that interfacial exchange coupling causes an increase in the resonance frequency of Ni₈₀Fe₂₀. **Imaging the magnetic structure of antiferromagnetic PtMn** – •BEATRICE BEDNARZ, CHRISTIN SCHMITT, HENDRIK MEER, ADITHYA RAJAN, MATHIAS KLÄUI, and GERHARD JAKOB — Institut für Physik, Johannes Gutenberg-Universität Mainz, Staudingerweg 7, 55128 Mainz, Germany

Antiferromagnetic materials (AFM) are gaining increasing interest in the recent years because of their high potential for new spintronic devices with very high bit packing densities and ultrafast dynamics. [1] PtMn is widely used, especially to pin ferromagnetic layers in magnetic devices. [2]  $Pt_{50}Mn_{50}$  has a CuAu-I type structure with a high bulk Néel temperature of 975 K. [3] THz spin dynamics [4] and periodic chiral structures [5] have been predicted in PtMn. However, to use it as the active layer of spintronic devices, the first crucial step is to read out its magnetic state. This was achieved now by imaging the domains with x-ray magnetic linear dichroism (XMLD). Additionally, the domain size was determined from a Fourier transform of the XMLD images for 40 nm PtMn grown on MgO (001) and capped with 1.6 nm Al. It shows a distinct ring, corresponding to an average domain periodicity of approximately 650 nm.

Ultrafast Magnetization Dynamics in spin Hall nano-oscillators layer-stacks with different heavy metals — •TAHEREH SADAT PARVINI, JAKOB WALOWSKI, and MARKUS MUENZENBERG — Institut für Physik, Universität Greifswald, Greifswald, Germany

We employed an all-optical time-resolved magneto-optical Kerr effect (TRMOKE) microscope for an unambiguous determination of oscillation frequency and Gilbert damping of spin Hall nano-oscillators. The structures of the stacks are  $WTa(5)/Py(7)/Pt(2)/HfO_X$ ,  $W(5)/Py(7)/Pt(2)/HfO_X$ ,  $Py(7)/PtCu(5)/HfO_X$ , and  $Py(7)/PtCr(5)/HfO_X$  (thicknesses are in nm). The oscillation frequency and effective damping parameters are investigated as a function of the intensity and direction of the external magnetic field, the intensity of the pump, and cap layer thicknesses. Our results show stacks with PtCr and PtCu cap layers have smaller Gilbert damping than stacks with Pt cap layers. This study paves the way for developing ultrafast spintronic devices for data storage and information processing.

#### MA 19.62 Tue 17:30 P2

Direct imaging of current-induced antiferromagnetic switching in NiO revealing a pure thermomagnetoelastic switching mechanism — •HENDRIK MEER¹, FELIX SCHREIBER¹, CHRISTIN SCHMITT¹, RAFAEL RAMOS^{2,3}, EIJI SAITOH^{2,4}, OLENA GOMONAY¹, JAIRO SINOVA¹, LORENZO BALDRATI¹, and MATHIAS KLÄUI¹ — ¹Institute of Physics, Johannes Gutenberg-University Mainz, Mainz, Germany — ²CIQUS, Departamento de Quimica-Fisica, Uni-

versidade de Santiago de Compostela, Santiago de Compostela, Spain — ³WPI-Advanced Institute for Materials Research, Tohoku University, Sendai, Japan — ⁴Department of Applied Physics, The University of Tokyo, Tokyo, Japan

Antiferromagnetic spintronics is considered as a disruptive approach, enabling scalable ultrafast and efficient spintronic devices. We observe current-induced magnetic switching of insulating antiferromagnet/heavy metal bilayers. Previously, different reorientations of the Néel order for the same current direction were reported for different device geometries and different switching mechanisms were proposed. Here, we combine concurrent electrical readout and optical imaging of the switching of antiferromagnetic domains with simulations of the current-induced temperature and strain gradients. By comparing the switching in specially engineered NiO/Pt device and pulsing geometries, we can rule out dominating spin-orbit torque based mechanisms and identify a thermo-magnetoelastic mechanism to switch the antiferromagnetic domains, reconciling previous reports.

Spin Hall magnetoresistance effect in orthoferrites/Pt heterostructures. S. Becker¹, •E.F. Galindez-Ruales¹, A. Ross¹, E. Pomjakushina², F. Schreiber¹, R. Lebrun^{1,3}, G. Jakob¹, O. Gomonay¹, and M. Kläul¹ — ¹Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Germany. — ²Laboratory for Multiscale Materials Experiments, PSI, 5232, Villigen PSI, Świtzerland-<br/> 3 Unité Mixte de Physique CNRS-Thales, Palaiseau, France Although there are advantages of antiferromagnetic systems [1], there are some limitations in the length of the spin transmission distance that only recently have been tackled using orthoferrites [2]. TmFeO₃ (TFO), a rare earth orthoferrite, possesses both collinear antiferromagnetic ordering and a net canted ferromagnetic moment. That is due to the bulk Dzyaloshinskii-Moriya interaction (DMI), which leads to a canting of the four magnetic iron sublattices [3]. Spin Hall magnetoresistance (SMR) is used to investigate the magnetic properties of a bulk sample [4]. We can identify the onset of the spin reorientation transition (SRT) as well as the spin-flop field, which changes approximately linearly with temperature around the SRT. We observe differences between the different devices likely stemming from the symmetry breaking at the TFO/Pt interface due to interfacial DML.

**Structure and magnetism of hematite nanodiscs** — •MARYNA SPASOVA and MICHAEL FARLE — Faculty of Physics and Center of Nanointegration (CENIDE), University of Duisburg-Essen, Germany

Hexagonal shaped, single crystal hematite nanodiscs with thickness of 20 nm and different lateral sizes from 110 nm up to 250 nm were synthesized by an alcohol-thermal reaction. High Resolution Transmission Electron Microscopy reveals a very high crystallinity with (0001) basal planes and (101-2) side surfaces. The temperature of the Morin transition (MT) decreases for smaller diameters of the nanodiscs. The magnetization above the MT, however, does not depend on the particle size. It is close to the bulk value (M = 0.3 Am2/kg) whereas the coercivity decreases with increasing diameter from 55 kA/m (110 nm) to 37 kA/m (250 nm). Below the MT the nanodiscs are ferromagnetic r due to uncompensated surface magnetic measured at 10K is proportional to the surface area of the sample. The coercivity at 10 K increases with increasing particle diameter, i.e. 50 kA/m for 110 nm up to 550 kA/m for 250 nm. A very high irreversibility field of 3000 kA/m indicates a high magnetic anisotropy of the sample.

## MA 20: Focus Session: Revealing Multidimensional Spin Textures and their Dynamics via X-rays and Electrons

Non-collinear spin textures in magnetic materials and excitations within such spin arrangements moved into the focus of research. These system host topological spin states and unique excitations providing access to versatile future spintronic applications. The imaging of such complex internal magnetic orders of materials is a fundamental problem of extreme importance for the successful implementation of these applications. Characterizing the electronic, magnetic and transport properties of structures such as vortices, magnetic singularities or hopfions lead to the development of novel experimental and theoretical techniques. For instance, magnetic hopfions have been unveiled via a combination of X-ray photoemission electron microscopy and soft X-ray transmission microscopy using element-specific X-ray magnetic circular dichroism effects. Recently, time-resolved magnetic laminography enabled access to the temporal evolution of three-dimensional (3D) magnetic microdiscs with nanoscale resolution, while quantitative reconstruction of the 3D spintexture of skyrmions with sub-10 nm resolution was demonstrated by holographic vector field electron tomography or soft x-ray vector ptychography. Pivotal to these experimental developments are theoretical proposals for the detection and manipulation protocols. Although making a strong impact in the field of magnetism, this area of research calls for an in-depth exchange between experts of different techniques, experimental and theoretical, to unravel many of the open questions and puzzling behavior discovered within the last couple of years. This motivates the present focus session as an opportunity for discussions and to attract more researchers to this fascinating field.

#### MA 20.1 Wed 9:30 H37 Recent developments in X-ray three-dimensional magnetic imaging -•Valerio Scagnoli — ETHZ - PSI

Three dimensional magnetic systems hold the promise to provide new functionality associated with greater degrees of freedom. Over the last years we have worked towards developing methods to fabricate and characterize three dimensional magnetic structures. Specifically, we have combined X-ray magnetic imaging with new iterative reconstruction algorithms to achieve X-ray magnetic tomography and laminography [1-4]. In a first demonstration, we have determined the three-dimensional magnetic nanostructure within the bulk of a soft GdCo2 magnetic micropillar and we have identified the presence of Bloch points of different types [1] as well as three-dimensional structures forming closed vortex loops [3]. Subsequently, we have used the flexibility provided by the laminography geometry to perform time resolved measurements of the magnetization dynamics in a two-phase micrometer size GdCo disk. Therefore, X-ray magnetic three-dimensional imaging, with its recent extension to the soft X-ray regime [5], has now reached sufficient maturity that will enable to unravel complex threedimensional magnetic structures for a range of magnetic systems.

MA 20.2 Wed 10:00 H37 Magnetic depth profiling with x-ray resonant magnetic reflectivity (XRMR) •Тімо Kuschel — Department of Physics, Bielefeld University, 33615 Bielefeld, Germany

Magnetic depth profiling is one of the important thin-film characterization techniques in today's condensed matter physics and, in particular, in the spintronic research field. The interference of reflected light from the interfaces of a magnetic thin-film system depends on its magnetic state. Thus, the detected reflectivity of typically circularly polarized light provides information on the depth profile of the sample's magnetization. By the use of synchrotron x-rays, this dependence becomes element-selective as long as the absorption energy of a specific chemical element is used as photon energy. Therefore, the analysis of the x-ray resonant magnetic reflectivity (XRMR) separates the individual magnetic depth profiles of different chemical elements [1].

In my contribution, I will introduce this experimental technique and emphasize advantages over standard x-ray magnetic circular dichroism detection [2]. I will discuss the quantitative comparability of XRMR with other experimental techniques [3] and present recent results on the magnetic proximity effect in platinum (Pt), palladium (Pd) and vanadium (V). Finally, I will highlight the cationand lattice-site sensitivity of XRMR for the study of Fe₃O₄ and its interfaces [4].

**Invited Talk** 

MA 20.3 Wed 10:30 H37 Magnetic Bragg Ptychography Studies of Spin Caloritronic - •DINA CARBONE¹, PENG LI², STEPHAN GEPRÄGS³, RUDOLF GROSS^{3,4}, PAUL EVANS⁵, VIRGINIE CHAMARD⁶, and DAN MANNIX⁷ – ¹MAX IV Laboratory, Lund SE – ²Diamond Light Source, Didcot UK – ³Walther-Meißner-Institut, BAdW, Garching DE – ⁴Physik-Department, TUM, Garching DE – ⁵Univ. of Wisconsin, Madison USA — ⁶Institut Fresnel, Marseille FR — ⁷ESS, Lund SE & Institut Néel, Grenoble FR

Spin-caloritronics refer to a class of materials in which spin, charge and heat currents can be interconverted. This gives rise to diverse functional properties that offer a great potential towards a new generation of fast and low power consumption electronics. Advances in the design and understanding of future spintronic nanotechnologies require the development of state-of-the-art 3D magnetic characterisation tools. In particular, for crystalline magnetic materials grown at nanoscales, understanding the interdependence of their magnetic properties with crystal structure and strain is crucial.

We have developed a magnetic and structural microscopy based on scanning diffraction, by combining circular polarisation and focussing of the X-ray beam. This has revealed spin texture in prototype spin caloritronics device structures and its relation with crystal orientation down to micron resolution[1]. New results obtained with coherent X-rays, using magnetic Bragg ptychography, push this technique towards a 3D spin microscopy with a resolution of few tens of nm.

#### Invited Talk MA 20.4 Wed 11:15 H37 Imaging the 3D magnetic texture of skyrmion tubes and approaches towards determining their Hall signature — •B. RELLINGHAUS¹, S. SCHNEIDER^{1,2}, D. WOLF², U.K. Rössler², M. SCHMIDT³, A. KOVÁCS⁴, R.E. DUNIN-BORKOWSKI⁴, D. POHL¹, A. THOMAS², D. KRIEGER², B. BÜCHNER², and A. LUBK² - ¹DCN, cfaed, TU Dresden, Germany – ²IFW Dresden, Germany – ³MPI CPfS, Dresden, Germany — ⁴FZ Jülich, Germany

Despite the large interest in magnetic skyrmions, their 3D magnetic texture when being extended to skyrmion tubes (SkTs) in volume samples is largely unknown. We have therefore determined the magnetic structure of SkTs using low temperature holographic vector field electron tomography in an external magnetic field [1]. The resulting high-resolution 3D magnetic images reveal deviations from a homogeneous Bloch character, a collapse of the skyrmion texture near surfaces, the coexistence of longitudinal and transverse skyrmion textures, and a correlated axial modulation of the SkTs. Spatially resolved energy density maps calculated from the experimental magnetic induction data prove that these magnetic solitons are stabilized by the Dzyaloshinskii-Moryia interaction, which overcompensates the exchange energy in the centers of the tubes. In order to correlate the occurrence of skyrmionic structures with anomalies in their magneto-transport properties, we have devised a setup for the in-situ measurement of the Hall effect in a transmission electron microscope, first results of which will be highlighted. The work is gratefully supported by DFG within SPP 2137.

MA 20.5 Wed 11:45 H37 Determination of spin chirality and helicity angle by circular dichroism in soft x-ray absorption and resonant elastic scattering — •GERRIT VAN DER LAAN — Diamond Light Source, Didcot, UK

The depth profile of the full 3D spin structure of magnetic skyrmions below the surface of bulk Cu2OSeO3 was obtained using the polarization dependence of resonant elastic x-ray scattering (REXS) [AIP Advances 11, 015108 (2021)]. While the bulk spin configuration showed the anticipated Bloch type structure, the skyrmion lattice changes to a Néel twisting (i.e., with a different helicity angle) at the surface within a distance of several hundred nm. The experimental penetration length of the Néel twisting is 7x longer than the theoretical value given by the ratio of J/D. This indicates that apart from the considered spin interactions, i.e., Heisenberg exchange interaction J and Dzyaloshinskii-Moriya interaction D, as well as the Zeeman interaction, other effects must play an important role.

A new rule for the rotational symmetry invariance of the XMCD signal is presented [PRB 104, 094414 (2021)]. A threefold symmetric kagome lattice with negative spin chirality can give a nonzero x-ray magnetic circular dichroism (XMCD), despite a total spin moment of zero. A necessary condition is the existence of an anisotropic XMCD signal for the local magnetic atom. The maximum dichroism is not aligned along the spin direction but depends on the relative orientation of the spin with respect to the atomic orientation.

# MA 20.6 Wed 12:15 H37

Identification of complex spin-textures by novel Hall effects - •JUBA BOUAZIZ¹, HIROSHI ISHIDA², SAMIR LOUNIS¹, and STEFAN BLÜGEL¹ - ¹Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich & JARA, D-52425 Jülich, Germany — ²College of Humanities and Sciences, Nihon University, Sakurajosui, Tokyo 156-8550, Japan

Chiral magnetic phases of matter are commonly found in non-centrosymmetric materials. The complex magnetic order is stabilized by the Dzyaloshinskii-Moriya interaction, which promotes topologically non-trivial spin textures such as skyrmions. These entities imprint a characteristic signature on the Hall signal known as the topological Hall effect, allowing their detection employing

magneto-transport measurements. In this talk, relying on perturbation theory, we disentangle the multiple contributions to the Hall signal originating from non-collinear magnetism and relativistic effects. We unveil a new contribution, the non-collinear Hall effect (NHE) [1], whose angular form is determined by the magnetic texture, the spin-orbit field of the electrons, and the underlying crystal structure. The NHE together with other components of the Hall resistivity enables the decoding of exotic non-collinear magnetic textures that have been observed in itinerant magnets [1,2]. The impact of the NHE on the Hall signal of several two and three-dimensional spin textures such as magnetic hopfions is examined. [1] J. Bouaziz et al. PRL 126, 147203 (2021), [2] A. Neubauer et al. PRL 102, 186602 (2009).

#### MA 20.7 Wed 12:45 H37

All-electron holography of hopfions enabled by magneto-induced charges - •MORITZ WINTEROTT^{1,2} and SAMIR LOUNIS^{1,2} — ¹Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich & JARA, D-52425 Jülich, Germany —  $^2 \rm Faculty$  of Physics, University of Duisburg-Essen and CENIDE, 47053 Duisburg, Germany

In recent years, far-reaching progress has been made in the field of topological particles. In addition to the well-known skyrmions, three-dimensional topological particles such as hopfions, bobbers and cocoons, are also becoming increasingly interesting. Thereby, a major challenge is the visualisation and recognition of such topological particles hidden in bulk materials. An intuitiv approach is to resolve their magnetic contrast, which is highly non-trivial, especially for antiferromagnetic textures where the overall signals are expected to vanish. Here we demonstrate that the charge carried by such topological objects carries specific dependencies on the misalignement of the magnetic moments, which enable their identification without the need for spin-resolved measurements. We utilize multiple-scattering theory and address the case of ferro- and anti-ferromagnetic hopfions. We identify the achiral and chiral-induced charges. Spin-orbit interaction (SOI) gives rise to the latter in 1st order similarly to the Dzyaloshinskii-Moriya interact and to anisotropic terms, 2nd order in SOI. We proceed to a systematic electron holography of the distinct magneto-induced charges, which provide a direct link to experiments.

## MA 21: Terahertz Spintronics

Time: Wednesday 9:30-12:15

MA 21.1 Wed 9:30 H43

Spintronic THz emitters for lightwave-driven scanning tunneling microscopy at MHz repetition rates — •Alkisti Vaitsi¹, Vivien Sleziona¹, Fabian Schulz², Luis Enrique Parra Lopez¹, Tom Sebastian Seifert^{1,3}, Martin Wolf¹, and Melanie Müller¹ — ¹Fritz Haber Institute of the Max Planck Society, Berlin, Germany — ²CIC NanoGUNE BRTA, San Sebastian, Spain — ³Freie Universität Berlin, Germany

Attaining simultaneous high temporal resolution and signal-to-noise ratio in THz lightwave-driven scanning tunneling microscopy (THz-STM) requires broadband single-cycle THz pulses at high repetition rates and electric field strength. In this context, we report on the operation of ultrabroadband spintronic THz emitters (STE) at MHz repetition rates and pump powers of several Watts. We discuss saturation mechanisms which can reduce THz emission efficiency, such as steady-state and transient heating, limiting the usable fluence at the STE. Furthermore, to maximize the THz field in the STM junction, we analyze and optimize THz propagation into the STM, which due to the ultrabroadband spectrum of the STE requires careful consideration of pump spot sizes in combination with the limitations arising from pump fluence and average pump power density. We present detailed experimental and theoretical analysis of the ideal excitation geometry, which allows STE operation up to 10 W average powers at 2 MHz repetition rate at optimized fluence and THz propagation into the STM.

#### MA 21.2 Wed 9:45 H43

Investigation of THz electromagnetic response in nanopatterned magnetic heterostructures by current confinement – •BIKASH DAS MOHAPATRA¹, Reza Rouzegar³, Evangelos Papaioannou¹, Tobias Kampfrath³, and Georg SCHMIDT^{1,2} — ¹Institut für Physik, Martin-Luther-Universität Halle-Wittenberg, Von-Danckelmann-Platz 3, D-06120 Halle, Germany — ²Interdisziplinäres Zentrum für Meterialwissenschaften, Martin-Luther-Universität Halle-Wittenberg, Heinrich-Damerow-Straße 4, D-06120 Halle, Germany — ³Department of Physical Chemistry, Fritz Haber Institute, Faradayweg 4-6, 14195 Berlin, Germany

STEs (Spintronic Terahertz Emitters) are novel THz radiation sources. Many studies have demonstrated that the STEs when illuminated with fs-laser pulse, ultrafast spin current is produced which leads to ultrafast transverse charge current by Inverse Spin Hall Effect, resulting in THz electromagnetic pulses. We were able to fabricate THz emitters into arrays of various squares and rectangles of micron or sub-micron size, using Sputter deposition and e-beam lithography. These emitters generate a different emission spectrum than large area reference emitters when irradiated with a fs laser. We propose that the confinement due to small size induces local charge buildup, which leads to additional currents that counterbalance the original charge current due to the Inverse Spin Hall Effect.

#### MA 21.3 Wed 10:00 H43

Location: H43

Coupling of a local broadband THz emitter to a 2D micro-resonator - •Christopher Rathje¹, Rieke von Seggern¹, Leon Gräper¹, Jana Kredl², Jakob Walowski², Markus Münzenberg², and Sascha Schäfer¹ - ¹Institut für Physik, Universität Oldenburg — ²Institut für Physik, Universität Greifswald

Recently, the advent of spintronic terahertz emitters (STE) has introduced a simple approach to generate broadband radiation in the terahertz (THz) spectral domain [1].

In this contribution, we utilize a resonator-grafted STE bilayer illuminated by a focused optical excitation pulse for the generation of a micrometer-scaled broadband THz emitter with a source size far below the THz diffraction limit [2]. The near-field of this localized transient electric dipole is coupled to a bow-tie antenna structure in direct proximity to the emitter. Depending on the position of the excitation focus, we detect the emitted THz time-domain signal in the far-field.

Our results show pronounced changes of the emission characteristics of the excited STE layer for a dipole positioned in the bow-tie gap, demonstrating the capability to tailor the emission spectrum including resonant enhancement of certain frequency components and increase of the overall bandwidth. We discuss the influence of different resonator designs and provide a model of the coupling process supported by numerical simulations. Further results for different isolated resonators and periodically structured metasurfaces are presented.

Spin pumping in noncollinear antiferromagnets — •MIKE ALEXANDER LUND, AKSHAYKUMAR SALIMATH, and KJETIL MAGNE DØRHEIM HALS — University of Agder, Norway

The spin pumping and spin-transfer torque mechanisms in antiferromagnets have been theoretically and experimentally investigated in recent years. However, most of these works have concentrated on collinear antiferromagnets, leaving the spin dynamics of the more complex noncollinear antiferromagnets largely unexplored. Apart from a few works on spin-transfer torque, there has been no thorough investigation of the spin pumping process in noncollinear antiferromagnets.

In this talk, I will present our latest work on ac spin pumping in noncollinear antiferromagnets. Starting from an effective action description of the spin system, we derive the Onsager coefficients connecting the spin pumping and spin-transfer torque associated with the dynamics of the SO(3)-valued antiferromagnetic order parameter. Our theory is applied to a kagome antiferromagnetic resonalty driven by a uniform external magnetic field. We demonstrate that the reactive (dissipative) spin-transfer torque parameter can be extracted from the pumped ac spin-current in phase (in quadrature) with the driving field. Furthermore, we find that the three spin-wave bands of the kagome antiferromagnet generate spin currents with mutually orthogonal polarization directions. This offers a unique way of controlling the spin orientation of the pumped spin current by exciting different spin-wave modes.

#### MA 21.5 Wed 10:30 H43

THz spin dynamics in antiferromagnetic Mn2Au — •YANNIC BEHOVITS^{1,2}, Alexander Chekhov^{1,2}, Stanislav Bodnar³, Mathias Kläui³, Martin Jourdan³, and Tobias Kampfrath^{1,2} - ¹Freie Universität Berlin, Insitut für Experimental<br/>physik, 14195 Berlin, Germany —  $^2 {\rm Fritz}$ -Haber-Institut der Max-Planck-Gesellschaft, Abteilung Physikalische Chemie, 14195 Berlin, Germany -³Johannes-Gutenberg-Universität, Institut für Physik, 55122 Mainz, Germany In metallic antiferromagnets, intrinsic terahertz (THz) magnons may allow highspeed spin information processing. For CuMnAs and Mn2Au, switching of the Néel vector has been demonstrated by using pulsed electrical currents and freespace THz pulses [1,2]. The switching was attributed to the current-induced Néel spin-orbit torque (NSOT)[3]. However, the underlying spin dynamics have not been observed on picosecond timescales. Here, we employ a THz-pump optical-probe setup to investigate dynamics of antiferromagnetic order induced by NSOT in Mn2Au. We observe a signal proportional to the driving THz field, which is consistent with NSOT-driven spin dynamics both in frequency and symmetry. Our results indicate a strongly damped magnon mode at 0.6 THz. By using a simple model, we can extract material properties and estimate the field strengths required for picosecond rotation of the antiferromagnetic order.

Spin-orbit interaction at terahertz rates —  $\bullet$ Tom S. Seifert and Tobias Kampfrath — FU Berlin

Spintronics aims at implementing the spin degree of freedom into conventional electronics. To be compatible and competitive, spintronic functionalities thus need to keep pace with the ever-increasing speeds of electronic devices that are foreseen to enter the terahertz range eventually [1]. Therefore, one needs to study fundamental spintronic phenomena at terahertz frequencies. Following this approach, one might not only hope to reveal new physics but also to apply these novel insights in terms of innovative terahertz photonic applications. Here, I will discuss our recent experimental efforts to study a central spintronic effect, the anomalous Hall effect (AHE) [2] in metallic magnets from DC to 40 THz. We find a largely frequency-independent AHE in DyCo5, Gd27Fe73 and Co32Fe68, which we attribute to the large Drude scattering rate in metallic thin films. The gained knowledge could further enhance the efficiency of a novel ultrafast spin tronic application, namely the spintronic terahertz source [3].

#### MA 21.7 Wed 11:00 H43

Spin-orbit torque mediated coupling of terahertz light with magnon modes in heavy-metal/ferromagnet heterostructures — •RUSLAN SALIKHOV¹, IGOR ILYAKOV¹, LUKAS KÖRBER¹, ATTILA KÁKAY¹, KILIAN LENZ¹, JÜRGEN FASSBENDER¹, STEFANO BONETTI^{2,3}, OLAV HELLWIG^{1,4}, JÜRGEN LINDNER¹, and SERGEY KOVALEV¹ — ¹Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — ²Stockholm University, Stockholm, Sweden — ³University of Venice, Italy — ⁴Chemnitz University of Technology, Chemnitz, Germany

Nonvolatile and energy-efficient spin-based technologies call for new prospects to realize computation and communication devices that are able to operate at terahertz (THz) frequencies. In particular, the coupling of electro-magnetic radiation to a spin system is a general requirement for future communication units and sensors. Here we propose a layered metallic system, based on a ferromagnetic film sandwiched in between two heavy metals that allows a highly effective coupling of millimeter wavelength THz light to nanometer-wavelength magnon modes. Using single-cycle broadband THz radiation we are able to excite spinwave modes with a frequency of up to 0.6 THz and a wavelength as short as 6 nm. Our experimental and theoretical studies demonstrate that the coupling

originates solely from interfacial spin-orbit torques. These results are of general applicability to magnetic multilayered structures, and offer the perspective of coherent THz excitation of exchange-dominated nanoscopic magnon modes.

#### MA 21.8 Wed 11:15 H43

Laser-induced charge and spin photocurrents in BiAg₂ surface from firstprinciples — •THEODOROS ADAMANTOPOULOS^{1,2}, MAXIMILIAN MERTE^{1,2,3}, FRANK FREIMUTH^{1,3}, DONGWOOK Go^{1,3}, STEFAN BLÜGEL¹, and YURIY MOKROUSOV^{1,3} — ¹Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — ²Department of Physics, RWTH Aachen University, 52056 Aachen, Germany – ³Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Germany

The physics of photo-induced effects in interfacial systems is intensively researched these days owing to numerous potential applications. Owing to the complexity of the problem, a comprehensive theoretical picture of photogalvanic effects is still lacking. Here we perform first-principles calculations of laserinduced currents in a BiAg₂ surface alloy, which is a well-known material realization of the Rashba model [1, 2]. Our results confirm the emergence of very large in-plane photocurrents as predicted by the Rashba model and establish a benchmark picture of photocurrents at Rashba-like surfaces and interfaces [3]. This work contributes to the study of the role of the interfacial Rashba spin-orbit interaction as a mechanism for the generation of in-plane photocurrents, which are of great interest in the field of ultrafast and terahertz spintronics.

 $MA \ 21.9 \ Wed \ 11:30 \ H43$ Transition of laser-induced terahertz spin currents from torque- to conduction-electron-mediated transport — •Oliver Gueckstock¹, Pilar JIMENEZ-CAVERO^{1,2}, LUKAS NADVORNIK¹, IRENE LUCAS², TOM S. SEIFERT¹, LUIS MORELLON², and TOBIAS KAMPFRATH¹ — ¹FU Berlin, Germany — ²Universidad de Zaragoza, Spain

Transport of spin angular momentum is a fundamental operation required for future spin-electronic devices. To be competitive with other information carriers, it is required to push the bandwidth of spin transport to the terahertz (THz) frequency range [1]. Here, we use femtosecond laser pulses to excite prototypical F|N bilayers consisting of a ferrimagnetic metal F and a nonmagnetic metal N [2,3]. Following absorption of the pulse, a spin current in F is launched and converted into a transverse charge current in N, giving rise to the emission of a THz electromagnetic pulse [2]. Depending on the conductivity of F, two driving mechanisms of the spin current can occur: (i) the ultrafast spin Seebeck effect [3] generating magnons and (ii) a spin voltage, generating a spin current carried by conduction electrons [4]. Remarkably, in the half-metallic ferrimagnet Fe3O4, we observe the coexistence of these contributions and disentangle them based on their distinctly different ultrafast dynamics. Our results shed new light on the magnetic structure of this mature material. References: [1] Vedmedenko et al., J. Phys. D: Appl. Phys. 53 453001 (2020), [2] T. Seifert et al., Nat. Ultrafast spintronic THz emission of thin CoFe/Pt films — •JANNIS BENSMANN¹, ROBERT SCHNEIDER¹, MARIO FIX², STEFFEN MICHAELIS DE VASCONCELLOS¹, MANFRED ALBRECHT², and RUDOLF BRATSCHITSCH¹ — ¹University of Münster, Institute of Physics and Center for Nanotechnology, 48149 Münster, Germany — ²University of Augsburg, Institute of Physics, 86159 Augsburg, Germany

THz radiation has great potential for spectroscopy, security and quality control applications. Recently, ultrafast spintronic THz emitters gained a lot of interest, as they are easy to handle and show high power and broadband emission. In these emitters, an ultrafast laser pulse launches a spin-polarized current from a nanometer-thin magnetic film into a non-magnetic metal layer. Due to the inverse spin Hall effect and the conversion to an ultrafast charge current, THz radiation is created. The THz emission of spintronic emitters can be tuned by the material compositions of the layers.

Here we present our recent results on THz emission spectroscopy of ultrathin  $Co_x Fe_{1-x}/Pt$  bilayers with varying Co content x. The THz amplitude changes only slightly with x, leading to the conclusion that both Fe and Co have a similar contribution to the THz generation process [1]. Moreover, we were able to boost the THz emission by using multilayer stacks of the mentioned structure.

MA 22.1 Wed 9:30 H47 Spin dynamics in coupled ferrimagnetic heterostructures - •FELIX Fuhrmann¹, Sven Becker¹, Akashdeep Akashdeep¹, Zengyao Ren^{1,2}, MATHIAS WEILER³, GERHARD JAKOB^{1,2}, and MATHIAS KLÄUI^{1,2,4} — ¹Institute of Physics, University of Mainz, Germany - ²Graduate School of Excellence "Materials Science in Mainz" (MAINZ), Germany — ³Fachbereich Physik and Landesforschungszentrum OPTIMAS, Technische Universität Kaiserslautern, Germany - ⁴Center for Quantum Spintronics, Norwegian University of Science and Technology, Trondheim, Norway

With growing demand for more energy efficient information technology, the utilization of magnons as information carriers entails potential advantages [1]. To successfully develop magnon-based devices, there are several requirements for the applied materials to meet. The insulating ferrimagnet Yttrium Iron Garnet (Y₃Fe₅O₁₂, YIG) and related garnets are good candidates with an outstanding low damping and large magnon propagation lengths [1]. Our heterostructures of YIG and Gadolinium Iron Garnet (Gd₃Fe₅O₁₂, GIG) were grown by pulsed laser deposition. We observe a ferromagnetic coupling between the Fe sublattices of the two layers, leading to complex magnetic response to external magnetic fields and a nontrivial temperature dependence [2]. We investigate the spin dynamics by broadband ferromagnetic resonance (FMR) experiments. Our observations are corroborated by measurements of SQUID magnetometry, spin Hall magnetoresistance and spin Seebeck effect [2]. [1] A. Chumak et al., Nat. Phys, 11, 453 (2015). [2] S. Becker et al., Phys. Rev. Appl., 16, 014047(2021).

MA 22.2 Wed 9:45 H47

Optical detection of magnon-phonon coupling using µFR-MOKE technique – •MANUEL MÜLLER^{1,2}, LUKAS LIENSBERGER^{1,2}, MATHIAS WEILER³, MATTHIAS ALTHAMMER^{1,2}, RUDOLF GROSS^{1,2,4}, and HANS HUEBL^{1,2,4} -¹Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — ²Physik-Department, Technische Universität München, Garching, Germany — ³Technische Universität Kaiserslautern, Kaiserslautern, Germany — ⁴Munich Center for Quantum Science and Technology (MCQST), München, Germany

Magnetoelastic coupling between wave-like excitations of the spin system (spin waves) and the lattice (elastic waves) can result in a hybridization of both modes. This coupling can reach the strong-coupling regime, which is of interest for future (quantum) applications, such as microwave-to-optics transducers and phononic spin valve devices.

We here present an experimental approach to investigate magnon-phonon coupling for the YIG layers in a YIG/GGG/YIG trilayer on an individual basis using the microfocused frequency-resolved magneto-optic Kerr effect(µFR-MOKE) technique [1]. We discuss the magnetization dynamics recorded individually for the top and bottom YIG layer with those acquired using broadband ferromagnetic resonance. This data gives further insight to the involved modes as well as their coupling. As a longterm perspective, we expect that this technique will allow the investigation of microstructures with enhanced coupling rates via their optimized geometry.

#### MA 22.3 Wed 10:00 H47

Experimental tests of the accuracy of the reflection matrix description in linear magneto-optics — •Carmen Martín Valderrama, Mikel Quintana, and ANDREAS BERGER - CIC nanoGUNE BRTA, E-20018 Donostia-San Sebastián, Spain

Magneto-Optical (MO) Kerr Effect (MOKE) techniques are frequently utilized to monitor magnetization M reversal, and even its vector information, in a non-destructive way [1]. The assumption is hereby that the Jonesformalism reflection matrix R, including  $1^{st}$  order MOKE, is given as R = $r_s = \alpha(m_x) + \gamma(m_z)$ , with  $m_{x,y,z}$  being the M components in  $\alpha(m_x) + \gamma(m_z) = r_p + \beta(m_y)$ ,

We used the setup described in [1] to study the laser driven lattice and spin dynamics of a 380 nm thick flake of the antiferromagnetic van der Waals semiconductor FePS₃ as a function of excitation photon energy and sample temperature. We found evidence of a coherent optical lattice mode at a frequency of 3.2 THz. The amplitude of the phononic signal vanishes as the phase transition to the paramagnetic phase occurs, revealing its close connection to the long-range magnetic order. These findings open a pathway towards the coherent manipulation of the magneto-crystalline anisotropy in a van der Waals antiferromagnet, scalable down to thinner flakes.

Location: H47

Cartesian coordinates,  $r_s$  and  $r_p$  as Fresnel coefficients and  $\alpha$ ,  $\beta$  and  $\gamma$  being MOKE coefficients for longitudinal, transverse and polar effects. Recently, however, there have been reports of linear MOKE that is independent of a sample's magnetization [2]. Thus, it is important to verify the above R expression experimentally, which to our knowledge has not been done rigorously. For this, we utilized a sample with uniform M, which can be precisely rotated by an applied field, thus systematically varying the MOKE coefficients, while monitoring all of them simultaneously by means of General MO Ellipsometry. For the pure inplane magnetization case, for instance, the  $\alpha$  vs.  $\beta$  relation will lead to an ellipse equation,  $\alpha^2/\alpha_0^2 + \beta^2/\beta_0^2 = 1$ , if R is correct. We have confirmed this behavior experimentally with a very high degree of precision. However, we also discovered deviations from it in cases where samples exhibit MO anisotropy. [1] Appl. Phys. Lett. 71, 965 (1997), [2] Phys. Rev. B 102, 140408(R) (2020)

XMCD investigation on Sm-Co magnetic thin films: strong orbital pinning on Co and the role of Sm — •DAMIAN GÜNZING¹, GEORGIA GKOUZIA², RUIwen  ${\rm Xie}^2,$  Teresa Wessels 1,  Hongbin Zhang 2,  Lambert  ${\rm Alff}^2,$  Alpha T. N'DIAYE³, HEIKO WENDE¹, and KATHARINA OLLEFS¹ - ¹Faculty of Physics, University of Duisburg-Essen — ²Institute of Materials Science, Technical University of Darmstadt — ³Advanced Light Source, Lawrence Berkeley National Lab Berkeley

We present the investigation of crystalline Sm-Co thin films manufactured via MBE on an Al₂O₃ substrate without additional buffer layers [1] by soft X-ray magnetic circular dichroism (XMCD). We use XMCD to investigate the elementspecific spin and orbital moments of the individual elements, here Sm and Co. Often, with soft X-rays only the first few nm are probed via electron yield detection, leading to significant surface effects. In contrast, here, we use the luminescence of the substrate and are able to study the entire sample over the whole film thickness. We see a surprisingly strong orbital pinning on the Co sites in applied fields up to 2T. From element-specific hysteresis curves we find that the Sm atoms are coupled to Co, but with spectroscopic features saturating different in high fields. We compare the experimental results obtained by XMCD with multiplet calculations using Quanty, which suggest an exchange field present at the Sm site. #### MA 22.5 Wed 10:30 H47

Temperature independent coercivity by means of nanoscale materials design — •Mikel Quintana¹, Adrián Meléndez^{1,2}, Carmen Martín Valderrama¹, Lorenzo Fallarino¹, and Andreas Berger¹ - ¹CIC nanoGUNE BRTA, E-20018 Donostia-San Sebastián, Spain — ²UPV/EHU, E-48940 Bizkaia, Spain

Thin film materials, in which the exchange coupling strength is designed to be depth-dependent, behave at each depth as if their properties were controlled by a "local" Curie temperature  $T_c^{loc}$ , down to the 1-2 nm length-scale [1]. This phenomenon enables the control and design of ferromagnetic (FM) magnetization profiles as a function of temperature T. For instance, it allows one to engineer films exhibiting FM exchange-coupling everywhere, but which can split into separate multilayers exhibiting seemingly isolated FM states in certain T-ranges. Here, we present a multilayer system composed by two CoRu films separated by a graded  $\text{Co}_{1-x(z)}$ Ru_{x(z)} spacer layer with varying Ru concentration x along the depth z of the film. The spacer layer is such that an effective-PM-state thickness dividing two FM films decreases when reducing T. This specific materials design allows us to obtain a coercive field H_c plateau in an extended temperature range, in which  $H_c$  changes less than 2% between 150 K and 225 K, while conventional films exhibit a change of 20% in the same T-range. The stable coercivity plateau can be designed at any temperature by means of an adapted  $T_c^{loc}(z)$ design, enabling T-independent operation points for technological applications. [1] L. Fallarino et. al., Materials 11, 251 (2018).

## MA 22.6 Wed 10:45 H47

Influence of adhesion layer and sputter gas pressure on structural and magnetic properties of Co/Pt multilayers — •RICO EHRLER¹, TINO UHLIG¹, and OLAV HELLWIG^{1,2} — ¹Chemnitz University of Technology, D-09107 Chemnitz, Germany — ²Helmholtz-Zentrum Dresden-Rossendorf, D-01328 Dresden, Germany

Co/Pt multilayers (MLs) are standard systems for perpendicular anisotropy layered thin films. The use of a specific underlayer, sometimes in combination with additional, very thin adhesion layers, is a common practice to define a crystalline texture for the ML on amorphous substrates. In addition, the sputter gas pressure during deposition can be used to tune the lateral heterogeneity and laminate order, which strongly affect the magnetic behavior of the system. However, the precise interplay between adhesion and sputter gas pressure, especially for the seed layer, is often neglected.

In this context, we will discuss the impact of the underlayers on the structural and magnetic properties of the Co/Pt ML system. We will emphasize the influence of an adhesion layer on the whole system and combine this with a systematic and separate variation of the sputter deposition pressure of Pt seed and Co/Pt ML. Carefully tuning these parameters enables us to exert a high degree of control on the structure of these systems, with characteristics ranging from continuous thin films to isolated grain structures.

#### MA 22.7 Wed 11:00 H47

**Evidence for perpendicular anisotropy gradients in Co thin films on Pt seeds** – •GAURAVKUMAR PATEL¹, SVEN STIENEN¹, RUSLAN SALIKHOV¹, RODOLFO GALLARDO², LORENZO FALLARINO^{1,3}, KILIAN LENZ¹, JÜRGEN LINDNER¹, and OLAV HELLWIG^{1,4} – ¹Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden – ²Universidad Tecnica Federico Santa Maria, Valparíso, Chile – ³CIC energiGUNE BRTA, 01510 Vitoria-Gasteiz, Spain – ⁴Chemnitz University of Technology, 09107 Chemnitz

Tailoring the magnetization dynamics and anisotropy in ferromagnetic thin films by different seed layers is of great fundamental and practical importance, e.g., different seed layer materials lead to different microstructure and magnetocrystalline anisotropy energy. We have used Ta and Pt as seed layers for thin Co films and studied their broadband ferromagnetic resonance (FMR) in outof-plane saturation as a function of Co thickness and determined the respective perpendicular magnetic anisotropy. For Ta seeds, the magnetic anisotropy decreases and shows an inverse thickness dependence. In contrast for Pt seeds the magnetic anisotropy is no longer monotonous with thickness, but shows an initial thickness dependent decrease with a distinct minimum and subsequently a steady increase again. XRD measurements show that for Pt seeds, the Co develops a well-defined hcp texture with a thickness dependent strain relaxation. As a result of this structural evolution for Co on Pt seeds our FMR measurements reveal a strong anisotropy gradient in growth direction for this system.

#### MA 22.8 Wed 11:15 H47

Magnetization reversal of Co/Pt multilayer systems with weak perpendicular magnetic anisotropy — •Peter Heinig^{1,2}, Ruslan Salikhov¹, Fabian Samad^{1,2}, LORENZO FALLARINO^{1,3}, ATTILA KAKAY¹, and OLAV HELLWIG^{1,2} — ¹Helmholtz-Zentrum Dresden-Rossendorf — ²Chemnitz University of Technology — ³CIC energiGUNE

Perpendicular anisotropy thin film systems are well known for their highly periodic magnetic stripe domains. Here we study  $[Co(3.0 \text{ nm})/Pt(0.6 \text{ nm})]_X$  multilayers in the regime of transitional in-plane to out-of-plane anisotropy. For this we vary the number of repeats X in order to tune the remanent state from purely in-plane (IP) via tilted stripe domains (tilted), i.e. with significant out-of plane as well as in-plane magnetization component, to fully out-of-plane stripe domains (OOP). Vibrating Sample Magnetometry and Magnetic Force Microscopy are used to investigate three characteristic samples with X = 6, 11 and 22, which represent the three above mentioned remanent states, respectively. In contrast to fully in-plane or fully out-of-plane systems experimental data and corresponding micromagnetic simulation of the tilted magnetization regime (X = 11) reveals fully reversible field regions as well as distinct points of irreversibility during an external field sweep. This collective reversal behavior seems at first sight somewhat counter intuitive for a macroscopic system and has qualitative similarities with microscopic systems, such as the Stoner Wohlfarth particle and the vortex reversal in an in-plane magnetized disk, which both show as well distinct points of irreversibility.

## MA 22.9 Wed 11:30 H47

Magnetic anisotropy and magnetic ordering of transition metal phosphorus trisulfides — •TAE YUN KIM^{1,2} and CHEOL-HWAN PARK^{1,2} — ¹Center for Correlated Electron Systems, Institute for Basic Science, Seoul, Korea — ²Department of Physics and Astronomy, Seoul National University, Seoul, Korea

Transition-metal phosphorus trisulfides (TMPS₃'s) — a family of antiferromagnetic materials to which FePS₃, the first discovered two-dimensional magnetic material [1], belongs — have been regarded as an ideal testbed for studying the strong influence of low dimensionality on the existence of magnetic order. We developed anisotropic magnetic models for TMPS₃'s from first-principles calculations; the bulk magnetic properties, including the critical temperatures ( $T_N$ 's), reported from previous experiments were explained very well [2]. Remarkably, it was predicted by applying our magnetic models to the few-layer cases that monolayer NiPS₃ exhibits a fairly high  $T_N$ , which is in contrast with the conclusion from a recent Raman study that the  $T_N$  is largely suppressed in monolayer NiPS₃ [3]. We discuss how the degeneracy in the magnetic ground state of monolayer onciliation between our theoretical predictions and the previous experimental results as to the existence of magnetic order in monolayer NiPS₃.

Atomic-scale Insights to Design of High-Performing SmCo based Sintered Permanent Magnets gained by Atom Probe Tomography — •NIKITA POLIN¹, STEFAN GIRON², ESMAEIL ADABIFIROOZIAEI², YANGYIWEI YANG², ALAUKIK

STEFAN GIRON⁷, ESMAEIL ADABIFIROOZJAEI², YANGYIWEI YANG², ALAUKIK SAXENA¹, OLIVER GUTFLEISCH², and BAPTISTE GAULT^{1,3} – ¹Max-Planck-Institut für Eisenforschung GmbH, Düsseldorf 40237, Germany – ²Institute of Materials Science, Technische Universität Darmstadt, 64287 Darmstadt, Germany – ³Department of Materials, Royal School of Mines, Imperial College, Prince Consort Road, London SW7 2BP, United Kingdom

Hard disc drives, electric cars and wind turbines - in all these devices permanent magnets are key components to translate mechanical into electrical energy and vice versa. Enhancing performance of permanent magnets thus contributes to energy transition and sustainability. However, practically the performance of permanent magnets only reaches 20% of the possible maximum (called Brown's paradox). This is related to imperfect nanostructure and nanocomposition where atom probe tomography is a suitable tool to gain atomic-scale insights.

In this talk I will present a structural and magnetical investigation of highend production-grade  $Sm_2(Co,Fe,Cu,Zr)_{17}$  permanent magnets which show unusual regions leading to suboptimal performance. Local differences of nanostructure and nano-composition between both regions are studied by atom probe tomography and transmission electron microscopy combined with micromagnetic simulations. These findings suggest design rules for higher performance of  $Sm_2Co_{17}$  magnets. **Magneto-Optic Effects and Domain Imaging in EuO/Co Heterostructure** — •SEEMA SEEMA¹, HENRIK JENTGENS¹, PAUL ROSENBERGER^{1,2}, and MARTINA MÜLLER¹ — ¹Fachbereich Physik, Universität Konstanz, 78457 Konstanz, Germany — ²Fakultät Physik, Technische Universität Dortmund, 44221 Dortmund, Germany

Ferromagnetic semiconductors and stable half-metallic ferromagnets with Curie temperatures (Tc) equal to or more than room temperature have been sought for their applications in novel spintronic devices. Europium oxide (EuO) is one of the potential candidates as it possesses strong ferromagnetism of 7  $\mu_B$ /Eu atom with a Tc of 69 K. The present work focuses on the magnetization reversal mechanisms and domain images in EuO probed using magneto-optic Kerr microscopy. We aimed to visualize magnetic proximity effect induced changes in magnetic domains and Tc of EuO in a EuO/Metal heterostructure. We synthesized EuO/Co thin film using molecular beam epitaxy and observed differences in the domain saturation behavior as well as the Kerr rotation below Tc. This had been performed by magnetic hysteresis measurement along with simultaneous domain imaging to explore the temperature-dependent magneto-optic effects in EuO in the proximity of Co. This study of magnetic domains in EuO/Co heterostructure can provide insights into achieving room-temperature ferromagnetism in EuO.

## MA 23.3 Wed 10:00 H48

Direct observation of bulk-DMI-stabilized Néel-type domain walls in ferrimagnetic rare-earth transition-metal alloys — •DANIEL METTERNICH¹, RICCARDO BATTISTELLI¹, CHEN LUO¹, FLORIN RADU¹, SEBASTIAN WINTZ¹, KAI LITZIUS², MARCEL MÖLLER³, JOHN GAIDA³, CLAUS ROPERS³, MANUEL

MA 23.1 Wed 9:30 H48

Time: Wednesday 9:30-10:45

 $\begin{array}{l} {\rm Valvidares}^4, \ {\rm Pierluigi} \ {\rm Gargiani}^4, \ {\rm Andrada-Oana} \ {\rm Mandru}^5, \ {\rm Yaoxuan} \\ {\rm Feng}^5, \ {\rm Hans} \ {\rm Josef} \ {\rm Hug}^5, \ {\rm and} \ {\rm Felix} \ {\rm Büttner}^1 \ - \ {}^1 {\rm Helmholtz-Zentrum} \\ {\rm Berlin,} \ {\rm Berlin,} \ {\rm Germany} \ - \ {}^2 {\rm Max} \ {\rm Planck} \ {\rm Institute} \ {\rm for} \ {\rm Intelligent} \ {\rm Systems}, \\ {\rm Stuttgart,} \ {\rm Germany} \ - \ {}^3 {\rm Georg-August-Universität} \ {\rm Göttingen}, \ {\rm Göttingen}, \ {\rm Germany} \ - \ {}^4 {\rm ALBA} \ {\rm Synchrotron}, \ {\rm Barcelona}, \ {\rm Spain} \ - \ {}^5 {\rm Empa}, \ {\rm Dübendorf}, \ {\rm Switzerland} \\ {\rm Intelligent} \ {\rm Switzerland} \ {\rm Synchrotron}, \ {\rm Barcelona}, \ {\rm Spain} \ - \ {}^5 {\rm Empa}, \ {\rm Dübendorf}, \ {\rm Switzerland} \\ {\rm Intelligent} \ {\rm Switzerland} \ {\rm$ 

Since the discovery of bulk DMI within rare-earth transition-metal alloys, the possibility of bulk-DMI-stabilized skyrmions within these materials is an enticing prospect for potential spintronics applications. However, so far, no direct observation of any bulk-DMI-induced chiral spin textures has been reported in this material class.

We present our study on 50-nm-thick DyCo films, which we imaged with transmission X-ray microscopy. We found domain walls and skyrmions, both of which exhibit strong local variations of the chirality up to pure Néel-type. Due to the large film thickness, we attribute the formation of such Néel walls to the presence of significant bulk DMI in our sample. Moreover, we attribute the strong variations of the chirality to lateral changes of the material composition. Lorentz transmission electron microscopy and magnetic force microscopy measurements support our observations.

## MA 23.4 Wed 10:15 H48

Electrostatic shaping of magnetic transition regions in La0.7Sr0.3MnO3 — •QIANQIAN LAN¹, MICHAEL SCHNEDLER¹, LARS FRETER¹, LEI JIN¹, XIAN-KUI WEI¹, THIBAUD DENNEULIN¹, ANDRÁS KOVÁCS¹, PHILIPP EBERT¹, XIAOYAN ZHONG², and RAFAL E. DUNIN-BORKOWSKI¹ — ¹Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons (ER-C 1) and Peter Grünberg Institut (PGI-5), Forschungszentrum Jülich GmbH, 52425 Jülich, Germany — ²Department of Materials Science and Engineering, City University of Hong Kong, Kowloon 999077, Hong Kong SAR, People's Republic of China

Ferroelectric domain walls with no rotation of polarization but a change of magnitude of polarization were reported theoretically and experimentally. However, magnetic domain walls with a similar configuration have not been observed experimentally yet to our knowledge. Here, we report an experimental example of a magnetic transition region in La0.7Sr0.3MnO3 films where the magnitude of magnetization gradually changes without rotation even well below Tc. The magnetic and electrostatic characterization reveals that a charge redistribution governs the shape, magnitude, and extent of the corresponding magnetic transition region. The charge redistribution is caused by the equilibrium between carrier diffusion and drift in the electrostatic field at an interface with sharp Mn compositional change in LSMO. Thus, our results demonstrate a case of the electrostatic shaping of magnetic transition regions, which can be expected to be a general property of complex oxide materials.

MA 23.5 Wed 10:30 H48

Strain-controlled Domain Wall injection into nanowires for sensor applications — •GIOVANNI MASCIOCCHI^{1,2}, MOUAD FATTOUHI³, ANDREAS KEHLBERGER², LUIS LÓPEZ DÍAZ³, and MATHIAS KLÄUI¹ — ¹Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Germany — ²Sensitec GmbH, 55130 Mainz, Germany — ³Department of Applied Physics, Universidad de Salamanca, E-37008 Salamanca, Spain

In this study, we address a well-known challenge in magnetic sensor development, which is the effect of packaging-induced strain on the sensor properties. While previously the field operation window has only been studied in idealized operation conditions, in real devices further external factors such as strain play a role.

In this experimental work, we investigate the injection of a 180° domain wall from a nucleation pad into a nanowire, as typically used for domain wall-based sensors, while straining the device along selected directions. Combining our experimental measurements by Kerr microscopy with micromagnetic simulations, we find that strain, regardless of its direction, increases the domain wall injection field due to the magnetoelastic coupling of the magnetic material. The above-described observations can be explained by an effective strain-induced anisotropy in the device.

We find additionally that a careful material preparation, comprising of an annealing step, can reduce the effective anisotropy caused by the strain in the magnetic layer. With this we show that a device free of magnetostrictive behavior can be achieved.

# MA 24: Spin Transport and Orbitronics, Spin-Hall Effects

Time: Wednesday 15:00-18:00

MA 24.1 Wed 15:00 H37

Interplay between ferroelectricity and orbital angular momentum in a twodimensional SnTe monolayer — •DIMOS CHATZICHRYSAFIS^{1,2}, DONGWOOK Go^{1,3}, and STEFAN BLÜGEL¹ — ¹Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — ²Physics Department, RWTH-Aachen University, 52062 Aachen, German — ³Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Germany

Recent work on Orbitronics has shown that the orbital angular momentum (OAM) plays an important role in transport phenomena. A question that has arisen concerns the exploration of physical mechanisms that can serve as a control knob for the OAM. For that, ferroelectrics comprise the perfect playground. In this talk, we theoretically investigate the interplay between the electrical polarization in 2D SnTe monolayer, the OAM, and its transport effects. Using a tight-binding model we analyze the influence of the ferroelectric polarization on the electronic structure and the OAM texture. Based on this, we show that electric order parameter. We believe that our work provides a novel route to controlling the OAM in 2D materials

#### MA 24.2 Wed 15:15 H37

Spin and orbital transport in rare earth dichalcogenides: The case of EuS2 — •MAHMOUD ZEER^{1,2}, DONGWOOK GO^{1,3}, JOHANNA P CARBONE^{1,2}, TOM G SAUNDERSON³, MATTHIAS REDIES^{1,2}, MATHIAS KLÄUI³, JAMAL GHABBOUN⁴, WULFHEKEL WULF³, STEFAN STEFAN BLÜGEL^{1,2}, and YURIY MOKROUSOV^{1,3} — ¹Peter Grünberg Institute and Institute for Advanced Simulation,Forschungszentrum Jülich and JARA, Jülich, Germany — ²Department of Physics, RWTH Aachen University, Aachen, Germany — ⁴Department of Physics, Bethlehem University, Bethlehem, Palestine

With first principles the electronic, magnetic and transport properties of rareearth dichalcogenides taking a monolayer of the H-phase  $\text{EuS}_2$  as a representative. We predict that the H-phase of the  $\text{EuS}_2$  monolayer exhibits a half-metallic behaviour upon doping with a very high magnetic moment.

We find the  $EuS_2$  is very sensitive to the value of Coulomb repulsion *U*. We further predict that the non-trivial electronic structure of  $EuS_2$  directly results in a pronounced anomalous Hall effect with non-trivial band topology. Moreover, while we find that the spin Hall effect closely follows the anomalous Hall

effect in the system, the orbital complexity of the system results in a very large orbital Hall effect, whose properties depend very sensitively on the strength of correlations. Our findings thus promote rare earth based dichalcogenides as a promising platform for topological spintronics and orbitronics. Work funded by MMBF 01DH16027.

Differences between magnetotransport properties of doped alloys and doped crystals via ab-initio calculations — •ONDREJ SIPR^{1,2}, SERGEY MANKOVSKY³, and HUBERT EBERT³ — ¹Institute of Physics, Czech Academy of Sciences, Praha — ²New Technologies Research Centre, University of West Bohemia, Plzeň — ³Ludwig-Maximilians-Universität München

The description of magnetotransport has so far focused on how doping influences clean crystals. However, interest is turning also to substitutional alloys as hosts. Our aim is to investigate to what extent the approaches that proved to be useful for doped crystals can be applied to doped alloys. Calculations are performed for permalloy  $Fe_{19}Ni_{81}$  doped with V, Co, Pt, and Au impurities, relying on the Kubo-Bastin equation implemented using the KKR-Green function method.

The dependence of the anomalous Hall and spin Hall conductivities  $\sigma_{xy}$  and  $\sigma_{xy}^z$  on the dopant concentration is nonmonotonic and strongly influenced by the temperature. The fact that the host is disordered and not crystalline has profound influence on how  $\sigma_{xy}$  and  $\sigma_{xy}^z$  depend on the dopant concentration. In particular,  $\sigma_{xy}$  and  $\sigma_{xy}^z$  are not proportional to  $\sigma_{xx}$  for low dopant concentrations. Consequently, the dependence of the anomalous Hall effect and spin Hall effect on the dopant concentration cannot be ascribed unambigously to skew scattering, side-jump scattering, or intrinsic contributions in the same way as it can be done when investigating the effect of doping for a crystalline host, i.e., the standard scaling laws do not apply.

MA 24.4 Wed 15:45 H37 **Atomic scale control of spin current transmission at interfaces** – •MOHAMED AMINE WAHADA¹, ERSOY SASIOGLU², WOLFGANG HOPPE³, XILIN ZHOU¹, HAKAN DENIS¹, REZA ROUZEGAR⁴, TOBIAS KAMPFRATH⁴, INGRID MERTIG², STUART PARKIN¹, and GEORG WOLTERSDORF³ – ¹Max Planck Institute of Microstructure Physics, Weinberg 2, 06120 Halle(Saale) – ²Institute of Physics, Martin Luther University Halle-Wittenberg, Von-Seckendorff-Platz 1, 06120 Halle, Germany — ³Institute of Physics, Martin Luther University Halle-Wittenberg, von Danckelmann Platz 3, 06120 Halle, Germany — ⁴Department of Physics, Freie Universität Berlin, Arnimalee 14, 14195 Berlin, Germany

Ferromagnet (FM)/heavy metal (HM) bilayers are a fundamental building block in the field of spintronics. Exciting such bilayers with a femtosecond laser pulse can trigger ultrafast spin current (SC) from the FM to the HM layer. In the HM layer, the spin Hall effect converts the SC pulse into a charge current pulse, enabling efficient spintronic THz emitters. Equally as important as the SC generation process is the efficiency of the SC transmission across the FM/HM interface. We show experimentally that the SC transmission is partially suppressed when Ta is interfaced directly with 3d FM materials while this effect is absent when Pt is used as a HM. Based on theoretical calculations, we show that this is due to 3d-5d hybridization effects causing a significant moment reduction at the interface. This effect is expected for all 5d elements with less than half-filled 5d shell. Furthermore, we show that this effect can be eliminated by atomic scale oxide interlayers.

MA 24.5 Wed 16:00 H37

Spin Dynamics in Magnetic Nanojunctions — •RUDOLF SMORKA¹, MARTIN ŽONDA², and MICHAEL THOSS^{1,3} — ¹Institute of Physics, Albert-Ludwigs-Universität Freiburg — ²Department of Condensed Matter Physics, Faculty of Mathematics and Physics, Charles University Prague — ³EUCOR Centre for Quantum Science and Quantum Computing, Albert-Ludwigs-Universität Freiburg

Recent experimental advances of atomic and nanoscale magnetism motivate the study of spin dynamics on ultrafast time scales. In this contribution, we use a quantum-classical hybrid approach to study current-driven magnetization dynamics in systems consisting of tight-binding electrons and localized classical spins. Using this approach, we show that both the electronic structure of the central system and the self-consistent feedback of spin and electron dynamics play a significant role in the dynamical properties of magnetic nano-junctions driven by a dc voltage. Specifically, relaxation dynamics can be enhanced by tuning the dc voltage in resonance with electronic levels of the central system. We analyze this characteristic in nano-junctions containing a single classical Kondo impurity. Furthermore, we investigate current-induced spin-transfer torques in a ferromagnetic spin valve far away from equilibrium and show that electronic levels in the bias window lead to an enhancement of the spin-transfer torques.

## MA 24.6 Wed 16:15 H37

Spin and orbital Edelstein effects in a bilayer system with Rashba interaction — •SERGIO LEIVA¹, INGRID MERTIG¹, and ANNIKA JOHANSSON² — ¹Martin Luther University Halle-Wittenberg, Institute of Physics, 06099 Halle, Germany — ²Max Planck Institute of Microstructure Physics, Halle, Germany

The spin Edelstein effect has proved to be a promising phenomenon to generate spin polarization from a charge current in systems without inversion symmetry. In recent years, current-induced orbital magnetization, also called the orbital Edelstein effect, has also been predicted for various systems with broken inversion symmetry [1-7].

In the present work, we calculate the current-induced spin and orbital magnetization for a bilayer system with Rashba interaction, using Boltzmann transport theory with a constant relaxation time. We compare the magnitudes of the spin and orbital Edelstein effects and find that their dependencies on model parameters such as effective mass, spin-orbit coupling, or energy, differ qualitatively, and they can even exhibit opposite signs.

**Dynamic and static detection of current-induced spin-orbit magnetic fields** – •LIN CHEN¹, MATTHIAS KRONSEDER², DIETER SCHUH², DOMINIQUE BOUGEARD², JAROSLAV FABIAN², DIETER WEISS², and CHRISTIAN BACK¹ – ¹Department of Physics, Technical University of Munich, Garching bei Munich, Germany – ²Institute of Experimental and Applied Physics, University of Regensburg, Regensburg

Quantifying current-induced effective spin-orbit magnetic-fields (SOFs) accurately is a central task for spin-orbitronics. Several methods, e.g., spin-transfer torque ferromagnetic resonance or second harmonic Hall measurements, have been frequently used in the past 10 years. However, most methods show weaknesses, and are not ideal to determine SOFs. Here, we will show two new approaches in this regard. Firstly, we show that it is possible to quantify the SOFs through an analysis of the shape of standing spin-wave patterns, which are probed by time-solved magneto-Kerr microscopy in a laterally confined Fe/GaAs system. This method, which is conceptually different from previous approaches based on lineshape analysis, is phase independent and self-calibrated1. Secondly, we show that one can simultaneously quantify the SOFs and the unidirectional magnetoresistance (UMR) by measuring the second harmonic longitudinal resistance in Co/Pt bi-layers2. From these measurements, we can: I) establish a connection between SOFs and UMR, and II) discuss the origin of SOFs.

MA 24.8 Wed 16:45 H37

Hidden current-induced spin and orbital torques in bulk Fe₃GeTe₂ from firstprinciples — •TOM G. SAUNDERSON^{1,2}, DONGWOOK GO^{1,2}, STEFAN BLÜGEL², MATHIAS KLÄUI^{1,3}, and YURIY MOKROUSOV^{1,2} — ¹Institute of Physics, JGU, 55099 Mainz, Germany — ²PGI and IAS, Forschungszentrum Jülich, Germany — ³Centre for Quantum Spintronics, NTNU, 7491 Trondheim, Norway

Within the field of spintronics, the two dimensional (2D) van der Waals (vdW) material Fe3GeTe2 has been in the spotlight in the last few years for exciting characteristics such as nodal line semimetallicity [1], highly efficient spin-orbit torque switching [2] and skyrmion formation [3]. In a recent collaboration [4] we found that spin-orbit torques were observed within the bulk, yet the clean crystal's bilayer system is centrosymmetric. Whilst this leads to overall vanishing spin-orbit torques, strong 'hidden' current-induced torques are harvested by each of the two-dimensional FGT layers separately. We demonstrate, from first principles [5], that an interplay of spin and orbital degrees of freedom has a profound impact on spin-orbit torques in this prototype material. We uncover a drastic difference in the behavior of the conventional spin flux torque and so-called orbital torque as the magnetization is varied resulting in a nontrivial evolution of switching properties. Our findings promote the design of non-equilibrium orbital properties as the guiding mechanism for crafting the properties of spin-orbit torques in layered vdW materials. [1] Nat. Mater. 794, 17 (2018) [2] Nano Lett. 4400, 19 (2019) [3] Nano Lett. 868, 20 (2020) [4] arXiv:2107.09420 [5] arXiv:2204.13052

## MA 24.9 Wed 17:00 H37

Modeling spin transport through thin antiferromagnetic insulators — •NIKLAS ROHLING¹ and ROBERTO E. TRONCOSO^{2,3} — ¹Department of Physics, University of Konstanz, D-78457 Konstanz — ²Center for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology (NTNU), NO-7491 Trondheim — ³Department of Mechanical and Industrial Engineering, NTNU

Experiments have shown spin transport enhancement by a thin antiferromagnetic insulator between a metal and a ferromagnetic insulator [1]. While previous theoretical work [2] was able to reproduce some of the features of those experiments, the interface is typically described by a single parameter only. We consider a model of a thin layer NiO oriented in (111) direction, sandwiched between a metal and a ferromagnetic insulator. We take into account nearest and next-nearest neighbor exchange coupling at the interfaces as well as different magnetic order. We compute the spin current through this system using Fermi's Golden Rule [3]. We find a sensitive dependence on the magnetic configuration as well as on the interface parameters.

## MA 24.10 Wed 17:15 H37

Unified theory of itinerant transport in magnetic platforms based on the slave-boson formalism — •RICARDO ZARZUELA¹ and JAIRO SINOVA^{1,2} — ¹Institut für Physik, Johannes Gutenberg Universität Mainz, D-55099 Mainz, Germany — ²Institute of Physics Academy of Sciences of the Czech Republic, Cukrovarnická 10, 162 00 Praha 6, Czech Republic

The slave-boson formalism, rooted in the idea that electron hopping in the lattice is accompanied by a backflow of spin excitations, has been widely used in the field of strongly correlated systems to describe metal-insulator transitions and high-Tc superconductivity, to name a few. It is also well suited to explore transport phenomena in spintronic platforms, since the spin exchange with the magnetic background can be easily incorporated into the representation of the electron operators. We show that the slave-boson approach to the Hubbard model for conduction electrons (near half filling) yields an effective low-energy longwavelength theory for the itinerant transport in magnetic conductors. In particular, an emergent coupling between the magnetization current and the itinerant spin current is responsible for the spin-transfer physics as well as the topological Hall effect observed in magnetic systems. Our slave-boson approach does not require the adiabatic dynamics of the itinerant carriers, so our findings hold for any itinerant spin polarization. We also show that topological defects (e.g., magnetic vortices and magnetic disclinations) mediate both spin-transfer and topological Hall responses in the magnetic medium, which have not been observed experimentally yet.

**Non-Collinear Spin Current for Switching of Chiral Magnetic Textures** — •DONGWOOK Go^{1,2}, MORITZ SALLERMANN^{1,3}, FABIAN R. LUX², STEFAN BLÜGEL¹, OLENA GOMONAY², and YURIY MOKROUSOV^{1,2} — ¹Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — ²Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Germany — ³Science Institute and Faculty of Physical Sciences, University of Iceland, VR-III, 107 Reykjavík, Iceland

We propose a concept of non-collinear spin current, whose spin polarization varies in space even in non-magnetic crystals. While it is commonly assumed that the spin polarization of the spin Hall current is uniform, asymmetric local crystal potential generally allows the spin polarization to be non-collinear in space. Based on microscopic considerations we demonstrate that such non-collinear spin Hall currents can be observed for example in layered Kagome  $Mn_3X$  (X = Ge, Sn) compounds. Moreover, by referring to atomistic spin dynamics simulations we show that non-collinear spin currents can be used to switch the chiral spin texture of  $Mn_3X$  in a deterministic way even in the absence of an external magnetic field. Our theoretical prediction can be readily tested in experiments, which will open a novel route toward electric control of complex spin structures in non-collinear antiferromagnets. Theory of charge and spin pumping in atomic-scale spiral magnets — DAICHI KUREBAYASHI^{1,2}, YIZHOU LIU¹, •JAN MASELL^{1,3}, and NAOTO NAGAOSA^{1,4} — ¹RIKEN CEMS, Wako, Japan — ²University of New South Wales, Sydney, Australia — ³Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany — ⁴University of Tokyo, Tokyo, Japan

An Archimedean screw is a classical pump that exploits the equivalence of rotation and translation in helices. Similarly, a spin spiral texture can pump charge and spin by rotating at a frequency. We study these pumping phenomena within a microscopic quantum model by both perturbation theory and numerical simulations. Inside the spiral region, the spin polarization and charge current are linear in the frequency whereas the spin current scales with its square. We find that the charge current is related to the mixed momentum-phason Berry phase which can be viewed as a novel approximate realization of a Thouless pump. It is nearly quantized in spirals with short pitch but decays with 1/lambda for longer pitches unlike true Thouless pumps or Archimedean screws. Moreover, we study the onset of non-adiabaticity, the impact of attached non-magnetic or magnetic contacts, the real-time evolution of the transport observables, and the efects of disorders which, surprisingly, might enhance the spin current but suppress the charge current.[1]

# MA 25: Ultrafast Magnetization Effects 2

Time: Wednesday 15:00-17:00

## MA 25.1 Wed 15:00 H43

Light-induced magnetization dynamics in a ferromagnetic semiconductor — •JINGWEN L1¹, MASAKAZU MATSUBARA², KRISTIN KLIEMT³, NAZIA KAYA³, IS-ABEL REISER³, CORNELIUS KRELLNER³, JOHANN KROHA⁴, SHOVON PAL⁵, and MANFRED FIEBIG¹ — ¹ETH Zurich, Switzerland — ²Tohoku University, Japan — ³Goethe University Frankfurt, Germany — ⁴Bonn University, Germany — ⁵NISER Bhubaneshwar, India

Ferromagnetic semiconductors are a rare class of materials that can provide a new platform with spin degrees of freedom in electronic and optical devices. All-optical control of the magnetic order is a demanding task, however. As one prototype example, EuO is intriguing for its high Curie Temperature ( $T_c = 69 \text{ K}$ ) induced by the indirect exchange interactions between the Eu atoms. The interactions can be enhanced by photo-doping in an ultrafast non-thermal way, strengthing the ferromagnetic order. This was verified in the ferromagnetic phase of the material [1], but evidence for an enhancement of the magnetic order around or above  $T_c$  is still lacking. In this contribution, we show the photoinduced presence of magnetic ordering even at temperatures higher than  $T_c$  by making use of the temperature-dependent spectral shift accompanying the magnetically ordered states using optical pump-probe spectroscopy. In optical reflection experiments, we observe two distinct types of ultrafast processes related to the optically driven magnetic order that show different relaxation rates. Our results provide clear evidence of short-range magnetic order above  $T_c$ , originating from the so-called exciton magnetic polarons.

## MA 25.2 Wed 15:15 H43

Non-thermal optical generation of non-collinear magnetic phase in insulat**ing ferrimagnetic iron garnet** — •Sergii Parchenko¹, Antoni Frej², Hiroki UEDA¹, ROBERT CARLEY¹, LAURENT MERCADIER¹, NATALIA GERASIMOVA¹, GIUSEPPE MERCURIO¹, JUSTINE SCHLAPPA¹, ALEXANDER YAROSLAVTSEV¹, NA-MAN AGARWAL¹, ANDREAS SCHERZ¹, ANDRZEJ STUPAKIEWICZ², and Urs SERGII³ — ¹European Free Electron Laser, Schenefeld, Germany — ²University of Bialystok, Bialystok, Poland — ³Paul Scherrer Institute, Villigen, Switzerland For a long time, nearly all experimental examples of magnetic switching by femtosecond pulses were demonstrated on metals and relied on mechanisms directly related to laser-induced heating close to the Curie temperature. The discovery of all-optical magnetization switching in Co: doped iron garnets via photomagnetic effect opened a new approach for magnetization control and raised a question about the microscopic nature of photo-magnetic spin dynamics. In order to reveal the magnetization dynamic of individual sublattices after excitation with NIR ultrashort laser pulses, we implement time-resolved XMCD techniques in a soft x-ray regime. We found that the dynamics of two antiferromagnetically coupled magnetic moments are drastically different during the first picosecond after the NIR excitation. The dynamics of Fe in tetrahedral oxygen surroundings showed a fast component lasting for about a picosecond. We state that the observed photoinduced noncolinear magnetic phase might be crucial for the alloptical magnetization switching in this material.

 $\label{eq:MA25.3} Med 15:30 H43$  Spin-dependent carrier dynamics in antiferromagnetic model systems — •Marius Weber¹, Kai Leckron¹, Benjamin Stadtmüller^{1,2}, Baerbel Rethfeld¹, and Hans Christian Schneider¹ — ¹Department of Physics and Research Center OPTIMAS, TU Kaiserslautern — ²Institute of Physics, Johannes Gutenberg University Mainz

The Elliot-Yafet mechanism for the relaxation of an electronic spin polarization was originally derived for the electron-phonon scattering in degenerate bands in semiconductors [1]. Recently, we investigated how the concept of Elliott-Yafet spin-flip scattering can be applied to a microscopic treatment of carrier scattering in ferromagnetic metals including a ferromagnetic splitting and spin-orbit coupling [2].

Here we use the microscopic approach of [2], which utilizes the equation of motion formalism for the k-resolved reduced spin density matrix, to calculate the electronic dynamics in antiferromagnets such as the minimal model system discussed in [3]. The band structure of this model is anisotropic with two twofold degenerate bands and pronounced spin mixing. We investigate the spin-resolved electronic dynamics for different scenarios of spin-polarized anisotropic excitation, such as spin injection and k-selective spin flips.

X-ray absorption spectroscopy is a powerful technique to investigate nonequilibrium dynamics combining a sensitivity to electron and lattice dynamics with element specificity. We report the time-resolved, spectroscopic analysis of Nickel-metal L_{2,3}-edge X-ray absorption spectra and their pump-induced changes measured at the SCS instrument of the European XFEL with unprecedented energy resolution and dynamic range. In addition, *ab initio* DFT and TD-DFT calculations connect the pump-induced changes to modifications of the electronic DOS. We find pump-induced redshifts and reduced absorption at the L_{2,3}-edges, which we explain by a loss of magnetic moment, changes in the electronic correlations and redistribution of electron population.

## MA 25.5 Wed 16:00 H43

Indirect optical manipulation of the antiferromagnetic order of insulating NiO by ultrafast interfacial energy transfer — •STEPHAN WUST¹, CHRISTO-PHER SEIBEL¹, HENDRIK MEER², PAUL HERRGEN¹, CHRISTIN SCHMITT², LORENZO BALDRATI², RAFAEL RAMOS³, TAKASHI KIKKAWA⁴, EIJI SAITOH⁴, OLENA GOMONAY², JAIRO SINOVA², YURIY MOKROUSOV², HANS CHRISTIAN SCHNEIDER¹, MATHIAS KLÄUI², BAERBEL RETHFELD¹, BENJAMIN STADTMÜLLER^{1,2}, and MARTIN AESCHLIMANN¹ — ¹Department of Physics and Research Center OPTIMAS, Technische Universität Kaiserslautern, 67663 Kaiserslautern, Germany — ²Institute of Physics, Johannes Gutenberg-University Mainz, 55128 Mainz, Germany — ³CIQUS, Departamento de Química-Física, Universidade de Santiago de Compostela, Santiago de Compostela, Spain — ⁴Department of Applied Physics, The University of Tokyo, Tokyo 113-8656, Japan

Antiferromagnets are promising candidates for improved future spintronic devices in terms of robustness and speed. Here, we report the ultrafast, (sub)picosecond reduction of the antiferromagnetic order of the insulating NiO thin film in a Pt/NiO bilayer. This reduction of the antiferromagnetic order is not present in pure NiO thin films after a strong optical excitation. This ultrafast phenomenon is attributed to an ultrafast and highly efficient energy transfer from the optically excited electron system of the Pt layer into the NiO spin system. We propose that this energy transfer is mediated by a stochastic exchange scattering of hot Pt electrons at the Pt/NiO interface.

# MA 25.6 Wed 16:15 H43

Heat-conserving three-temperature model for ultrafast demagnetisation simulations of nickel and iron — •MARYNA PANKRATOVA¹, IVAN MIRANDA¹, DANNY THONIG^{2,1}, MANUEL PEREIRO¹, ERIK SJÖQVIST¹, ANNA DELIN³, OLLE ERIKSSON^{1,2}, and ANDERS BERGMAN¹ — ¹Department of Physics and Astronomy, Uppsala University, Box 516, Uppsala, Sweden — ²School of Science and Technology, Örebro University, Örebro, Sweden — ³Department of Applied Physics, School of Engineering Sciences, KTH Royal Institute of Technology, AlbaNova University Center, Stockholm, Sweden

In this work, we introduce a new heat-conserving three temperature model (HC3TM) for calculations of spin, electron, and lattice temperatures during ultrafast magnetisation dynamics simulations.

The proposed HC3TM has several advantages in comparison with the threetemperature model (3TM), proposed by Beurepaire. It reduces the reliance on heat transfer parameters, such as electron-spin, electron-lattice, and spin-lattice. These parameters are often hard to estimate which impedes the comparison with experimental data.

We apply HC3TM for the simulations of ultrafast demagnetisation of nickel and iron and compare the results with 3TM. HC3TM gives a demagnetisation rate during the first picoseconds after the absorption of a laser pulse which is in line with experiments. Overall, the proposed HC3TM reproduces experimental observations for nickel and iron better than most existing 3TM while it reduces the number of required parameters.

## MA 25.7 Wed 16:30 H43

X-ray absorption spectroscopy on spin-crossover molecules — •LEA SPIEKER¹, TOBIAS LOJEWSKI¹, CAROLIN SCHMITZ-ANTONIAK², FLORIN RADU³, TORSTEN KACHEL³, LAURENT MERCADIER⁴, ANDREAS SCHERZ⁴, LOÏC LE GUYADER⁴, MARTIN TEICHMANN⁴, ROBERT CARLEY⁴, GIUSEPPE MERCURIO⁴, NATALIA GERASIMOVA⁴, BENJAMIN VAN KUIKEN⁴, CAMMILLE CARINAN⁴, DAVID HICKIN⁴, DAMIAN GÜNZING¹, SOMA SALAMON¹, GÉRALD KÄMMERER¹, PETER KRATZER¹, KLAUS SOKOLOWSKI-TINTEN¹, MANUEL GRUBER¹, ANDREA ESCHENLOHR¹, KATHARINA OLLEFS¹, SENTHIL KUMAR KUPPUSAMY⁵, MARIO RUBEN^{5,6}, UWE BOVENSIEPEN¹, and HEIKO WENDE¹ — ¹University of Duisburg-Essen and CENIDE — ²University of Applied Science Wildau — ³Helmholtz Center Berlin — ⁴European XFEL — ⁵Karlsruhe Institute of Technology — ⁶CNRS-University of Strasbourg

Spin-crossover molecules with abrupt spin-state switching in the room temperature regime are of great interest for future device applications. With X-ray absorption spectroscopy (XAS), it is possible to investigate their temperature-, visible light-, or X-ray induced spin-state switching. Recently, we performed static, temperature-dependent XAS measurements to study X-ray induced switching behavior as well as ultrafast time-resolved XAS measurements to analyze lightinduced spin-state switching. We acknowledge European XFEL in Schenefeld, Germany, for the provision of X-ray free-electron laser beamtime at the SCS instrument. The financial support by CRC 1242 Projects A05, A07, B02, and C01 (Project-ID 278162697) is gratefully acknowledged.

MA 25.8 Wed 16:45 H43

Ultrafast magnetization dynamics in heterogeneous material compositions — •SEBASTIAN T. WEBER¹, CHRISTOPHER SEIBEL¹, MARIUS WEBER¹, MARTIN STIEHL¹, SANJAY ASHOK¹, SIMON HÄUSER¹, MARTIN AESCHLIMANN¹, HANS CHRISTIAN SCHNEIDER¹, BENJAMIN STADTMÜLLER^{1,2}, and BAERBEL RETHFELD¹ — ¹Department of Physics and Research Center OPTIMAS, TU Kaiserslautern — ²Institute of Physics, Johannes Gutenberg University Mainz

Ultrafast magnetization dynamics plays a key role in the development of spintronic devices. The dynamics are influenced by the composition of material systems as well as the wavelength of the optical excitation. The latter can create spatially inhomogeneous excitation profiles in thick nickel films [1,2] or Ni|Au heterostructures [3].

In this contribution, we compare results of the thermodynamic  $\mu$ T-model with kinetic Boltzmann calculations and MOKE-measurements to investigate the influence of the wavelength on magnetization dynamics in different compositions. Our results show that laser and material parameters can enhance or hinder the interplay of relaxation processes, leading to different laser-induced magnetization dynamics.

Density functional theory studies of a Fe(II) spin-crossover complex — •GERALD KÄMMERER and PETER KRATZER — University Duisburg-Essen, Duisburg, Germany

We investigate the spin-state switching of a Fe(II) spin-crossover complex ( $[Fe(1 - bpp - COOC_2H_5)_2](BF_4)_2CH_3CN$ ) from a diamagnetic low-spin (S=0) to a paramagnetic high-spin (S=2) state in the framework of density functional theory (DFT). The calculations were carried out with FHI-Aims code using PBE and B3LYP functionals. Due to the switching, the bond length Fe-N increases by up to 20%. In addition, calculations for Raman spectra were done for both spin-states and compared to temperature-dependent Raman measurements. This allows us the analysis of a unique fingerprint of the molecular bondings as well as the assignment of specific Raman modes. The financial support by DFG within CRC 1242 (*Project B 02*) and computation time on the MagnitUDE supercomputer system are gratefully acknowledged.

MA 26.2 Wed 15:15 H48

Inelastic Neutron Scattering and Magnetic Studies on Families of 3d-4f Heterometallic  $M_2Ln_2$  Single-Molecule Magnets — •JULIUS MUTSCHLER¹, THOMAS RUPPERT², YAN PENG², JACQUES OLLIVIER³, QUENTIN BERROD³, JEAN-MARC ZANOTTI³, CHRISTOPHER E. ANSON², ANNIE K. POWELL², and OLIVER WALDMANN¹ — ¹Physikalisches Institut, Universität Freiburg, D-79104 Freiburg, Germany — ²Institut of Inorganic Chemistry, Karlsruhe Institute of Technology (KIT), D-76131 Karlsruhe, Germany — ³Institut Laue-Langevin, F-38042 Grenoble Cedex 9, France

The discovery of slow relaxation and quantum tunnelling of the magnetization in the single molecule magnets (SMMs) two decades ago has led to a flurry of research towards improving their magnetic properties. This class of molecules has been expanded to heterometallic clusters incorporating transition metal and rare earth ions. The 4*f* ions are of interest because of their large angular momenta and magnetic anisotropies, but exactly the latter feature leads to unexnexted de large in the series of the exactly the latter feature leads to unex-

pected challenges in the numerical analysis of experimental susceptibility and magnetization curves. Inelastic neutron scattering (INS) experiments were performed on the time-of-flight disk-chopper spectrometers IN5 and IN6 at ILL on the SMMs  $Mn_2Ln_2$ -squares with Ln = Y, Tb, Ho, Dy, and the  $M_2Ln_2$ -butterflies with M = Fe, Al and Ln = Dy, Er. High quality INS data were recorded, even for the Dy containing species besides the strong neutron absorbtion of this ions. The analysis and interpretation of the INS data, and of magnetic data, by means of a linked fit approach and using effective models is presented.

Study of VOPc/TiOPc layers on Ag(100) using X-ray absorption spectroscopy — •JAEHYUN LEE^{1,2}, STEFANO REALE^{1,2}, KYUNGJU NOH^{1,2}, LUCIANO COLAZZO¹, DENIS KRYLOV¹, CHRISTOPH WOLF¹, ANDRIN DOLL³, ANDREAS HEINRICH^{1,2}, YUJEONG BAE^{1,2}, and FABIO DONATI^{1,2} — ¹Center for Quantum Nanoscience — ²Ewha Womans University, Seoul, Republic of Korea — ³Swiss Light Source, Paul Scherrer Institut (PSI), Villigen Switzerland

Vanadyl Phthalocyanine (VOPc) shows spin 1/2 and long coherence time of almost 1 microseconds up to room temperature [M. Atzori et al., J. Am. Chem.Soc. 138, 2154 (2016)]. Investigating the orbital splitting when absorbed on a surface and the interactions between the molecular spin and the supporting substrate is crucial to optimize their quantum coherence properties. Here, we use x-ray absorption spectroscopy to investigate the spin properties of VOPc on Ag(100) and on TiOPc/Ag(100). To interpret our data, we simulate x-ray spectra combining machine learning with multiplet calculations. We find that the interaction with the metal surface changes the orbital structure of VOPc when directly on the Ag(100). Decoupling from the metal using a TiOPc layer is sufficient to restore the spin and orbital structure of the free standing VOPc, which shows no changes upon annealing up to 450K. This robust molecular spin architecture shows the potential in quantum computing technology.

MA 26.4 Wed 15:45 H48

High-frequency EPR studies on monomeric 4f complexes — LENA SPILLECKE, CHANGHYUN KOO, and •RÜDIGER KLINGELER — Kirchhoff Institute for Physics, Heidelberg University, Germany

Tuning of magnetic anisotropy by appropriate design of crystal fields in 4f monomeric complexes is guided by experimental determination of relevant parameters – here by high-frequency electron paramagnetic resonance (HF-EPR)

studies – and by numerical results. Our recent study on pentagonal-bipyramidal Er(III) [1] complexes is motivated by a reported difference in relaxation behavior [2]. Evaluating the data in a S = 1/2 pseudo spin approximation for each Kramers doublet (KD) results in the precise determination of the crystal field splitting energies and effective g-values of the three lowest KDs. Relaxation behaviour is directly traced back to changes in electronic structure, induced by the crystal field and are attributed to a pronounced non-axiality of the ground-state g-tensor promoting a fast QTM magnetic relaxation. Another confirmation of a guided approach is provided by recent data on a set of [Ln(III)L12]-complexes (Ln = Dy, Tb) involving tetradentate ligands [3] as well as by studies of a novel nonadentate bispidine-based ligand where the experimentally determined relaxation barrier of 46 cm⁻¹ is rather modest but in excellent agreement with that predicted by ab-initio calculations [4].

Complementary investigations of magnetic textures in the antiskyrmion compound  $Mn_{1.4}$  PtSn with REXS and LTEM — M. WINTER^{1,2,3,4}, M. RAHN⁴, D. WOLF³, S. SCHNEIDER², M. VALVIDARES⁵, •C. SHEKAR¹, P. VIR¹, B. ACHINUQ⁶, H. POPESCU⁷, N. JAOUEN⁷, G. VAN DER LAAN⁸, T. HESJEDAL⁶, B. RELLINGHAUS², and C. FELSER¹ — ¹MPI CPfS, Dresden, Germany — ²DCN, TU Dresden, Germany — ³IFW Dresden, Germany — ⁴IFMP, TU Dresden, Germany — ⁵ALBA Synchrotron, Barcelona, Spain — ⁶Clarendon Laboratory, University of Oxford, UK — ⁷Synchrotron SOLEIL, Saint-Aubin, France — ⁸Diamond Light Source, UK

The Heusler compound  $Mn_{1.4}$ PtSn is known to host multiple non trivial magnetic textures like antiskyrmions (aSks). It's phase diagram depends not only on temperature and sample shape, but also on strength and orientation of an external magnetic field as well as on the history of its application. In order to better understand the formation of aSks, we have conducted complementary experiments of resonant elastic x-ray scattering (REXS) and Lorentz transmission electron microscopy (LTEM) on an identical lamella of  $Mn_{1.4}$ PtSn. Our complementary approach allows for the first time to directly relate the REXS patterns to the underlying magnetic phase as determined from LTEM. Along this approach, LTEM has proven an ideal pre-characterization tool to navigate the high-dimensional parameter space and subsequently take advantage of the better control of magnetic field directions, temperature as well as of energy resolved measurements as provided by REXS. Part of this work is gratefully supported by DFG within SPP 2137.

## MA 27.2 Thu 9:45 H37

Doping control of magnetic anisotropy for stable antiskyrmion formation in schreibersite (Fe,Ni)3P with S4 symmetry — KOSUKE KARUBE¹, LICONG PENG¹, •JAN MASELL^{1,2}, MAMOUN HEMMIDA³, HANS-ALBRECHT KRUG VON NIDDA³, ISTVÁN KÉZSMÁRKI³, XIUZHEN YU¹, YOSHINORI TOKURA^{1,4}, and YA-SUJIRO TAGUCHI¹ — ¹RIKEN CEMS, Wako, Japan — ²Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany — ³University of Augsburg, Augsburg, Germany — ⁴University of Tokyo, Tokyo, Japan

Recently, growing attention has also been paid to antiskyrmions emerging in non-centrosymmetric magnets with D2d or S4 symmetry. [1] In these magnets, complex interplay among anisotropic Dzyaloshinskii-Moriya interaction, uniaxial magnetic anisotropy, and magnetic dipolar interactions generates a variety of magnetic structures. We control the uniaxial magnetic anisotropy of schreibersite (Fe,Ni)3P with S4 symmetry by doping and investigate its impact on the stability of antiskyrmions. With magnetometry, supported by ferromagnetic resonance spectroscopy, Lorentz transmission electron microscopy, and micromagnetic simulations, we quantitatively analyze the stability of antiskyrmion as functions of uniaxial anisotropy and demagnetization energy, and demonstrate that subtle balance between them is necessary to stabilize antiskyrmions.

Magnetic and Morphological Phases in the 2D van der Waals Magnet FexGeTe2 — •KAI LITZIUS¹, MAX BIRCH^{1,5}, LUKAS POWALLA^{2,3,5}, SEBASTIAN WINTZ¹, FABIAN ALTEN¹, MICHAEL MILLER¹, MARKUS WEIGAND⁴, KLAUS KERN^{2,3}, MARKO BURGHARD², and GISELA SCHÜTZ¹ — ¹Max-Planck-Institute for Intelligent Systems, 70569 Stuttgart, Germany — ²Max-Planck-Institute Location: H37

for Solid State Research, 70569 Stuttgart, Germany — ³Institut de Physique, École Polytechnique Fédérale de Lausanne, CH-1015 Lausanne, Switzerland — ⁴Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, 12489 Berlin, Germany — ⁵These authors contributed equally to the work

Recently, observations of magnetic skyrmions in 2-dimensional (2D) itinerant ferromagnets opened many possibilities for technological implementation of 2D van der Waals structures in spintronics. However, the stability of the different magnetic states and morphological phases in FexGeTe2 remains an unresolved issue. In this work, we utilize real-space imaging to determine magnetic phase diagrams of exfoliated FexGeTe2 films. Our findings show besides complex, history-dependent magnetization states also that changes in the crystalline structure significantly alter the magnetic behavior. Ultimately, the choice of material and a proper nucleation mechanism result in the stabilization of a variety of (meta-) stable magnetic configurations, including skyrmions. These findings open novel perspectives for designing van der Waal heterostructure-based devices incorporating topological spin textures.

## MA 27.4 Thu 10:15 H37

Antiskyrmions in B20-type FeGe — •NIKOLAI S. KISELEV¹, FENGSHAN ZHENG^{2,3}, LUYAN YANG², VLADYSLAV M. KUCHKIN¹, FILIPP N. RYBAKOV^{4,5}, STEFAN BLÜGEL¹, and RAFAL E. NIKOLAI² — ¹Peter Grünberg Institute and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany — ²Le Brandst. 1 — ³Spin-X Institute, School of Physics and Optoelectronics, State Key Laboratory of Luminescent Materials and Devices, Guangdong-Hong Kong-Macao Joint Laboratory of Optoelectronic and Magnetic Functional Materials, South China University of Technology, Guangzhou 511442, China — ⁴Department of Physics and Astronomy, Uppsala University, SE-75120 Uppsala, Sweden — ⁵Department of Physics, KTH-Royal Institute of Technology, SE-10691 Stockholm, Sweden

We report the highly reproducible observations of statically stable antiskyrmion [1] – skyrmion antiparticle in thin plates of B20-type FeGe chiral magnet where only skyrmions were observed earlier. Using Lorents TEM and electron holography, we showed that skyrmions and antiskyrmions could coexist in a wide range of fields and temperatures. These findings are entirely consistent with micromagnetic simulations and prior theoretical studies of two-dimensional systems [2]. The mechanism of antiskyrmion stability, nucleation, and annihilation with ordinary skyrmions is discussed in detail.

Asymmetric magnetization reversal in perpendicularly magnetized micro stripes induced by exchange-bias effect and Dzyaloshinskii-Moriya interaction — •SAPIDA AKHUNDZADA¹, PIOTR KUŚWIK², CHRISTIAN JANZEN¹, ARNO EHRESMANN¹, and MICHAEL VOGEL¹ — ¹Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Kassel, Germany — ²Institute of Molecular Physics, Polish Academy of Sciences, Poznań, Poland

In a systematic study, the magnetization reversal in exchange-biased Ti/Au/Co/NiO/Au micro stripes with perpendicular magnetic anisotropy is characterized using high-resolution magneto-optical Kerr microscopy. Thereby, the remagnetization process is observed to be asymmetric with respect to the two branches of the hysteresis loop, being quantified as a higher nucleation density formed along one field branch with decreasing structure width. Additionally, a

local asymmetry in the domain nucleation and domain wall movement within the stripe geometry is observed. The influence of the exchange bias effect and the Dzyaloshinskii-Moriya interaction is investigated by field-cooling and the application of additional in-plane magnetic fields during the magnetization reversal process. XMCD and XMLD experiments reveal the corresponding domain texture in the ferromagnetic and antiferromagnetic layers. These experiments show how the interplay between chiral Dzyaloshinskii-Moriya interaction and the unidirectional anisotropy modify the magnetic domain texture and the resulting magnetization reversal in microstructures.

**Magnetic skyrmion braids** — •NIKOLAI S. KISELEV¹, FENGSHAN ZHENG², FIL-IPP N. Rybakov³, Dongsheng Song², András Kovács², Haifeng Du⁴, Ste-FAN BLÜGEL¹, and RAFAL E. DUNIN-BORKOWSKI² - ¹Peter Grünberg Institute and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany – ²Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons and Peter Grünberg Institute, Forschungszentrum Jülich, 52425 Jülich, Germany — ³Department of Physics, KTH-Royal Institute of Technology, Stockholm, SE-10691 Sweden — ⁴The Anhui Key Laboratory of Condensed Matter Physics at Extreme Conditions, High Magnetic Field Laboratory, Chinese Academy of Science (CAS), Hefei, Anhui Province 230031, China In cubic chiral magnets, the magnetization of skyrmions resembles a string-like or filamentary texture. Skyrmion strings are naturally expected to interwind and form complex three-dimensional superstructures by analogy to elastic strings. We found that skyrmion strings in cubic crystals of chiral magnets can form braids - statically stable configurations where skyrmion strings wind around one another [1]. This finding is confirmed by direct observations of skyrmion braids in B20-type FeGe using transmission electron microscopy. The theoretical analysis predicts that the discovered phenomenon is general for a wide family of chiral magnets and can be observed in thick plates and bulk crystals.

#### MA 27.7 Thu 11:00 H37

Tunable ellipticity of Bloch skyrmions in antiskyrmion-hosting materials — SEBASTIAN SCHNEIDER^{1,2}, •JAN MASELL^{1,3}, FEHMI S. YASIN¹, LICONG PENG¹, KOSUKE KARUBE¹, YASUJIRO TAGUCHI¹, DARIUS POHL², BERND RELLINGHAUS², YOSHINORI TOKURA^{1,4}, and XIUZHEN YU¹ — ¹RIKEN CEMS, Wako, Japan — ²TU Dresden, Dresden, Germany — ³Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany — ⁴University of Tokyo, Tokyo, Japan

Magnetic skyrmions are usually stabilized and studied in materials with isotropic Dzyaloshinskii-Moriya interaction (DMI). In materials with D2d or S4 symmetry, however, the sign of the DMI is exactly opposite in two orthogonal directions such that it favors antiskyrmions instead of skyrmions. [1,2] Yet, uniaxial anisotropy and dipolar interactions can also help stabilizing skyrmions in such materials which, as a consequence of the anisotropic DMI, are rendered elliptical. We quantify the elliptical distortion of skyrmions in an S4 symmetric material as function of magnetic field and temperature using LTEM holography. Our micromagnetic simulations and simple analytical modelling explain the experimentally observed behavior and provide a technique to quantitatively estimate the DMI.

#### MA 27.8 Thu 11:15 H37

Long-range non-collinearity and spin reorientation in the centrosymmetric hexagonal magnet NiMnGa — •PARUL DEVI¹, SANJAY SINGH², THOMAS HERMANNSDÖRFER¹, and JOACHIM WOSNITZA^{1,3} — ¹Dresden High Magnetic Field Laboratory, HZDR, Germany — ²Institut für Festkörper und Materialphysik, TU Dresden, Germany — ³School of Materials Science and Technology, Indian Institute of Technology (BHU), Varanasi-221005, India

The recent discovery of biskyrmions and skyrmions in globally centrosymmetric crystals has raised questions about the role of the Dzyaloshinskii-Moriya interactions (DMI) in causing the topologically stable spin vortex textures, since DMI vanishes in such crystal structures. Here, we present a detailed crystal and magnetic structure investigation of the non-collinear hexagonal magnetic material NiMnGa exhibiting biskyrmions [1]. We show an investigation on the nature of the phase transitions, evidence of magnetoelastic coupling and anomalous thermal expansion in hexagonal, centrosymmetric NiMnGa using combined studies of magnetization and high-resolution synchrotron x-ray powder diffraction data. Magnetization data exhibits spin reorientation transition * 200 K. By means of powder neutron diffraction data, we investigate the change of the magnetic structure in NiMnGa. This study will help to understand the origin of biskyrmions in the absence of Dzyaloshinskii-Moriya interaction in magnetic materials.

Zero-field skyrmionic states and in-field edge-skyrmions induced by boundary tuning — •Jonas Spethmann, Elena Y. Vedmedenko, Roland Wiesendanger, André Kubetzka, and Kirsten von Bergmann — Universität Hamburg, Hamburg, Germany

When magnetic skyrmions are moved via currents, they do not strictly travel along the path of the current, instead their motion also gains a transverse component. This so-called skyrmion Hall effect can be detrimental in potential skyrmion devices because it drives skyrmions towards the edge of their hosting material where they face potential annihilation. To mitigate this problem it was proposed to create a potential well within the skyrmion hosting material and thereby guide the skyrmions along a desired pathway[1]. Here we have experimentally modified a skyrmion model system-an atomic Pd/Fe bilayer on Ir(111)[2]-by growing a self-assembled ferromagnetic Co/Fe bilayer adjacent to it. Employing spin-polarized scanning tunneling microscopy, we demonstrate that this ferromagnetic rim has an immediate effect on the spin spiral ground state of the Pd/Fe bilayer, stabilizes skyrmions and target states in zero field and prevents skyrmion annihilation at the film edge. Furthermore we show that in applied magnetic fields the Co/Fe gives rise to edge-skyrmions pinned to the Pd/Fe island rim. Finally we have performed spin dynamics simulations to investigate the role of different magnetic parameters in causing these edge effects. [1] I. Purnama et al., Scientific Reports 5, 10620 (2015).

Real-space determination of the isolated magnetic skyrmion deformation under electric current flow — Fehmi S. Yasın¹, •Jan Masell^{1,2}, Kosuke Karube¹, Akiko Kikkawa¹, Yasujiro Taguchi¹, Yoshinori Tokura^{1,3}, and Xiuzhen Yu¹ — ¹RIKEN CEMS, Wako, Japan — ²Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany — ³University of Tokyo, Tokyo, Japan

The effect of electric current on topological magnetic skyrmions, such as the current-induced deformation of isolated skyrmions, is of fundamental interest. The deformation has consequences ranging from perturbed dynamics to modified packing configurations. [1] We measure the current-driven real-space deformation of isolated, pinned skyrmions within CoZn at room temperature. We observe that the skyrmions are surprisingly soft, readily deforming during electric current application into an elliptical shape with a well-defined deformation axis. We find that this axis rotates towards the current direction, in agreement with our simply Thiele-based theoretical analysis. We quantify the average eccentricity and how the skyrmion size expands during current application. This first evaluation of in-situ electric current-induced skyrmion deformation paints a clearer picture of spin-polarized electron-skyrmion interactions and may prove essential when designing spintronic devices.

Magnetocrystalline anisotropy in cubic chiral magnets — •VIVEK KUMAR¹, ANDREAS BAUER¹, SCHORSCH MICHAEL SAUTHER¹, MICHELLE HOLLRICHER¹, MARKUS GARST², MARC ANDREAS WILDE¹, and CHRISTIAN PFLEIDERER¹ — ¹Physik-Department, Technische Universität München, D-85748 Garching, Germany — ²Institut für Theoretische Festkörperphysik, Karlsruhe Institute of Technology, D-76131 Karlsruhe, Germany

Magnetocrystalline anisotropy plays an important role in the stabilization, orientation and manipulation of exotic spin textures like skyrmions in cubic chiral magnets [1-3]. Here, we report the determination of the fourth and sixth order anisotropy constants of MnSi as a function of temperature and field using the cantilever torque magnetometry option in a physical property measurement system. Torque curves were recorded by rotating the single-crystalline spherical sample in the field polarized state. This allows us to extract anisotropy constants by fitting the experimental data to the theoretical expressions of torques belonging to the symmetry class ( $P_{21}$ ). In addition, we discuss technical issues in measurement related to sample shape and geometry. The present technique is used to obtain the anisotropy constants of other cubic chiral magnets including Cu₂OSeO₃, Mn_{1-x}Fe_xSi and Fe_{1-x}Co_xSi series.

Change of electronic Chern number induced by phase shifts in multiple-Q textures — •PASCAL PRASS¹, FABIAN R. LUX¹, DUCO VAN STRATEN², and YURIY MOKROUSOV^{1,3} — ¹Institute of Physics, Johannes Gutenberg University Mainz, Germany — ²Institute of Mathematics, Johannes Gutenberg University Mainz, Germany — ³Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, Germany

A multiple-*Q* spin texture is given by the superposition of multiple spin spirals and gives rise to a periodic array of topological spin structures, such as skyrmions. Using the emergent magnetic field formalism [1] the topological Hall current in the texture is proportional to the real-space winding number of its

spin vector field. In recent articles [2,3], it was illustrated how tuning the relative phase shifts of the spin waves as well as the textures' net magnetization leads to topological phase transitions in the spin texture, i.e. integer jumps of its winding number. Combining these ideas implies the existence of significant discontinuous jumps in the topological Hall current and its associated Chern numbers in the underlying electronic spectrum. In this work, we directly investigate the spin textures' electronic band topology to determine the relationship between its real-space winding number and quasi-momentum space Chern numbers. Understanding the electronic behaviour during these transitions will have far-reaching implications for developing tunable topological Hall devices. [1] T. Schulz et al. Nat. Phys. 8, 301-304 (2012). **Imaging and phase-locking of non-linear spin waves** — •ROUVEN DREYER¹, ALEXANDER F. SCHÄFFER¹, HANS G. BAUER², NIKLAS LIEBING¹, JAMAL BERAKDAR¹, and GEORG WOLTERSDORF¹ — ¹Martin Luther University Halle-Wittenberg, Institute of Physics, Von-Danckelmann-Platz 3, 06120 Halle (Saale), Germany — ²Jahnstrasse 23, 96050 Bamberg, Germany

Non-linear processes are a key feature in the emerging field of spin-wave based information processing since they allow to convert uniform spin-wave excitations into propagating modes at different frequencies. Typically, non-linear spin-wave generation is well described by three and four-magnon scattering processes in the small modulation limit. Recently, the existence of non-linear magnons at odd half-integer multiples of the driving frequency (such as 3/2  $f_{rf}$ , 5/2  $f_{rf}$ , etc.) has been predicted for Ni₈₀Fe₂₀ at low bias fields [1]. However, it is an open question under which conditions these non-linear spin waves emerge coherently and how they can be manipulated in devices. Using super-Nyquist sampling MOKE [2] we directly image these non-linear spin waves in the strong modulation regime. The spatially-resolved investigation of such excitations in Ni₈₀Fe₂₀ elements reveals two distinct phase states [3]. Moreover, we use phase-locking to an external 'seed' frequency to activelymanipulate the phase state. These results open new possibilities for spin-wave sources and phase-encoded information processing with magnons.

**Frequency multiplication by collective nanoscale spin wave dynamics** — •CHRIS KÖRNER¹, ROUVEN DREYER¹, MARTIN WAGENER², NIKLAS LIEBING¹, HANS G. BAUER³, and GEORG WOLTERSDORF¹ — ¹Department of Physics, Martin Luther University HalleWittenberg, Von-Danckelmann-Platz 3, 06120 Halle, Germany — ²Institute for Quantum Electronics, ETH Zürich, Otto-Stern-Weg 1, 8093 Zürich, Switzerland — ³Jahnstrasse 23, 96050 Bamberg, Germany

We observe all-magnetic frequency multiplication and the generation of a 6octave spanning frequency comb within an extended polycrystalline NiFe layer [1]. We investigate this process by means of super Nyquist sampling MOKE microscopy [2] and diamond NV center spectroscopy. Our experimental observations in conjunction with micromagnetic simulations reveal the mechanism of this unexpected phenomenon.

At low bias fields the magnetization locally tilts due to a magnetic ripple effect in the NiFe film. Driving the magnetization with frequencies far below ferromagnetic resonance, i.e. in the MHz range, causes rapid synchronous switching. These switching processes lead to high harmonic spin wave emission. The spin waves emitted by multiple switching events across the film interfere and form a phase stable coherent spin wave frequency comb extending into the GHz regime.

Hybridization Induced Spin-Wave Stop Band — •CHRISTIAN RIEDEL, TAKUYA TANIGUCHI, and CHRISTIAN H. BACK — Technische Universität München We present complex spin-wave diffraction patterns in the near-field diffraction limit by using a custom-made time-resolved magneto-optical Kerr effect (TR-MOKE) microscope for visualizing the local and time-resolved dynamic magnetization, i.e. propagating spin-waves. To investigate magnonic interference Physical reservoir computing is an information processing scheme that enables energy efficient temporal pattern recognition to be performed directly in physical matter [1]. Previously, random topological magnetic textures have been shown to have the characteristics necessary for efficient reservoir computing [2] and allowed for simple pattern recognition with two input channels [3].

We propose a skyrmion mixture reservoir computing model with multidimensional inputs. Through micro-magnetic simulations, we show that our implementation can solve audio classification tasks at the nanosecond timescale to a high degree of accuracy. Due to the quality of the results shown and the low power properties of magnetic texture reservoirs, we argue that skyrmion magnetic textures are a competitive substrate for reservoir computing.

behaviors, we fabricate a diffraction grating in a 200 nm thick ferrimagnetic YIG film by argon ion-beam etching. A coplanar waveguide (CPW) located parallel to the grating, is used to coherently excite spin-waves. Our results represent the experimental realization of complex spin-wave interference patterns arising from various diffraction gratings, as preliminary investigated by Mansfeld et al.. We further demonstrate that the interference pattern behind the diffraction grating can be tuned through careful selection of the external magnetic field strength. A reduction in the effective magnetic field between the grating antidots can lead to a hybridization of two spin-wave modes and with this to a spin-wave interference behaviors for enhancing the performance of future magnonic devices.

## MA 28.4 Thu 10:15 H43

Investigation of Spin Wave Caustics Phenomena — •FRANZ VILSMEIER¹, ALEXIS WARTELLE², TAKUYA TANIGUCHI¹, and CHRISTIAN BACK¹ — ¹Technische Universität München — ²Grenoble Institute of Technology

We present a systematic survey of caustic spin wave beams and their properties in an anisotropic magnetic environment.

Based on the theory from Kalinikos and Slavin for spin waves in soft films [Journal of Physics C: Solid State Physics, 1986, 19, 7013-7033], an anisotropic dispersion relation allows caustic points to exist. Here, several wavevectors with the same group velocity direction can be excited over a broad angular range within the sample plane. These caustic points result in nondiffractive spin wave beams and are characterised by their propagation direction, wavefront angle and wavelength.

Experimentally, we excite the caustic points in 200 nm thick Yttrium Iron Garnet by sending an rf current through a bow-shaped antenna. Time Resolved Kerr Microscopy is used to investigate the propagation behaviour both, spatially, as well as time resolved. We are able to access one caustic pocket and detect causticlike beams over a range of different rf frequencies and external magnetic field values. Furthermore, the caustic-like beams are used to directly observe anisotropic reflection phenomena and steering of the beams with rotation of the externally applied field. The findings are compared to micromagnetic simulations with the help of Mumax3.

#### MA 28.5 Thu 10:30 H43

The Optimization of Yttrium Iron Garnet Spin-wave Lenses for Amplification of Spin Waves — •STEPHANIE LAKE¹, PHILIPP GEYER¹, ROUVEN DREYER¹, NIKLAS LIEBING¹, PHILIP TREMPLER¹, EVANGELOS PAPAIOANNOU¹, GEORG WOLTERSDORF¹, and GEORG SCHMIDT^{1,2} — ¹Institut für Physik, Martin-Luther-Universität Halle-Wittenberg, 06120 Halle, Germany — ²Interdisziplinäres Zentrum für Materialwissenschaften, MartinLuther-Universität Halle-Wittenberg, 06120 Halle, Germany

Exciting magnons in magnetic materials for high-frequency applications is inefficient; one way to improve the process is to focus a manifold of spin waves. Following this idea, we create a magnon counterpart to the nonimaging Fresnel lens concentrator called a "spin-wave lens."

We simulate spin-wave (SW) propagation through funnel-like SW lenses based on the material Yttrium Iron Garnet (YIG) using Mumax [1]. When a frequency of 3.25 GHz and field of 51.62 mT are applied, SW modes with wavelengths 9.4  $\mu$ m are excited, and furthermore, have a 384-fold increase in their intensity relative to the structure's start. To test the simulation's accuracy, we fabricate SW lenses out of YIG [2] and measure the precession of excited SWs by a magneto-optic Kerr effect (MOKE) measurement scheme. We conduct several parameter sweeps of geometric characteristics and experimental conditions and currently attain a 51-fold increase in intensity near the funnel's exit for a frequency of 3.68 GHz and magnetic field of 66.15 mT.

Spin waves, and their quanta magnons, meet all the requirements and are prospective data carriers in future signal processing systems. However, an efficient method for the excitation of short-wavelength spin waves is still an unsolved problem and a major obstacle for broadband spin-wave applications. Here, we present a universal approach to excite spin waves with wavelengths from micrometers down to tens of nanometers in nanoscale waveguides by exploiting deep nonlinear phenomena and validate it experimentally by microfocused Brillouin light scattering spectroscopy. The novel excitation method removes the wavelength limitations imposed by the antenna size, increases the excitation efficiency of short spin waves, and enables direct on-chip integration.

## MA 28.7 Thu 11:00 H43

Symmetry of the magnetoelastic interaction of Rayleigh- and shear horizontal-magnetoacoustic waves — •MATTHIAS KÜSS¹, MICHAEL HEIGL¹, LUIS FLACKE^{2,3}, ANDREAS HEFELE¹, ANDREAS HÖRNER¹, MATHIAS WEILER^{2,3,4}, MANFRED ALBRECHT¹, and ACHIM WIXFORTH¹ — ¹University of Augsburg, Experimental Physics I and IV — ²Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften — ³Physics-Department, Technical University Munich, 85748 Garching, Germany — ⁴Fachbereich Physik and Landesforschungszentrum OPTIMAS, Technische Universität Kaiserslautern

Surface acoustic waves (SAWs) have made their way into many everyday devices. These "nano earthquakes" can be efficiently launched and detected on piezoelectric substrates with periodic metallic gratings. Resonant coupling of SAWs with spin waves (SWs) is the basis for an energy-efficient approach towards SW manipulation. In addition, magnetoacoustic interaction affects the properties of the SAW, which in turn can be used to devise new types of microwave devices. However, SAW-SW coupling is limited to certain experimental geometries, defined by the orientation of the static magnetization with respect to the SW wave vector. This orientation dependence is caused by the SAW mode-specific symmetry of the magnetoelastic driving fields. In this contribution, we demonstrate how the SAW mode-shape determines the symmetry of the magnetoelastic interaction and its nonreciprocal behavior, caused by the SAW-SW helicity mismatch effect [M. Küß et al., Phys. Rev. Applied 15, 034046 (2021)].

## MA 28.8 Thu 11:15 H43

Direct maskless magnetic patterning using a cobalt focused ion beam — JAVIER PABLO-NAVARRO¹, •KILIAN LENZ¹, NICO KLINGNER¹, GREGOR HLAWACEK¹, RYSZARD NARKOWICZ¹, LOTHAR BISCHOFF¹, RENE HÜBNER¹, WOLFGANG PILZ², FABIAN MEYER², PAUL MAZAROV², and JÜRGEN LINDNER¹ — ¹Institut für Ionenstrahlphysik und Materialforschung, Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden — ²Raith GmbH, Konrad-Adenauer-Allee 8, 44263 Dortmund

We present direct maskless magnetic patterning of ferromagnetic nanostructures using a novel liquid metal alloy ion source for focused ion beam systems (FIB). We used a Co₃₆Nd₆₄ alloy as the FIB source. A Wien mass filter allows for quick switching between the ion species in the alloy without changing the source. A single  $5 \times 1 \times 0.05 \ \mu\text{m}^3$  permalloy strip served as the sample. Using the FIB we implanted a 300 nm wide track with Co ions. We observed the Co-induced changes by measuring the sample with microresonator ferromagnetic resonance before and after the implantation. Structures as small as 30 nm can be implanted up to a concentration of 10 % at the surface. Such lateral resolution is hard to reach for other lithographic methods. In contrast to electron beam lithography with broad beam ion implantation, the maskless FIB process does not require the complicated and difficult removal of the ion-hardened resist if optical measurements like BLS or MOKE are needed.

MA 28.9 Thu 11:30 H43

**Experimental Detection of Magnon Noise Enhancement near Spin Reorientation in Sm**_{0.7}**Er**_{0.3}**FeO**₃ — •MARVIN WEISS¹, ANDREAS HERBST¹, JULIUS SCHLEGEL¹, MARTIN EVERS¹, TOBIAS DANEGGER¹, ANDREAS DONGES¹, MAKOTO NAKAJIMA², SEBASTIAN T. B. GOENNENWEIN¹, ALFRED LEITENSTORFER¹, ULRICH NOWAK¹, and TAKAYUKI KURIHARA^{1,3} — ¹Department of Physics, University of Konstanz — ²ILE, Univ. Osaka — ³ISSP, Univ. Tokyo

Disentangling intrinsic quantum mechanical interactions and thermal fluctuations is especially important for understanding and controlling magnetic phase transitions. In solids, the dynamics of thermal fluctuations of elementary excitations typically proceed on a picosecond timescale. Although optical pump-probe experiments give access to this range, the experimental detection of ultrafast spin fluctuations remains largely unexplored due to their incoherent character. We investigate the elementary dynamics of thermally excited incoherent magnons in the time domain with femtosecond resolution. The experiments are enabled by a novel setup that allows for extracting the correlation of the pulse-to-pulse polarization fluctuations between two temporally and spectrally separated femtosecond probe pulses that transmit through the sample. As a proof-of-principle demonstration, we study the critical phenomena around the spin reorientation transition (SRT) of the orthoferrite  $Sm_{0.7}Er_{0.3}FeO_3$ . Distinct changes of magnon noise amplitude and dynamics are mapped out around the SRT.

## MA 28.10 Thu 11:45 H43

Lattice-driven femtosecond magnon dynamics in  $\alpha$ -MnTe — •KIRA DELTENRE¹, DAVIDE BOSSINI², MIRKO CINCHETTI¹, GÖTZ S. UHRIG¹, and FRITHJOF B. ANDERS¹ — ¹Department of Physics, TU Dortmund University, D-44227 Dortmund — ²Department of Physics and Center for Applied Photonics, University of Konstanz, D-78457 Konstanz

The femtosecond dynamics of the sublattice magnetizations in the antiferromagnetically ordered phase of  $\alpha$ -MnTe is investigated theoretically with linear spin wave theory as a function of an external drive [1]. We assume that collective coherent lattice vibrations generated by laser pulses induce an oscillating Heisenberg coupling thus inducing the driving. The calculated dynamics of the antiferromagnetic order parameter exhibits damped coherent longitudinal oscillations, which decay due to dephasing. The frequency of the oscillations is determined by the external driving phonon. We make contact to experiments [2] by analyzing the spin dynamics for realistic parameters and discussing the effect of oscillating Heisenberg couplings between different types of (next-)nearest neighbors.

Hybrid magnon-quantum spins systems have been gathering scientific interest in the last years due to their increased coupling strength, scalability down to the nanoscale regime and their potential as energy efficient quantum buses. While magnon-mediated control of quantum spins has been demonstrated with NVcenters in diamond, it has remained elusive on the silicon carbide (SiC) platform mainly due to the absence of a resonance overlap between the magnetic system and the spin-defect center. Here we circumvent this challenge by harnessing non-linear magnon scattering processes taking place in a magnetic vortex to access spin-wave eigenmodes that overlap with the intrinsic resonance of silicon vacancy defect centers in 4H-SiC. Our results offer a route to develop hybrid magnon-quantum spins systems that benefit from the electrical and optical properties of SiC for future quantum computing applications. This work was supported in part by the German Research Foundation under Grants SCHU 2922/4-1 and AS 310/9-1.

Topological magnons driven by the Dzyaloshinskii-Moriya interaction in the centrosymmetric ferromagnet  $Mn_5Ge_3 - \cdot MANUEL DOS SANTOS DIAS^{1,2}$ , NIKOLAOS BINISKOS³, FLAVIANO JOSÉ DOS SANTOS⁴, KARIN SCHMALZL⁵, JÖRG PERSSON⁶, NICOLA MARZARI⁴, STEFAN BLÜGEL², THOMAS BRÜCKEL⁶, and SAMIR LOUNIS^{1,2} - ¹Peter Grünberg Institut and Institute for Advanced Simulation, FZ Jülich & JARA, Jülich, DE - ²Faculty of Physics, University of Duisburg-Essen and CENIDE, Duisburg, DE - ³FZ Jülich, Jülich Centre for Neutron Science at MLZ, Garching, DE - ⁴Theory and Simulation of Materials and National Centre for Computational Design and Discovery of Novel Materials, EPFL, Lausanne, CH - ⁵FZ Jülich, Jülich Centre for Neutron Science at ILL, Grenoble, FR - ⁶FZ Jülich, Jülich Centre for Neutron Science and Peter Grünberg Institut, JARA-FIT, Jülich, DE

The Berry phase of electrons and magnons can lead to various unique transport effects and protected edge states of topological nature. Here, we show theoretically and via inelastic neutron scattering experiments that bulk ferromagnetic  $Mn_5Ge_3$  hosts topological Dirac magnons. Although inversion symmetry prohibits a net Dzyaloshinskii-Moriya interaction in the unit cell, it is locally allowed and is responsible for the gap opening in the magnon spectra. This gap is predicted and experimentally verified to close by rotating the magnetization from being parallel to being perpendicular to the *c*-axis. The tunability of  $Mn_5Ge_3$  by chemical doping or by thin film nanostructuring makes it an exciting new platform to explore and design topological magnons.

Electric field control of magnons in magnetic thin films: Ab initio predictions for two-dimensional metallic heterostructures — •ALBERTO MARMODORO¹, SERGIY MANKOVSKY², HUBERT EBERT², JAN MINÁR³, and ONDŘEJ ŠIPR^{1,3} — ¹Institute of Physics (FZU) of the Czech Academy of Sciences, Prague, Czech Republic — ²Department of Chemistry, Ludwig-Maximilians-University (LMU), Munich, Germany — ³New Technologies Research Centre, University of West Bohemia, Pilsen, Czech Republic

We report on a possible venue to control magnons in 2D heterostructures by an external electric field acting across a dielectric barrier [1]. By performing ab initio 2D TB-KKR calculations for a Fe monolayer and Fe bilayer, both suspended in vacuum and deposited on Cu(001), we demonstrate that external electric field can significantly modify magnon lifetimes and that these changes can be related to field-induced changes in layer-resolved electronic Bloch spectral function. Further changes appear in cases with more than a single magnetic layer, and are strongly dependent on the presence of the substrate.

# MA 29: Caloric Effects in Magnetic Materials

Time: Thursday 9:30-11:45

MA 29.1 Thu 9:30 H47

"Giant" magnetocaloric effects for 2nd order phase transition near 20 K: a study on rare-earth Laves phases for hydrogen liquefaction — •WEI LIU¹, FRANZISKA SCHEIBEL¹, TINO GOTTSCHALL², EDUARD BYKOV², KONSTANTIN SKOKOV¹, and OLIVER GUTFLEISCH¹ — ¹Funktionale Materialien, Technische Universität, TU Darmstadt, Germany — ²Hochfeld- Magnetlabor Dresden, Helmholtz-Zentrum Dresden-Rossendorf, Germany

Hydrogen will play a key role for building a climate-neutral society, where renewables are the major energy sources [1]. Liquid hydrogen is essential for efficient storage and transport of hydrogen, but expensive due to the low efficiency of traditional gas-compression refrigeration [2]. As an emerging and energy-saving technology, magnetocaloric gas liquefaction can be an a "game-changer". Here we report a noticeable, but unaddressed feature for magnetocaloric hydrogen liquefaction using rare-earth-based intermetallic alloys: magnetocaloric effect of a 2nd order magnetocaloric materials can become "giant" when the Curie temperature TC is near the hydrogen boiling point of 20 K. Based on our study on rare-earth Laves phases for hydrogen liquefaction and a comprehensive literature review, we summarized two phenomenological rules for a rare-earth-based intermetallic series: (1) magnetic entropy change increases with decreasing TC; (2) adiabatic temperature change decreases firstly with decreasing TC but increases in cryogenic temperature range. These findings are well interpreted by a mean-field approach. Our studies can guide the materials design for hydrogen liquefaction.

# MA 29.2 Thu 9:45 H47

Magnetocaloric effect in Tb₃Ni studied in high magnetic fields for cryogenic applications — •T. NIEHOFF^{1,2}, T. GOTTSCHALL¹, C. SALAZAR MEJIA¹, A. HERRERO³, A. OLEAGA³, A.F. GUBKIN⁴, and J. WOSNITZA^{1,2} — ¹Dresden High Magnetic Field Laboratory (HLD-EMFL), HZDR, Dresden, Germany — ²Technische Universität Dresden, Dresden, Germany — ³Universidad del País Vasco, Bilbao, Spain — ⁴Ekaterinburg, Russia

 $Tb_3Ni$  exhibits a large variety of temperature and magnetic-field dependent phase transitions in a temperature range of 3 to 90 K. This gives rise to a very competitive conventional magnetocaloric effect and an inverse magnetocaloric effect at very low temperature. These properties make this material an interesting candidate for magnetic refrigeration applications in the gas liquefaction temperature range. In this work, we present a comprehensive analysis of the magnetocaloric effect in a  $Tb_3Ni$  single crystal in pulsed magnetic fields up to 50 T and by heat capacity measurements in static fields.

#### MA 29.3 Thu 10:00 H47

**Direct measurements of the adiabatic temperature change of holmium for cryogenic applications** — •E. BYKOV^{1,2}, T. GOTTSCHALL¹, Y. SKOURSKI¹, C. SALAZAR MEJIA¹, J. WOSNITZA^{1,2}, M. D. KUZ'MIN³, Y. MUDRYK⁴, D. L. SCHLAGEL⁴, and V. PECHARSKY^{4,5} — ¹1Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, Dresden, Germany — ²Technische Universität Dresden, Dresden, Germany — ³Aix-Marseille Université, IM2NP, Marseille, France — ⁴Ames Laboratory, U.S. Department of Energy, Iowa State University, Ames, USA

Rare-earth elements and their intermetallic compounds are interesting candidate materials for magnetic cooling at and below room temperature. Holmium demonstrates one of the largest magnetic moment in the lanthanide series and possesses other unusual magnetic properties. This metal exhibits numerous magnetic phase transitions as the temperature and/or magnetic field vary. Its

#### Location: H47

Néel temperature accounts for  $T_N = 132$  K, and its Curie temperature is  $T_C = 20$  K resulting in a strong magnetocaloric effect in a large temperature window. This fact makes holmium a promising single-stage refrigerator material in an AMR (active magnetic regenerator) scheme for the liquefaction of natural gas and hydrogen. In this work, we present a comprehensive analysis of the magnetocaloric effect in a holmium single crystal in high magnetic fields up to 60 T.

MA 29.4 Thu 10:15 H47

Anomalous Nernst effect in ferromagnetic  $\tau$ -MnAl thin films — •DANIEL SCHEFFLER¹, HELENA REICHLOVA¹, SEBASTIAN BECKERT¹, TORSTEN MIX², THOMAS G. WOODCOCK², SEBASTIAN T. B. GOENNENWEIN³, and ANDY THOMAS^{1,2} — ¹Technische Universität Dresden — ²Leibniz Institute for Solid State and Materials Research Dresden (IFW Dresden) — ³University of Konstanz

 $\tau$ -MnAl is a ferromagnetic compound with high uniaxial magnetocrystalline anisotropy. In single crystalline films, the anomalous Hall effect and the tunnel magnetoresistance effect have been investigated, the magneto-thermal transport properties of  $\tau$ -MnAl films are unknown. Given the unique anisotropy, this material could allow for a robust spontaneous anomalous Nernst effect generated by a thermal gradient applied in the film plane.

We have successfully grown single crystalline  $\tau$ -MnAl thin films via cosputtering. X-ray diffraction and DC magnetometry confirm a good structural quality and strong perpendicular magnetic anisotropy. We observe a robust anomalous Hall effect with a coercivity of 1 T in magneto-transport measurements. In the same device, a defined thermal gradient can also be applied in the sample plane, resulting in a clear anomalous Nernst effect response.

We will present results from our magneto-transport and magnetothermopower experiments, which in particular allow to quantify the anomalous Nernst effect coefficient. Our results show that  $\tau$ -MnAl in thin film form is an interesting material for spin-caloritronic research and devices.

#### MA 29.5 Thu 10:30 H47

Magnonic to electronic spin current conversion in a quantum dot hybrid system with magnetic insulator — •EMIL SIUDA and PIOTR TROCHA — Faculty of Physics, Institute of Spintronics and Quantum Information, Adam Mickiewicz University, ul. Uniwersytetu Poznańskiego 2, 61-614 Poznań, Poland

One of the challenges of further miniaturization of electronic components is managing heat generated due to the Joule heating and other effects. While magnonics offers a way to reduce generation of the waste heat in the device it is still impossible to get rid of it entirely. Hence a way of converting heat to useful electric power is desirable.

We investigate a hybrid system which utilizes a temperature gradient to produce a magnon current and converts it to a spin electronic current. The considered system consists of a quantum dot coupled to the two ferromagnetic insulators or one ferromagnetic insulator and one ferromagnetic metal. This work focuses on the influence of energy-dependent density of states and manybody magnon interactions in the magnonic reservoirson the thermally induced spin transport through the system. Energy-dependent density of states is crucial for boson-like particles, especially in the low energy limit where the lowest momentum states dominate the tranport. Thus, in the present work we consider explicit energy dependence of the density of states for the magnonic reservoirs. Moreover, taking into account many-body magnon interactions leads to a temperature-dependent density of states of magnons which results in temperature-dependent couplings of the dot to the magnonic reservoirs.

## MA 29.6 Thu 10:45 H47

 $\begin{array}{l} \textbf{Magneto-thermal transport in non-collinear antiferromagnetic thin films } \\ \bullet \textbf{Sebastian Beckert}^1, João Godinho^{2,4}, Freya Johnson^3, Jozef Kimák^4, Eva Schmoranzerová^4, Zbyněk Šobáň^2, Kamil Olejník^2, Jan Zemen^5, Joerg Wunderlich⁶, Petr Němec⁴, Dominik Kriegner^{1,2}, Lesley F. Cohen³, Andy Thomas^{1,7}, Sebastian T. B. Goennenwein⁸, and Helena Reichlová^{1,2} \\ - ¹TU Dresden - ²IoP ASCR Prague - ³Imperial College London - ⁴Charles University - ⁵Czech TU - ⁶University of Regensburg - ⁷IFW Dresden - ⁸University of Konstanz$ 

Understanding the interplay between topological properties and transport phenomena in non-collinear antiferromagnets is important for exploiting their unconventional characteristics in spintronics. Non-collinear antiferromagnets can exhibit phenomena previously known to be exclusive to ferromagnets, such as the anomalous Hall Effect (AHE) or the anomalous Nernst effect (ANE).

We experimentally study magneto-thermal transport in a  $Mn_3NiN$  thin film antiferromagnet. In our films the spins are arranged in the (111) plane, resulting in a component of the Hall vector in both out-of plane and in-plane direction. This makes  $Mn_3NiN$  an ideal candidate for a systematic study of magnetothermal transport phenomena. We will present measurements of ANE, AHE, magnetoresistance and magneto-Seebeck effect measured in a single device. We will compare the amplitudes of the magneto-thermal transport coefficients and discuss them in context of the Mott relation.

## MA 29.7 Thu 11:00 H47

Multicaloric all-d-metal Ni-Co-Mn-Ti Heusler alloys: Heat treatment optimization and arrested martensitic transformations — •BENEDIKT BECKMANN¹, ANDREAS TAUBEL¹, LUKAS PFEUFFER¹, DAVID KOCH¹, TINO GOTTSCHALL², FRANZISKA SCHEIBEL¹, KONSTANTIN P. SKOKOV¹, and OLIVER GUTFLEISCH¹ — ¹TU Darmstadt, Institute of Material Science, 64287 Darmstadt, Germany — ²Dresden High Magnetic Field Laboratory (HLD-EMFL), Helmholtz-Zentrum Dresden-Rossendorf, Dresden 01328, Germany

Ni-Mn-based Heusler alloys display precisely tunable first-order martensitic transformations and are promising candidates for multicaloric cooling applications [1]. In our work, all-d-metal Ni_{50-x}Co_xMn_{50-y}Ti_y Heusler alloys, showing an enhanced mechanical stability, are analyzed in detail [2]. A systematic heat treatment optimization results in a tailored microstructure and leads to large isothermal entropy changes up to 38 J(kgK)⁻¹ and adiabatic temperature changes up to -3.8 K for the first field application in moderate magnetic field changes of 2 T. The contradictory role of the magnetic entropy contribution [3], which leads to arrested martensitic transformations in Ni_{50-x}Co_xMn_{50-y}Ti_y inverse magnetocaloric Heusler alloys, is discussed in detail.

We acknowledge financial support from DFG (CRC/TRR 270) and ERC (Adv. Grant No. 743116).

MA 29.8 Thu 11:15 H47

**Magnetocaloric effect of Gd** - an realistic ab-initio study — •RAFAEL VIEIRA^{1,2}, OLLE ERIKSSON^{1,3}, TORBJÖRN BJÖRKMAN², and HEIKE C. HERPER¹ — ¹Department of Physics and Astronomy, Uppsala University, Box 516, SE-75120 Uppsala, Sweden — ²Physics, Faculty of Science and Engineering, Åbo Akademi University, FI-20500 Turku, Finland — ³School of Science and Technology, Örebro University, SE-701 82 Örebro, Sweden

We present a computational approach to evaluate field-dependent entropy of magnetocaloric materials from ab-initio calculations. Taking hcp Gd as a test system, we fully characterize the entropy associated with the magnetocaloric effect by including the entropy's electronic, lattice, and magnetic contributions.

The 2nd order nature of the ferromagnetic (FM) $\rightarrow$ paramagnetic (PM) transition in Gd implies considering intermediate states of magnetic disorder. We describe the properties of these intermediate states as weighted averages of the properties of the FM and PM phases, with mixing weights defined by the magnetization of the system at a given temperature, to which we use the results from the Monte Carlo simulations. This approach allows a realistic system description, bringing the total entropy variation in agreement with reported measurements.

We find, as expected that the magnetic entropy is the dominant entropy. However, we also observe that the lattice contribution has a role in total entropy variation.

Interplay of magnetic states and hyperfine fields of iron dimers on MgO(001) —•SUFYAN SHEHADA^{1,2,3}, MANUEL DOS SANTOS DIAS^{4,1}, MUAYAD ABUSAA³, and SAMIR LOUNIS^{1,4} — ¹Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich & JARA, 52425 Jülich, Germany — ²Department of Physics, RWTH Aachen University, 52056 Aachen, Germany — ³Department of Physics, Arab American University, Jenin, Palestine — ⁴Faculty of Physics, University of Duisburg-Essen, 47053 Duisburg, Germany

Individual nuclear spin states can have very long lifetimes and could be useful as qubits. Progress in this direction was achieved on MgO/Ag(001) via detection of the hyperfine interaction (HFI) of Fe, Ti and Cu adatoms using scanning tunneling microscopy (STM)[1,2]. Previously, we systematically quantified from first-principles the HFI for the whole series of 3d transition adatoms (Sc-Cu) deposited on various ultra-thin insulators, establishing the trends of the computed HFI with respect to the filling of the magnetic s- and d-orbitals of the adatoms and on the bonding with the substrate[3]. Here we take one step further by investigating the impact of the magnetic coupling between the dimer atoms on the HFI of Fe dimers on MgO(001) and its dependence on where the Fe atoms are located on the surface[4]. –Work funded by (BMBF–01DH16027).

MA 30.2 Thu 9:45 H48 Low-energy end states in proximitized antiferromagnetic nanowires — •LUCAS SCHNEIDER¹, PHILIP BECK¹, THORE POSSKE^{2,3}, LEVENTE RÓZSA⁴, JENS WIEBE¹, and ROLAND WIESENDANGER¹ — ¹Department of Physics, Universität Hamburg, D-20355 Hamburg, Germany — ²I. Institute for Theoretical Physics, Universität Hamburg, D-20355 Hamburg, Germany — ³The Hamburg Centre for Ultrafast Imaging, Luruper Chaussee 149, 22761 Hamburg, Germany — ⁴Department of Physics, University of Konstanz, D-78457 Konstanz, Germany

Magnetically ordered nanowires coupled to a superconducting surface have been proposed to host Majorana modes (MMs) at their ends, which form a single, highly non-local fermionic state together. While multiple experiments claim the observation of MMs via a zero-bias resonance in tunneling conductance at the ends of nanowires, this is not a unique signature of MMs. In this work, we study the emergence of low-energy end states in artificially crafted antiferromagnetic nanowires on two different superconducting surfaces using scanning tunneling spectroscopy. While some of the end states are observed close to zero energy, we find that they can be split into two non-degenerate components localized on the left and right ends by local defects - in clear contrast to expectations for a single non-local state. The phenomenology of these trivial bound states can be explained by simple toy-model calculations. We propose that similar perturbations by local defects could be used on other sample systems to probe the stability of candidate topological edge modes against local disorder.

MA 30.3 Thu 10:00 H48 **Spin-resolved Fermi Surface of "Half-Metallic" FePd Alloy Monolayers** — •XIN LIANG TAN^{1,2}, KENTA HAGIWARA^{1,2}, YING-JIUN CHEN^{1,2}, VITALIY FEYER¹, CLAUS M. SCHNEIDER^{1,2}, and CHRISTIAN TUSCHE^{1,2} — ¹Forschungszentrum Jülich, Peter Grünberg Institut, Jülich — ²Fakultät für Physik, Universität Duisburg-Essen, Duisburg

Magnetism in reduced dimensions is one of the preconditions for the realization of nanoscale spintronics. Despite the recent discovery of ferromagnetism in monolayers of two-dimensional materials, tunability and engineering on such systems are challenging. Here we present the electronic structure of ultrathin ferromagnetic iron-palladium alloy films using spin-resolved momentum microscopy. Momentum microscopy enables the two-dimensional detection of photoelectrons with an in-plane crystal momentum over the full Brillouin zone. By employing an imaging spin filter, spin-resolved momentum maps of the ironpalladium alloy were acquired. Breaking of time reversal symmetry by the remanent magnetization of the film manifests in a pronounced anisotropy of the elec-

372

tron states in the Fermi surface. In particular, the competition between exchange interaction and strong spin-orbit coupling in the FePd alloy leads to the formation of wave-vector dependent local gaps in the Fermi surface. Moreover, the spin-resolved maps recorded by the momentum microscope give evidence for a non-collinear spin texture of the electron states at the Fermi surface, where the local spin polarization vector points orthogonal to the remanent magnetization of the sample.

MA 30.4 Thu 10:15 H48

**Real-time MOKE measurements of CoTMPP on magnetic Ni/Cu(110)**-(**2x1)O** — •GIZEM MENDIREK¹, ALEKSANDER BROZYNIAK², MICHAEL HOHAGE¹, ANDREA NAVARRO-QUEZADA¹, and PETER ZEPPENFELD¹ — ¹Institute of Experimental Physics, Johannes Kepler University Linz, Altenberger Str. 69, 4040 Linz, Austria — ²Christian Doppler Laboratory for Nanoscale Phase Transformations, Johannes Kepler University Linz, Altenberger Str. 69, 4040 Linz, Austria

In this work, we report the detailed analysis employing a fitting algorithm on a setup consisting of a combination of a sinusoidal modulation of the magnetic field with the synchronous detection of the reflectance difference spectroscopic MOKE (RD-MOKE) signal. This setup allows recording hysteresis loops continuously revealing relevant magnetic properties like magnetization amplitude, remanent magnetic signal and coercive field as a function of coverage, time or temperature with high precision in real-time. The capabilities of our setup and our analysis algorithm is demonstrated for Ni thin films grown on a Cu(110)-(2×1)O reconstructed surface with a sharp spin reorientation transition at 9 ML. Subsequently, the deposition of cobalt tetramethoxyphenylporphyrin (CoTMPP) thin films on the Ni/Cu(110)-(2×1)O system is investigated. The adsorption of the decrease of the Curie temperature of the Ni thin films upon CoTMPP deposition with different thicknesses.

MA 30.5 Thu 10:30 H48 **Thermally-induced magnetic order from glassiness in elemental neodymium** — BENJAMIN VERLHAC¹, •LORENA NIGGLI¹, ANDERS BERGMANN², UMUT KAMBER¹, ANDREY BAGROV^{1,2}, DIANA IUŞAN², LARS NORDSTRÖM², MIKHAIL I. KATSNELSON¹, DANIEL WEGNER¹, OLLE ERIKSSON^{2,3}, and ALEXANDER A. KHAJETOORIANS¹ — ¹Institute for Molecules and Materials, Radboud University, Nijmegen, The Netherlands — ²Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden — ³School of Science and Technology, Örebro University, SE-701 82 Örebro, Sweden

While traditional spin glasses are characterized by randomness and frustration, elemental neodymium shows glassy behavior as a result of competing interactions, particularily without extrinsic disorder [1]. Adding to the list of intriguing effects found in spin glasses, e.g. aging and memory, we observe an unconventional magnetic phase transition from a glassy to a long-range ordered phase in Nd as temperature is increased [2]. To characterize the spatially varying magnetization patterns, we employ temperature-dependent spin-polarized scanning tunnelling microscopy between 5-15K along with atomistic spin dynamics simulations that support our findings. A new analysis method allows us to extract the phase transition temperature directly by evaluating our experimental data. Notably, such an unusual magnetic phase transition serves as a counterexample to the common thermodynamic understanding of temperature and disorder being synonymous.

**Distorted** 3Q **state driven by topological-chiral magnetic interaction** — •SOUMYAJYOTI HALDAR¹, SEBASTIAN MEYER², ANDRÉ KUBETZKA³, and STEFAN HEINZE¹ — ¹Institute of Theoretical Physics and Astrophysics, University of Kiel, Leibnizstr. 15, 24098 Kiel, Germany — ²Nanomat/Q-mat/CESAM, Université de Liège, B-4000 Sart Tilman, Belgium — ³Department of Physics, University of Hamburg, 20355 Hamburg, Germany Non-collinear spin structures are of fundamental interest in magnetism since they allow to obtain insight into the underlying microscopic interactions and are promising for spintronic applications [1,2]. Here, we demonstrate that recently proposed topological-chiral magnetic interactions [3] can play a key role for magnetic ground states in ultrathin films at surfaces [4]. Using density functional theory we show that significant chiral-chiral interactions occur in hexagonal Mn monolayers due to large topological orbital moments which interact with the emergent magnetic field. Superposition states of spin spirals such as the 2Q state or a distorted 3Q state arise due to the competition with biquadratic and four-spin interactions. Simulations of spin-polarized scanning tunneling microscopy images suggest that the distorted 3Q state could be the magnetic ground state of a Mn monolayer on Re(0001).

MA 30.7 Thu 11:00 H48

The mutual impact of magnetism on proximity-induced superconductivity — •URIEL ACEVES^{1,2}, FILIPE GUIMARAES³, and SAMIR LOUNIS^{1,2} — ¹Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich & JARA, 52425 Jülich, Germany — ²Faculty of Physics & CENIDE, University of Duisburg-Essen, 47053 Duisburg, Germany — ³Jülich Supercomputing Centre, Forschungszentrum Jülich & JARA, 52425 Jülich, Germany

In a conventional superconductor (SC), vibrations on the crystal lattice can cause electrons to attract mutually and bind in the so-called Cooper pairs. At the interface of a normal metal (NM), Cooper pairs can wander from SC to NM resulting in a proximity induced gap. Electrons from NM can also travel into SC by normal transport or Andreev reflection. This exchange of electrons can impact the properties of both materials. Moreover, if the NM is magnetic new and exciting physics appears. In this work, we explore NM/SC interface phenomena by introducing a method to extract the tensor of magnetic exchange interactions within the framework of the Bogoliubov-de Gennes equations where superconductivity is induced via an effective electron-phonon coupling constant  $\lambda$ and accounting for spin-orbit coupling. Based on a realistic description of the electronic structure, we analyze the behaviour of the isotropic exchange and the Dzyaloshinskii-Moriya interaction as a function of  $\lambda$  on a Mn monolayer on top of a superconducting Nb (110) slab. Additionally, we investigate the impact of  $\lambda$  on the proximity-induced gap as a function of the direction of the magnetic moment in Mn.

Observation of spin-correlated exciton-polaritons in a van der Waals magnet — •FLORIAN DIRNBERGER¹, REZLIND BUSHATI^{1,2}, BISWAJIT DATTA¹, AJESH KUMAR³, ALLAN H. MACDONALD³, EDOARDO BALDINI³, and VINOD M. MENON^{1,2} — ¹Department of Physics, City College of New York, New York, NY 10031, USA — ²Department of Physics, The Graduate Center, City University of New York, New York, NY 10016, USA — ³Department of Physics, University of Texas at Austin, Austin, TX 78712, USA

The recent discovery of optically active excitons in magnetic van der Waals crystals offers extraordinary opportunities to study collective phenomena in quantum materials via light-matter interactions. A prime candidate in this endeavor is nickel phosphorus trisulfide (NiPS₃), a van der Waals antiferromagnet with highly correlated magnetic and electronic degrees of freedom. By coupling optical fields to its excitonic excitations, we demonstrate a previously unobserved class of polaritons with unique signatures of excitons, photons and spins. A detailed spectroscopic analysis of these newly formed quasiparticles in conjunction with our microscopic theory shows that magnetically coupled excitations can have an origin and interactions that are distinct from those of excitons in conventional band semiconductors.

Invited TalkMA 31.1Thu 15:00H37Neutron scattering on magnetic topological materials:From topologicalmagnon insulators to emergent many-body effects- YIXI SU — Jülich Centrefor Neutron Science JCNS at MLZ, Forschungszentrum Jülich, 85747 Garching,Germany

Recent theoretical predictions and experimental realizations of exotic fermions and topologically protected phases in condensed matter have led to tremendous research interests in topological quantum materials. Especially, magnetic topological materials, such as magnetic Dirac and Weyl semimetals, and intrinsic magnetic topological insulators etc., in which non-trivial topology of singleelectron band structures and electronic correlation effects are often intertwined, have emerged as an exciting platform to explore novel phenomena. Here I will present our recent neutron scattering studies. In the Dirac semimetal EuMnBi2, the evidence for the possible impact of magnetism on Dirac fermions is obtained via a detailed neutron diffraction study of the spin-flop transition [1]. Based on our inelastic neutron scattering study and theoretical analysis of spin-wave excitations, the exotic topological magnon insulators, the bosonic analogs of topological insulators, have been experimentally realized in the two-dimensional van der Waals honeycomb ferromagnets CrSiTe3 and CrGeTe3 [2]. Furthermore, in the magnetic Weyl semimetal Mn3Sn, an unusual magnetic phase transition that is driven by emergent many-body effects is revealed via a combined neutron scattering study and band-structure calculations [3].

**Tuning the magnetic gap of a topological insulator** – •MARCUS LIEBMANN¹, PHILIPP KÜPPERS¹, JANNIK ZENNER¹, STEFAN WIMMER², GUNTHER SPRINGHOLZ², OLIVER RADER³, and MARKUS MORGENSTERN¹ – ¹II. Phys. Inst. B, RWTH Aachen Univ., Germany – ²Inst. Halbleiter- u. Festkörperphysik, Johannes Kepler Univ., Linz, Austria – ³Helmholtz-Zentrum Berlin f. Mater. u. Energie, Germany

Mn-rich MnSb₂Te₄ is a ferromagnetic topological insulator with yet the highest Curie temperature  $T_{\rm C} = 45 - 50$  K. It exhibits a magnetic gap at the Dirac point of the topological surface state that disappears above  $T_{\rm C}$ . We probe the gap size by scanning tunneling spectroscopy, varying in-plane magnetic field B_{||} and temperature. We demonstrate shrinkage of the average gap size with  $B_{\parallel}$  revealing that the gap opening originates from out-of-plane magnetization. In line, the gap does not close completely up to  $B_{\parallel} = 3 \text{ T}$  as the magnetization is only partially rotated in-plane. In addition, we demonstrate significant spatiotemporal fluctuations of the gap size at temperatures as low as  $T_{\rm C}/2$ , above which the remanent magnetization indeed decays. Thus, the gap is tightly bound to the out-of-plane magnetization, as expected theoretically but not demonstrated experimentally yet. The partial in-plane rotation at  $B_{\parallel} = 3 \text{ T}$  and the low temperature onset of fluctuations stress the important role of competing magnetic orders in the formation of the favorable ferromagnetic topological insulator in Mn-rich MnSb₂Te₄, providing insight into the complex magnetic gap opening that is decisive for quantum anomalous Hall devices.

Local magnetic and electronic properties of the intrinsic magnetic topological insulator  $\text{MnBi}_6\text{Te}_{10}$  — •ABDUL-VAKHAB TCAKAEV¹, VOLODYMYR ZABOLOTNYY¹, BASTIAN RUBRECHT², LAURA CORREDOR², JORGE FACIO², LAURA FOLKERS³, ANJA WOLTER², ANNA ISAEVA², and VLADIMIR HINKOV¹ — ¹Experimentelle Physik IV and R ontgen Research Center for Complex Materials (RCCM), Fakult at f ur Physik und Astronomie, Universit at W urzburg, Am Hubland, D-97074 W urzburg, Germany — ²Leibniz IFW Dresden, Helmholtzstraße 20, D-01069 Dresden, Germany — ³Faculty of Physics, Technische Universit at Dresden, D-01062 Dresden, Germany

The recent observation of novel phenomena in the intrinsic magnetic topological insulator MnBi₂Te₄, such as the quantum anomalous Hall effect and the topological magnetoelectric effect has prompted research of the higher-*n* members of the (MnBi₂Te₄)(Bi₂Te₃)_n family. Here we combine x-ray absorption spectroscopy, and x-ray circular and linear dichroism at the Mn  $L_{2,3}$  edges, with density-functional (DFT) and multiplet ligand-field (MLFT) theory to investigate the ground state of Mn in MnBi₆Te₁₀ single crystals. Our magnetometry data reveal FM state with finite remanence consistent with the spectroscopy data. Our spectroscopy results together with DFT and *ab initio* MLFT calculations allow us to determine in full detail the local magnetic and electronic properties of the Mn ions in the bulk and near the surface, and deliver important microscopic physical parameters, including Mn 3*d*-shell occupation, the spin and orbital magnetic moments.

## MA 31.4 Thu 16:00 H37

Probing the Superconductor / Quantum Anomalous Hall Interface — •ANJANA UDAY¹, GERTJAN LIPPERTZ^{1,2}, ANDREA BLIESENER¹, ALEXEY TASKIN¹, and YOICHI ANDO¹ — ¹University of Cologne, Cologne, Germany — ²KU Leuven, Leuven, Belgium

Recently, crossed Andreev conversion was reported in a hybrid quantum Hall (QH) / Superconductor (SC) system [1]. The evidence was based on the observation of a negative downstream resistance  $R_D$  in a three-terminal measurement of a Hall-bar device with respect to the grounded SC electrode. Similar experiments would be of great interest in the quantum anomalous Hall (QAH) / SC hybrid system, where superconductivity can be suppressed for control experiments by applying a magnetic field while keeping the 1D edge state unchanged. We fabricated Hall-bar devices from V-doped  $(Bi_xSb_{1-x})_2Te_3$  thin films contacted with Nb electrodes having various widths. We found a finite positive  $R_D$  which increases with decreasing the widths of the SC electrode due to the QAH breakdown mechanism [2]. We also found a clear increase in  $R_D$  upon killing the superconductivity with a magnetic field for Nb electrodes narrower than 200 nm; this can be attributed to either non-local Andreev reflections on top of the breakdown-induced finite  $R_D$  or local Andreev reflections on the 2D normal metal/SC interface, which can be created by the charge transfer from the Nb electrode to the gapped VBST surface state. In both cases our observation implies a high transparency of the SC/QAH interface.

MA 31.5 Thu 16:15 H37 **Magnetotransport Properties of MnSb2Te4** — •MICHAEL WISSMANN^{1,2,3}, JOSEPH DUFOULEUR², ANNA ISAEVA⁴, BERND BÜCHNER^{2,3}, and ROMAIN GIRAUD^{1,2} — ¹Université Grenoble-Alpes, CNRS, CEA, SPINTEC, F-38000 Grenoble, France — ²Leibniz Institute for Solid State and Materials Research IFW Dresden, 01069 Dresden, Germany — ³Institute of Solid State Physics, TU Dresden, 01069 Dresden, Germany — ⁴Department of Physics and Astronomy, University of Amsterdam,1098 XH Amsterdam, Netherlands

The new family of intrinsically magnetic van-der-Waals layered topological insulators Mn(Bi,Sb)Te, with strong spin-orbit coupling, is of great interest to investigate the interplay between topology and magnetic order in electronic band structures. When introducing magnetism into a 3D topological insulator, this interplay can generate topological quantum states like the quantum anomalous Hall effect (QAH) or the axion insulator, which can be modified by tuning the magnetization.

Our recent studies consider the MnSb2Te4 compound, a ferromagnet with a perpendicular-to-plane anisotropy and a critical Curie-Weiss temperature as high as 50K. MnSb2Te4 has been controversially discussed to be a magnetic Weyl semimetal or a candidate to realize the axion insulator. We investigated the thickness-dependent properties of exfoliated nanoflakes using magnetotransport, revealing the change in important parameters such as the resistivity, the Curie temperature and the magnetic coercive field. The influence of both the intrinsic electrical doping and disorder in magnetic topological insulators is considered as well.

## MA 31.6 Thu 16:30 H37

Investigation of the magnetic and electronic properties of topological insulator/ferromagnet heterostructures — •SIMON MAROTZKE^{1,2}, ANDRÉ PHILIPPI-KOBS^{1,2}, LEONARD MÜLLER^{1,3}, MATTHIAS KALLÄNE², JENS BUCK², WOJCIECH ROSEKER¹, NILS WIND³, SANJOY MAHATHA⁴, NILS HUSE³, GERHARD GRÜBEL^{1,3}, MARTIN BEYE¹, and KAI ROSSNAGEL^{1,2} — ¹Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — ²Christian-Albrechts-Universität zu Kiel, Germany — ³Universität Hamburg, Germany — ⁴Thapar Institute of Engineering and Technology, Patiala, India

Heterostructures of the design  $Bi_2Se_3/X/Co/Pt$ , with X = None, Pt,  $B_4C$  or  $B_4C/Pt$  as separation layer between the topological insulator (TI) and the ferromagnetic overlayer are studied. By means of magneto-optical Kerr effect, the magnetic behaviour is characterised, showing that perpendicular magnetic anisotropy can be achieved in the overlayer and minutely tuned by changing layer properties. In X-ray photoemission spectroscopy measurements, two Bi phases are identified in the heterostructures. By systematically varying the photon energy, the depth, in which the two Bi phases are located, is analysed. Significant differences of the chemical properties at the interface to the TI are found for heterostructures consisting of  $Bi_2Se_3$  with a metallic or insulating overlayer, respectively. Finally, a scheme to invert the heterostructures is presented, potentially enabling angle-resolved photoemission spectroscopy measurements on the TI's surface in future in order to study the influence of the magnetisation state on the TI's surface states.

The quantum anomalous Hall (QAH) effect is characterised by zero longitudinal resistivity and quantized Hall resistance without the need of an external magnetic field. However, when reducing the device dimensions or increasing the current density, an abrupt breakdown of the dissipationless state occurs. In this talk, the mechanism of breakdown will be adressed, and the electric field created between opposing chiral edge states will be shown to lie at its origin. Electric-field-driven percolation of two-dimensional charge puddles in the gapped surface states of compensated topological-insulator films is proposed as the most likely cause of the breakdown [1].

Moreover, it was recently reported that the interplay between the 1D chiral edge state and the 2D surface state can give rise to nonreciprocity in the longitudinal resistance [2]. In this talk, it will be shown that the onset of 2D conduction due to breakdown is sufficient to create the nonreciprocal effect, allowing for efficient switching between the dissipationless and nonreciprocal transport regime of the QAH state.

Thermal Hall Effect of Magnons in Collinear Antiferromagnets: Signatures of Magnetic and Topological Phase Transitions — •ROBIN R. NEUMANN¹, ALEXANDER MOOK², JÜRGEN HENK¹, and INGRID MERTIG¹ — ¹Institut für Physik, Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Germany — ²Department of Physics, University of Basel, Basel, Switzerland

While chiral edge states of topological bosons lack clear hallmarks and are difficult to detect, topological electrons can directly be identified by means of the quantized transverse conductivity intrinsic to the quantum anomalous Hall effect. In this talk I consider magnons, the bosonic quanta of collective spin excitations, in a collinear antiferromagnet that is driven from its antiferromagnetic phase via a spin-flop phase to the field-polarized phase by an external magnetic field. Besides the magnetic phase transitions, topological phases occur in the spin-flop and field-polarized phases. To identify these phase transitions, the thermal Hall effect (THE), i. e. the transversal heat transport induced by a longitudinal temperature gradient, is studied across the phase transitions. It is demonstrated that the THE exhibits pronounced signatures of the phase transitions and the temperature tunes the sensitivity to these phase transitions oppositely, allowing for their distinction in transport experiments.

### MA 32.3 Thu 15:30 H43 Effects of disorder on the magnetic properties of L1₀-FeNi — Ankit Izardar and •Claude Ederer — ETH Zürich. Switzerland

L1₀-ordered FeNi is a promising candidate for cheap mid-range permanent magnets. However, since the synthesis of fully ordered samples is very challenging, it is important to understand how deviations from perfect chemical order affect the magnetic properties of FeNi, in particular the magneto-crystalline anisotropy surements, we demonstrate how the combination of co-planar glide symmetries and large Eu2+ magnetic moments in the Zintl phase Eu5In2Sb6 produces an unusual two-step ordering process. At 14 K, Eu5In2Sb6 first forms a complex non-collinear weak Ising-ferrimagnet, which we identify as a trivial insulator. Below 7.5 K, this phase is continuously displaced by a growing volume fraction of a compensated antiferromagnetic arrangement that may have axion insulating character. This discovery also implies the presence of a solitonic antiferromagnetic domain structure on the mesoscale, which demonstrably couples to charge transport and, due to the net magnetization of some domains, should be highly susceptible to manipulation. This may open up a platform to engineer interfaces of trivial and non-trivial insulators on the mesoscale.

Invisible flat bands on a topological chiral edge — •YOUJIANG XU, IRAKLI TITVINIDZE, and WALTER HOFSTETTER — Institut für Theoretische Physik, Goethe-Universität, 60438 Frankfurt am Main, Germany

We prove that invisible bands associated with zeros of the single-particle Green's function exist ubiquitously at topological interfaces of 2D Chern insulators, dual to the chiral edge/domain-wall modes. We verify this statement in a repulsive Hubbard model with a topological flat band, using real-space dynamical mean-field theory to study the domain walls of its ferromagnetic ground state. Moreover, our numerical results show that the chiral modes are split into branches due to the interaction, and that the branches are connected by invisible flat bands. Our work provides deeper insight into interacting topological systems.

Location: H43

and Curie temperature. We use DFT in combination with a sampling over different supercell configuration to address effects of chemical disorder in FeNi. Our results show that a decrease in chemical order of up to 25 % does not cause a significant reduction of the magneto-crystalline anisotropy, and that the anisotropy can even be increased for Fe-rich compositions. We also show that the dominant magnetic coupling is strongly dependent on the specific chemical environment and vary drastically in the partially disordered system. We discuss these results in relation to alternative approaches to disorder, such as, e.g., the coherent potential approximation.

#### MA 32.4 Thu 15:45 H43

Influence of filler morphology, arrangement and filling fraction on the magnetic properties of polymer-bonded magnets produced by laser powder bed fusion — •KILIAN SCHÄFER¹, TOBIAS BRAUN¹, STEFAN RIEGG¹, JENS MUSEKAMP², and OLIVER GUTFLEISCH¹ — ¹1Functional Materials, Institute of Materials Science, , Technical University Darmstadt, Darmstadt — ²2Institute for Materials Technology (MPA-IfW), Technical University Darmstadt, Grafenstraße 2, D-64283 Darmstadt

Bonded permanent magnets are key components in many energy conversion, sensor and actuator devices. These applications need high magnetic performance, customizability, and freedom of shape. With additive manufacturing processes, for example laser powder bed fusion (LPBF), it is possible to produce bonded magnets with tailored stray field distribution.

Up to now, most studies use spherical powders as magnetic fillers due to their good flowability. Here, the behavior of large SmFeN platelets with a high aspect ratio as filler material and its influence on the arrangement and the resulting magnetic properties were examined. To study the distribution and orientation of the magnetic filler in 3D, computed tomography measurements were conducted and analyzed with the open-source software ImageJ. It is shown that the plateletshaped particles align themselves perpendicular towards the buildup direction during the process. In addition, the effect of filling fraction on the magnetic properties of the composites is investigated.

## MA 32.5 Thu 16:00 H43

magnetocrystalline anisotropy in easy-plane kagomé ferromagnet Fe₃Sn — •LILIAN PRODAN¹, VLADIMIR TSURKAN^{1,2}, and ISTVÁN KÉZSMÁRKI¹ — ¹Experimental Physics V, Institute of Physics, University of Augsburg, D-86159 Augsburg, Germany — ²Institute of Applied Physics, MD 2028, Chisinau, Republic of Moldova

Kagomé magnets are expected to host exotic magnetic and electronic properties due to possible interplay of spin-orbit coupling (SOC) and specific topology of the energy band structures [1,2,3]. Here, we present the field-dependent and angular-dependent magnetization studies of the kagomé -lattice easy-plane ferromagnet Fe₃Sn. The SOC is probed by the measurements of the magnetocrystalline anisotropy in high-quality bulk single crystals. Measurements in high fields reveal the difference in the saturation magnetization along the *a* and the *c* axes, which does not vanish up to the highest applied field of 14 T. The anisotropy evidenced in the saturation moment indicates a possible contribution of the orbital moment. The temperature dependence of the magnetocrystalline anisotropy constants  $K_1$  and  $K_2$  was determined. [1] L. Ye et al., Nature 555, 638 (2018), M. Altthaler et al., Phys. Rev. Research 3, 043191 (2021), J. Watanabe, et al., arXiv:2202.06665 (2022).

First principles study of the complex magnetism in  $Ce_2Fe_{17}$  — Alena VISHINA¹, OLLE ERIKSSON^{1,2}, ANDERS BERGMAN¹, and •HEIKE C. HERPER¹ — ¹Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden — ²School of Science and Technology, Örebro University, Örebro, Sweden

With its comparably low cost and high magnetization the intermetallic Ce₂Fe₁₇ has potential to become a candidate for permanent magnets. Problems arising from the in-plane magnetocrystalline anisotropy and the low  $T_C$  could be overcome by doping with light elements. Despite that, there is an ongoing debate regarding the magnetic phases in Ce₂Fe₁₇. While a large number of partially seemingly contradicting experimental findings have been reported, only few theoretical studies exist and they do not capture the experimental findings. Performing a comprehensive study of the magnetic properties of Ce₂Fe₁₇ we applied various approaches for the exchange-correlation functional to identify the best theoretical treatment of the system. To account for the mixed valent nature of Ce₂Fe₁₇ we tested several approximations including an analysis of the hybridization function. We used a combination of ab initio methods (VASP, FP-LMTO RSPt) to obtain geometrical and magnetic data including magnetic exchange parameters.

Our results [1] clearly show that the ground state is non-collinear with a strong FM component which explains the low magnetic moment reported in experiment. At 93 K the FM component vanishes and we observe correctly the transition to the helical state.

MA 32.7 Thu 16:30 H43

**High-throughput and data-mining search for novel rare-earth-free permanent magnets** — •ALENA VISHINA¹, HEIKE HERPER¹, and OLLE ERIKSSON^{1,2} — ¹Department of Physics and Astronomy, Uppsala University, Se-75120 Uppsala, Sweden — ²School of Science and Technology, Örebro University, SE-701 82 Örebro, Sweden

Rare-earth (RE) magnetic materials dominate the market when highperformance permanent magnets are needed (e.g. the area of 'green' energy technology, such as electric vehicles and windmills). At the same time, there is a growing interest in RE-free alternatives, since the heavier RE elements are quite expensive and are often mined with methods that leave an environmental footprint. We propose to use the data-mining approach to search for high-performance RE-free/lean magnetic materials. Filtering through a large number of known structures from ICSD database, we are looking for materials with high magnetization M > 1 T, uniaxial MAE > 1 MJ/m3, and Tc >300 K. Sometimes, additional elements alterations are attempted to make the material more cost-effective. Two searches have already been performed. New magnetic material has been found and consequently synthesized by experimental collaborators - Co3Mn2Ge. From the ab-initio calculations, the defect-free material was predicted to have the saturation magnetization of 1.71 T, the uniaxial magnetocrystalline anisotropy of 1.44 MJ/m3, and the Curie temperature of 700 K. Its magnetism depends critically on the amount of disorder of the Co and Ge atoms, a further improvement of the magnetism is possible.

Fast non-volatile electrical switching of the magnetoelectric domain states in the cubic spinel  $Co_3O_4$  — •MAXIMILIAN WINKLER, SOMNATH GHARA, KO-RBINIAN GEIRHOS, LILIAN PRODAN, VLADIMIR TSURKAN, STEPHAN KROHNS, and ISTVAN KEZSMARKI — Universität Augsburg, Augsburg, Deutschland Here, we investigate the magnetoelectric effect of  $Co_3O_4$  at temperatures far below the Neel-temperature of  $T_N = 30$ K. A large magnetoelectric coefficient of up to 14ps/m is achieved if the system is cooled through TN while magnetic and/or electric fields are applied. According to these poling procedures we provide a systematic analysis of how the magnetoelectric domain state can be controlled and even in situ switched by reversing the direction of either the electric or the magnetic field. The complete switching of the antiferromagnetic state is found to be faster than microseconds. Altogether, the control of the magnetoelectric domains and the fast switching dynamics makes the linear magnetoelectric coupling of  $Co_3O_4$  highly interesting for spintronics.

## MA 33.2 Thu 15:15 H47

**Contribution of charge and strain coupling in artificial multiferroic Fe3O4/PMN-PT heterostructures** — •PATRICK SCHÖFFMANN^{1,2}, ANIRBAN SARKAR², MAI H. HAMED², TANVI BHATNAGAR-SCHÖFFMANN³, SABINE PÜTTER⁴, PHILIPPE OHRESSER¹, BRIAN J. KIRBY⁵, ALEXANDER J. GRUTTER⁵, JURI BARTHEL⁶, EMMANUEL KENTZINGER², ANNIKA STELLHORN², MARTINA MÜLLER⁷, and THOMAS BRÜCKEL² — ¹Synchrotron SOLEIL, France — ²Forschungszentrum Jülich GmbH, JCNS-2 and PGI-4, JARA-FIT, Germany — ³Centre de Nanoscience et de Nanotechnologies, CNRS, Université Paris-Saclay, France — ⁴Forschungszentrum Jülich GmbH, JCNS@MLZ, Germany — ⁵NIST Center for Neutron Research, USA — ⁶Forschungszentrum Jülich GmbH, ER-C-2, Germany — ⁷Fachbereich Physik, Universität Konstanz, Germany

To be able to develop denser and faster data storage and computing solutions artificial multiferroic heterostructures are a promising approach, as they enable direct switching of magnetic states with voltage. We grow ferrimagnetic Fe3O4 thin films on ferroelectric PMN-PT substrates to study the effect of strain and polarisation induced by the substrate onto the magnetic properties of the film. We found that the coupling due to strain and charge is strongly dependent on the orientation of the sample in an external magnetic field as well as the sub-

strate cut. We will present a simple model to explain the contribution of strain and charge for different substrate and magentic field orientations.

## MA 33.3 Thu 15:30 H47

Microscopic theory of the THz modes and their nonreciprocal directional dichroism in the antiferromagnet Fe2Mo3O8 — •KIRILL VASIN^{1,2}, ALEXEY NURMUKHAMETOV², MIKHAIL EREMIN², ANNA STRINIC¹, LILIAN PRODAN¹, VLADIMIR TSURKAN¹, ISTVÁN KÉZSMÁRKI¹, and JOACHIM DEISENHOFER¹ — ¹Augsburg University, Augsburg, Germany — ²Kazan, Russia

In the present work, the transmission measurements of a polar dielectric Fe2Mo3O8 were performed by THz time-domain spectroscopy. The origin of the low-lying excitations is not clear, but they were assigned to electromagnons and magnons due to their appearance below TN.

Our microscopic model successfully describes the origin of the optical excitation spectrum in a broad frequency range from the THz to the near-infrared frequency range and the observed dichroism of the low-lying optical modes because of the on-site excitations of the Fe2+ ions in this material. We used the technic of the effective Hamiltonian, including the effects of the crystal field, superexchange interaction and spin-orbit coupling, to model the level schemes of Fe ions projected on the ground configuration of 3d6 electrons.

The directional dichroism in Fe2Mo3O8 can be described by the interference of magnetic and electric-dipole matrix elements, which depend on the applied magnetic field. Our modelled results agrees to the acquired experimental data.

## MA 33.4 Thu 15:45 H47

**Magnetization reversal through an antiferromagnetic state** — •SOMNATH GHARA¹, EVGENII BARTS², KIRILL VASIN¹, DMYTRO KAMENSKYI¹, LILIAN PRODAN¹, VLADIMIR TSURKAN¹, MAXIM MOSTOVOY², ISTVAN KEZSMARKI¹, and JOACHIM DEISENHOFER¹ — ¹Experimentalphysik V, University of Augsburg, Augsburg, Germany — ²University of Groningen, Groningen, The Netherlands The polar magnet Fe₂Mo₃O₈ has recently attracted tremendous interests due its versatile properties, such as magnetoelectric effect and giant thermal hall effect. This compound has a polar hexagonal (space group *P*6₃*mc*) structure at room temperature and undergoes a collinear antiferromagnetic ordering of Fe²⁺ moments below *T_N* = 60 K, accompanied by a large electric polarization

besides that of the structural origin. Upon application of (high) magnetic field, a metamagnetic transition from the antiferromagnetic to a ferrimagnetic state takes place. The ferrimagnetic state can also be stabilized by partially substituting  $Fe^{2+}$  ions by  $Zn^{2+}$  ions. The magnetic symmetry (6m'm') of the ferrimagnetic state is compatible with a linear magnetoelectric effect. In this talk, I will show that at the coercive field of the isothermal reversal of a ferrimagnetic state in  $Fe_{1.86}Zn_{0.14}Mo_3O_8$  the pristine antiferromagnetic state re-emerges as a metastable state. The reappearance of the antiferromagnetic state, supported by the theoretical calculations, is reflected in a large change of electric polarization and directly established by the reoccurrence of the characteristic low-energy THz excitation of the AFM state.

# MA 33.5 Thu 16:00 H47

Transfer of a domain pattern between ferroic orders — •YANNIK ZEMP¹, EHSAN HASSANPOUR¹, YUSUKE TOKUNAGA², YASUJIRO TAGUCHI³, YOSHINORI TOKURA³, THOMAS LOTTERMOSER¹, MANFRED FIEBIG¹, and MADS C. WEBER^{1,4} — ¹Department of Materials, ETH Zurich — ²University of Tokyo — ³Riken CEMS, Japan — ⁴IMMM, Université Le Mans

In multiferroic materials with two ferroic orders, the order parameters and their respective domain patterns may be rigidly coupled or completely independent, with both of these cases having their merits. We show that in materials with three ferroic order parameters, unusual combinations of coupling and independence are possible. One such material is  $Dy_{0.7}Tb_{0.3}FeO_3$ . Here, an antiferromagnetic order of the rare earth ions (L) and a ferromagnetic order of the iron ions (M) induce an electric polarisation (P) and a trilinear coupling term  $M \cdot L \cdot P$  contributes to the free energy. This coupling term dictates that a reversal of one order parameter needs to be compensated by the product of the other two order parameters to minimise the free energy. Using this fact, we show that a domain pattern in M can be transferred to P while erasing it in the original order parameter, and vice versa, by the application of magnetic and electric fields. We measure the Pand M patterns independently by optical second harmonic generation imaging and Faraday rotation microscopy, respectively. The third order parameter L acts as the "memory buffer" for the transfer. The presented work demonstrates the significance of exploration in multiferroics beyond a bilinear coupling.

 $MA \ 34.1 \ \ Thu \ 15:00 \ \ H48$  Giant and tunneling magnetoresistance in unconventional compensated magnets with nonrelativistic d-wave spin-momentum couplings — LIBOR ŠMEJKAL^{1,2}, •ANNA B. HELLENES¹, RAFAEL GONZÁLEZ-HERNÁNDEZ³, JAIRO SINOVA^{1,2}, and TOMAŠ JUNGWIRTH^{2,4} — ¹Johannes Gutenberg Universität Mainz, Germany — ²Czech Academy of Sciences, Prague, Czech Republic — ³Universidad del Norte, Barranquilla, Colombia — ⁴University of Nottingham, United Kingdom

The magnetoresistance effects used in commercial spintronics devices rely on spin current generated by the time-reversal broken band structure of ferromagnets. Realizing counterpart effects with all-antiferromagnetic electrodes has remained experimentally elusive, as conventional compensated antiferromagnets exhibit symmetries combining time-reversal with translation or inversion and thus prohibit nonrelativistic spin-polarized bands and spin currents. Recently, we have predicted large magnetoresistance effects in multilayers with an unconventional compensated magnetic phase[1]. It is characterized by zero magnetization and a time-reversal broken band structure[2], with d-wave spin-momentum coupling and alternating spin polarization [1,3] (thus also referred to as altermagnetism[3]). In the present contribution, we will describe mechanisms for giant and tunneling magnetoresistance relying on the anisotropic and valley-dependent forms of the d-wave spin-momentum coupling[1]. **Exploring the magnetic ground states in different layers of Mn on Ir (111) by SP-STM** — •VISHESH SAXENA, ARTURO RODRIGUEZ SOTA, ROLAND WIESEN-DANGER, and KIRSTEN VON BERGMANN — Institut für Nanostruktur- und Festkörperphysik, Hamburg

Conventional magnetic skyrmions are susceptible to unwanted phenomena such as the skyrmion Hall effect. This is a highly undesirable effect that hinders the application of such skyrmions in spintronic devices. An alternative are antiferromagnetic skyrmions which do not show a skyrmion Hall effect [1]. In the quest to explore systems that can host antiferromagnetic skyrmions, we have studied Domains and domain walls reflect the different interdependence of magnetic and electric order in multiferroics. For example, in type-II multiferroics, magnetic and electric domain patterns are one-to-one linked, whereas in type-I multiferroics, magnetic and electric domain morphologies can be different, and their coupling no longer mandatory. We show - using experiment and theory - that multiferroics with separately emerging magnetic and electric order can have a strong bulk magnetoelectric coupling even though the leading magnetoelectric cross-coupling is symmetry-forbidden. We show, taking ErMnO3 as example, that the structural distortions that lead to the ferroelectric polarization also break the balance of the competing superexchange contributions. The resulting bulk coupling leads to novel types of topological defects, like magnetoelectric domain walls and multifold vortex-like singularities. We argue that the apparent independence of magnetic and electric orders in type-I multiferroics leads to uncommon phenomena, not open to the type-II class, which can open additional degrees of freedom for the future control of their magnetoelectric functionality [1].

## MA 33.7 Thu 16:30 H47

Measuring Antiferromagnets with a SQUID Setup in Magnetically Shielded Environments — •MICHAEL PAULSEN¹, JÖRN BEYER¹, MICHAEL FECHNER², RALF FEYERHERM³, KLAUS KIEFER³, BASTIAN KLEMKE³, JULIAN LINDNER³, and DENNIS MEIER⁴ — ¹Physikalisch-Technische Bundesanstalt, Berlin, Germany — ²Max Planck Institute for the Structure and Dynamics of Matter, CFEL, Hamburg, Germany — ³Helmholtz-Zentrum Berlin, Berlin, Germany — ⁴Norwegian University of Science and Technology, Trondheim, Norway

Antiferromagnets possess zero net dipole magnetization. While predictions of higher order magnetizations have been made for  $Cr_2O_3$ , few confirmed measurements exist. In this contribution, we present low-temperature measurements gained on different systems with antiferromagnetic order in very low magnetic backgrounds using a dedicated SQUID setup. In particular, we discuss our results on exterior quadrupolar magnetic fields and relate the distinct quadrupolar magnetic signals to the microscopic spin arrangement in our model systems.

# Location: H48

the magnetism of Mn on Ir (111) using spin-polarized scanning tunneling microscopy (SP-STM). Having an antiferromagnetic spin order on a periodic lattice can induce magnetic frustration. It has already been shown that the magnetic ground states of Mn monolayers on Re (0001) can be the row-wise antiferromagnetic state or the 3Q state depending on the stacking of Mn [2]. In the present work, the magnetic behavior of the monolayer, double layer, and the triple layer of Mn on Ir(111) is studied. Different magnetic ground states are observed depending on the Mn layer thickness.

## MA 34.3 Thu 15:30 H48

Identification of Néel vector orientation in antiferromagnetic NiO thin films – •CHRISTIN SCHMITT¹, LUIS SANCHEZ-TEJERINA², RAFAEL RAMOS³, EIJI SAITOH^{3,4}, GIOVANNI FINOCCHIO², LORENZO BALDRATI¹, and MATHIAS KLÄUI¹ – ¹Institute of Physics, Johannes Gutenberg-University Mainz, Germany – ²Department of Mathematical and Computer Sciences, Physical Sciences and Earth Sciences, University of Messina, Italy – ³WPI-AIMR, Tohoku University, Japan – ⁴Department of Applied Physics, The University of Tokyo, Japan

Spintronics using antiferromagnets (AFM) is promising due to intrinsic dynamics in the THz range and the absence of stray fields. However, efficient writing and reading is necessary in terms of applications. Recently, current-induced writing of the Néel order in AFMs has been reported and different switching mechanisms have been put forward [1,2]. The mechanisms depend on the type of domains present. Here, we focus on antiferromagnetic NiO/Pt thin films, and image reversible electrical switching by photoemission electron microscopy (PEEM) employing the x-ray magnetic linear dichroism (XMLD) effect. By varying the x-ray polarization and sample azimuthal angle, we identify the crystallographic orientation of the domains that can be switched and quantify the Néel vector direction, showing that the switching occurs between different T-domains [3]. Finally, we characterize the domain walls showing that they are non-chiral and reveal a large anisotropy in the NiO thin films. [1] T. Moriyama, et al., Sci. Rep. 8, 14167 (2018). [2] P. Zhang, et al., Phys. Rev. Lett. 123, 247206 (2019). [3] C. Schmitt, et al., Phys. Rev. Appl. 15, 034047 (2021).

MA 34.4 Thu 15:45 H48 **Magnon Hanle effect in easy-plane antiferromagnets** — •JANINE GÜCKELHORN^{1,2}, AKASHDEEP KAMRA³, TOBIAS WIMMER^{1,2}, MATTHIAS OPEL¹, STEPHAN GEPRÄGS¹, RUDOLF GROSS^{1,2,4}, HANS HUEBL^{1,2,4}, and MATTHIAS ALTHAMMER^{1,2} — ¹Walther-Meißner-Institut, BAdW, 85748 Garching, Germany — ²Physik-Department, TUM, 85748 Garching, Germany — ³IFIMAC and Departamento de Fisica Teorica de la Materia Condensaga, Universidad Autonoma de Madrid, 28049 Madrid, Spain — ⁴Munich Center for Quantum Science and Technology, 80799 München, Germany

Antiferromagnets have drawn much attention due to their unique properties and potential for interesting device applications. In analogy to a spin-1/2 system, antiferromagnetic magnon pairs can be described in terms of a magnonic pseudospin. Recently, first experimental observations of the associated dynamics and the magnon Hanle effect have been reported and described using a 1D pseudospin transport model. Here, we discuss the effects of dimensionality on the magnon spin signal by studying insulating hematite ( $\alpha$ -Fe₂O₃) films with varying thickness [1]. For both a thin and a thick film, we find a pronounced signal caused by the magnon Hanle effect. However, the magnonic spin signal exhibits clear differences in both cases. We extend the theoretical description by taking into account low-energy finite-spin magnons and use it to explain our observations. This provides deeper insight into the detailed understanding of magnonic pseudospin dynamics.

#### MA 34.5 Thu 16:00 H48

Role of substrate clamping on anisotropy and domain structure in the canted antiferromagnet  $\alpha$ -Fe₂O₃ — •ANGELA WITTMANN¹, OLENA GOMONAY¹, KAI LITZIUS², ALEXANDRA CHURIKOVA³, NORMAN BIRGE⁴, FELIX BÜTTNER⁵, SEBASTIAN WINTZ², MOHAMAD MAWASS⁵, MARKUS WEIGAND⁵, FLORIAN KRONAST⁵, JAIRO SINOVA¹, GISELA SCHÜTZ², and GEOFFREY BEACH³ — ¹Johannes Gutenberg Universität Mainz, Germany — ²Max Planck Institute for Intelligent Systems, Stuttgart, Germany — ³Massachusetts Institute of Technology, Cambridge, USA — ⁴Michigan State University, East Lansing, USA — ⁵Helmholtz-Zentrum für Materialien und Energie GmbH, Berlin, Germany

Antiferromagnets are at the forefront of research in spintronics and demonstrate high potential for revolutionizing memory technologies. For this, understanding the formation and driving mechanisms of the domain structure is paramount. In this work, we investigate the domain structure in a thin-film canted antiferromagnet  $\alpha$ -Fe₂O₃ using x-ray linear dichroism (XMLD) and spin Hall magnetoresistance (SMR) measurements. We find that the internal destressing fields driving the formation of domains do not follow the crystal symmetry of  $\alpha$ -Fe₂O₃ but fluctuate due to substrate clamping. This leads to an overall isotropic distribution of the Néel order with locally varying effective anisotropy in antiferromagnetic thin films. The insights gained from our work serve as a foundation for further studies of electrical and optical manipulation of the domain structure of antiferromagnetic thin films. Thursday

Correlation of Atomic Disorder and Anomalous Hall Effect in a Non-Collinear Antiferromagnet — •BERTHOLD H. RIMMLER¹, BINOY K. HAZRA¹, HOLGER L. MEYERHEIM¹, ARTHUR ERNST², and STUART S. P. PARKIN¹ — ¹Max Planck Institute for Microstructure Physics, Weinberg 2, 06120 Halle, Germany — ²Johannes Keppler University, Altenbergerstrβe 69, Linz 4040, Austria

Non-collinear antiferromagnets (NCAFs) such as the well-studied alloy Mn3Sn have compensated triangular magnetic structures with vanishing net magnetization. Due to magnetic symmetry breaking, they can display a large Anomalous Hall Effect (AHE). Measurement of the AHE requires an imbalance of antiferromagnetic domains. Domain structure control by magnetic field or spin torques is possible in Mn3Sn, because crystalline anisotropy induces weak canted moments. In contrast, these moments are not intrinsic to cubic NCAFs. In this work, we investigate the crystallographic, magnetic and magneto-transport properties of thin films of the cubic NCAF Mn3SnN. We find that the manganese atoms can be displaced from their high-symmetry positions. This atomic site disorder correlates with a finite AHE. We employ ab-initio calculations to show that the manganese site displacement can induce canting. In analogy to Mn3Sn, these canted moments may allow for domain structure control leading to the observed AHE. This work provides new insight into the microscopic origin of canted moments in cubic NCAFs and their correlation with the AHE. Our findings have implications for other magneto-transport effects such as the anomalous Nernst effect or the spin Hall effect.

MA 34.7 Thu 16:30 H48

Spontaneous anomalous Hall effect arising from antiparallel magnetic order in a semiconductor — •RUBEN DARIO GONZALEZ BETANCOURT^{1,2,3,4}, JAN ZUBÁČ^{3,4}, RAFAEL JULIAN GONZALEZ HERNANDEZ⁵, KEVIN GEISHENDORF³, ZBYNEK ŠOBÁŇ³, GUNTHER SPRINGHOLZ⁶, KAMIL OLEJNÍK³, LIBOR ŠMEJKAL³, TOMAS JUNGWIRTH^{3,7}, SEBASTIAN TOBIAS BENEDIKT GOENNENWEIN^{1,8}, ANDY THOMAS^{1,2}, HELENA REICHLOVÁ³, JAKUB ŽELEZNÝ³, and DOMINIK KRIEGNER^{1,3} — ¹IFMP, TU Dresden — ²IFW Dresden — ³Institute of Physics, AV ČR, Prague — ⁴Charles University, Prague — ⁵University of Nottingham — ⁸University of Konstanz

It is known that collinear antiferromagnets cannot host a spin split band structure and therefore not show any anomalous Hall effect. Following the recent theory development [1], we experimentally show that this paradigm needs to be revised. We theoretically identify and experimentally confirm the symmetry components of the longitudinal and transversal anisotropic magnetoresistance in thin films of the compensated collinear antiferromagnet MnTe. We experimentally find a hysteretic signal odd in magnetic field in the transversal magnetoresistance, i.e. spontaneous anomalous Hall effect [2]. This effect can be rationalized considering nonmagnetic atoms at non-centrosymmetric lattice sites which break additional symmetries and cause a spin splitting in certain parts of the Brillouin zone.

MA 35.1 Thu 16:00 P4 **Magnetic Coupling in Y3Fe5O12/Gd3Fe5O12 Heterostructures** — SVEN BECKER¹, ZENGYAO REN^{1,2,3}, •AKASHDEEP AKASHDEEP¹, and GERHARD JAKOB^{1,2} — ¹Institute of Physics, Johannes Gutenberg-University Mainz, Staudingerweg 7, Mainz 55128, Germany — ²Graduate School of Excellence *Materials Science in Mainz* (MAINZ), Staudingerweg 9, Mainz 55128, Germany — ³School of Materials Science and Engineering, University of Science and Technology Beijing, Beijing 100083, China Location: P4

Ferrimagnetic Y3Fe5O12 (YIG) is the prototypical material for studying magnonic properties due to its exceptionally low damping. By substituting the yttrium with the temperature-dependent magnetic moment of gadolinium, we can introduce an additional spin degree of freedom in form of a magnetic compensation point. Here, we study the magnetic coupling in epitaxial Y3Fe5O12/Gd3Fe5O12 (YIG/GIG) heterostructures grown by pulsed laser deposition. The XRD patterns show Laue oscillations and a narrow rocking curve indicating a smooth surface and interface. From bulk sensitive magnetometry and surfacesensitive spin Seebeck effect and spin Hall magnetoresistance mea-

surements, we determine the alignment of the heterostructure magnetization as a function of temperature and external magnetic field. We show that we can control the magnetic properties of the heterostructures by tuning the thickness of the individual layers. These bilayer devices could potentially control the magnon transport analogously to electron transport in giant magnetoresistive devices[1].

GHz frequency layered antiferromagnets for novel Magnonic computing applications — •SALLY LORD and JOHN GREGG — Clarendon Laboratory, Department of Physics, University of Oxford, Parks Road, Oxford, OX1 3PU, United Kingdom

Magnonic computing is a novel computing paradigm that exploits the unusual behaviour of magnons to develop faster, more efficient devices, that have the potential to rival existing CMOS technologies. Antiferromagnetic materials are a prime candidate for such applications, primarily due to their typical THz resonant frequencies, which offer the possibility of creating devices with faster operating speeds. However, studying the THz frequencies of these materials, using conventional electronic methods, is challenging. Layered antiferromagnetic materials offer a promising solution to this challenge, since the weak interlayer coupling results in resonant frequencies that exist in the easily accessible microwave range. Furthermore, these materials can be artificially created by coupling two ferromagnetic layers via a non-magnetic spacer layer to create synthetic antiferromagnet. In this contribution, we report on the experimental setup designed to explore the magnetic properties of such materials.

#### MA 35.3 Thu 16:00 P4

Towards Integration: On-chip Excitation of Spin Waves using Meander Antennas tailored to practical Applications — •JOHANNES GREIL¹, MARTINA KIECHLE¹, MATTHIAS GOLIBRZUCH¹, ÁDÁM PAPP², GYÖRGY CSABA², and MARKUS BECHERER¹ — ¹Technical University of Munich (TUM), Germany — ²Pázmány Peter Catholic University, Budapest, Hungary

Albeit spin-wave (SW) computation principles are understood well, integrating SW-based devices makes an efficient excitation of SWs inevitable. Electrical measurements are performed most conveniently with inductive antennas that transfer radio frequency (RF) power into the SW system and pick up the output signals.

We demonstrate the realization of broadband efficient excitation of SWs with meander antennas in a chip-on-platform system. The platform is a PCB that carries the RF signal to a 100nm thin YIG film with metallized bond pads and meander antennas on top. Despite the lower spectral bandwidth of meander antennas compared to CPW structures they have better impedance matching over a wide frequency range and thus provide efficient SW excitation.

We also demonstrate a new design for a dual-wavelength spin wave antenna that consists of a meander structure with two linewidths and gap sizes. Feeding the antenna with two RF frequencies enables for simultaneous excitation of SWs with two wavelengths at one magnetic bias field. Thus, it can be seen as a first realization of purely SW frequency modulation or as the basis for SW-based frequency-division multiplexing (FDM) with two sub-bands.

## MA 35.4 Thu 16:00 P4

Non-linear spin waves at low bias fields in  $Ni_{80}Fe_{20}$  elements — •MATTHIAS VOLZ, ROUVEN DREYER, and GEORG WOLTERSDORF — Martin Luther University Halle-Wittenberg, Institute of Physics, Von-Danckelmann-Platz 3, 06120 Halle (Saale), Germany

Magnetic rf fields can be used to excite non-linear spin waves in Ni₈₀Fe₂₀ elements at low bias fields. At a certain rf threshold field, spin waves oscillating at odd half-integer multiples of the driving frequency can be excited [1]. Here, the  $\frac{3}{2}\omega$  mode is investigated with frequency resolved magneto-optical Kerr microscopy [2]. Specifically we determine the dynamical response at  $\frac{3}{2}$  multiple of the driving frequency. By simultaneously detecting real and imaginary parts of the response at  $\frac{3}{2}$  of the driving frequency, we reveal phase stable regimes for these  $\frac{3}{2}\omega$  non-linear spin wave modes. These modes are investigated as a function of the pump power level, the bias field, and the Ni₈₀Fe₂₀ element thickness. We show that a phase stable non-linear regime can be established for Ni₈₀Fe₂₀ thicknesses between 10 nm and 20 nm.

**Sensing of magnetic excitations in 2D-materials with NV-spins** — •HOSSEIN MOHAMMADZADEH, DOMINIK MAILE, and JOACHIM ANKERHOLD — ICQ and IQST, University of Ulm, Ulm, Germany

Magnetism in two-dimensional (2D) van der Waals (vdW) materials has recently emerged as one of the most promising areas in condensed matter research, with many exciting emerging properties and significant potential for applications ranging from topological magnonics to low-power spintronics, quantum computing, and optical communications [1]. The nitrogen-vacancy (NV) center in diamond is an excellent platform to detect nanoscale signatures in magnetic materials [2]. The spin state of the NV center can be easily initialized and read out in the optical domain and coherently manipulated with microwave fields. Motivated by and in collaboration with recent experimental activities in this direction [3], in this poster we describe the general strategy and first theoretical results. The latter is based on a description of low energy magnetic excitations in terms of a Kitaev-Heisenberg model and the coupling of magnons in the trivial and in the topological phase to single NV-electronic spins.

MA 35.6 Thu 16:00 P4

**Microwave Control of Magnon Transport in Nanostructures** — •FRANZ WEIDENHILLER^{1,2}, JANINE GÜCKELHORN^{1,2}, MANUEL MÜLLER^{1,2}, HANS HUEBL^{1,2,3}, MATTHIAS ALTHAMMER^{1,2}, and RUDOLF GROSS^{1,2,3} — ¹Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — ²Physik-Department, Technische Universität München, Garching, Germany — ³Munich Center for Quantum Science and Technology, München, Germany

Magnon transport in magnetically ordered insulators is of great interest for the implementation of magnonic devices. We here present our results on the diffusive magnon transport signal in yttrium iron garnet (YIG) due to the simultaneous excitation of magnons with electromagnetic microwaves. Using E-beam lithography, we pattern two platinum strips on top of the YIG for the injection and detection of magnons. The Pt strips are electrically insulated from an aluminum microwave antenna, which covers both strips and the gap in between. Via the antenna, microwave driven generation of magnons in the active device area through ferromagnetic resonance is possible. We investigate how these microwave injected magnons affect the magnon transport between the two Pt strips. We compare these results to spin pumping experiments using the two Pt strips as electrical detectors. Finally, we discuss relevant magnon relaxation mechanisms in our experiments.

## MA 35.8 Thu 16:00 P4

Spontaneous emergence of spin-wave frequency combs mediated by vortex gyration — •CHRISTOPHER HEINS¹, KATRIN SCHULTHEISS¹, LUKAS KÖRBER^{1,2}, ATTILA KÁKAY¹, TOBIAS HULA^{1,3}, MAURICIO BEJARANO^{1,2}, VADYM IURCHUK¹, JÜRGEN LINDNER¹, JÜRGEN FASSBENDER^{1,2}, and HELMUT SCHULTHEISS^{1,2} — ¹Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — ²Fakultät Physik, Technische Universität Dresden, Dresden, Germany — ³Institut für Physik, Technische Universität Chemnitz, Chemnitz, Germany

We present experimental investigations of the spin-wave frequency comb formation in a confined system, a magnetic vortex. The magnetic vortex shows rich spin-wave dynamics like the formation of whispering gallery magnons and non locally induced three-magnon scattering, all with frequencies in the GHz range. Additionally, there is the low frequency gyration of the vortex core itself. The combination of these dynamics on two different time scales inside magnetic vortices, results in the generation of spin-wave frequency combs with their spacing given by the vortex gyration frequency.

Using Brillouin light scattering microscopy, we show that large amplitude excitations of spin waves purely in the GHz range can induce a gyration of the vortex core, which leads to the formation of frequency combs. Analyzing the mode profiles of the sidebands by micromagnetic simulations, shows that the comb is generated via three magnon scattering under conservation of energy and angular momentum.

Magnetooptical Investigation of non-reciprocal Phonon- Magnon interaction — •YANNIK KUNZ¹, MICHAEL SCHNEIDER¹, MORITZ GEILEN¹, TORBEN PFEIFER¹, MATTHIAS KÜSS², MANFRED ALBRECHT², PHILIPP PIRRO¹, and MATHIAS WEILER¹ — ¹Fachbereich Physik und OPTIMAS, TU Kaiserslautern — ²Institut für Physik, Universität Augsburg

Surface acoustic waves (SAWs) are employed to achieve miniaturization of telecommunication devices, as they live in the Gigahertz-regime with wavelengths on the micrometre scale. The coupling of SAWs with spin waves (SWs) leads to nonreciprocal SAW-propagation, induced by symmetry breaking coupling mechanisms [1]. We investigated the coupling of SAWs, excited by Interdigital Transducers (IDTs), with SWs in a LiNbO₃/Co₄₀Fe₄₀B₂₀(10 nm)/SiN(5 nm)-structure using well-established micro-focused Brillouin Light Scattering Spectroscopy and the novel micro-focused frequency-resolved magneto-optical Kerr effect with phase resolution, empowered by vector network analysis [2]. We model the magnetic field and angle-dependent SAW-SW- coupling using an extended theoretical model for continuous, viscoelastic Rayleigh-mode SAWs [3] as well as a theoretical model to describe the magneto-elastic coupling [4]. We acknowledge the funding by DFG via project No. 492421737.

#### MA 35.10 Thu 16:00 P4

Magnon Bose-Einstein condensates in microscopic thermal landscapes — •FRANZISKA KÜHN, MATTHIAS R. SCHWEIZER, GEORG VON FREYMANN, ALEXANDER A. SERGA, and BURKARD HILLEBRANDS — Fachbereich Physik and Landesforschungszentrum OPTIMAS, TU Kaiserslautern, Kaiserslautern, Germany

This contribution is focused on the behavior of a magnon Bose–Einstein condensate (BEC) in artificial magnetization landscapes at the scale of the wavelengths of condensed magnons. In our work, the magnon condensate is created by overpopulation of a magnon gas using microwave parametric pumping. By combining a heating laser with a microscopic phase-based wave front modulation technique, a temperature pattern is imprinted on the yttrium-iron-garnet film sample. Accordingly, the saturation magnetization, on which the dispersion relation of the magnons depends, is shifted. The corresponding spatial variation of the condensate frequency, acting as an artificial potential for the BEC, affects its dynamics and propels magnon supercurrents and Bogoliubov waves. Since the size of these patterns is small compared to the area of BEC formation, it is possible to investigate the BEC in two-dimensional thermal landscapes. In the experiment, by utilizing microfocused Brillouin light scattering spectroscopy, we study the anisotropy of the two-dimensional density distribution of a magnon BEC and the possibility of interference effects between Bogoliubov waves.

Magnons, the quanta of spin-waves, also exist in paramagnetic materials and are known as paramagnons. Paramagnon properties are governed by the exchange interactions, which do not vanish above Curie/Neel temperature and the dipolar interactions. Here we present our results on the investigation of electron paramagnetic resonance (EPR) spectroscopy in gadolinium gallium garnet (GGG) and DPPH bulk slabs in a wide range of temperatures down to 20 mK. GGG is one of the materials of choice, as  $Gd^{3+}$  ions have a large spin S = 7/2 and its saturation magnetization is about  $M_s = 800$  kA/m. Millikelvin temperatures allow reaching the saturation of the GGG magnetization, by applying magnetic fields of hundreds mT. However, the EPR linewidth of GGG is strongly influenced by the phenomenon of dipolar broadening, while DPPH is known to have a very narrow resonance line. These studies form an initial step toward investigations of long-propagating paramagnons.

Aharonov-Casher effect in spin-wave refraction — •ANDRII SAVCHENKO^{1,2}, VLADIMIR KRIVORUCHKO², and STEFAN BLÜGEL¹ — ¹Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich, D-52425 Jülich, Germany — ²Donetsk Institute for Physics and Engineering, National Academy of Sciences of Ukraine, 03028 Kyiv, Ukraine

It has been shown that in a homogeneous magnetic film there is a possibility of electric field control on the reflection and refraction of spin waves at the interface formed by regions under the effect of different electric fields. Under these conditions, the critical angles for Snell's law, the positive or negative refraction of the spin waves, and their non-reciprocity with respect to the incident angle are determined by the electric field. This is possible due to the electrically induced Aharonov-Casher phase shift of the spin-wave phase, that is equivalent to adding a Dzyaloshinskii-Moriya-like interaction between the spins of neighboring ions.

**Ring-shaped multi-bandpass spin wave filter** — •TAKUYA TANIGUCHI, MICHAEL LINDNER, CHRISTIAN RIEDEL, and CHRISTIAN BACK — Technische Universität München

Spin waves (SWs) are fundamental collective excitations of magnetic order and their wave character makes it possible to potentially realize next generation logic devices. As one of the possible logic devices, multi-bandpass filters are desired in order to forbid certain frequency bands of SWs. In this work, we design a SW wave-guide, which has a ring shape attached to the middle of a stripe. In the device, SWs (SW1s) travel through the stripe part and are split to the ring part and the stripe part at the middle of the stripe. The SWs traveling through the ring (SW2s) interfere with the SW1s after traveling one round and SW1s are suppressed when the phase difference between SW1s and SW2s is pi. We fabricate devices from 200-nanometer-thick YIG films and observe SW propagation using Brillouin light scattering (BLS). Since the phase difference depends on the wavelength of the SWs, we control the wavelength by varying the SW excitation frequency and evaluate the filtering effect. In the presentation, we report the efficiency of the ring-shaped SW filter and provide some key parameters for determining the forbidden frequencies of SWs.

Orientation and Shape of 180° Magnetoelastic Domain Walls in Antiferromagnets — •Bennet Karetta, Olena Gomonay, and Jairo Sinova — Institut für Physik, Johannes Gutenberg Universität Mainz, D-55099 Mainz, Germany Antiferromagnets are potential candidates to be used in the future for active spintronics elements as they are faster and more stable than the ferromagnets in recent devices. However, without a net magnetization it is more difficult to manipulate their magnetic state. Recent studies suggested that the magnetoelastic coupling can be used to overcome this problem. Thus, it is essential to understand the interaction between the strains in the antiferromagnet and the Néel vector. In this study, we investigate the 180° antiferromagnetic domain wall and the influence on it from the strains. It is known that non-180° domain walls have preferred alignments in antiferromagnets since strains in the respective domains are incompatible for certain orientations. We show, that there is a similar anisotropy for the orientation of 180° domain walls, which now is induced by incompatibilities at the domain wall itself. We further investigate this anisotropy to determine how magnetoelasticity affects the shape of the closed  $180^\circ$  domain wall loop in the antiferromagnet. With this, we demonstrate that the shape of the loop significantly changes in comparison to a purely magnetic system and thus verify the strong influence of the magnetoelastic coupling on the equilibrium domain structure.

 $MA \ 35.16 \quad Thu \ 16:00 \quad P4$  Current-induced Creation of domain walls in synthetic antiferromagnets — ROBIN MSISKA¹, •OMER FETAI¹, RAPHAEL KROMIN², DAVI RODRIGUES³, and KARIN EVERSCHOR-SITTE^{1,4} — ¹Faculty of Physics, University of Duisburg-Essen, Duisburg, Germany — ²Institute of Physics, Johannes Gutenberg Uni-

versity Mainz, Mainz-  $^3{\rm Politecnico}$ di Bari, Bari, Italy-  $^4{\rm Center}$  for Nanointegration Duisburg- Essen (CENIDE)

Improvements in the storage capacity of modern-day memory devices are slowing down and new concepts for storing data are required. A suggestion for a three-dimensional data storage is the racetrack memory which stores information in terms of magnetic domains. The use of synthetic antiferromagnets (SAF), i.e., antiferromagnetically coupled ferromagnetic bilayer systems, accelerates the information access time because the domain walls can be moved up to ten times faster [1]. To obtain a market-ready device, many challenges must be overcome, one of which is integrating a controlled domain wall write process into SAFs. We study the controlled creation of domain walls in SAFs by electrical means. In the case of spin-transfer torques, we find a critical current strength above which antiferromagnetic case[2] we show that the critical current density is an order of magnitude higher.

Magnetization patterns in biaxial Fe32Co68 core-shell nanostructures with hexagonal cross-section — •ANASTASIIA KORNIIENKO¹, ALEXIS WARTELLE², MATTHIAS KRONSEDER³, MICHAEL FOERSTER⁴, MIGUEL ÁNGEL NIÑO⁴, SANDRA RUIZ-GOMES⁴, MUHAMMAD WAQAS KHALIQ^{4,5}, and CHRISTIAN H. BACK¹ — ¹Technical Univ. of Munich, Garching, Germany — ²Univ. Grenoble Alpes, Grenoble, France — ³Univ. of Regensburg, Regensburg, Germany — ⁴Alba Synchrotron Light Facility, CELLS, Barcelona, Spain — ⁵Univ. of Barcelona, Barcelona, Spain

We fabricate nanostructures with a Fe32Co68 shell on GaAs nanorods with hexagonal cross-section. Such a FeCo alloy, deposited on the (110) GaAs planes (the rod's facets), shows a thickness-dependent spin-reorientation transition [1]. At a thickness of 32 monolayers, we expect our tube walls to feature a biaxial behavior, with distinct azimuthal components of magnetization. Here we use Photoemission Electron Microscopy in combination with X-ray Magnetic Circular Dichroism (XMCD-PEEM) to image the magnetic configuration of individual nanostructures [2]. The XMCD-PEEM imaging was done at remanence, between applications of magnetic fields and for different angles between the x-rays and the tube axis. Some of our nanostructures feature a large number of unexpectedly persistent magnetic domains. We observed a switching between almost longitudinal and azimuthal magnetization for some domains, confirming system's biaxial behavior.

**Exploring transient ferromagnetism in La_{0.9}Sr_{0.1}MnO_3 thin films — •KAREN P. STROH, TIM TITZE, HENRIKE PROBST, STEFAN MATHIAS, DANIEL STEIL, and VASILY MOSHNYAGA — I. Physikalisches Institut, Georg-August-Universität Göttingen** 

In perovskite manganites such as La_{1-x}Sr_xMnO₃ (LSMO), complex phase diagrams with different magnetic, electric, and structural phases are obtained as a function of chemical doping. Whilst x = 0.33 is referred to as optimal doping, underdoped LSMO with  $x \sim 0.1-0.15$  is close to a PM-I/FM-M phase boundary for T>T_C [1] and thus a suitable candidate for photo-induced transitions. Ultrafast laser pulses may photoionize electrons from Mn³⁺ to Mn⁴⁺, establishing a double exchange interaction and a FM state, so that the compositional phase boundary might temporarily also be crossed via "optical" doping [2].

Underdoped LSMO/SrTiO₃(100) thin films were epitaxially grown by metalorganic aerosol deposition (MAD) and investigated by time-resolved magnetooptical Kerr effect (MOKE) and pump-probe reflectivity (PPR). Temperature-, fluence-, and magnetic field-dependent measurements have been performed on timescales from femtoseconds to nanoseconds using a pulsed fs laser setup. Our results indicate a possibility to optically drive a paramagnetic-insulating LSMO into a transient ferromagnetic state above  $T_C$  on a sub-ps timescale.

Financial support by the DFG via Project 399572199 and within the SFB 1073 (TP A02) is acknowledged.

## MA 35.19 Thu 16:00 P4

Influence of metallic substrates on the OISTR effect in permalloy thin films – •MARTIN ANSTETT¹, SIMON HÄUSER¹, JONAS HOEFER¹, LAURA SCHEUER¹, PHILIPP PIRRO¹, BURKARD HILLEBRANDS¹, BENJAMIN STADTMÜLLER^{1,2}, and MARTIN AESCHLIMANN¹ – ¹Department of Physics and Research Center OP-TIMAS, TU Kaiserslautern, 67663 Kaiserslautern, Germany – ²Institute of Physics, Johannes Gutenberg University Mainz, 55128 Mainz, Germany

Optical manipulation of magnetic materials on extremely short, sub-100 fs timescales can be achieved either by generation and injection of optically induced (ballistic) spin currents or by direct excitation of the spin system, for instance by the optically induced spin transfer (OISTR) effect as shown in [1, 2].

In this work, we aim to reveal the mutual interplay of these spin-transfer effects on ultrafast timescales. Therefore, we investigate the ultrafast demagnetization of a thin Fe₂₀Ni₈₀ alloy on a non-magnetic Au substrate and how it is influenced by the spin-dependent charge transport into the Au substrate. As an element-resolved probe of the spin dynamics, we employ time-resolved Kerr spectroscopy with fs-XUV radiation in transversal geometry to disentangle the spectroscopic signatures of the OISTR and ballistic spin transport in this material. Our results will be compared to the magnetization dynamics of a Fe₂₀Ni₈₀ film on an insulating substrate.

MA 35.20 Thu 16:00 P4

Ultrafast magnetization dynamics in perovskite manganites — •MAREN SCHUMACHER, HENRIKE PROBST, MARIANA BREDE, CHRISTINA MÖLLER, KAREN STROH, TIM TITZE, CINJA SEICK, SABINE STEIL, MARCEL REUTZEL, G. S. MATTHIJS JANSEN, DANIEL STEIL, VASILY MOSHNYAGA, and STEFAN MATHIAS — 1. Physikalisches Institut, Göttingen, Germany

Correlated manganese oxides are promising materials to realize new functionalities in spintronic applications, which are enabled by strong correlations between electrons, lattice, and spins. Femtosecond time-resolved spectroscopy has proven to be a powerful probe of these interactions. Here, we study demagnetization dynamics in thin-film perovskite manganites using magneto-optical Kerr spectroscopy (MOKE) in the visible and extreme ultraviolet (XUV) range of the spectrum. This allows us to study the samples as a function of temperature (T=10 - 400 K), magnetic field (up to B=1 T), and, in the case of using XUV probe light, with element-specificity. We will show first results of elementspecific HHG-MOKE data on high-quality manganite thin film of LSMO and compare it to standard visible-MOKE.

#### MA 35.21 Thu 16:00 P4

Wide spectral range ultrafast pump-probe magneto-optical spectrometer at low temperature, high-magnetic and electric fields — •FABIAN MERTENS¹, MARC TERSCHANSKI¹, DAVID MÖNKEBÜSCHER¹, STEFANO PONZONI¹, DAVIDE BOSSINI^{1,2}, and MIRKO CINCHETTI¹ — ¹Department of Physics, TU Dortmund University, Otto-Hahn-Straße 4, 44227 Dortmund, Germany — ²Department of Physics and Center for Applied Photonics, University of Konstanz, Germany.

We developed a table-top setup to perform magneto-optical pump-probe measurements with the possibility to independently tune the photon-energy of both pump and probe beams in the 0.5 eV - 3.5 eV range[1]. Our apparatus relies on a commercial turn-key amplified laser system, able to generate light pulses with duration shorter than or comparable to 100 fs throughout the whole spectral range. The repetition rate of the source can be modified via the computer in the 1 kHz - 1 MHz range. A commercial balanced detector is connected to a high-frequency digitizer, allowing for a highly-sensitive detection scheme: rotations of the probe polarization as small as 70  $\mu$ deg can be measured. Additionally, a DC magnetic field as high as 9 T and voltages in the kV regime can be applied on the sample. A cryostat allows us to precisely set the temperature of the sample in the 4 K - 420 K interval. We test the performance of our setup by measuring the ultrafast demagnetization of a cobalt crystal as a function of a wide variety of experimental parameters.

Integration of a supercontinuum probe line in a setup for time-resolved magneto-optical spectroscopy — •SOPHIE BORK, RICHARD LEVEN, MARC TER-SCHANSKI, FABIAN MERTENS, UMUT PARLAK, and MIRKO CINCHETTI — Department of Physics, TU Dortmund University, Otto-Hahn-Straße 4, 44227 Dortmund, Germany

We have recently developed a setup for wide spectral range ultrafast pump-probe magneto-optical spectroscopy at low temperature, high-magnetic and electric fields [1]. Here we present an upgrade of this setup that allows to measure the transient reflectivity (AR/R) in a broad spectral range and with femtosecond time-resolution. To this end, we have generated a broadband supercontinuum (white light) probe beam that covers the wavelengths from the near UV to the near IR region. The detection of the white light spectrum reflected or transmitted from the sample is achieved by a 1D-array of CMOS detectors that allow for simultaneous data acquisition of all available wavelengths. This upgraded setup can work at high repetition rates (< 100 kHz) and allows to perform measurements with high temporal and spectral resolution. This is particularly useful, for example, to fully map the photo-driven transient evolution of the band gap energy in magnetically ordered semiconducting systems and to assess whether it is linked to the magnetization dynamics [2]. In this poster contribution we will present all technical details of the setup together with first characterization measurements to specify its performance.

All-optical switching of magnetically hard CoPt and L1₀-FePt in contact with a Gd-layer — •JOHANNES SEYD¹, JULIAN HINTERMAYR², MANFRED ALBRECHT¹, and BERT KOOPMANS² — ¹Institute of Physics, University of Augsburg, 86159 Augsburg, Germany — ²Department of Applied Physics, Eindhoven University of Technology, 5600 MB Eindhoven, The Netherlands

All-optical switching (AOS) by single femtosecond laser pulses promises to be an ultrafast, energy-efficient alternative to conventional writing in magnetic recording using magnetic fields.  $L1_0$ -FePt is a magnetic material with high perpendicular magnetic anisotropy (PMA), which makes it an interesting candidate for future ultrahigh-density magnetic recording applications, and for which helicity-dependent multi-shot AOS has already been confirmed [1].

Thermally-induced single-shot AOS is not only possible in ferrimagnetic alloys with a compensation temperature near room temperature, but also in synthetic ferrimagnets consisting of a ferromagnetic (multi-) layer in contact with a Gd layer, as shown for Co and Co/Ni [2]. These results suggest the possibility of reproducing the same kind of switching in other magnetic thin films, which in the case of L10-FePt would circumvent the problem of writing the magnetically hard material in magnetic recording applications.

We show the most recent results on the thermally-induced AOS behaviour of thin CoPt and  $L1_0$ -FePt films in contact with a Gd layer.

Phy., FU Berlin — ⁵DIPC, Basque, Spain — ⁶IOAP, TU Berlin

Antiferromagnets, due to their zero net magnetization, offer faster manipulation of spins and more robust devices. But this also makes the interaction with magnetic order challenging. One way to achieve this is to utilize the magnetic anisotropy to manipulate the spin arrangement which we demonstrated recently using ultrafast optical excitation [1]. For practical applications, understanding the interaction of this effect with external magnetic fields is of strong interest. To this end, we perform time-resolved resonant soft X-ray diffraction in the prototypical A-type antiferromagnet GdRh₂Si₂. Consistent with our previous study, we observe a coherent rotation of the antiferromagnetic (AF) arrangement of Gd 4f spins followed by oscillations of the AF order as a consequence of a lightinduced change in the anisotropy potential. Surprisingly, upon increasing magnetic field, the frequency of the oscillations as well as the extent of demagnetization upon photoexcitation increases. These observations indicate a change in the magnetic anisotropy potential and may offer a new way towards deterministic control of spin order using combined electromagnetic and magnetic fields. #### MA 35.25 Thu 16:00 P4

Studying double pulse toggle switching of GdFe — •RAHIL HOSSEINIFAR¹, IVAR KUMBERG¹, SANGEETA THAKUR¹, EVANGELOS GOLIAS¹, SEBASTIEN HADJADJ¹, JENDRIK GÖRDES¹, JORGE TORRES¹, FLORIAN KRONAST², MARIO FIX³, MANFRED ALBRECHT³, and WOLFGANG KUCH¹ — ¹Institut für Experimentalphysik, Freie Universität Berlin, Arnimallee 14,14195 Berlin, Germany — ²Helmholtz-Zentrum Berlin, Albert-Einstein-Straße 15, 12489 Berlin, Germany — ³Institut für Physik, Universität Augsburg, Universitätsstraße 1, 86159 Augsburg, Germany

Switching of magnetization without the help of a magnetic field by using an ultrafast laser pulse is a popular topic for both applied and fundamental research. We study the effect of double-pulse optical excitation on all-optical toggle switching in  $Gd_{26}Fe_{74}$  ferrimagnetic alloys with perpendicular magnetic anisotropy by X-ray magnetic circular dichroism photoelectron emission microscopy. Varying the temporal separation of the two pulses and their intensities reveals a lowering threshold for toggle switching compared to a single pulse, and the formation of three areas in the footprint of the laser pulses for time delays below 1 ps. First, an area is located at lower fluences that does not switch. The second area is a higher fluences where multi-domain nucleation is observed, and the third area is in between and switches deterministically. The experiment is done starting from either a saturated state or in presence of magnetic domains. In both cases, a deterministically switching area is observed which would be desirable for many applications.

## MA 35.26 Thu 16:00 P4

**Magneto-optical study of proximity effects at the EuO/Co interface** – •David Mönkebüscher¹, Paul Rosenberger^{1,2}, Davide Bossini^{1,2}, Umut Parlak¹, Martina Müller², and Mirko Cinchetti¹ – ¹Department of Physics, TU Dortmund University, Germany – ²Department of Physics, University of Konstanz, Germany

Europium monoxide has shown great potential as a magnetic insulator and was successfully employed in various spintronic applications as a spin filter with nearly

100% spin polarized currents [1]. For the use in practical applications, an increase of its relatively low Curie temperature ( $T_C = 69$  K) is necessary. One approach relies on proximity effects, i.e. the coupling with a high  $T_C$  ferromagnetic layer [2]. Following this approach, we prepared YSZ/EuO/Co multilayers using molecular beam epitaxy (MBE) [3], and studied them using the magneto-optical setup described in Ref. [4]. First, we measured static hysteresis to gain insight about the nature of the proximity-induced coupling of the two magnetic sublattices. Then we used that the pump-probe experimental scheme to manipulate this coupling by varying the pump laser fluence and the delay between the pump and the probe beam.

MA 35.27 Thu 16:00 P4

**Wavelength-dependent magnetization dynamics in Ni|Au heterostructures** – •STEPHANIE RODEN¹, CHRISTOPHER SEIBEL¹, MARIUS WEBER¹, MARTIN STIEHL¹, SEBASTIAN T. WEBER¹, MARTIN AESCHLIMANN¹, BENJAMIN STADTMÜLLER^{1,2}, HANS CHRISTIAN SCHNEIDER¹, and BAERBEL RETHFELD¹ – ¹Department of Physics and Research Center OPTIMAS, TU Kaiserslautern, Kaiserslautern, Germany – ²Institute of Physics, Johannes Gutenberg University Mainz, Mainz, Germany

For a long time, the ultrafast magnetization dynamics of ferromagnets has predominantly been studied for optical excitation using only one photon energy. However, recent experiments have shown that the dynamics of the demagnetization and remagnetization process can be altered by the wavelength of the exciting laser pulse [1, 2].

In this contribution, we extend the temperature-based  $\mu$ T-model to investigate the ultrafast magnetization dynamics of Ni|Au heterostructures. Our model is based on realistic densities of states of both materials and includes energy and spin transfer at the interface. Thereby, we explicitly consider the wavelength- and layer-dependent absorption profile within multilayer structures. This allows us to show the influence of the wavelength-dependent excitation on the magnetization dynamics [3], which is also affected by the substrate thickness.

Optical manipulation of the antiferromagnetic order in a Pt/NiO bilayer system by ultrafast energy transfer — •PAUL HERRGEN¹, STEPHAN WUST¹, CHRISTOPHER SEIBEL¹, HENDRIK MEER², CHRISTIN SCHMITT², LORENZO BALDRATI², RAFAEL RAMOS³, TAKASHI KIKKAWA⁴, EIJI SAITOH⁴, OLENA GOMONAY², JAIRO SINOVA², YURIY MOKROUSOV², HANS CHRIS-TIAN SCHNEIDER¹, MATHIAS KLÄUL², BAERBEL RETHFELD¹, BENJAMIN STADTMÜLLER^{1,2}, and MARTIN AESCHLIMANN¹ — ¹Department of Physics and Research Center OPTIMAS, Technische Universität Kaiserslautern, 67663 Kaiserslautern, Germany — ²Institute of Physics, Johannes Gutenberg-Universität Mainz, 55128 Mainz, Germany — ³CIQUS, Departamento de Química-Física, Universidade de Santiago de Compostela, Santiago de Compostela, Spain — ⁴Department of Applied Physics, The University of Tokyo, Tokyo 113-8656, Japan

Antiferromagnets are promising materials for future spintronic devices due to their resilience against external magnetic fields and their high frequency magnon modes. Here, we explore the subpicosecond magnetization dynamics of the antiferromagnet NiO after strong optical excitation with fs light pulses. We find a clear reduction of the magnetic order for a Pt/NiO bilayer systems on subpicosecond timescales. Our observations are discussed in the framework of an extended  $\mu T$  model. We conclude that the ultrafast loss of antiferromagnetic order in the Pt/NiO bilayer system is mediated by a highly efficient energy transfer between the hot Pt electrons and the NiO spins.

## MA 35.29 Thu 16:00 P4

**Spin-transport-driven ultrafast magnetization dynamics in a ferrimagnetic Gd/Fe bilayer** — •HUIJUAN XIAO, BO LIU, and MARTIN WEINELT — Fachbereich Physik, Freie Universität Berlin, Arnimallee 14, 14195, Berlin

Laser-induced spin transport has been proven to be a key ingredient in ultrafast spin dynamics, such as femtosecond demagnetization and all-optical switching (AOS). We use time- and spin-resolved photoemission spectroscopy of the gadolinium surface state to study spin dynamics in a ferrimagnetic Gd/Fe bilayer. This prototype system for AOS was epitaxially grown on W(110). Our findings suggest that spin transport between the antiferromagnetically coupled gadolinium and iron layers leads to an ultrafast drop of the spin polarization and an increased exchange splitting at the Gd surface. The Gd surface state shows an ultrafast decrease of the spin polarization by 20% within the first ~ 100 fs and a subsequent slower decrease by about 5% on the picosecond timescale. The increase of the exchange splitting counterbalances the overall demagnetization of the Gd layer. In contrast, the pure Gd/W(110) film shows a constant spin polarization and a reduced exchange splitting of the surface state upon optical excitation. These findings are corroborated by the transient electron temperature. Our results provide clear evidence that magnetization dynamics in the Gd/Fe bilayer can be driven by spin transport. We see distinct signatures in the spin-dependent electronic structure that allow us to gain microscopic insights into ultrafast spin dynamics (supported by SFB/TRR 227 Ultrafast Spin Dynamics).

## MA 35.30 Thu 16:00 P4

**Ultrafast demagnetization of 2d ferromagnets** — •NELE STETZUHN^{1,2}, FE-LIX STEINBACH¹, MARTIN BORCHERT¹, ABHIJEET KUMAR², DENIS JAGODKIN², CLEMENS VON KORFF SCHMISING¹, STEFAN EISEBITT¹, and KIRILL BOLOTIN² — ¹Max-Born-Institut, Max-Born-Straße 2 A, 12489 Berlin — ²Fachbereich Physik der Freien Universität Berlin, Arnimallee 14, 14195 Berlin

Two-dimensional ferromagnets are one of the latest additions to the family of 2d materials and offer a new platform to study ultrafast magnetic phenomena. When combining 2d ferromagnets with other 2d materials such as transition metal dicalchogenides (TMDs), the absence of lattice mismatch between layers also makes the resulting heterostructures promising for high-performance spintronic devices. Here, we measure the ultrafast demagnetization of 2d ferromagnets with the structure  $Fe_x GeTe_2$  (x = 3, 5) after excitation by a pump laser using time-resolved MOKE. The usually low Curie temperature of  $Fe_x GeTe_2$  (x = 3, 5) can be increased above room temperature, e.g. by doping with *Ni*, allowing us to do element-resolved demagnetization measurements at the free-electron laser facility FERMI. This can give insight into effects such as optical inter-site spin transfer (OISTR) in the material.

## MA 35.31 Thu 16:00 P4

Heat capacities and Curie curve in the Stoner and Heisenberg models — •NABIL MAKADIR, STEPHANIE RODEN, SANJAY ASHOK, SEBASTIAN T. WEBER, FELIX DUSABIRANE, H. CHRISTIAN SCHNEIDER, and BAERBEL RETHFELD — Department of Physics and Research Center OPTIMAS, TU Kaiserslautern, Germany

The excitation of a metallic ferromagnet with an ultrashort laser pulse leads to a demagnetization on the femtosecond timescale. The response of the material is governed by macroscopic properties, like the heat capacities and the equilibrium magnetization (Curie curve). They can be calculated for instance with either the Stoner model or the Heisenberg model. The former attributes the change of magnetization to the shifting of the spin-resolved density of states. The latter describes the reduction of the magnetization through collective angular oscillation of the individual magnetic moments.

In this contribution, we derive the temperature-dependent heat capacities and the Curie curves for Nickel. We compare the results of the Stoner and the Heisenberg model and analyze the advantages and drawbacks of both approaches. Finally, we investigate the transition between Stoner and Heisenberg excitations.

## MA 35.32 Thu 16:00 P4

**Hybrid simulation tracing non-equilibrium spin-dynamics and -transport** — •LUKAS JONDA, JOHAN BRIONES, SEBASTIAN T. WEBER, CHRISTOPHER SEIBEL, SANJAY ASHOK, and BAERBEL RETHFELD — Department of Physics and Research Center OPTIMAS, TU Kaiserslautern, Germany

We simulate the complex phenomena arising in a magnetic film after femtosecond laser irradiation with help of a hybrid model. This model consists of a combination of two methods: The  $\mu$ T model [1] and a kinetic Monte Carlo method [2]. The former treats the low-energetic electrons as an ensemble, tracing spin resolved temperatures and chemical potentials, as well as their gradients [3]. The latter traces individual high-energetic non-equilibrium electrons, including spin-dependent scattering processes and spin-flip probabilities. We present first investigations of how non-equilibrium electrons influence the magnetization dynamics for Nickel.

The long-term perspective of this project is to develop a model that can describe both the transport of the electron ensemble and individual high-energetic super-diffusive electrons. This allows to study the different types of nonequilibrium transport and their effects on magnetization dynamics.

#### MA 35.33 Thu 16:00 P4

**Ultrafast Tunnel Magnetoresistance** — •THOMAS JAUK¹, KAZMA KOMATSU¹, HANA K. HAMPEL¹, JANA KREDL², JAKOB WALOWSKI², FLORIAN LACKNER¹, SANGEETA SHARMA³, MARKUS MÜNZENBERG², and MARTIN SCHULTZE¹ — ¹Institute of Experimental Physics, Graz University of Technology, Graz, Austria — ²Institute of Physics, University of Greifswald, Greifswald, Germany — ³Max Born Institute, Berlin, Germany

Magnetic tunnel junctions (MTJ) have been arousing ongoing interest due to their peculiar spin-transfer mechanism since the discovery of the large tunnel magnetoresistance. However, a complete microscopic understanding of the underlying physics is still lacking. We put the spotlight on the interface between a MgO-based tunnel barrier and a CoFeB wedge-like electrode in order to disentangle intertwined phenomena which come along with ultrafast demagnetization. By employing circularly-polarized visible light pulses and utilizing magnetic circular dichroism in a two-photon-photoemission (2PPE) experiment we establish a direct route to the buried interface, providing insight into the spatial arrangement and the electronic behaviour of the magnetic pattern near the Fermi level. Beside the typical demagnetization curve we observe a light-induced increase in magnetic moment for specific energy/momentum intervals. Together with DFT calculations we try to shed light on the microscopic processes involved in the ultrafast demagnetization and, especially, emphasize on the peculiarity of MTJs acting as an energy- and spin-filter.

**Ferromagnetic resonance study of spin pumping in epitaxial Fe/Rh bilayers** — •JONAS WIEMELER, ALI CAN ACTAS, MICHAEL FARLE, and ANNA SEMISA-LOVA — Faculty of Physics and CENIDE, University of Duisburg-Essen, 47057 Duisburg, Germany

The alloy FeRh has been studied extensively for structural, electrical and magnetic properties. On the other hand spin dynamics in a Fe/Rh thin film bilayer system in detail has not been addressed yet. In this work, 5 nm Fe films capped with Rh of thicknesses (0, 1, 2, 3, 5, 10, 15) nm were grown on GaAs(100) substrates using molecular beam epitaxy (MBE). Ferromagnetic resonance (FMR) experiments at room temperature, utilising both angular X-Band and frequency dependence (1-40GHz), were used to characterise the magneto dynamic properties of these bilayers. The growth characteristics of Rh on a 5 nm substrate Fe layer have been investigated using Auger electron spectroscopy (AES) measurements during the Rh growth. It was found, that Rh grows epitaxially on Fe in a layer-by-layer manner. The thickness dependence of the magnetisations precession damping, measured using FMR, shows an exponential behaviour which was analysed in terms of a spin pumping effect. We found, that the spin pumping efficiency of Rh is comparable to Pt, while the spin flip rate compares to that of Pd.

Funding by DFG Project No. 392402498 (SE 2852/1-1  $\mid$  AL 618/37-1) and helpful discussion with R. Meckenstock and T. Strusch are acknowledged.

Magnetization dynamics of *y*-Fe₂O₃ thin films with reduced effective magnetization — •MONIKA SCHEUFELE^{1,2}, MANUEL MÜLLER^{1,2}, JANINE GÜCKELHORN^{1,2}, LUIS FLACKE^{1,2}, ANDREAS HASLBERGER^{1,2}, MATHIAS WEILER³, HANS HUEBL^{1,2,4}, STEPHAN GEPRÄGS¹, RUDOLF GROSS^{1,2,4}, and MATTHIAS ALTHAMMER^{1,2} — ¹Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — ²Physik-Department, Technische Universität München, Garching, Germany — ³Fachbereich Physik und Landesforschungszentrum OPTIMAS, Technische Universität Kaiserslautern, Kaiserslautern, Germany — ⁴Munich Center for Quantum Science and Technology (MCQST), München, Germany

Magnetic insulators (MI) are of key importance in the emerging fields of magnonics and spin-caloritronics. In this respect, the room-temperature MI  $\gamma$ -Fe₂O₃ is a promising candidate offering a variety of application perspectives. Here, we report on the static and dynamic magnetic properties of pseudomorphic-grown  $\gamma$ -Fe₂O₃ thin films on MgO (001). We find a strain-induced small effective magnetization  $M_{\rm eff}$ , showing a sign change at 200 K. In addition, we also observe the impact of slowly relaxing impurities to the ferromagnetic resonance (FMR) field and the linewidth as a function of temperature. Moreover, above 150 K we detect an increase of the FMR linewidth, which we attribute to valence-exchange damping induced by Fe²⁺-ions in  $\gamma$ -Fe₂O₃ [1]. [1] M. Müller *et al.*, arXiv:2204.11498.

## MA 35.36 Thu 16:00 P4

Spin pumping in embedded lateral nanostructures in Fe60Al40 — TANJA STRUSCH¹, RALF MECKENSTOCK¹, RANTEJ BALI², JONATHAN EHRLER², KAY POTZGER², KILIAN LENZ², JÜRGEN LINDNER², MICHAEL FARLE¹, and •ANNA SEMISALOVA¹ — ¹Faculty of Physics and CENIDE, University of Duisburg-Essen, Duisburg, Germany — ²Helmholtz-Zentrum Dresden-Rossendorf, Institute of Ion Beam Physics and Materials Research, Dresden, Germany

The magnetic properties of an Fe60Al40 (FeAl) alloy are tailorable from paramagnetic (PM) to ferromagnetic (FM) state by variation of the structure through ion beam irradiation, making it a promising material for the fabrication of magnetic landscapes and magnonic crystals. Here, we report on ferromagnetic resonance (FMR) detected spin pumping in FeAl/Pd and Py/FeAl bilayers and laterally patterned nanostructures and show that FeAl can be used as spin source and as spin sink. Using FMR, we estimate the spin pumping efficiency and find a spin-mixing conductance of g_FeAl=2.1(+/-0.2) nm^(-2) and a spin diffusion length of  $\lambda$ _FeAl=11.9(+/-0.2) nm for paramagnetic FeAl, and g_Pd=3.8(+/-0.5) nm^(-2) and  $\lambda$ _Pd=9.1(+/-2.0) nm for Pd. Further, we investigate the spin pumping in laterally patterned FeAl nanostructures representing 500 nm wide FM strips separated by PM strips of different width (100-400 nm) produced in a 40 nm thick FeAl film. We find an enhancement of the damping parameter with decreasing width of the PM FeAl areas due to an increase of the number of FM/PM interfaces. Financial support from DFG is gratefully acknowledged (project No. 392402498 (SE 2852/1-1 | AL 618/37-1)).

MA 35.37 Thu 16:00 P4 Growth optimization of ferromagnetic gadolinium nitride (GdN) thin films for magnon transport phenomena — •RAPHAEL HOEPFL^{1,2}, MANUEL MÜLLER^{1,2}, MATTHIAS OPEL¹, STEPHAN GEPRÄGS¹, HANS HUEBL^{1,2,3}, RUDOLF GROSS^{1,2,3}, and MATTHIAS ALTHAMMER^{1,2} — ¹Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany – ²Physik-Department, Technische Universität München, Garching, Germany — ³Munich Center for Quantum Science and Technology (MCQST), München, Germany Ferromagnetic (FM) semiconductors are of great interest for spintronics devices. Gadolinium nitride (GdN) is one candidate for a semiconducting ferromagnet with a Curie temperature  $T_{\rm C}$  of 65-70 K [1]. In this study, we investigate the static and dynamic properties of FM GdN thin films by SQUID magnetometry and broadband ferromagnetic resonance experiments in a cryogenic environment. In detail, we prepare tantalum nitride (TaN)/GdN/TaN thin films on thermally oxidized Si substrates using DC magnetron sputtering, where the TaN is used as seed and protective top layer. Here, we discuss the impact of the various deposition parameters, such as deposition pressure, temperature, rate and reactive N2 gas flow on the static and dynamic magnetic properties of GdN. [1] W. Spin polarized band engineering for spin-photocatalyst in ZnO nanowires — Hua Shu Hsu¹, Jun-Xiao Lin¹, •Jutathip Thaomonpun¹, Wei-Jhong Chen¹, Shih Jye Sun², and Zdenek Remeš³ — ¹No. 4-18, Minsheng Road, Pingtung City, 90044, Taiwan (R.O.C.) — ²700, Kaohsiung University Rd., Nanzih District, Kaohsiung 811, Taiwan(R.O.C.) — ³Na Slovance 1999/2, Praha 8, Czech Republic

Transition metal-doped oxides with spin-polarization energy bands have been expected as potential materials for semiconductor spintronics applications. In our work, we found that through surface-doped Co/ZnO nanowires (NWs), the generation of spin-polarized energy bands can be confirmed in the ultraviolet (UV) region by magnetic circular dichroism measurements. Because ZnO itself can be applied in the UV photocatalytic material. Therefore, the magnetic field-enhanced photocurrent and magnetic field-enhanced photocatalytic effect due to modulation of the spin-polarized energy band can be observed. And spin-polarized energy band engineering can be extended to non-magnetic ion-doped ZnO NWs. The realization of these spin photocatalytic effects will also provide new opportunities for the study of spin-polarized energy bands in semiconductors.

Electric transport properties of Ni-Mn-In alloy exposed to external stimuli — •SERGIY KONOPLYUK¹ and ALEXANDR KOLOMIETS² — ¹Institute of magnetism of NASU and MESU, Kyiv, Ukraine — ²Department of Physics, Lviv Polytechnic National University, Lviv, Ukraine

The polycrystalline Ni45.4Mn40In14.6 Heusler alloy was studied to find dominant factors affecting its electric transport behavior in austenitic and martensitic phases. Analysis of three main contributions into temperature dependent resistivity has shown that prevalent mechanisms of carrier scattering in the austenitic phase are scattering on structural and magnetic disorders rather than on thermal fluctuations.

In spite of the small transformation volume effect of 0.09 %, application of hydrostatic pressure of 2 GPa results in almost threefold rise in the longitudinal resistivity and twofold rise in the Hall resistivity due to the pressure-induced martensitic transformation. The measurements of the ordinary Hall resistivity have shown that main charge carriers in both phases are holes whose mobility is ten times as high in the austenitic phase as in the martensitic one.

The anomalous Hall resistivity (AHE) of the Ni45.4Mn40In14.6 reaches significant magnitude of 20 microOhm*cm in the martensitic phase. Unusual scaling relation between AHE and the longitudinal resistivity is discussed.

#### MA 35.40 Thu 16:00 P4

**Magnetometry of Buried Co-based Nanolayers by Hard X-ray Photoelectron Spectroscopy** — •ANDREI GLOSKOVSKII¹, CHRISTOPH SCHLUETER¹, and GER-HARD FECHER² — ¹Photon Science / DESY, Hamburg — ²Max Planck Institute for Chemical Physics of Solids, Dresden

The intensity and shape of photoelectron lines of magnetic materials depend on the relative orientation of the sample magnetization, the X-ray beam polarization and the spectrometer axis, i.e. the electron emission direction. In the hard X-ray regime, the beam polarization can be conveniently modified utilizing the phase shift produced by a diamond phase plate in the vicinity of a Laue or Bragg reflection. A single-stage in-vacuum phase retarder is installed and commissioned in 2020 at the HAXPES beamline P22 at PETRA III (Hamburg) [1].

The electronic and magnetic properties of CoFe and Co-based Heusler nanolayers were studied using the linear and circular magnetic dichroism in the angular distribution of photoelectrons. The layers were remanently magnetized in-situ and Co  $2p_{1/2}$  and  $2p_{3/2}$  core levels were probed at room temperature [2-

3]. Both the polarization-dependent spectra and the dichroism indicate that the lines of the multiplet extend over the entire spectral range. In particular, the dichroism does not vanish between the two main parts of the spin-orbit doublet.

## MA 35.41 Thu 16:00 P4

Ultrafast optical Spectroscopy of La $MnO_3/SrMnO_3$  Superlattices — •TIM TITZE, LEONARD SCHUELER, JANNIK BRUMM, VITALY BRUCHMANN-BAMBERG, VASILY MOSHNYAGA, DANIEL STEIL, and STEFAN MATHIAS — I. Physikalisches Institut, Goettingen, Germany

We investigate photoinduced dynamics of a LaMnO₃/SrMnO₃ superlattice, using transient reflectivity  $\Delta R/R$  at various temperatures. The superlattice exhibits a low- $T_C$  ferromagnetic (FM) phase below  $T_{C,LMO} = 200$  K with a bulk-LMO-like behavior. Further, Keunecke *et al.* reported on a high- $T_C$  interfacial quasi-2D FM phase below  $T_{C,2D} = 350$  K that results from an LMO to SMO charge transfer during sample growth [1].

By studying the system response on timescales from fs to ns we aim to determine whether the 2D interfacial phase shows a distinctly different response to an ultrafast optical stimulus than the bulk FM phase. We find that on the subps timescale the T-dependent dynamics mimic the static M(T)-curve, i.e., both ferromagnetic phases seem to contribute to the ultrafast system response. On the 100 ps timescale spin-phonon coupling leads to an additional component in  $\Delta R/R$  within the bulk FM phase, which is not observed for the high- $T_C$  quasi-2D FM phase. An additional signature in the T-dependent relaxation time on a ns timescale around 300 K is tentatively attributed to the vanishing of the 2D FM phase already below its  $T_{C,2D}$  due to optical excitation.

Financial support by the DFG within the CRC 1073 is acknowledged.

MA 35.42 Thu 16:00 P4 **Frustrated triangular magnetism in new copper based single crystals.** – •Aswathi Mannathanath Chakkingal¹, Chloe Fuller², Dmitry CHERNYSHOV², MAXIM AVDEEV³, MAREIN CHRISTOPHER RAHN¹, FALK PABST⁴, YIRAN WANG⁴, DARREN PEETS¹, and DMYTRO INOSOV¹ – ¹IFMP, TU Dresden, Germany – ²ESRF, Grenoble, France – ³ANSTO, Sydney, Australia – ⁴Professur f. Anorganische Chemie II, TU Dresden, Germany

The hydrothermal technique is an efficient strategy to synthesize mineralogically inspired structures, including natural and synthetic cuprate minerals with a variety of exciting frustrated magnetic lattices. We report the hydrothermal synthesis of single crystals of a new material  $Cu_4(SO_4)(OH)_6$ . Single-crystal x-ray and neutron diffraction studies performed to determine the crystal structure reveal the presence of three copper layers which stack in an ABACABAC pattern in the crystal, which results in a large *b* lattice constant of 25Å. Seemingly-distorted and -expanded  $SO_4^{2-}$  tetrahedra in the system are likely attributable to vacancies and structural disorder. The  $Cu^{2+}$  copper ions are arranged in buckled sheets consisting of ribbons of edge-sharing and corner-sharing octahedra, and form a heavily distorted triangular lattice. Diffuse scattering measured with synchrotron x-rays also reveals strong stacking-fault disorder in this system. We report details of the crystal structure and its low temperature magnetic properties.

High-pressure crystal growth and the magnetic phase diagram of hexagonal  $GdInO_3 - \bullet$ Ning Yuan, Ahmed Elghandour, Lukas Gries, Waldemar Hergett, and Rüdiger Klingeler — Kirchhoff Institute for Physics, Heidelberg University, Germany

GdInO₃ is hexagonal structured system which exhibits strong geometrical frustration and improper geometric ferroelectricity [1,2]. We report the growth of macroscopic GdInO₃ single crystals which are used to study magnetization, specific heat, and thermal expansion in magnetic field up to 16 T. The data are used to construct the magnetic phase diagram. Anomalies in the specific heat confirm the evolution of long-range magnetic order at  $T_N = 2.1$  K. At the antiferromagnetic phase boundary, anomalies in thermal expansion and magnetostriction imply significant spin-lattice coupling. A modest net magnetic phase diagrams for B||*c* and B||*ab* are presented for temperatures down to 400 mK and magnetic fields up to 14 T. Isothermal magnetization curves indicate a narrow 1/3 magnetization plateau as well as a sharp anomaly at about 5 T.

Spin Excitations, Accidental Soft Modes, and Phase Diagram of the Triangular-Lattice t-t'-U Hubbard Model — •JOSEF WILLSHER¹, HUI-KE JIN¹, and JOHANNES KNOLLE^{1,2,3} — ¹TUM, Munich, Germany — ²MCQST, Munich, Germany — ³Imperial College London, London, UK

The structure factor is an important probe of quantum magnets but due to numerical limitations it remains a challenge to make theoretical predictions beyond linear spin wave calculations of Heisenberg-like models. In this work we study the excitation spectrum of the triangular lattice Hubbard model including next-nearest neighbour hopping within a self-consistent random phase approximation. Starting from the 120-degree and stripe magnetic orders we compute the relevant magnon spectra and discuss connections to recent experiments on triangular lattice compounds. In addition, we show that the condensation of accidental soft-modes allows us to construct the phase diagram of the model, which is consistent with previous results of the variational cluster approximation. We discuss the implications of our findings for unconventional magnon spectra and even for the presence of quantum disordered phases without long range order.

MA 35.45 Thu 16:00 P4

**Exchange Enhancement of Ferromagnetic Resonance in Mn_2Au/Py -** •TOBIAS WAGNER and OLENA GOMONAY — Johannes Gutenberg-University Mainz, Germany

In the future, AFMs as active components will bring favourable advantages to spintronics: Robustness to external magnetic fields, temperature stability of the Néel ordered state and lack of stray fields. Therefore, AFMs are suitable for ultrafast and ultra high density spintronics. Recently, strong exchange coupling between  $Mn_2Au$  and thin layers of Permalloy ( $Ni_{80}Fe_{20}$ ) has been shown [1]. As a consequence, the coercive field of  $Mn_2Au/Py$  was reported to be 5000 Oe, which is high compared to 200 Oe in CuMnAs/Fe [1]. High coercive fields lead to long term stability at room temperature. Due to strong exchange coupling, the AFM Néel vector and the FM magnetisation rotate coherently, when an external field is applied to the FM. Ferromagnetic resonance spectroscopy revealed two distinct frequencies for the coupled bilayer system, both of which lie above the resonance frequency of Permalloy. We model these findings using a phenomenological model. Our model enables us to demonstrate how the interfacial exchange coupling enables tuning of the ferromagnetic resonance frequency by variation of the thickness of the ferromagnetic layer.

Voltage induced magneto-ionic interactions controlling magnetic properties of synthetic antiferromagnets — •MARIA-ANDROMACHI SYSKAKI^{1,2} of synthetic antiferromagnets — •Maria-Andromachi Syskaki^{1,2}, Takaaki Dohi², Jürgen Langer¹, Mathias Kläui², and Gerhard Jakob² — ¹Singulus Technologies AG, 63796 Kahl am Main, Germany —  2 Institut für Physik, Johannes Gutenberg-Universität Mainz, Staudingerweg 7, 55128 Mainz, Germany Voltage control of magnetic properties in spintronic devices is one of the most promising device-compatible and energy-efficient ways for future storage applications [1]. This approach can be ideally realized with the advantages of a synthetic antiferromagnet (SAF) system, which provides higher thermal stability and a wide dynamic range, e.g. high domain wall velocities for nearly compensated SAFs [2] when integrated into MRAM devices. In our work, we have grown a SAF stack by magnetron sputtering consisting of two ferromagnetic layers coupled by a non-magnetic spacer layer. A thermodynamically stable skyrmion state at elevated temperatures is achievable in this stack [3]. With room temperature voltage-controlled magneto-ionic effects, we focus on the modulation of the magnetic properties in this system, i.e., the voltage control of the compensation ratio between the layers, the perpendicular magnetic anisotropy, and the antiferromagnetic RKKY coupling strength. Micromagnetic simulation of magnetic reversal processes in exchange biased micro stripes — •LUKAS PAETZOLD, SAPIDA AKHUNDZADA, CHRISTIAN JANZEN, MICHAEL VOGEL, and ARNO EHRESMANN — Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Heinrich-Plett-Strasse 40, 34132 Kassel, Germany

Exchange bias, being first observed by Meiklejohn and Bean [1] and described as a unidirectional anisotropy, is a well-known interface effect between antiferromagnetic and ferromagnetic thin films. Initiated by field cooling [1], sputter deposition [2], or light-ion bombardment [3] the effect appears as a shift of the hysteresis loop and increased coercive fields [4]. Micromagnetic simulations [5,6] are presented for investigating the magnetic reversal processes in exchange biased micro stripes with a polycrystalline uncompensated antiferromagnetic layer. Special focus is put on the nucleation processes occurring in the microscopic range depending on the stripe width.

Exchange-spring behavior at magnetic perovskite oxide interfaces •Antonia Rieche, Martin Michael Koch, Michael Enders, Aurora Di-ANA RATA, and KATHRIN DÖRR — Martin-Luther-Universität Halle-Wittenberg Advances in ultrathin film deposition allow the investigation of exceptional properties at interfaces which significantly differ from those of bulk materials. A particular kind of interface coupling between magnets is the exchange spring, whose magnetic switching is distinctly different from that of exchange-bias coupling. To explore exchange springs in oxides, high quality SrRuO₃/La_{0.7}Sr_{0.3}MnO₃ (SRO/LSMO) and La_{0.7}Sr_{0.3}CoO₃ (LSCO/LSMO) bilayers were grown by pulsed laser deposition on different substrates with systematically varied layer thicknesses. Strong antiferromagnetic Mn-O-Ru or ferromagnetic Mn-O-Co exchange coupling connects the magnetic moments at the interface. An exchange spring resembling a Bloch wall is formed in the hard magnet due to a striking reduction of the magnetocrystalline anisotropy near the interface and return to bulk behavior further away from the interface. The thickness-dependent switching is analyzed to derive the exchange and anisotropy energies of the spring, its length and field-temperature "phase diagram". We discuss the impact of such interfacial spin textures on magnetic switching as well as on further properties which are important for spintronics applications.

## MA 35.49 Thu 16:00 P4

Effect of laser annealing on the magnetic properties of Co/Pt based multilayers — •LOKESH RASABATHINA¹, APOORVA SHARMA¹, SANDRA BUSSE³, BENNY BÖHM¹, FABIAN SAMAD^{1,2}, GEORGETA SALVAN¹, ALEXANDER HORN³, and OLAV HELLWIG^{1,2,4} — ¹Institute of Physics, Chemnitz University of Technology, 09107 Chemnitz, Germany — ²Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstraße 400, 01328 Dresden, Germany — ³Laserinstitut Hochschule Mittweida, Schillerstraße 10, 09648 Mittweida, Germany — ⁴Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Chemnitz University of Technology, 09107 Chemnitz, Germany

Two modes of laser annealing, namely, Continuous Wave (CW) and Pulsed Wave (PW) mode, are used for modifying the magnetic properties of perpendicular magnetic anisotropy (PMA) multilayers in a controlled manner. For this we compare two types of samples - a PMA (Co/Pt)₁₀ multilayer and an antiferromagnetically interlayer exchange coupled PMA (Co/Pt)₄/Co/Ir/(Co/Pt)₅ multilayer. Room temperature hysteresis loops using polar MOKE magnetometry are measured for the different laser annealing modes. Thus, a relationship between the applied laser parameters and the magnetic properties is extracted, which provides an opportunity to alter magnetic properties of PMA multilayer systems locally with high spatial resolution on demand.

## MA 35.50 Thu 16:00 P4

Anisotropic spin dynamics in  $Mn_2Au/Ni_{80}Fe_{20}$  thin-film bilayers — •GUTENBERG KENDZO¹, HASSAN AL-HAMDO¹, VITALIY VASYUCHKA¹, PHILIPP PIRRO¹, YARYNA LYTVYNENKO², OLENA GOMONAY², MATHIAS KLÄUI², MARTIN JOURDAN², and MATHIAS WEILER¹ — ¹Fachbereich Physik and Landesforschungszentrum OPTIMAS, Technische Universität Kaiserslautern, Kaiserslautern, Germany — ²Institut für Physik, Johannes Gutenberg-Universität Mainz, Mainz, Germany

Ferromagnets and antiferromagnets host qualitatively different spin dynamics. At the ferromagnet/antiferromagnet interface we thus expect coupled spin dynamics of hybrid character. We experimentally investigate the anisotropic coupling of spin dynamics in antiferromagnetic/ferromagnetic ( $Mn_2Au/Ni_{80}Fe_{20}$ ) thin-film heterostructures by ferromagnetic resonance spectroscopy. To this end, we carried out measurements on two samples  $Mn_2Au(40nm)/Ni_{80}Fe_{20}(10nm; 7,5nm)$  as a function of the orientation of the static external magnetic field. For each orientation, the ferromagnetic resonance frequency at fixed magnetic field magnitude was measured. We find a pronounced anisotropy of the  $Ni_{80}Fe_{20}$  ferromagnetiz resonance. This finding is attributed to coupling of the  $Ni_{80}Fe_{20}$  magnetization to the  $Mn_2Au$  Néel vector in conjunction with the  $Mn_2Au$  crystalline anisotropy.

Funding by DFG via CRC/TRR 173 "Spin+X", projects A01, A05, B12 & B13 is gratefully acknowledged.

 $MA 35.51 \quad Thu \ 16:00 \quad P4$ Magnetic Anisotropies and Large Exchange Bias of Ultrathin Ni0.95Fe0.05/NiFeO Multilayers — Dimitrios Anyfantis¹, Camillo Ballani², Nikolaos Kanistras², Alexandros Barnasas¹, Georg Schmidt², •Evangelos Th. Papaioannou², and Panagiotis Poulopoulos¹ — ¹Department of Materials Science, University of Patras, 26504 Rio, Patras, Greece — ²Institute of Physics, Martin-Luther University Halle-Wittenberg, 06120 Halle, Germany

Magnetic anisotropy at metal/oxide interfaces has played a significant role in the development of technological applications in recording, spintronics, sensors and actuators over the years[1]. In this work we present a novel method to produce

high quality Ni(0.95)Fe(0.1)/NiFeO multilayers with the aid of the natural oxidization procedure and with the help of a single magnetron sputtering head [2]. Doping of Ni by only 5% Fe results in enhanced layering quality as X-ray reflectivity reveals. Due to magnetostatic anisotropy, the multilayers were found to be in-plane magnetized. Mild thermal annealing (T = 525 K) results in the enhancement of perpendicular magnetic anisotropy, mainly due to an increase in the uniaxial volume anisotropy term. Temperature-dependent hysteresis measurements between 4-400 K revealed considerable enhancement of coercivity and appearance of strong exchange bias effect.

## MA 35.52 Thu 16:00 P4

Additive Manufacturing of (Pr,Nd)-Fe-Cu-B Permanent Magnets using functionalized microparticles — •JIANING LIU¹, LUKAS SCHÄFER¹, HOLGER MERSCHROTH², JANA HARBIG², YING YANG³, ANNA ZIEFUSS³, MATTHIAS WEIGOLD², STEPHAN BARCIKOWSKI³, OLIVER GUTFLEISCH¹, and KONSTANTIN SKOKOv¹ — ¹Functional Materials, Technical University of Darmstadt, Germany — ²Alarich-Weiss-Str. 16 — ³Technical Chemistry I, University of Duisburg-Essen, Germany

Additive Manufacturing (AM) of permanent magnets is an upcoming and challenging task in material science and engineering. A microstructure with engineered grain boundaries and grain sizes necessary for high coercivity is not easily obtainable, especially when using Laser Powder Bed Fusion (L-PBF) to obtain fully dense magnets. In order to achieve the desired microstructure and hard magnetic properties after printing, we proposed Pr-Fe-Cu-B based alloy as a useful alloy system and compare this with its Nd-based counterpart. Our studies describe the Pr-Fe-Cu-B alloys and their annealing optimization for L-PBF. In order to achieve an improved flowability and refined microstructure, the grain boundary engineering with nanoparticles shows great potential. The nanoparticle functionalized Pr-Fe-Cu-B powder was being validated as a precursor for AM. During L-PBF, the hypothesis of heterogeneous nucleation induced by NP inoculums during resolidification is explored with the goal of grain refinement and realizing more uniaxial growth. We acknowledge the support of the Collaborative Research Centre/Transregio 270 HoMMage.

MA 35.53 Thu 16:00 P4

**In-situ rotation of sample in the magnet with a rotator** – •M. SAFIRI, P. Y. PORTNICHENKO, M. SIEGEL, and D. S. INOSOV – TU Dresden, Germany

Field-induced collective excitations in f-electron systems with multipolar order parameters were recently shown to exhibit significant anisotropy in field space even in structurally cubic systems, such as CeB6 [P. Y. Portnichenko et al., Phys. Rev. X 10, 021010 (2020)]. However, following such changes in the excitation spectrum in a neutron scattering experiment currently requires a tedious and time-consuming sample realignment for every field direction. To enable a much faster in-situ rotation of the sample inside a cryomagnet, we have designed and manufactured a compact piezo-driven rotator with a diameter of 32 mm that is compatible with cryomagnets used on the time-of-flight or triple-axis neutron spectrometers, up the maximum field of 10 T. This new piece of sample environment will allow us to change the sample orientation within 360° by rotating it precisely around the momentum transfer Q at low temperatures, which corresponds to a rotation of magnetic field in the vertical plane orthogonal to Q. This is supposed to add a new dimension to neutron-spectroscopy measurements, facilitating continuous scans vs. magnetic field angle that contain crucial information about magnetic anisotropy and other spin-orbit coupling effects.

MIASANS at the longitudinal neutron resonant spin echo spectrometer RESEDA — •JONATHAN LEINER^{1,2}, CHRISTIAN FRANZ^{1,2,3}, JOHANNA JOCHUM^{1,2}, and CHRISTIAN PFLEIDERER¹ — ¹Technical University of Munich, Garching, Germany — ²Heinz Maier-Leibnitz Zentrum (MLZ), Garching, Germany — ³JCNS at MLZ, FZ Jülich GmbH, Garching, Germany

The RESEDA (Resonant Spin-Echo for Diverse Applications) instrument has been optimized for neutron scattering measurements of quasi-elastic and inelastic processes over a wide parameter range. One spectrometer arm of RESEDA is configured for the MIEZE (Modulation of Intensity with Zero Effort) technique, where the measured signal is an oscillation in neutron intensity over time prepared by two precisely tuned radio-frequency (RF) flippers. With MIEZE, all of the spin-manipulations are performed before the beam reaches the sample, and thus the signal from sample scattering is not disrupted by any depolarizing conditions there (i.e. magnetic materials and fields). The MIEZE spectrometer is being further optimized for the requirements of small-angle neutron scattering (MIASANS), a versatile combination of the spatial and dynamical resolving power of both techniques. We present the current status of (i) newly installed superconducting solenoids as part of the RF flippers to significantly extend the dynamic range and (ii) development and installation of a new detector on a translation stage within a new larger SANS-type vacuum vessel for flexibility with angular coverage and resolution.

An Efficient Magnetic Hyperthermia Setup for Controlled Nanoparticle Heating — •DANIEL KUCKLA, JULIA-SARITA BRAND, VINZENZ JÜTTNER, and CORNELIA MONZEL — Heinrich-Heine-Univerity,Düsseldorf,Germany

Magnetic hyperthermia is a promising approach to enable a remote and localized heating of magnetic nanoparticles (MNPs) with various applications in condensed matter or biomedical physics. The MNPs may be positioned precisely in space and act as hot spots by increasing the temperature in the nanometer vicinity of the particle while causing minimal effects on the macroscopic environment. The heat dissipation arises from energy delivered to the nanoparticle in the form of an alternating magnetic field with ~100kHz frequency and 50mT magnetic flux density. A particular challenge is to realize an efficient magnetic hyperthermia setup and to image the localized heating. Here, we present such setup consisting of an electromagnet in a resonance circuit and exhibiting a small form factor to be implemented under a microscope. We provide a profound characterization of the different components of this setup - the electromagnet and electric circuit, essential improvements to reduce power loss arising from electromagnetic induction as well as strategies to directly record thermal changes. We demonstrate efficient heating/cooling cycles using well-defined MNP samples in suspension and create MNP lithographically structured substrates. Our setup may be used to create localized hot spots in condensed matter samples, to create thermofunctional switches or to study heat-sensitive molecules in biophysics, among other examples.

Investigation of de Haas-van Alphen oscillations under temperature modulation in Bi — •MICHELLE HOLLRICHER, CHRISTIAN PFLEIDERER, and MARC A. WILDE — Physik-Department, Technical University of Munich, D-85748 Garching, Germany

The properties of Bi have become the drosophila of studies of the electronic structure and the Fermi surface of metals [1-4]. An inherent constraint of presentday detection techniques of quantum oscillations concerns the separation of signal components associated with large differences of the effective charge carrier masses. We report the development of a detection technique for measurements of the de Haas-van Alphen (dHvA) effect by means of an inductive signal pickup that is driven by temperature oscillations of the sample [1]. Resulting in an effective convolution of the oscillatory signal components with the derivative of the effective charge carrier mass with respect to temperature, our setup permits to discriminate elegantly light from heavy masses, and allows in-situ determination of the charge carrier effective masses. We have revisited the dHvA effect in Bi, focusing on the nature and character of the electron pockets.

MA 35.57 Thu 16:00 P4

**Visualization of Exchange Spin Coupling Constants** — •LAWRENCE RYBAKOWSKI^{1,2}, TORBEN STEENBOCK², and CARMEN HERRMANN¹ — ¹Institut for Inorganic and Applied Chemistry, Luruper Chaussee 149, Hamburg, Germany — ²Institut for Physical Chemisrtry, Luruper Chaussee 149, Hamburg, Germany

Most current methods for calculating the magnetic exchange interactions can calculate coupling constants for two and multi-spin systems, but a single number, the exchange spin coupling constant, is often poorly informative about the origins of the coupling. With our method, footing on nonrelativistic first-principle electronic structure calculations, the coupling constant can be decomposed into atomic and basis function contributions, which allows to plot a three-dimensional density distribution of the coupling constant weighted by the atomic orbital basis contributions and thus to analyze the influences of ligands and co-ordinations on the coupling behavior of different magnetic ions. In addition, exchange–correlation functional dependencies and influences of structure distortions on the strength and character of the exchange coupling constant can be investigated.

We can show that in complex compounds with competing exchange pathways, individual ligand classes can be associated with characteristic contributions to the total coupling constant. Furthermore, the inclusion and enhancement of exact exchange in the exchange-correlation functional induces an alternating contribution of neighboring atomic orbitals, having a direct impact on the calculated exchange coupling constants.

## MA 35.58 Thu 16:00 P4

A Sacrificial Magnet System for Flux Dependent Surface Science Studies — •DANYANG LIU¹, JENS OPPLIGER¹, ALEŠ CAHLÍK¹, CATHERINE WITTEVEEN^{1,2}, FABIAN O. VON ROHR², and FABIAN DONAT NATTERER¹ — ¹Department of Physics, University of Zurich, Winterthurerstrasse 190, CH-8057 Zurich, Switzerland — ²Department of Quantum Matter Physics, University of Geneva, 24 Quai Ernest-Ansermet, CH-1211 Geneva, Switzerland Here we describe the design and characterization of a NbFeB permanent magnet system that can be retrofitted to the sample holders of existing STM. Our design produces a magnetic field of up to 400 mT that is compatible with high temperature sample cleaning routines above the Curie point of the magnet frequently used in UHV experiments. We characterize the flux density using superconducting vortices in NbSe2 and BSCCO and demonstrate the life-cycle of the magnet from sample preparation to characterization. Our magnet is an accessible way to flux-dependent surface science, ranging from vortices in high-temperature superconductors to STM-enabled electron spin resonance.

## MA 35.59 Thu 16:00 P4

**DC-Mode Background Subtraction for the MPMS3 SQUID Magnetometer by Quantum Design** — •BÖRGE MEHLHORN¹, ANJA WOLTER¹, and BERND BÜCHNER^{1,2} — ¹Leibniz IFW Dresden, D-01069 Dresden, Germany — ²Institute for Solid State and Materials Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, D-01062 Dresden, Germany

Due to vibrating-sample SQUID magnetometry becoming more common in magnetization studies, the software satisfying the needs of slow linear DC mode became rather sparse. As one example raw-voltage background subtraction software is no longer supplied with the instruments, but is needed, whenever the background signal becomes large compared to the intrinsic magnetization signal of the sample.

As a response a handful of scientists began developing their own solutions. Most commonly known is the open source software published by M. J. Coak et al.¹ at the universities of Warwick and Cambridge free for academic use and based on *MathWorks MATLAB*.

The solution presented here is an independent work published as free (as in freedom) open source software. It is founded on the ecosystem of scientific software in the Python programming language. Therefore, it does not only allow frictionless future contributions by the scientific community, but also makes use of the countless human hours invested in that open source ecosystem in the past.

As an interesting scientific example the software will be demonstrated on a low-moment small-size 2D van-der-Waals crystal mounted on a horizontal rotator.

## MA 35.60 Thu 16:00 P4

Mössbauer study of anisotropic magnetic nanoparticle systems — •JURI KOPP¹, JOACHIM LANDERS¹, SOMA SALAMON¹, ROBERT MÜLLER², SARAH ESSIG³, SILKE BEHRENS³, and HEIKO WENDE¹ — ¹Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen — ²Leibniz Institute of Photonic Technology — ³Institute of Catalysis Research and Technology (IKFT), Karlsruhe Institute of Technology

Liquid crystalline (LC) systems have a wide range of applications as they combine the properties of a liquid and orientability in electric fields. In turn, if magnetic nanoparticles are added to such systems, we obtain magneto-responsive liquid crystals. Barium ferrite particles can be considered as possible candidates for use in such magneto-responsive LC systems. Accordingly, this work is geared towards the study of doped and undoped anisotropic barium ferrite nanoparticles using magnetic field and temperature dependent Mössbauer spectroscopy. In pure barium ferrite samples, the five different sublattice positions could be resolved and reorientation in magnetic fields was observed. In the doped samples an asymmetry in the Mössbauer lines as well as partial overlap of the individual sublattices' contributions was visible, which points towards altered environments of the iron atoms. In particular, the 2b site with its relatively high quadrupole level shift provides information about the magnetic orientation relative to the crystal structure. These results enable us to analyze orientation phenomena in future barium ferrite based magnetic liquid crystalline systems.

#### MA 35.61 Thu 16:00 P4

**Fe3N nanoparticles as alternative material for magnetic fluid hyperthermia** — •YEVHEN ABLETS, IMANTS DIRBA, and OLIVER GUTFLEISCH — Technical University of Darmstadt, Darmstadt, Germany

Magnetic fluid hyperthermia (MFH) is one of the modern individual and adjuvant methods for cancer treatment. Usually, iron oxide nanoparticles (IONP) are used for this purpose due to their chemical stability, non-toxicity, well-established and cost-effective production, well-known metabolism of iron in the human body. However, the heating performance of IONP is limited due to moderate values of saturation magnetization and magnetocrystalline anisotropy. Using particles with enhanced magnetic properties will enable more effective tumor treatment, and within AC magnetic field amplitude (H) and frequency (f) conditions of the so-called Brezovich-Atkinson criteria (H*f =  $5x10^8 \text{ A/m*s}$ ), which leads to less discomfort for the patients.

In this work, a new synthesis method of crystalline Fe3N nanoparticles is demonstrated. Metal-organic compound iron pentacarbonyl is thermally decomposed in the presence of polyisobutylene succinimide under continuous ammonia flow. Varying gas flow concentrations and type of surfactant (oleic acid, oleylamine) Fe3O4 and Fe homogeneous spherical particles were obtained with an average diameter of 14 nm. Fe3N particles show better magnetic properties and heating performance than Fe3O4 and better chemical stability compared to Fe particles. First stage biocompatible studies are ongoing.

## MA 35.62 Thu 16:00 P4

**Origin of magnetic loss and noise in magnetoelastic magnetic field sensors** — •ELIZAVETA GOLUBEVA¹, BENJAMIN SPETZLER², FRANZ FAUPEL¹, and JEFFREY McCORD¹ — ¹Kiel University, Kiel, Germany — ²Technical University Ilmenau, Ilmenau, Germany

Magnetoelastic magnetic field sensors based on the delta-E effect have proven their high potential for detecting small-amplitude and low-frequency magnetic fields. The concept of such sensors evolves from the dependency of the stiffness tensor on the applied magnetic field and can be utilized in various device configurations, including surface acoustic wave sensors and composite cantilevers. Previous research has shown that the main factor limiting the performance of such sensors comes from the sensor's intrinsic noise. However, the challenge of quantifying different noise sources has not been resolved yet. In this work, we suggest a general methodology for estimating the magnetic noise in magnetoelectric delta-E-effect sensors. Here, we present a complete physical device model and experimental analysis at the example of a millimeter-sized cantilever sensor. In this case, the magnetic noise associated with the hysteresis loss dominates the sensor performance and determines a minimal detectable field for the sensor of about 300 pT/Hz^1/2 @ 10 Hz. The described principles can also be applied to other magnetoelastic magnetic field sensors.

This work was funded by the German Research Foundation (DFG) through the Collaborative Research Centre CRC 1261 "Magnetoelectric Sensors - From Composite Materials to Biomagnetic Diagnostics" and the Carl-Zeiss Foundation via the Project MemWerk.

Giant and Tunneling Magnetic Resistance sensor elements based on Focused Ion Beam methods and chemical synthesis — •LAILA BONDZIO, BJÖRN BÜKER, NADINE FOKIN, PIERRE PIEL, and ANDREAS HÜTTEN — University of Bielefeld, Germany

Common GMR and TMR sensors are based on sputter deposited multilayer stacks. Structuring these thin films using lithography can be expensive and time consuming, thus alternative ways of structuring are explored such as nanoparticle synthesis or high-precision milling via ion beam.

A dual-beam Focused Ion Beam (FIB) microscope can be used for Focused Electron Beam Induced Deposition (FEBID) to deposit small Co dots as nanoparticles, which are afterwards covered with a slightly conductive material to fill the gaps, so that a granular highly ordered, 2 dimensional GMR array is created in a bottom-up method. Alternatively, the ion beam can be used for a top-down approach by milling grid-like structures into a deposited magnetic layer to create rectangular particles. In spite of successful proof of concept measurements, higher particle densities are needed to produce a sufficiently high effect for sensor applications.

With chemical nanoparticle synthesis arrays of randomly arranged nanoparticles can be created representing the ferromagnetic layers. The organic ligand shells of e.g. oelic acid create the isolated TMR barrier between the particles. Measurements on these otherwise untreated random, 3 dimensional particle arrays have shown a broad TMR curve for high fields.

Two-photon lithography as a fabrication tool for 3D curved magnetic thin film arrays — •CHRISTIAN JANZEN¹, SAPIDA AKHUNDZADA¹, ARNE Vereijken¹, Michał Matczak², Piotr Kuświk², Arno Ehresmann¹, and MICHAEL VOGEL¹ - ¹Institute of Physics and Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Heinrich-Plett-Str. 40, 34132 Kassel, DE — ²Institute of Molecular Physics, Polish Academy of Science, ul. Mariana Smoluchowskiego 17 60-179 Poznań, PL Fabrication of 3D magnetic nanostructures of complex geometry is a challenging task not easily achievable by standard lithography techniques. Two-photon lithography exploits the non-linear absorption properties of the utilized resist to initialize its polymerization at the volume of highest intensity, called voxel. By manipulating the three-dimensional position of the voxel, it is possible to prepare microstructures with varying Gaussian curvature (e.g., torus), being used as templates for the deposition of magnetic thin films. For preparing high-quality thin films, minimal surface roughness is required. Hence, the latter was investigated by atomic force microscopy depending on process parameters. By spatially separating the curved template from the substrate surface with an additional spacer, the magnetostatic interaction between the magnetic cap and the flat full film becomes negligible. Individual template structures are written with variable spacing to their nearest neighbors, enabling the magnetostatic interaction via strayfields as a tunable parameter of the interaction within the magnetic arrav.

BORNSCHEUER¹, ROBERT BLICK², SWADHIN MANDAL⁴, ALEXANDER PAARMANN⁵, and MARKUS MÜNZENBERG¹ — ¹University of Greifswald, Germany — ²Universität Hamburg, Germany — ³VŠB-Technical University of Ostrava, Czech Republic — ⁴Indian Institute of Science Education and Research Kolkata, India — ⁵Fritz Haber Institute of the Max Planck Society, Berlin, Germany

3D 2-Photon-Lithography, originally developed for 3D photonic crystals, opens a wide range of new possible applications in many fields, e.g. life sciences, microoptics and mechanics. We will present our recent applications of 3D 2-Photonlithography and show 3D evaporation masks for in-situ device fabrication using different deposition angles, infra-red laser light focusing lenses directly fabricated on optical fibers, tunnel structures for guiding growth of neurons [1], pillars for investigation of cell mechanics and master-mold fabrication for Polydimethylsiloxane (PDMS) micro-fluidic channels. Based on our experience we will discuss possible applications in magnetism. [1] C. Fendler et al., Adv. Biosys. 5 (2019) doi: 10.1002/adbi.201970054

## MA 35.66 Thu 16:00 P4

Monte-Carlo study of commensurate-incommensurate phase transiton of YBaCuFeO5 — •MUKESH SHARMA and TULIKA MAITRA — Indian Institute of Technology Roorkee, Roorkee Uttrakhand, India

Type-II multiferroic materials where ferroelectricity is driven by magnetic order are highly sought after these days. Intense research is being carried out to increase the transition temperature of multiferroicity to near room temperature. YBaCuFeO5(YBCFO) is one such rare material where it has been reported that incommensurate spiral magnetic ordering is stable upto temperatures higher than room temperature even though the presence of ferroelectricity is still debated. Motivated by the recent experimental evidence of tuning commensurateincommensurate magnetic phase transition temperature in this system via Fe-Cu disorder, we have studied the role of anisotropic exchange and Fe-Cu site disorder on this transition. Using various exchange interactions obtained from density functional theory, our Monte-Carlo simulations show that both anisotropic exchange and site disorder play significant roles in giving rise to spiral magnetic ordering at lower temperatures.

## MA 35.67 Thu 16:00 P4

Formation, effects and suppression of M-Type hexaferrite in barium titanatespinell ferrite multiferroic composites — •DANIIL LEWIN, SOFIA SHAMSUL-BAHRIN, VLADIMIR V. SHVARTSMAN, and DORU C. LUPASCU — Institute for Materials Science and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Germany

The combination of a ferroelectric barium titanate-based perovskite with a magnetic ferrite is a common approach for creating multiferroic composites. In some cases, however, a hexagonal phase, usually identified as barium ferrite (BaFe12O19, BaM), appears during sintering. As a noticeable difference exists in the optimal sintering temperature for both phases, it may become a challenge to create an electrically well insulating ceramic. Confronted with strong formation of BaM at high sintering temperatures (1270 °C), we investigate efficient ways to suppress its formation for combinations of barium titanate with cobalt ferrite or nickel ferrite. We show that by using a reducing atmosphere, the formation of BaM is heavily suppressed, while addition of extra cobalt oxide or nickel oxide during the synthesis can further improve the magnetoelectric coefficient while minimizing the remaining amount of BaM. A clear correlation between the amount of BaM and the polarizability and magnetoelectric coupling of the composites is established.

## MA 35.68 Thu 16:00 P4

**Transport properties of systematically disordered Cr**₂**AlC films** — •JOAO S. CABACO¹, ULRICH KENTSCH¹, JURGEN LINDNER¹, JURGEN FASSBENDER¹, CHRISTOPH LEYENS^{2,3}, RANTEJ BALI¹, and RICHARD BOUCHER² — ¹Institute of Ion Beam Physics and Materials Research, Helmholz Zentrum, Dresden-Rossendorf, Germany — ²Institute for Materials Science, TU Dresden, Germany — ³Fraunhofer Institute for Material and Beam Technology IWS, Dresden, Germany.

Nano-lamellar composite materials, known as MAX-phases, can possess a combination of ceramic and metallic properties. A prototype compound is  $Cr_2AIC$ , formed from a unit cell of  $Cr_2C$  sandwiched between atomic planes of Al.

In this work we study the modifications to the structural, transport and magnetic behavior of 500 nm thick Cr₂AlC after irradiation with Co⁺ ions, and Ar⁺ noble gas ions as control. X-ray diffraction shows that ion-irradiation induces a suppression of the 0002 reflection, indicating a deterioration of the crystal structure. Increasing the ion fluence leads to an increase of the saturation magnetization at 1.5 K, whereby both Ar⁺ and Co⁺ cause an increased magnetization, respectively to 150 kA.m⁻¹ and 190 kA.m⁻¹, for the highest fluences used. At Co⁺ fluences of  $5\times10^{13}$  ions.cm⁻² the magnetoresistance (MR) shows a 2-order of magnitude increase, up to 3% (10 T) at 100 K. A similar effect also occurs for  $5\times10^{12}$  ions.cm⁻² Ar⁺ irradiated films, however, with a smaller MR-increase. The disordering of MAX phase films may reveal interesting spin-related transport phenomena.

A Floquet Green's Function technique to study ESR spectra — •JOSE REINA GALVEZ — Center for Quantum Nanoscience, Ewha University, Seoul, Republic of Korea

This poster presents a theoretical framework to describe experiments directed to controlling single-atom spin dynamics by electrical means using a scanning tunneling microscope. The model consists of a quantum impurity connected to electrodes while an electrical time-dependent bias is applied. The quantum impurity consists of a localized electronic state, with a Coulomb repulsion U term, connected magnetically to a localized spin S.

Applying the Heisenberg picture, in the limit of weak coupling between the impurity and the electrodes, Born-Markov approximation, a quantum master equation can be obtained. The rates in this equation are derived by the non-equilibrium Green's function formalism. The Floquet theorem is used to transform the differential equation into algebraic one.

We show results in two cases. The first case is just a single atomic orbital subjected to a time-dependent electric field, and the second case consists of a single atomic orbital coupled to a second spin-1/2. This first case reproduces the main experimental features Ti atoms on MgO/Ag (100) but in a sequential tunneling regime and for different U values. The second case directly addresses the experiments on two Ti atoms.

These calculations permit us to explore the effect of different parameters to reproduce experimental fingerprints of the ESR technique.

MA 35.70 Thu 16:00 P4

Characterization of thin MgO layers grown on Fe(100) and Fe(100)- $p(1x1)O - \cdot$ Mira Arndt, David Janas, Giovanni Zamborlini, and Mirko Cinchetti — Department of Physics, TU Dortmund University, Otto-Hahn-Straße 4, 44227 Dortmund, Germany

In the field of spintronics, thin magnesium oxide (MgO) interlayers play a major role as dielectric tunneling barriers in magnetic tunnel junctions. As the most prominent example, MgO enhances the tunneling magnetoresistance of Fe/MgO/Fe heterolayers. Crucially, exposing Fe to oxygen results in rapid oxidation of the surface, which in turn highly influences the MgO growth process and makes it less reproducible, eventually, changing the device performances. This problem can be overcome by controlled passivation of the Fe surface with oxygen prior to MgO deposition. In this contribution we present the characterization of the growth of MgO layers with variable thickness on the clean Fe(100) and the passivated Fe(100)-p(1x1)O surface. The studies have been performed by employing various surface sensitive techniques, such as Auger electron spectroscopy, low energy electron diffraction (LEED), reflective medium energy electron diffraction (MEED), and photoelectron spectroscopy (PES). Our data show that, despite evident differences in the growth behavior, the electronic properties of the two interfaces are very similar.

#### MA 35.71 Thu 16:00 P4

Correlation of Magnetism and Disordered Shiba bands in Fe Monolayer Islands on Nb(110) — JULIA J. GOEDECKE¹, LUCAS SCHNEIDER¹, YINGQIAO MA³, •KHAI TON THAT¹, DONGFEI WANG², JENS WIEBE¹, and ROLAND WIESENDANGER¹ — ¹Department of Physics - University of Hamburg, Hamburg, Germany — ²CIC Nanogune, Donostia - San Sebastian, Spain — ³Institute of Chemistry - Chinese Academy of Sciences, Beijing, China

Two-dimensional (2D) magnet-superconductor hybrid systems are intensively studied due to their potential for realizing 2D topological superconductors with Majorana edge modes. It is theoretically predicted that this quantum state can occur in spin-orbit coupled ferromagnetic or skyrmionic 2D layers in proximity to an s-wave superconductor. However, recent examples suggest, that the requirements for topological superconductivity are complicated by the multi-orbital nature of the magnetic components and disorder effects.

Here, we investigate Fe monolayer islands grown on a surface of the s-wave superconductor with the largest gap of all elemental superconductors, Nb, with respect to magnetism and superconductivity using spin-resolved scanning tunneling spectrosopy. We find three types of Fe monolayer islands which significantly differ by their reconstruction, by the magnetism and the disordered Shiba bands, without any signs of topological gaps or edge states.

Our work illustrates, that a reconstructed growth mode of magnetic layers on superconducting surfaces is detrimental for the formation of 2D topological superconductivity.

#### MA 35.72 Thu 16:00 P4

In the Ruddlesden-Popper perovskite series,  $Sr_{n+1}Ru_nO_{3n+1}$ , intense experimental and theoretical efforts have been dedicated to unravel the nature of unconventional superconductivity in single-layer  $Sr_2RuO_4(n = 1)$  as well as a putative electronic nematic phase masking the quantum critical endpoint in the double-

Thursday

layer itinerant metamagnet  $Sr_3Ru_2O_7$  (n = 2). We report an experimental study of the zero temperature ferromagnetic-to-paramagnetic transition under pressures up to 20GPa in high quality single crystals of the infinite layer itinerant ferromagnet  $SrRuO_3(n = \infty)$ . Electrical transport measurements in Bridgman anvil high pressure cells, as well as neutron depolarization measurements in diamond anvil cells were performed on  $SrRuO_3$ . Our study aims to investigate quantum criticality in  $SrRuO_3$  and reconcile the properties of  $Sr_3Ru_2O_7$  and  $Sr_2RuO_4$  with the generic temperature-pressure-magnetic field phase diagram of itinerant ferromagnets.

## MA 35.73 Thu 16:00 P4

**Magneto-transport in (Bi,Sb)Te nanostructures** – •TITOUAN CHARVIN^{1,2}, FE-LIX HANSEN², SILKE HAMPEL², JOSEPH DUFOULEUR², BERND BÜCHNER^{2,3}, and ROMAIN GIRAUD^{1,2} – ¹Université Grenoble Alpes, CNRS, CEA, IRIG/Spintec, F-38000 Grenoble, France – ²Leibniz Institute for Solid State and Materials Research Dresden, Helmholtzstrasse 20, D-01069 Dresden, Germany – ³Institut für Festkörperphysik, TU Dresden, D-01062 Dresden, Germany

The investigation of Dirac fermions surface states in binary 3D topological insulators, such as  $Bi_2Te_3$  or  $Sb_2Te_3$ , is limited by their large bulk-carrier densities. This shift of the Fermi level, away from the bulk band gap, is caused by a high density of point defects, acting as donors or acceptors. With the aim to achieve a bulk-charge compensation, we grew  $(Bi_xSb_{1-x})_2Te_3$  nanostructures by chemical vapor transport, with different stoichiometries, in order to vary both the band structure and the relative contributions of different types of point defects. From magneto-transport measurements, we infer the bulk and surface carrier densities and mobilities. Although the bulk contribution to the conductivity can be reduced for some stoichiometries, all samples show a metallic-like behavior of their conductivities, with coexisting bulk and surface states contributions.

## MA 35.74 Thu 16:00 P4

Electrical and thermal hall transport in compensated topological insulator  $BiSbTeSe_2 - \bullet$ ROHIT SHARMA, MAHASWETA BAGCHI, OLIVER BREUNIG, YOICHI ANDO, and THOMAS LORENZ - II. Physikalisches Institut, Universität zu Köln, Zülpicher Straße 77, D-50937 Köln, Germany

The existence of puddles in BiSbTeSe₂ at low temperature (T < 50K) has been detected using optical conductivity measurements, where DC electrical conductivity data shows an insulating behaviour, but above 50K, optical and transport results agree well with each other due to evaporation of charge puddles with increasing T[1]. By comparing thermal conductivity  $\kappa_{xx}$  and thermal hall effect  $\kappa_{xy}$  data with the electrical counterparts ( $\sigma_{xx} & \sigma_{xy}$ ), we study a possible influence of charge puddles on thermal transport. Electrical hall conductivity ( $\sigma_{xy}$ ) shows hole like (p-type) behaviour at elevated T, which changes to multi-band behaviour at low T. From the electrical transport data electronic contribution to thermal transport  $\kappa_e$  was calculated by using Wiedemann-Franz law and then compared with the measured thermal transport data where it was found that both  $\kappa_{xx}$  and  $\kappa_{xy}$  shows phonon dominated behaviour. When compared  $\kappa_{xy}$  and  $\kappa_e$ , data matches well with each other above 50K. In contrast, below 50K  $\kappa_{xy}$  shows a sign change and evolves to a large thermal hall signal, whereas  $\kappa_e$  has

no sign change and smoothly decreases. Possible reason for large thermal hall effect in  $BiSbTeSe_2$  will be discussed.

Funded by the DFG via CRC 1238 Projects A04 and B01 [1] N. Borgwardt et al. Phys. Rev. B. 93, 245149 (2016)

MA 35.75 Thu 16:00 P4

# **Topology and DC quantum transport in Floquet-driven systems** — •Aya Abouelela and Johannes Kroha — University of Bonn

Recently, several works have investigated the topological properties emerging in periodically driven systems, where a periodic drive is used to engineer the band structure such as to support topologically stabilized edge modes. The topological phases of periodically driven systems have been classified across all dimensions in the periodic table of Floquet topological insulators. The Floquet multiplicity of bands implies the emergence of anomalous edge states which cross bulk gaps that do not occur in static systems. Here, we present our studies on the non-interacting topological Qi-Wu-Zhang (QWZ) model under the influence of a periodic drive, and analyze its drive-induced edge modes, using the Floquet formalism. Investigating two regimes of the driving frequency , higher or lower than the static bandwidth, the latter is shown to support anomalous edge modes. For the experimental detection of edge states, we calculate the dI/dV spectra at non-zero DC bias voltage V, using the Keldysh-Floquet formalism. We predict quantized conductance plateaus when the transport voltage is within a normal gap (V centered around V = 0, normal edge mode) or within an anomalous gap (V centered around  $V = \pm \Omega/2$ , anomalous edge mode). We also perfom a spatially resolved computation of the chiral tranmission channels of the finitesize system with finite bias applied, showing that the transport is along an edge and that it is spatially modulated corresponding to the wave number  $\pi$  of the (anomalous) edge mode.

## MA 35.76 Thu 16:00 P4

Effects of the chiral anomaly on charge and heat transport in Weyl semimetals — •ALINA WENZEL^{1,2}, ANNIKA JOHANSSON¹, and INGRID MERTIG² — ¹Max Planck Institute of Microstructure Physics, Halle, Germany — ²Martin Luther University Halle-Wittenberg, Halle, Germany

The chiral anomaly in Weyl semimetals, which corresponds to nonconservation of chiral charge if a magnetic field is applied nonorthogonal to an electric field or a temperature gradient, leads to unconventional contributions to longitudinal charge and thermal transport, strongly depending on the external magnetic field [1-3]. We calculate the thermoelectric transport properties for Weyl systems by solving the semiclassical Boltzmann equation including a temperature gradient. To analytically calculate the transport coefficients the Sommerfeld expansion is used. The isotropic Weyl Hamiltonian [2] and an anisotropic, more realistic model to describe pairs of Weyl points [4,5] are discussed. Using the latter, Weyl semimetals with either broken time reversal or inversion symmetry are simulated and the influence of symmetry on the electric and thermal transport properties is discussed.

Emergence of zero-field non-synthetic single and catenated antiferromagnetic skyrmions in thin films — •AMAL ALDARAWSHEH^{1,2}, IMARA LIMA FERNANDES¹, SASCHA BRINKER¹, MORITZ SALLERMANN¹, MUAYAD ABUSAA³, STEFAN BLÜGEL¹, and SAMIR LOUNIS^{1,2} — ¹Peter Grünberg Institute and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, D-52425 Jülich, Germany — ²Faculty of Physics, University of Duisburg-Essen and CENIDE, 47053 Duisburg, Germany — ³Department of Physics, Arab American University, Jenin, Palestine

Antiferromagnetic (AFM) skyrmions are envisioned as ideal topological magnetic bits in future information technologies. In contrast to ferromagnetic (FM) skyrmions, they are immune to the skyrmion Hall effect, might offer potential terahertz dynamics [1] while being insensitive to external magnetic. Although observed in synthetic AFM structures [2], their realization in non-synthetic AFM films has been elusive. Here[3], we unveil their presence in a row-wise AFM Cr film deposited on PdFe bilayer grown on fcc Ir(111) surface. Using first-principles, we demonstrate the emergence of single and catenated AFM skyrmions, which can coexist with the rich inhomogeneous exchange field, including that of FM skyrmions, hosted by PdFe. Besides the identification of an ideal platform of materials for intrinsic AFM skyrmions, we anticipate the uncovered solitons to be promising building blocks in AFM spintronics. - Work funded by (BMBF-01DH16027) [1] Gomonay et al., Nat. **Chiral standing spin waves in 3D skyrmion lattice** • ANDRII SAVCHENKO^{1,2}, VLADYSLAV KUCHKIN¹, FILIPP RYBAKOV^{3,4}, STEFAN BLÜGEL¹, and NIKOLAI KISELEV¹ — ¹Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, D-52425 Jülich, Germany — ²Donetsk Institute for Physics and Engineering, National Academy of Sciences of Ukraine, 03028 Kyiv, Ukraine — ³Uppsala University, SE-75120 Uppsala, Sweden — ⁴KTH Royal Institute of Technology, SE-10691 Stockholm, Sweden

The resonance excitations of the three-dimensional skyrmions lattice in the finite thickness plate of an isotropic chiral magnet were studied using spin dynamics simulations. We calculated the absorption spectra and resonance mode profile configurations for the cases of in-plane and out-of-plane excitations. These results differ from those predicted by the two-dimensional model and the model of the unconfined bulk crystal. In the case of in-plane excitation, absorption spectra dependencies on film thickness have the periodic zones with fading intensity. This effect can be explained by the formation of chiral standing spin waves, which, contrary to conventional standing spin waves, are characterized by the helical profile of dynamic magnetization of fixed chirality defined by the Dzyaloshinskii-Moriya interaction [1]. The chiral standing spin waves are localized in the inter-skyrmion area or the skyrmion core. Under out-of-plane excitation, the absorption spectrum also demonstrates the appearance of standing spin waves, which are localized in the skyrmion shell. 1. A.S. Savchenko et al, arXiv:2205.05466

Generalization of the collective variables approach for skyrmion strings. — •VOLODYMYR KRAVCHUK^{1,2} and MARKUS GARST¹ — ¹Karlsruhe Institute of Technology, Germany. — ²Bogolyubov Institute for Theoretical Physics, Kyiv, Ukraine

In a bulk saturated chiral magnet, the skyrmion core penetrates the ferromagnet volume forming a string-like object [1]. Here we describe the small-amplitude dynamics of the string, applying the generalized collective variable approach. For the collective variables, we use the coordinate- and time-dependent string position defined as the first moment of topological charge calculated for the continuously stacked horizontal cross-sections perpendicular to the applied magnetic field. The simplest "plane-wave" solution corresponds to the helix-shaped deformation of the string. In a nonlinear regime, this solution is unstable due to the Lighthill criterion, that results in a self-modulation of the wave. Using a multiscale analysis both in space and time, we show that this modulation is captured by a non-linear Schroedinger equation of focusing type. Two classes of non-linear periodic waves of skyrmion string (so-called dc- and cn-waves) are analytically predicted and numerically verified. The separatrix soliton solution just corresponds to the solitary wave found previously [1]. The developed approach is generalized for the case of arbitrary meaning of the collective variables. The latter enables us to describe the string excitations of various symmetries, e.g. breathing and elliptical modes in a nonlinear regime.

## MA 37.4 Fri 10:15 H37

Fermi-surface origin of helical single Q-state and skyrmion lattice in centrosymmetric Gd compounds — •JUBA BOUAZIZ¹, EDUARDO MENDIVE-TAPIA¹, STEFAN BLÜGEL¹, and JULIE STAUNTON² — ¹Forschungszentrum Jülich, Germany — ²University of Warwick, Coventry CV4 7AL, United Kingdom We show from first principles that cylindrical structures within the Fermi surface are the origin of the single-Q helical state in the GdRu₂Si₂ and Gd₂PdSi₃ intermetallic compounds. The geometry of the Fermi surface nesting describes the strength and sign of the underlying pairwise Ruderman-Kittel-Kasuya-Yosida interactions between the Gd moments as the main mechanism. These interactions are quasi-two-dimensional, isotropic within the Gd layers, and provide a transition temperature and helix period in very good agreement with experiment. Using atomistic spin-dynamical simulations, we investigate the effects of magnetic anisotropy and construct a general magnetic phase diagram that explains the stabilization of the 2Q-skyrmion lattice observed in experiment with applied magnetic fields.

**Non-Abelian Vortices in Magnets** — •FILIPP RYBAKOV¹ and OLLE ERIKSSON^{1,2} —  1 Uppsala University, Sweden —  2 Örebro University, Sweden

The non-Abelian (non-commutative) topological states in ordered media may exhibit interesting physics emerging from purely topological arguments [1].

Here we show that non-Abelian vortices also can exist in magnets [2]. We give a topological classification of these vortices and reveal their connection with Abelian topological structures, such as usual vortices, merons, skyrmions. We analyze the potential of non-Abelian magnetic vortices for memory devices and emphasize their advantage, since they provide topological protection of all information, rather than individual bits, as in Abelian cases.

MA 37.6 Fri 10:45 H37

**Thermal properties of magnetic skyrmions** — •BALÁZS NAGYFALUSI¹, LÁSZLÓ UDVARDI^{2,3}, and LÁSZLÓ SZUNYOGH^{2,3} — ¹Wigner Research Center for Physics, Institute for Solid State Physics and Optics, Budapest, Hungary — ²Budapest University of Technology and Economics, Budapest Hungary — ³MTA-BME Condensed Matter Research Group, Budapest, Hungary

We have recently implemented metadynamics in Monte Carlo simulation code¹, which has been modified to use the topological charge Q of magnetic skyrmions as collective variable. The free energy can thus be determined as a function of Q and its equilibrium value can be explored as a function of temperature. The knowledge of the free energy F(Q; T) also permits to evaluate the chemical potential  $\mu$  of the skyrmions.

We investigated the thermal evolution of magnetic skyrmions in a Pt₉₅Ir₅/Fe bilayer on Pd(111) and an FePd bilayer on Ir(111) substrate in the presence of a normal-to-plane external magnetic field. The equilibrium number of skyrmions and the phase boundaries are in good agreement with previous studies^{2,3}. For the former system we found that *Q* has a maximum around 60 K and below this temperature this number drops rapidly, while for the later system it freezes in as the skyrmion lattice is a ground state of the system. The slope of  $\mu(T)$  also distinguishes the different ground states of the two system.

MA 37.7 Fri 11:00 H37

**Constructing coarse-grained skyrmion potentials from experimental data with Iterative Boltzmann Inversion** — •JAN ROTHÖRL, YUQING GE, MAARTEN A. BREMS, NICO KERBER, RAPHAEL GRUBER, FABIAN KAMMERBAUER, TAKAAKI DOHI, MATHIAS KLÄUI, and PETER VIRNAU — Institut für Physik, Johannes Gutenberg-Universität, Staudinger Weg 9, D-55099 Mainz, Germany

In an effort to understand skyrmion behavior like skyrmion lattice formation [1] or commensurability effects [2], skyrmions are often described as 2D quasi particles on a coarse-grained level evolving according to the Thiele equation. In particular, the interaction potentials are the key missing parameters for predictive modeling of experiments. We apply the Iterative Boltzmann Inversion technique commonly used in soft matter simulations to construct potentials for skyrmionskyrmion and skyrmion-magnetic material boundary interactions from a single experimental measurement without any prior assumptions of the potential form. We find that the two interactions are purely repulsive and can be described by an exponential function for experimentally relevant micrometer-sized skyrmions. This captures the physics on experimental time and length scales that are of interest for most skyrmion applications and typically inaccessible to atomistic or micromagnetic simulations. [3]

MA 37.8 Fri 11:15 H37

**Development of a current solver for studying non-linear skyrmion dynamics** — •THORBEN PÜRLING^{1,2}, DANIELE PINNA³, FABIAN LUX⁴, JONATHAN KIPP^{1,3}, STEFAN BLÜGEL^{1,3}, ABIGAIL MORRISON^{2,5}, and YURIY MOKROUSOV^{3,4} — ¹Department of Physics, RWTH Aachen University, Aachen, Germany — ²Institute of Neuroscience and Medicine 6 and Institute for Advanced Simulation 6 and JARA BRAIN Institute I, Jülich Research Centre, Jülich, Germany — ³Peter Grünberg Institute 1 and Institute for Advanced Simulation 1, Forschungszentrum Jülich and JARA, Jülich, Germany — ⁴Institute of Physics, Johannes Gutenberg University Mainz, Mainz, Germany — ⁵Computer Science 3 - Software Engineering, RWTH Aachen University, Aachen, Germany

Transport phenomena in skyrmionic textures have recently gained attention owing to possible applications in spintronics and in cognitive computing. While the reservoir computing aspect of skyrmions relies heavily on their nonlinear response properties, little is known about the real-space distribution of the current density that reflects the non-trivial structure of the local conductivity tensor of these complex objects. Here we report on the development of a method that provides the local current distribution for arbitrary spin textures under bias, and apply that method to study the current distribution of isolated skyrmions. We address the importance of diagonal and Hall components of the conductivity tensor for the current distribution and discuss possible relevance of our findings to reservoir computing applications.

Atomistic spin simulations of electric-field assisted nucleation and annihilation of magnetic skyrmions — •MORITZ A. GOERZEN¹, STEPHAN V. MALOTTKI^{1,4}, GRZEGORZ J. KWIATKOWSKI², PAVEL F. BESSARAB^{2,3}, and STEFAN HEINZE¹ — ¹Institute of Theoretical Physics and Astrophysics, University of Kiel, Germany — ²University of Iceland, Reykjavík, Iceland — ³St. Petersburg, Russia

— ⁴Thayer School of Engineering, Dartmouth College, Hannover, USA

We demonstrate electric-field assisted thermally activated writing and deleting of magnetic skyrmions in ultrathin transition-metal films. We apply an atomistic spin model which is parameterised from density functional theory (DFT) calculations for a Pd/Fe bilayer on the Ir(111) surface for electric fields of  $\mathscr{E} = 0, \pm 0.5$  V/Å. Based on harmonic transition-state theory [1,2], we calculate the transition rates for skyrmion nucleation and annihilation. Using these rates we quantify the probability for electric-field assisted deleting and writing of skyrmions by means of Master equations. The magnetic-field dependent skyrmion probability can be directly related to the free energy differences of the skyrmion and the ferromagnetic state and resembles a Fermi-Dirac distribution function. The obtained probability function at opposite electric fields is in striking agreement with experimental results [3].

#### MA 37.10 Fri 11:45 H37

Strain and electric field control of magnetic skyrmions in Fe3GeTe2 van der Waals heterostructures — •DONGZHE L1¹, SOUMYAJYOTI HALDAR², and STE-FAN HEINZE² — ¹CEMES, Université de Toulouse, CNRS, 29 rue Jeanne Marvig, F-31055 Toulouse, France — ²Institute of Theoretical Physics and Astrophysics, University of Kiel, Leibnizstrasse 15, 24098 Kiel, Germany

Magnetic skyrmions are topologically protected chiral spin structures with particle-like properties, which are often induced by the Dzyaloshinskii-Moriya interaction (DMI). The recent discovery of truly two-dimensional (2D) magnetic materials opened up new opportunities for exploring magnetic skyrmions in atomically thin vdW materials. Here, using density functional theory and atomistic spin simulations, we predict the emergence of a large DMI in 2D vdW heterostructures where a 2D ferromagnetic metal Fe3GeTe2 monolayer is deposited on a nonmagnetic vdW layer. In particular, the DMI turns out to be highly tunable by strain and electric-field, leading to giant DMI comparable to that of ferromagnetic/heavy metal interfaces, which have been recognized as prototype multilayer systems to host skyrmion states. Our atomistic spin simulations further show that the efficient control of the DMI, the exchange coupling, and the magnetic anisotropy energy by strain, lead to the stabilization of isolated skyrmions.

## MA 37.11 Fri 12:00 H37

**Resonant optical Hall conductivity from skyrmions** — •SOPHEAK SORN¹, LUYI YANG², and ARUN PARAMEKANTI³ — ¹Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, Karlsruhe, Germany — ²Department of Physics, Tsinghua University, Beijing, China — ³Department of Physics, University of Toronto, Toronto, Canada

Metallic magnets hosting topological skyrmions exhibit the topological Hall effect, which arises from a real-space Berry-phase mechanism, and it has been used as an indirect signature of skyrmions in transport experiments. This talk will focus on the less explored impact of skyrmions on optical Hall conductivity which is studied using a two-dimensional model of conduction electrons coupled to a background skyrmion spin texture via an effective Hund's coupling. For a skyrmion crystal, a Kubo-formula calculation reveals a resonant feature in the optical Hall response at a frequency set by the Hund's coupling. A linear relation between the area under the Hall resonant curve and the skyrmion density is discovered numerically and is further elucidated in a gradient expansion analysis. The presence of the resonance is robust, persisting in a system with an isolated skyrmion and even in a three-site system hosting a trimer of noncoplanar spins, which implies the indispensable role of the local noncoplanarity. Our results suggest that the resonance can be used as a basis for a magneto-optical Kerr microscopy for visualizing skyrmions.

MA 37.12 Fri 12:15 H37

Artificial neuron based on a magnetic biskyrmion — •ISMAEL RIBEIRO DE AS-SIS, BÖRGE GÖBEL, and INGRID MERTIG — Institut für Physik, Martin-Luther-Universität Halle-Wittenberg

Skyrmionics and neuromorphics are among the most promising fields of physics with the perspective of creating future devices and technologies. Magnetic skyrmions are extremely stable and can be moved by currents which has lead to the prediction of a skyrmion-based artificial neuron [1]: When a skyrmion is pushed by current pulses, it will eventually reach a designated location and can be detected electrically. This resembles the excitation process of a neuron that fires ultimately. However, a realistic refractory process has not been achieved, so far, for such a device. The skyrmion-based neuron would keep on firing when more current pulses are applied which renders this device not useful.

In this talk we suggest that a biskyrmion solves this major issue. The attractive interaction of the two partially overlapping skyrmions and their skyrmion Hall effects lead to a unique trajectory when they are driven by current pulses: The two subskyrmion move along opposite directions to the two designated detection areas where they reverse their direction of motion until they come back and eventually reestablish the biskyrmion. During the second period the skyrmion cannot fire again. Our suggested device resembles the response of a biological neuron better than all existing skyrmion-based devices so far.

**Magnetoelastic surface states of skyrmion textures** — •LARS FRANKE and MARKUS GARST — Institute for Theoretical Solid State Physics, Karlsruhe Institute for Technology, Germany

At the surface of chiral magnets uncompensated Dzyaloshinskii-Moriya interaction modifies the boundary conditions for the magnetization resulting in a so-called a surface twist. Consequently, skyrmions are expected to change their helicity from Bloch-like within the bulk of the chiral magnet to Néel-like close to the surface [1]. Resonant elastic X-ray scattering experiments [2] have confirmed this predicted change of helicity close to the surface, but the experimentally observed penetration depth was found to be an order of magnitude larger than theoretically expected. In order to account for this discrepancy, we investigate theoretically the influence of a magnetoelastic coupling on the surface twist. Analytical calculations are complicated by broken translational invariance and nontrivial boundary conditions at the surface. However, as in the uncoupled system the length scale for helicity variations is already encoded in the bulk equation. We demonstrate how to extract the length scale from a perturbative approach. The validity of these calculations is checked using micromagnetic simulations, extended with magnetoelastic coupling, of the complete surface state including boundary conditions.

Magnetic torque and DMI-like spin-lattice-coupling parameters from first principles — •S. MANKOVSKY¹, H. LANGE¹, S. POLESYA¹, M. WEISSENHOFER², U. NOWAK², and H. EBERT¹ — ¹Dept. Chemistry, LMU Munich, Germany — ²Fachbereich Physik, Uni. Konstanz, Germany

Magneto-elastic couplings can play a crucial role both for ground state magnetic properties of materials giving rise to modified forms of the magnetic ground state accompanied by a spontaneous lattice deformation, as well as for spin-lattice dynamics, e.g. having a leading role for Gilbert damping in insulators.

As the magneto-elastic properties are fully determined by the electronic structure, the corresponding spin-lattice coupling (SLC) parameters can be calculated at a first-principles level. Aiming at that, we start with the phenomenological atomistic spin-lattice Hamiltonian which can be seen as an extension of the standard Heisenberg spin Hamiltonian. Focusing on the SOC-driven SLC effects, we discuss the torque on the magnetic moment as well as the modification of the Dzyaloshinskii-Moriya interaction (DMI) induced by an atomic displacement, giving access to corresponding SLC parameters. The expressions for these SLC parameters have been worked out based on the fully-relativistic KKR Green functions formalism. Corresponding calculations have been done for different two-dimensional and three-dimensional systems. Their properties as well as possible impact on the magnetic structure are discussed in comparison with the ordinary MCA and DMI parameters.

Angular momentum transfer via relativistic spin-lattice coupling from first principles — •HANNAH LANGE¹, SERGIY MANKOVSKY¹, SVITLANA POLESYA¹, MARKUS WEISSENHOFER², ULRICH NOWAK², and HUBERT EBERT¹ — ¹Dept. Chemistry, LMU Munich, Butenandtstr. 11, 81377 Munich — ²Dept. Physics, Uni Konstanz, 78457 Konstanz

The transfer and control of angular momentum is a key aspect for spintronic applications. Only recently, it was shown that it is possible to transfer angular momentum from the spin system to the lattice on ultrashort time scales [1]. Hence, combined molecular-spin dynamics simulations using first-principles parameters might give access to the central aspects of the underlying mechanisms.

To contribute to the understanding of angular momentum transfer between spin and lattice degrees of freedom we present a scheme to calculate fullyrelativistic spin-lattice coupling parameters from first-principles. By treating changes in the spin configuration and atomic positions at the same level, closed expressions for the atomic spin-lattice coupling parameters can be derived in a coherent manner up to any order. Analyzing the properties of these parameters, in particular their dependence on spin-orbit coupling, we find that even in bcc Fe the leading term for the angular momentum exchange between the spin system and the lattice is a Dzyaloshiskii-Moriya-type interaction, which is due to the symmetry breaking distortion of the lattice.

## MA 38.3 Fri 10:00 H43

**Double-Exchange Enhanced Magnetic Blue-Shift of Mott Gaps** — •MOHSEN HAFEZ-TORBATI¹, DAVIDE BOSSINI², FRITHJOF B. ANDERS¹, and GOETZ S. UHRIG¹ — ¹Technical University of Dortmund, Dortmund, Germany — ²University of Konstanz, Konstanz, Germany

Strong correlations in Mott insulators induce a substantial charge excitation energy known as the Mott gap. We study how the Mott gap is affected by long-range antiferromagnetic ordering upon reducing the temperature below the Néel temperature. Our finding is that the Mott gap is increased by the magnetic ordering: a magnetic blue-shift (MBS) occurs. We unveil the origin of the MBS of the Mott gap by analyzing the Hubbard model and the Hubbard-Kondo model and clarify the subtle differences. We show that in the Hubbard-Kondo model and additional contribution proportional to the hopping is induced by the double-exchange mechanism. We describe the magnetic contribution to the band gap blue-shift observed in the optical conductivity of  $\alpha$ -MnTe and pinpoint a hopping contribution of 64% and a magnetic exchange interaction bears the potential to enable spin-to-charge conversion on extreme time scales, highly promising for spintronic and magnonic applications.

## MA 38.4 Fri 10:15 H43

A Theory for Colors of Strongly Correlated Electronic Systems — •SWAGATA ACHARYA¹, CEDRIC WEBER², DIMITAR PASHOV², MARK VAN SCHILFGAARDE³, ALEXANDER I LICHTENSTEIN⁴, and MIKHAIL I KATSNELSON¹ — ¹Radboud University, Nijmegen, The Netherlands — ²King's College London, London, UK — ³National Renewable Energy Laboratory, Colorado, US — ⁴Institute of Theoretical Physics, University of Hamburg, Germany

Many strongly correlated transition metal insulators are colored, even though they have large fundamental band gaps and no quasi-particle excitations in the visible range. We pick two archetypal cases as examples: NiO with green color and MnF2 with pink color. We show that a perturbative theory based on loworder extensions of the GW approximation is able to explain the color in NiO, and indeed well describe the dielectric response over the entire frequency spectrum, while the same theory is unable to explain why MnF2 is pink. We show its color originates from higher order spin-flip transitions that modify the optical response. This phenomenon is not captured by low-order perturbation theory, but is contained in dynamical mean-field theory (DMFT), which has a dynamical spin-flip vertex that contributes to the charge susceptibility. Within our combined self-consistent GW-BSE approximation and DMFT approach we can describe the peaks in subgap charge susceptibilities in both NiO and MnF2 . As a secondary outcome of this work, we establish that the one-particle properties of paramagnetic NiO and MnF2 are both well described by an adequate single Slater-determinant theory and do not require a dynamical vertex.

## MA 38.5 Fri 10:30 H43

**Electron-plasmon and electron-magnon scattering in ferromagnets from first principles by combining** *GW* **and** *GT* **self-energies** — DMITRII NABOK, •STEFAN BLÜGEL, and CHRISTOPH FRIEDRICH — Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, 52425 Jülich, Germany

This work combines two powerful self-energy techniques: The well-known GW method and a self-energy recently developed by us [1] that describes the renor-

malization caused by the scattering of electrons with magnons and Stoner excitations. This GT self-energy, which is fully **k** dependent and contains infinitely many spin-flip ladder diagrams, was shown to have a profound impact on the electronic band structure of Fe, Co, and Ni. For example, it predicted a band anomaly in iron that was later confirmed experimentally. In the present work [2], we refine the method by combining GT with the GW self-energy. The resulting GWT spectral functions exhibit strong lifetime effects and emergent dispersion anomalies. They are in a better agreement with experimental spectra than those obtained with GW or GT alone, even showing partial improvements over local-spin-density approximation dynamical mean-field theory. The shape of the iron band anomaly improves, too. We acknowledge the Center of Excellence MaX Materials Science at the Exascale (EU H2020-INFRAEDI-2018) for financial support.

#### MA 38.6 Fri 10:45 H43

Effective exchange interaction in non-collinear states from electronic structure theory — •SIMON STREIB¹, RAMON CARDIAS², MANUEL PEREIRO¹, AN-DERS BERGMAN¹, ERIK SJÖQVIST¹, CYRILLE BARRETEAU³, ANNA DELIN², OLLE ERIKSSON^{1,4}, and DANNY THONIG^{4,1} — ¹Department of Physics and Astronomy, Uppsala University, Sweden — ²Department of Applied Physics, School of Engineering Sciences, KTH Royal Institute of Technology, Sweden — ³SPEC, CEA, CNRS, Université Paris-Saclay, France — ⁴School of Science and Technology, Örebro University, Sweden

The determination of exchange parameters in non-collinear magnetic configurations directly from the electronic structure has been a challenge since the initial development of the Lichtenstein-Katsnelson-Antropov-Gubanov (LKAG) formalism for collinear configurations. Usually, the isotropic exchange interaction between two magnetic moments is only taken into account to bilinear order (Heisenberg exchange). We introduce instead a generalized isotropic two-spin exchange interaction, which takes all orders into account, and from which we derive an effective exchange interaction. We demonstrate how in an arbitrary non-collinear configuration this effective exchange interaction can be extracted from the energy curvature tensor, which describes the local energy curvature with respect to the directions of two magnetic moments. We apply our formalism to examples from tight-binding electronic structure and demonstrate strong fluctuations of the effective exchange interaction during spin dynamics simulations [1].

**Electric-field control of the exchange interactions** — •SVITLANA POLESYA¹, SERGIY MANKOVSKY¹, ESZTER SIMON¹, ALBERTO MARMODORO², and HUBERT EBERT¹ — ¹Dept. Chemistry, LMU Munich, Butenandtstrasse 11, D-81377 Munich, Germany — ²Inst. of Physics, Czech Academy of Sciences, Cukrovarnicka 10, 162 00 Praha 6, Czech Republic

The impact of an applied electric field on the exchange coupling parameters has been investigated based on first-principles electronic structure calculations by means of the KKR Green function method. The calculations have been performed for a Fe monolayer (ML) and for deposited Fe films on different substrates, i.e., metallic (Pt) and semiconducting (GaAs). We analyze the origin of the field-induced change of the exchange interactions  $J_{ij}$  and the features of their field-dependent behavior specific for the studied systems. In particular, rather pronounced changes of  $J_{ij}$  have been found for the Fe/Pt(111) system due to the localized electronic states at the Fe/Pt interface. In the case of Fe/GaAs(001) films we discuss also the dependence of the field-induced modification of  $J_{ij}$  on the thickness of the Fe film. For all studied systems, a strong impact of surface relaxation is found both for the ground-state exchange parameters as well as for their field induced modification.

Direct determination of magnetic properties from energy lansdscapes around trapped magnetic beads — FLORIAN OSTERMAIER, MORITZ QUINCKE, BENJAMIN RIEDMÜLLER, MENG LI, MANUEL HERSCHEL, and •ULRICH HERR — Institut für Funktionelle Nanosyteme, Universität Ulm

Many Lab-on-Chip applications make use of micrometer sized polystyrene beads containing superparamagnetic iron oxide nanoparticles. Precise knowledge of magnetic properties is important for well-controlled manipulation by magnetic fields. We present a study of pairs of magnetic beads trapped in a currentcarrying micro ring structure combined with a superimposed homogeneous field [1]. The trapped particles interact via repulsive dipole-dipole interaction. From analysis of the Brownian motion of the trapped particles we can extract information about the trap stiffness as well as the magnetic moments of the beads. The trap stiffness obtained in this way is compared to analytical and numerical calculations of the magnetic field distribution in the vicinity of the micro ring structure. We find that the restricted movement of the two interacting beads in the trap structure leads to a faster and more accurate measurement of the beads compared to observations made on single beads trapped in the same structure.

**Room-temperature synthesis of AuFe solid solution nanoparticles and their transformation to Au/Fe Janus nanostructures** — MARIA V. EFREMOVA¹, MARINA SPASOVA², MARKUS HEIDELMANN³, MICHAEL FARLE², and •ULF WIEDWALD² — ¹Department of Applied Physics, Eindhoven University of Technology, Netherlands — ²Faculty of Physics and Center for Nanointegration Duisburg-Essen, University of Duisburg-Essen, Germany — ³ICAN - Interdisciplinary Center for Analytics on the Nanoscale and Center for Nanointegration Duisburg-Essen, University of Duisburg-Essen, Germany

AuFe solid solution nanoparticles (NPs) are synthesized in ambient conditions by colloidal chemistry previously established for a  $Fe_3O_4$  – Au core-shell morphology [1]. These AuFe NPs preserve the fcc structure of Au with paramagnetic Fe ions incorporated. Interestingly, the solid solution is metastable at room temperature forming Fe-rich regions in the Au matrix during storage. In situ annealing experiments up to 700°C in a transmission electron microscope and vibrating sample magnetometer leads to segregation of metallic Fe from the AuFe solid solution finally forming Au/Fe Janus NPs. The ferromagnetic bcc Fe grows epitaxially on low index fcc Au planes. The study facilitates the reassessment of possible applications of such NPs leading to a new material for magnetoplasmonics. First tests for biomedical applications are presented.

Structural, chemical and magnetic properties of iron-oxide core-shell nanocubes — •ALADIN ULLRICH, MICHAEL KÜHN, and MANFRED ALBRECHT — Institut für Physik, Universität Augsburg, 86159 Augsburg, Germany

Iron oxide nanoparticles in the size range from 8 to 17 nm were synthesized by thermal decomposition of iron oleate precursor in a high-boiling solvent with Na-oleate as surfactant to produce cubic nanoparticles. The structural composition of the nanoparticles was investigated by transmission electron microscopy and electron energy loss spectroscopy, revealing a core-shell structure with a wustite like structure in the core and a spinel like structure in the shell [1]. Changes in the oxidation state of the iron as well as the core/shell ratio were determined. The core/shell ratio was tuned by successive oxidation until the core had disappeared completely. A sample series consisting of 8 different core/shell ratios was produced during the oxidation process. The magnetic properties of this antiferromagnetic core - ferrimagnetic shell system like exchange bias, coercivity, and blocking behaviour were investigated. With decreasing core/shell ratio the blocking temperature, the coercivity, as well as the exchange anisotropy decreased. Besides this, the influence of the particle size on the magnetic properties was studied as well. Here, for rising particle size an increasing blocking temperature, as well as an increasing exchange anisotropy in the blocked state at low temperatures was found.

#### MA 39.4 Fri 10:15 H47

Effect of laser treatment on catalyst materials investigated by Mössbauer spectroscopy — •Soma Salamon¹, Joachim Landers¹, Swen Zerebecki², Sven Reichenberger², Stephan Barcikowski², and Heiko Wende¹ — ¹Faculty of Physics and CENIDE, University of Duisburg-Essen — ²Institute for Technical Chemistry I and CENIDE, University of Duisburg-Essen

Mössbauer spectroscopy is utilized as a non-destructive, element-specific measurement method to probe hyperfine interactions in spinels that are promising candidates for application in electrocatalysis. By recording low temperature (4.3 K) high field (5-10 T) spectra, it is possible to discern individual contributions from tetrahedrally and octahedrally coordinated crystallographic sites found in the spinel lattice of materials such as  $CoFe_2O_4$ , enabling access to the

degree of inversion. Latter provides the distribution of Fe ions across these sites, while also allowing insight regarding the displacement of other ions within the lattice. This enables us to correlate changes in ion distribution in the lattice with improvements in catalytic activity, also giving clues about which ions on which positions serve as active sites during catalysis. Our results show that single-pulse laser excitation can selectively modify the ion distribution, while leaving the particles and their morphology largely intact. Further experiments also include tests of laser-induced diffusion of Fe into  $Co_3O_4$  particles, with the use of isotope-pure ⁵⁷Fe allowing Mössbauer experiments to be performed on samples that do not normally contain any Fe. Funding by the DFG via the CRC/TRR 247 (ID 388390466, Projects B2, C5) is acknowledged.

## MA 39.5 Fri 10:30 H47

Towards FeRh nanoparticles for printable magnetocaloric media — •JOACHIM LANDERS¹, SOMA SALAMON¹, RUKSAN NADARAJAH², SHABBIR TAHIR², BENEDIKT EGGERT¹, BILAL GÖKCE², and HEIKO WENDE¹ — ¹Faculty of Physics and CENIDE, University of Duisburg-Essen — ²Materials Science and Additive Manufacturing, University of Wuppertal

Magnetocaloric (MC) materials are promising candidates for energy efficient cooling applications. Here, FeRh nanoparticles prepared via laser ablation in liquids (LAL) are studied as possible means towards printable MC media. First experiments focused on how to minimize surface oxidation during nanoparticle preparation in solution. After ensuring low oxidation levels, our main interest was to find a method to regain the FeRh B2 structure and its MC properties during further processing. For that purpose, extensive studies via magnetometry, XRD and Mössbauer spectroscopy were performed to analyze magnetic structure and phase composition when exposing the particles to elevated temperatures, as would occur during laser printing of MC structures. We observed a transition from the predominant y-FeRh-phase formed during laser particle synthesis to the B2-phase we aimed for, constituting a maximum B2-fraction of ca. 90 % of the material. Ongoing studies are currently searching for optimum processing parameters for laser-sintering of the FeRh-NP-based inks in an approach to form 2D magnetocaloric structures, with first results indicating the presence of the field-induced B2-phase antiferro- to ferromagnetic transition. This work is supported by the DFG through CRC/TRR 270.

Drifting inwards in protoplanetary discs: The role of hydrogen on planetesimal formation — •Cynthia Pillich¹, Janosch Tasto¹, Tabea Bogdan² JOACHIM LANDERS¹, GERHARD WURM², and HEIKO WENDE¹ – ¹Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, Lotharstr. 1, 47057 Duisburg, Germany – ²Faculty of Physics, University of Duisburg-Essen, Lotharstr. 1, 47057 Duisburg, Germany Dust particles in protoplanetary discs, which can be seen as building blocks for planetesimals, are coupled to gas, mostly hydrogen. Due to this coupling, those particles may drift towards the inner part of the disc and are therefore exposed to very high temperatures, allowing for compositional and structural changes. To simulate the conditions at the early phase of planetary formation, two chondrites were milled to dust and subjected to temperatures up to 1400 K in a hydrogen atmosphere of approximately 1 mbar. The changes in composition were then studied by the means of ⁵⁷Fe Mössbauer spectroscopy and magnetometry. Comparing these results to vacuum tempered dust, we observe an influence of the heating atmosphere on compositional changes in the meteorites. At very high temperatures (>1200 K), Fe silicates are mostly reduced to metallic FeNi, altering adhesive properties of protoplanetary dust and therefore the potential for planetesimal growth.

Funding by the DFG (projects WE 2623/19-1 and WU 321/18-1) is gratefully acknowledged.

# MA 40: Weyl Semimetals

Time: Friday 9:30-10:45

MA 40.1 Fri 9:30 H48

**Magneto-optical detection of topological contributions to the anomalous Hall effect** — •FELIX SCHILBERTH^{1,2}, NICO UNGLERT³, LILIAN PRODAN¹, CHRISTINE KUNTSCHER⁴, LIVIU CHIONCEL³, and SÁNDOR BORDÁCS² — ¹Experimentalphysik V, Augsburg University, Augsburg, Germany — ²Department of Physics, BME Budapest, Hungary — ³Theoretische Physik III, Augsburg University, Augsburg, Germany — ⁴Experimentalphysik II, Augsburg University, Augsburg, Germany

The anomalous Hall effect (AHE) is a profound manifestation of non-trivial band structure topology in magnetic materials. The ambiguous separation of its intrinsic and extrinsic contributions leads to a fundamental limitation in identifying topological states based on common magnetotransport experiments. Here we demonstrate, via a case study on the prominent topological kagome magnet  $Fe_3Sn_2$ , that the intrinsic contribution to AHE can be determined un-

ambiguously from the broadband spectrum of the optical Hall effect, obtained by energy-resolved magneto-optical Kerr-effect (MOKE) measurements. Using MOKE spectroscopy complemented with material-specific theory, we identified the interband excitations responsible for the intrinsic AHE. We found that lowenergy transitions, tracing "helical volumes" in momentum space reminiscent of the formerly predicted helical nodal lines, substantially contribute to the AHE, which is further increased by contributions from multiple higher-energy interband transitions. Our calculation also shows that local Coulomb interactions lead to important band reconstructions near the Fermi level.

# MA 40.2 Fri 9:45 H48

Magnetic and transport properties of  $Mn_3Sn$  and Fe doped  $Mn_3Sn$  Weyl semimetal — •SUBHADIP JANA — Jülich Centre for Neutron Science (JCNS-2) and Peter Grünberg Institute (PGI-4), JARA-FIT, Forschungszentrum Jülich GmbH, D-52425 Jülich, Germany

A large Anomalous Hall Effect (AHE) has been found in Mn₃Sn due to the nonvanishing Berry flux emerging from the Weyl points. This compound draws enormous interest due to the complicated magnetic structure and its correlation with the transport properties. We observed AHE from 420 K ( $T_{\rm N}$  = 420 K) down to 5 K for  $Mn_{3.17}Sn$ . From single-crystal neutron diffraction, we conclude that the magnetic structure is commensurate with magnetic moments in the hexagonal basal plane between 420 K ( $T_{\rm N})$  < T < 5 K. An additional incommensurate phase appears below 250 K. The presence of AHE in the whole temperature range is consistent with the commensurate magnetic structure. Fe doping influences the nearest-neighbor exchange energy, thereby changing the magnetic and transport properties. The Néel temperature was found to be 405 K for Mn_{3 02}Fe_{0 08}Sn, slightly lower than the parent compound. The commensurate magnetic structure has been observed between 210 K < T < 405 K from neutron powder diffraction. An incommensurate magnetic phase was observed below 210 K. The electrotransport study of Fe-doped sample shows vanishing AHE below 207 K. Therefore, we conclude that Fe doping significantly influences the magnetic structure in the commensurate region and that AHE completely vanishes in the incommensurate region.

#### MA 40.3 Fri 10:00 H48

Anomalous transport properties of the topological (Weyl) semimetal: Hexagonal -  $(Mn_{1-\alpha}Fe_{\alpha})_3Ge$  - •VENUS RA1¹, SHIBABRATA NANDI¹, ANNE STUNAULT², WOLFGANG SCHMIDT³, SUBHADIP JANA¹, JIAN-RUI SOH⁴, JÖRG PERSSON¹, and THOMAS BRÜCKEL¹ - ¹Jülich Centre for Neutron Science (JCNS-2) and Peter Grünberg Institute (PGI-4), JARA-FIT, Forschungszentrum Jülich, Germany - ²Institut Laue-Langevin, 71 avenue des Martyrs, CS20156, Grenoble, France - ³Forschungszentrum Jülich GmbH, Jülich Centre for Neutron Science at ILL, 71 Avenue des Martyrs, Grenoble, France - ⁴Institute of Physics, Ecole Polytechnique Fédérale de Lausanne (EPFL), CH-1015 Lausanne, Switzerland

Weyl semimetal (WS) - Mn₃Ge displays a large anomalous Hall effect (AHE), which originates from the non-zero Berry curvature. The location and separation of the Weyl nodes can be tuned using a suitable dopant. So, we have studied the evolution of transport properties of single-crystal (Mn_{1- $\alpha$}Fe_{$\alpha$})₃Ge. We observed that the strength of AHE and chiral anomaly weakens drastically with an increase in Fe doping and vanishes beyond  $\alpha = 0.22$ . Polarized and unpolarized neutron diffraction of  $\alpha = 0.22$  showed that the magnetic structure of the compound remains the same as that of the parent compound, only in the

MA 41.1 Fri 11:30 H47

Dynamic properties of magnetic Nanoparticles: arrangement-, distance-& frequency-dependent properties — •NILS NEUGEBAUER^{1,2}, HELMUT SCHULTHEISS³, XINGCHEN YE⁴, and PETER KLAR^{1,2} — ¹Institute of Experimental Physics I, Justus Liebig University Giessen, Heinrich-Buff-Ring 16, 35392 Giessen, Germany — ²Center for Materials Research (LaMa), Justus Liebig University Giessen, Heinrich-Buff-Ring 16, 35392 Giessen, Germany — ³Helmholtz-Center Dresden-Rossendorf, Institute of Ion Beam Physics and Materials Research, Bautzner Landstraße 400, 01328 Dresden, Germany — ⁴Department of Chemistry, Indiana University, Bloomington, 47405 Indiana, University States

Investigations focusing on the mutual dipolar interactions of magnetic nanoparticles (MNPs) are presented. As nanoparticles may be arranged into highly ordered, crystal-like structures, so called mesocrystals, novel properties may arise due to the introduction of an additional degree of freedom in manipulating the magnetic properties of a material. Manipulating the interparticle distance, distinct spectral features related to the dipole-dipole interaction can be observed. Based on these nano-building blocks, assemblies of MNPs of well-defined size and shape can be constructed. Such assemblies show distinct collective properties, e.g. well-localized magnetic vibrational modes, frequency- and fielddependent characteristics. The experiments are supported by utilizing numerical simulations of corresponding model systems to underline the observed characteristics.

# MA 41.2 Fri 11:45 H47

Quantitative analysis of magnetic states in an artificial spin ice by off-axis electron holography — •TERESA WESSELS^{1,2}, SEBASTIAN GLIGA³, SIMONE FINIZO³, ANDRAS KOVACS², and RAFAL DUNIN-BORKOWSKI² — ¹Faculty of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), Univer-

temperature regime where AHE and the chiral anomaly are observed. These observations suggest the location of Weyl points and separation between a pair of Weyl points change significantly with Fe doping. Therefore, suitable dopants can be used to tune the transport properties of the WS.

## MA 40.4 Fri 10:15 H48

Prediction of a new type-I Weyl semimetal in a full-Heusler compound — •DAVIDE GRASSANO and NICOLA MARZARI — Theory and Simulations of Materials (THEOS) and National Center for Computational Design and Discovery of Novel Materials (MARVEL), Ecole Polytechnique Federale de Lausanne, CH-1015 Lausanne, Switzerland

Weyl semimetals are a class of topological semimetals with linear band crossings close to the Fermi level with non-trivial chirality, the existence of which gives rise to several exotic physical properties[1,2]. In order for such crossings to exist, either time-reversal or inversion symmetry must be broken[3]. Here we identify a new inversion-breaking Weyl semimetal. This material shows several features that are comparatively more intriguing with respect to other known inversionbreaking Weyl semimetals. The distance between two neighboring nodes is large enough to observe a wide range of linear dispersion in the band and only one kind of nodes can be identified. Finally, the lack of other trivial points insures that the low-energy properties of the material can be directly related to the presence of the Weyl nodes.

**Multifold Hopf semimetals** — •ANSGAR GRAF and FRÉDÉRIC PIÉCHON — Université Paris-Saclay, CNRS, Laboratoire de Physique des Solides, 91405, Orsay, France

Three-dimensional (3D) topological semimetals exhibit linear energy band crossings that act as monopole sources of Berry curvature. Here, we introduce *multifold Hopf semimetals (MHSs)*, which feature linear *N*-fold crossing points each of which acts as a *Berry dipole*. We construct models with N = 3, 4, 5 bands and show that their physical properties are crucially affected by the Berry dipole: First, it makes the Landau level spectrum strongly dependent on the orientation of an external magnetic field. Second, it causes an anomalous Hall effect and weak field magnetoconductivities resembling the chiral anomaly, chiral magnetic and magnetochiral effects familiar from a pair of coupled Weyl nodes. Gapping out MHSs, we obtain multiband Hopf insulators (MHIs) with Hopf numbers up to  $\mathcal{N}_{\rm Hopf} = 10$ . MHSs and MHIs provide a fertile playground to explore delicate topology and exhibit analogies to 2D Dirac semimetals and Chern insulators.

sity Duisburg-Essen, 47057 Duisburg, Germany — ²Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons and Peter Grünberg Institute, Forschungszentrum Jülich, 52425 Jülich, Germany — ³Swiss Light Source, Paul Scherrer Institut, 5232 Villigen PSI, Switzerland

The study of emergent phenomena in artificial spin ices (ASIs) consisting of patterned nanomagnets is presently the focus of intense research. We used off-axis electron holography in the transmission electron microscope to quantitatively measure the magnetic phase shift induced by ASI with chiral geometry. The phase shift of the electron wave was measured using an electron biprism and interpreted using a model-based iterative reconstruction algorithm to retrieve the projected in-plane magnetization. The permalloy nanomagnets were patterned on a SiN membrane using lift-off lithography. Magnetic interactions within individual arrays were studied by applying in-plane magnetic fields to the sample. The reconstructed magnetization shows a single-domain state of the nanomagnets with an average magnetic polarization of 0.73 T. The low magnetic polarization value may result from a combination of the microstructure, composition, and oxidation. The project received funding from the ERC (856538) and the DFG (392476493, 405553726).

#### MA 41.3 Fri 12:00 H47

Monolayer MnX and Janus XMnY (X, Y= S, Se, Te): A New Family of 2D Antiferromagnetic Semiconductors — •SHAHID SATTAR, MD FHOKRUL ISLAM, and CARLO MARIA CANALI — Department of Physics and Electrical Engineering, Linnaeus University, Kalmar SE-39231, Sweden

We present first-principles results on the structural, electronic, and magnetic properties of a new family of two-dimensional antiferromagnetic (AFM) manganese chalcogenides, namely monolayer MnX and Janus XMnY (X, Y= S, Se, Te). By carrying out calculations of the phonon dispersion and ab-initio molecular dynamics simulations, we first confirmed that these systems, characterized by an unconventional strongly-coupled-bilayer atomic structure (consisting of Mn atoms buckled to chalcogens forming top and bottom ferromagnetic (FM) planes with antiparallel spin orientation) are dynamically and thermally stable. The analysis of the magnetic properties shows that these materials have robust AFM order, whereas electronic structure calculations reveal that pristine MnX and their Janus counterparts are indirect-gap semiconductors, covering a wide energy range and displaying tunable band gaps by the application of biaxial tensile and compressive strain. Interestingly, owing to the absence of inversion and time-reversal symmetry, and the presence of an asymmetrical potential in the out-of-plane direction, Janus XMnY become spin-split gapped systems, presenting a rich physics yet to be explored. Our findings provide novel insights in this physics, and highlight the potential of two-dimensional manganese chalcogenides in AFM spintronics.

## MA 41.4 Fri 12:15 H47

Magnetic properties of cobalt - nanomagnets: towards spin qubit control — •LIZA ZAPER^{1,2}, PETER RICKHAUS², ALEXANDER STARK², FLORIS BRAAKMAN¹, and MARTINO POGGIO¹ — ¹University of Basel, Basel, Switzerland — ²Qnami AG, Muttenz, Switzerland

A promising platform to realise quantum computation uses the spin states of confined electrons to define the qubit. In order to achieve reliable control and high integration of spin qubit devices on a chip, we aim to pattern nanometerscale magnets that have large magnetic field gradients at the position of the confined electron. We fabricate highly magnetic cobalt nanostructures using focused-electron-beam-induced deposition. We characterize the magnetization properties of the nanomagnets by NV scanning microscopy, as well as magnetotransport. The scanning probe images indicate the structure of the magnetic domains and the profile of the magnetic stray fields, which can be further used as a guideline for qubit device optimisation.

## MA 41.5 Fri 12:30 H47

Cellulose nanocomposite with  $SrFe_{12}O_{19}$  nanoparticles as a novel magnetic nanopaper coating — •ANDREI CHUMAKOV¹, KORNELIYA GORDEYEVA², CALVIN J. BRETT^{1,2}, ANASTASIA V. RIAZANOVA², DIRK MENZEL³, DANIEL SOEDERBERG², and STEPHAN V. ROTH^{1,2} — ¹DESY, Hamburg, Germany — ²KTH Royal Institute of Technology, Stockholm, Sweden — ³TU Braunschweig, Braunschweig, Germany

The possibility of the coating by a new magnetic nanocomposite based on negatively charged cellulose colloids (1360  $\mu$ mol/g) and positively charged hard magnetic hexaferrite (SrFe₁₂O₁₉) nanoparticles with a large permanent magnetic moment was demonstrated. Thin nanofilms of magnetic cellulose composite were obtained by spray deposition on a silicon substrate and studied by microscopic imaging, surface-sensitive X-ray scattering, and magnetic determining techniques. Ferromagnetic nanoparticles are uniformly distributed in the cellulose matrix and form a nanocomposite due to the opposite charges of the initial components. Magnetic nanoplates show a predominant orientation parallel to the plane of the substrate and the resulting nanocomposite has the highest intrinsic coercivity field inherent in the properties of individual nanoparticles. Coatings of magnetic nanopaper with a large coercive field can be widely used from catalysis to promising nanoelectronic devices.

First-principles study of magnetic tunnel junctions based on half-metallic and spin-gapless semiconducting Heusler compounds: Reconfigurable diode and inverse TMR effect — •THORSTEN AULL, ERSOY SASIOGLU, and INGRID MERTIG — Martin-Luther-Universität Halle-Wittenberg, Institut für Physik, 06120 Halle (Saale)

Magnetic tunnel junctions (MTJs) based on half-metallic magnets (HMMs) and spin-gapless semiconductors (SGSs) exhibit unique properties, such as current rectification, i.e., diode effect, and reconfigurability in addition to a tunnel magnetoresistance (TMR) effect [1]. We investigate from first-principles MTJs based on SGS and HMM quaternary Heusler compounds [2]. Our quantum transport calculations have demonstrated that these MTJs exhibit current rectification with high on/off ratios. Moreover, depending on the relative orientation of the magnetization of the electrodes, the MTJ allows the electrical current to pass either in one or the other direction, which leads to an inverse TMR effect. We show that, in contrast to conventional semiconductor diodes, the rectification bias voltage window of the MTJs is limited by the spin gap of the HMM and SGS Heusler compounds. The combination of nonvolatility, reconfigurable diode functionality, and high Curie temperatures of the electrode materials makes the proposed MTJs very promising for room temperature spintronic applications and opens new ways to magnetic memory and logic concepts.

**Exploring all 3d-metal Heusler alloys for functional properties: density functional theory + Monte Carlo study** — •MADHURA MARATHE and HEIKE C. HERPER — Department of Physics and Astronomy, Uppsala University, 75120 Uppsala, Sweden.

The search for cost-effective and rare-earth metal free permanent magnets is essential for various applications. In this study, we explore a novel class of Heusler alloys consisting of all 3d-metals. We do high-throughput studies using an electronic structure database to search for  $X_2YZ$ -type Heuslers (X = Fe, Ni) with tetragonal symmetry and high magnetic moments. We perform density functional theory calculations to obtain the ground state structure, magnetic anisotropy energy (MAE) as well as the exchange interaction parameters  $J_{ij}$  for selected materials. Using the calculated  $J_{ij}$ 's, we map our system on a Heisenberg model and perform Monte Carlo simulations to calculate the Curie temperature. Through such multiscale modeling, we aim to identify potential candidates for permanent magnets. We find that for these systems  $J_{ij}$ 's have oscillations over a long range with both ferromagnetic and antiferromagnetic interactions, and it is essential to include these in the model to capture correct transition. Location: H48

MA 42.3 Fri 12:00 H48

High-throughput calculations on Co-based Heusler alloys assisted with the measurement of phase diagram in the related ternary system —  $\cdot$ Kun Hu — Technical University Darmstadt Otto-Berndt-Straße 3, 64287 Darmstadt

Abstract: High-throughput (HTP) density functional theory (DFT) calculations have been carried out on Co-based Heusler alloys, combined with Exact Muffin-Tin Orbitals (EMTO) methods and Uppsala Atomistic Spin Dynamics (UppASD) package. Firstly, the stability of the Co2XY and X2CoY phases have been calculated and selected as parent phases which mainly center on the crystal structure and the tetragonal distortion considering formation energy and distance to the convex hull. And then, the specific properties of curie temperature (Tc) and magneto-crystalline anisotropy energy (MAE) of these phases have been calculated, of which some typical compounds show a high Tc and large MAE. Furthermore, the phase diagram of Co-Pt-Ti, Co-Ge-Ti, Co-Ge-Zr, and Co-Ge-Hf ternary systems were measured through a technique of alloy sampling and diffusion triple. Based on the results from Electron Probe Microanalysis (EPMA) and X-ray diffraction (XRD) techniques, the isothermal sections of these systems were constructed at different temperatures. Several ternary phases were detected and the relevant composition range was confirmed. The current study found interesting results that the Heusler phase Co2TiGe showed a remarkable composition range.

#### MA 42.4 Fri 12:15 H48

Tuning of the effective magnetic decoupling in Ni-Mn-(In,Sn) Heusler alloys — •OLGA N. MIROSHKINA¹, FRANCESCO CUGINI^{2,3}, SIMONE CHICCO², FABIO ORLANDI⁴, GIUSEPPE ALLODI², PIETRO BONFÀ², VINCENZO VEZZONI², LARA RIGHI^{2,3}, FRANCA ALBERTINI³, ROBERTO DE RENZI², MASSIMO SOLZI^{2,3}, and MARKUS E. GRUNER¹ — ¹Department of Physics and CENIDE, University of Duisburg-Essen, Duisburg, Germany — ²University of Parma, Parma, Italy — ³IMEM-CNR, Parma, Italy — ⁴Rutherford Appleton Laboratory, Chilton, Didcot, Oxfordshire, United Kingdom

The magnetocaloric effect at first-order phase transitions is considered as an efficient and ecologically friendly alternative to conventional compressor cooling. This contribution is devoted to the complex magnetic ordering mechanisms in magnetocaloric Ni-Mn-(In,Sn) Heusler alloys, which we explore by means of density functional theory. The calculations accompany extensive experimental investigations, which reveal a non-monotonic trend in the Curie temperature and an effective magnetic decoupling of 4a and 4b sublattices [1]. Our first-principles calculations confirm a composition-dependent competition of the effective ferromagnetic and antiferromagnetic coupling between the sublattices, which can be directly controlled by electron doping in terms of In/Sn substitution. This result shows the possibility of fine-tuning of Heusler materials via exchanging the main-group element increasing the range of their potential applications. This work is funded by DFG within CRC/TRR 270 (project no. 405553726).

Noncollinear magnetic order in epitaxial thin films of the MnPtGa hard magnet — •REBECA IBARRA^{1,2}, EDOUARD LESNE¹, BACHIR OULADDIAF³, KETTY BEAUVOIS³, ALEXANDR SUKHANOV², RAFAL WAWRZYŃCZAK¹, WALTER SCHNELLE¹, ANTON DEVISHVILI³, DMYTRO INOSOV², CLAUDIA FELSER¹, and ANASTASIOS MARKOU¹ — ¹Max-Planck-Institute für Chemische Physik fester Stoffe, D-01187 Dresden, Germany — ²Institut für Festkörper- und Materialphysik, Technische Universität Dresden, D-01069 Dresden, Germany — ³Institut Laue-Langevin, CS20156, 38042 Grenoble Cedex 9, France

Noncollinear magnetism has attracted great attention in the recent years and promise rich exotic properties with potential for spintronic applications. In this work, we present a detailed analysis of the structural and magnetic properties of high-quality thin films of the hexagonal MnPtGa hard magnet grown on Al₂O₃(0001) substrates. The films crystalize in the *P*6₃/*mmc* space group, with an ordering temperature of  $T_C = 263$  K into a ferromagnetic (FM) state, followed by a spin reorientation transition at  $T_{sr} \sim 160$  K. A large uniaxial magnetic anisotropy is observed in this centrosymmetric compound. We further investigate the magnetic transitions by single-crystal neutron diffraction at zero applied magnetic field. The emergence of the structurally forbidden (001) Bragg reflection for T < 160 K, unequivocally determines a transition to a spin canted state, where the Mn magnetic moments align ferromagnetically along the *c*-axis and antiferromagnetically in the basal plane, resulting in a spin canting angle of 20° respect to the *c*-axis.

# MM 1: Invited Talk Carolin Körner

Time: Monday 9:30-10:00

Invited TalkMM 1.1Mon 9:30H44A novel mechanism to generate metallic single crystals — •CAROLIN KÖRNER,JULIAN PISTOR, JOHANNES BÄREIS, and MATTHIAS MARKL — Friedrich-Alexander Universität Erlangen-Nürnberg, Germany

Single crystals are used for high strength materials with high creep resistance such as turbine blades from nickel-base superalloys. The fabrication techniques applied to produce single crystals involve highly controlled and therefore relatively slow crystallization. For turbine blades, the Bridgman technique, i.e. investment casting combined with direction solidification, is the standard. The single crystal either develops starting from a single crystalline seed or by a geometric grain selection process. Microstructure evolution is determined by the solidification conditions resulting in a dendrite arm spacing of several hundreds of microns. This contribution shows how single crystals from nickel-base superalloys develop without seed during layer by layer metal additive manufacturing (AM) in the powder bed. These AM single crystals develop under rapid and directional solidification conditions with solidification microstructures one or two orders of magnitude finer than in the conventional Bridgman process. In addition, the underlying mechanism to generate the single crystal is based on thermo-mechanical provoked texture formation. The latter allows a very precise orientation of the single crystal. A manipulation of the orientation is possible by applying adequate process strategies. The basis mechanisms leading to the single crystal and the implications on the resulting properties are discussed.

# MM 2: Computational Materials Modelling: Energy Materials

# MM 2.1 Mon 10:15 H44

Importance of electronic correlations in exploring the exotic phase diagram of Li ion battery cathodes — •HRISHIT BANERJEE^{1,2}, CLARE P. GREY¹, and ANDREW J. MORRIS² — ¹Department of Chemistry, University of Cambridge, UK — ²School of Metallurgy and Materials, University of Birmingham, UK.

We explore electronic and magnetic states of layered Li_xMnO₂, a well known cathode material for Li ion batteries, as a function of states of charge x, using abinitio dynamical mean-field theory. Projecting onto low-energy subspace of Mn 3d states, and solving a multi-impurity problem, we find that an antiferromagnetic insulating state appears in  $\mathrm{LiMnO}_2,$  with a moderate Néel temperature in agreement with experimental studies. As the system is delithiated we find various exotic states emerge such as ferrimagnetic correlated metals, charge ordered ferromagnetic correlated metals with large quasiparticle weight, ferromagnetic metals with small quasiparticle weight, as a function of various states of delithiation of LiMnO₂ and finally an antiferromagnetic insulator for the fully delithiated state, which is albeit unstable. At moderate states of charge, x=0.67-0.33, a mix of +3/+4 formal oxidation states of Mn is observed, while its overall nominal oxidation state changes from +3 in  $LiMnO_2$  to +4 in  $MnO_2$ . In all these cases the high-spin state emerges as the most likely state. The quasiparticle peaks in the correlated metallic states could be attributed to polaronic states. We explore the temperature vs. state of charge phase diagram and conclude that the state of charge is a key ingredient for the emergence of the exotic correlated phase transitions in this material.

# MM 2.2 Mon 10:30 H44

#### Quantum-mechanical characterization of sulfur/carbon co-polymer cathodes for Li-S batteries — •POUYA PARTOVI-AZAR — MLU Halle-Wittenberg, Germany

Lithium-sulfur (Li-S) batteries are among the candidates for next-generation energy-storage systems thanks to their high energy density which arises from a high lithium capacity of elemental sulfur. However, cycling performance of Li-S batteries is drastically declined by a reversible capacity fade which is brought about by the diffusion of soluble Li-polysulfides through the electrolyte.^[1,2]

It has been recently shown that polymeric sulfur cathodes exhibit a promising performance in limiting the shuttle effect during the discharge.^[2] However, a clear atomistic picture on the favorable structures and their lithiation mechanism is still not fully established.

Here, we report our recent works on structural and electronic properties as well as finite-temperature vibrational spectra of polymeric sulfur cathodes, namely sulfur/1,3-diisopropenylbenzene^[3] and sulfur/polyacrylonitrile-based nanofiber^[4] co-polymers obtained through quantum-mechanical calculations. MM 2.3 Mon 10:45 H44 Si nanostructure formation in quenched AlSi μ-droplets for application as anode material in lithium-ion-batteries — •DAVID TUCHOLSKI and KARL-HEINZ HEINIG — Helmholtz-Center Dresden-Rossendorf, Dresden, Germany Location: H44

We report on 3D lattice kinetic Monte Carlo (3DlkMC) simulation of nanostructure formation during rapid quenching in gas-atomization (up to  $10^8$ K/s) of droplets of AlSi alloy melt. The nanostructured Si particles (with the Al selectively etched away) promise to enable about 10x the capacity of the current state-of-the-art graphite in lithium-ion batteries by mitigating Si pulverization.

This work reproduces the experimentally found nanosponge and core-shell particles and reveals heteronucleation at Al2O3 sites resulting from trace oxygen at the surface as the formation mechanism for core-shell particles.

The computer simulation uses a memory-efficient bit-encoded lattice, enabling large scale atomistic calculations, while kinetics is implemented via CPUefficient bit-manipulation for atom jumps between lattice sites. The jump probabilities are described by the metropolis algorithm with a look-up-table of energies calculated with an angular dependent potential for the Si-Al-Au system in LAMMPS.

This work is supported by the federal ministry for economic affairs and climate protection under grant number 01221755/1.

#### MM 2.4 Mon 11:00 H44

Tackling structural complexity in Li₂S-P₂S₅ solid-state electrolytes using Machine Learning — •TABEA HUSS, CARSTEN STAACKE, JOHANNES MARGRAF, KARSTEN REUTER, and CHRISTOPH SCHEURER — Fritz-Haber-Institut der MPG The lithium thiophosphate (LPS) material class provides promising candidates for solid-state electrolytes (SSE) in lithium ion batteries due to high lithium ion conductivities, non-critical elements, and low material cost. LPS materials are characterized by complex thiophosphate microchemistry and structural disorder influencing the material performance. Ab-initio studies probing lithium ion conductivity are constrained in system size and simulated time scales. This limits the transferability of computational results to industrial applicable LPS materials. Therefore, we present the development of a data efficient training protocol for the LPS material class using the Gaussian Approximation Potential (GAP). The GAP model can likewise describe crystal and glassy materials and different P-S connectivities  $P_m S_n$ . We apply the GAP model to probe lithium ion conductivity and discuss the influence of poly-anions on the latter. The sampling approach allows for a variety of extension and transferability to other SSE.

MM 2.5 Mon 11:15 H44

**Exploration of cathode-stable layered solid-state electrolytes** — •SINA ZIEGLER, CHRISTOPH SCHEURER, and KARSTEN REUTER — Fritz-Haber-Institut der MPG, Berlin, Germany

Promising higher safety and capacity, all-solid-state lithium batteries are envisioned to replace standard lithium-ion batteries in the future. Lithium thiophophates achieve the highest Li ion conductivities of SSEs to date exceeding liquid electrolytes at 10 mS/cm [1].

Until now, the instability of most SSEs towards high-performance electrodes remains a critical challenge, with hardly any known SSE withstanding the reducing/oxidizing conditions at the lithium metal anode and/or high-voltage cathodes or forming electrochemically benign interfaces with the electrode active materials.

To address this issue, we investigate the concept of rare earth lithium halides as a material-efficient, nm thick cathode coating in contact with thiophosphate

401

electrolytes as they provide wide electrochemical stability windows (0.36-6.71 V vs Li/Li⁺) as well as good chemical and thermodynamic stability [2,3].

In order to validate this approach, the thermodynamic stabilities of the emerging SSE / halide interfaces are examined by ab initio thermodynamics to screen reaction free enthalpies of possible interface reactions. Furthermore, (stable) products of selected material combinations are surveyed for sufficient lithium ion mobility.

MM 2.6 Mon 11:45 H44

Ab-initio core spectroscopy of LiCoO2 and CoO2 — DANIEL DUARTE RUIZ and •CATERINA COCCHI — Carl von Ossietzky Universität Oldenburg, Institut für Physik, Oldenburg, Deutschland

X-ray absorption spectroscopy (XAS) is one of the most widely used technique to study the electronic structure of cathode active materials in operando conditions. From a theoretical point of view, many-body perturbation theory on top of density-functional theory [1] is the state of the art in the prediction of XAS and in the interpretation of corresponding experimental results. In this work, we investigate core spectroscopy in LiCoO2 and CoO2, considering excitations from the Co K- and L23-edges as well as from the O K-edge. Our results, in agreement with experimental data, indicate that excitonic effects are negligible for the absorption spectra. The spectral fingerprints are well reproduced already by the independent particle approximation and, on a qualitative level, by the atomic, orbital features in the projected density states. These findings suggest that monitoring the electronic structure of LiCoO2 during the delithiation process is sufficient to capture the evolution of XAS signatures even in a possible high-throughput fashion.

#### MM 2.7 Mon 12:00 H44

High-throughput computational screening of fast Li-ion conductors — •TUSHAR THAKUR, LORIS ERCOLE, and NICOLA MARZARI — THEOS, EPFL, Switzerland

We present a high-throughput computational screening to find fast Li-ion conductors to identify promising candidate materials for application in solid-state electrolytes. Starting with ~30,000 experimental structures sourced from COD, ICSD and MPDS repositories, we performed highly automated calculations using AiiDA at the level of Density Functional Theory (DFT) to identify electronic insulators and to estimate lithium ion diffusivity using the pinball model [1] which describes the potential energy landscape of diffusing lithium at near DFT level accuracy while being orders of magnitude faster. We present the workflow where the accuracy of the pinball model is improved self-consistently and which is necessary in automatically running the thousands of required calculations and analysing their results. Promising conductors are further studied with first principles Molecular Dynamics simulations.

#### MM 2.8 Mon 12:15 H44

Adaptive kinetic Monte Carlo driven by local environment recognition — •KING CHUN LAI, SEBASTIAN MATERA, CHRISTOPH SCHEURER, and KARSTEN REUTER — Fritz Haber Institute of the Max Planck Society, Berlin, Germany Efficient lattice kinetic Monte Carlo (kMC) simulation generally relies on a complete prior-understanding of the possible elementary processes and their corresponding energy barriers. Adaptive kMC (akMC) overcomes this limitation by searching for those kinetics during the simulation, but the transition state searches (TSSs) become a bottleneck. To address this, we augment akMC with machine learning on local atomistic environments. Assigning a Smooth Overlap of Atomic Positions vector to each found process, we build up a database during simulation. This database is used to propose initial guesses for TSSs on basis of the proximity of the current local environments and the database entries. This proximity measure is self-adjusted based on statistics from TSSs on-the-fly. As the database fills, the proposed guesses from the database become close to the true transition states. These high quality TSS guesses improve simulation efficiency in two ways. First, the number of TSSs per kMC step gets significantly reduced by avoiding unsuccessful or repeating random TSSs. Second, damped Newton-Raphson becomes practical, which completes a proposed TSS in only a handful iterations. Taking a Pd surface as an illustrative example, we demonstrate the performance of the approach and also discuss how clustering and proximity learning can improve the TSS guesses further.

#### MM 2.9 Mon 12:30 H44

Atomistic Simulation Study of Li-Aluminosilicate Glass Scintillators — •EL MEHDI GHARDI, PRINCE RAUTIYAL, FIONA PEARCE, ANITA CROMPTON, LEE EVITS, SIMON MIDDLEBURGH, WILLIAM LEE, and MICHAEL RUSHTON — Nuclear Futures Institute, Bangor University, Gwynedd, LL57 2DG, United Kingdom

Radiation sensors are an important enabling technology in a number of fields, such as medicine, research, energy, military and homeland security. Glass base scintillators have been in use for more than 50 years and offer some benefits including their ability to respond to different types of radiation, and to be formed into various shapes. There is, however the possibility to discover and improve glass scintillators. With this in mind, this work provides insight from atomic scale simulations on the cerium doped Li-Aluminosilicate (SiO2-Al2O3-MgO- $Li_2O - Ce_2O_3$ ) glass scintillators. Three glass compositions were studied using Molecular Dynamics (MD) and Density functional Theory (DFT) to investigate the effect of the ratio  $R=([Al_2O_3])/([MgO]+[Li_2O])$  (with  $R=[0.3,\,0.8$  and 2]) on structural, electronic and optical properties. The effect of R on the complex structure of the system of interest was mainly associated to the increase of  $Q_4$  population that replaced  $Q_3$ 's within the network, while electronic mid gap defects were found to be present when R < 1. The optical properties including absorption coefficients and energy loss spectra are calculated and analysed based on the electronic structures.

Bonding descriptor based approach for analysing and finding new Photovoltaic absorbers — •JAKOB JOHANNES LÖTFERING and MATTHIAS WUTTIG — RWTH Aachen University, Aachen, Germany

The discovery of Halide Perovskites as good Photovoltaic absorbers and their rapid optimization lead to the question whether there are other materials yet undiscovered for Photovoltaic applications. In order to find new Photovoltaic absorbers, many approaches focus on structural data. We propose a bonding descriptor based approach using two quantities called electrons shared (ES) and electrons transferred (ET), which can be calculated using Density Functional Theory (DFT) calculations. ES and ET are derived from the Quantum Theory of Atoms in Molecules (QTAIM). The first quantity we employ is twice the delocalization index ( $\delta(\Omega', \Omega)$ ) between neighboring atoms. The second one is the number of electrons transferred to/from an atom compared to the unbonded atom.  $\delta(\Omega', \Omega)$  is a measure for the number of electron pairs shared between two atoms. It can be obtained by integrating the exchange-correlation pair density over two domains  $\Omega$  and  $\Omega'$ , which correspond to the two atoms. ES and ET have already shown to be good bonding descriptors and property predictors, e.g. for Halide Perovskites and Phase Change Materials. We propose that these quantities can also be used to analyse chemical bonding in Photovoltaic absorbers and predict novel materials in this category.

# MM 3: Microstructures and Phase Transformations: Metals & Alloys

Time: Monday 10:15-12:45

#### MM 3.1 Mon 10:15 H45

Analysis of the precipitates in rapidly quenched Al-Cu alloys obtained in a magnetic pulse weld and through a melt spinning process — •DAVID STEIN, MAXIMILIAN GNEDEL, and FERDINAND HAIDER — Universität Augsburg, Institut für Physik, Universitätsstraße 1, 86159 Augsburg, Germany

Magnetic pulse welding (MPW) is a collision welding technique, where a flyer is accelerated towards a target using induced magnetic fields. This technique enables the welding of dissimilar metals. The microstructure of the interface is well described in the literature and typically displays a wave like structure. In the eye and wake of these waves an area of intermetallic phases can be found, depending on the materials and welding parameters. In this case an Al 1050 flyer and Cu DHP target were used. The structure of the interface has given strong indications

of melting. Atomic resolution HAADF STEM was performed on this part and GP I and GP II Zones and disc shaped  $\Theta'$  phases were found in the same area. The latter typically only form after longer heat treatments at elevated temperature. Albeit the theoretically predicted shape of  $\Theta'$  Phases is disc shaped with very large diameter to thickness ratio, in the case studied here, they are much more compact and have a far smaller diameter to thickness ratio. The current working hypothesis is, that in the MPW process rapid solidification of the melt occurs, which leads to a high density of excess vacancies in the crystal structure, allowing for higher atom mobility. In an ongoing study we follow the precipitation process in rapidly quenched Al-Cu alloys obtained through a melt spinning process.

#### MM 3.2 Mon 10:30 H45

**Crystal nucleation in undercooled Cu-Ge melts** — •MANOEL W. DA SILVA PINTO, MARTIN PETERLECHNER, and GERHARD WILDE — Institut für Materialphysik, WWU Münster

Experimental calorimetric data obtained by differential thermal analysis on the nucleation of undercooled Cu-Ge melts are presented. Deep undercooling levels have been reached throughout the entire composition range of this binary alloy in an experimental setup using an inorganic glass as an embedding medium. The heating and cooling cycles are statistically analyzed and lead to quantitatively determining nucleation rates independent of a specific nucleation kinetics model. Parameters of the classical nucleation theory, such as the kinetic pre-factor and nucleation work, are extracted. We further discuss the data using different solution models for the alloy melts and consider their impact on nucleation kinetics. Thus, the nucleation kinetics parameters for the binary alloy system have been determined as a function of composition throughout the entire composition range and allow comparison with simplified models for concentration-dependent nucleation kinetics.

**Experimental investigation of the early stage precipitation reactions in Al-Cu alloys** — •JOHANNES BERLIN, TOBIAS STEGMÜLLER, and FERDINAND HAIDER — Chair for Experimental Physics I, University of Augsburg, Universitätsstraße 1, 86159 Augsburg

Due to their superior strength to weight ratio heat treatable Al-Cu alloys (2XXX-Series) are widely used particularly in aerospace industry. Although the hardening precipitates in these alloys are well-known, the very early stages of decomposition are still topic of ongoing research. Based on state-of-the-art scanning transmission electron microscopy, single Cu atoms can be imaged and natural ageing in form of Guinier*Preston zone formation accelerated by excess vacancies can be investigated, which was possible before only by diffraction experiments. Scanning transmission electron microscopy is used to investigate the influence of different parameters, such as thermal history, on early-stage precipitation in Al. The growth of GP I Zones is followed by ex-situ recording of a detailed time series during natural aging. In addition, resistivity and hardness measurements are performed to evaluate the temper state of the specimens. The results are compared to numerical simulations. A better understanding of the mechanisms leading to precipitate formation in these alloys for light-weight construction could be tuned more precisely regarding their intended use.

2D precipitate growth in a 3D matrix – Revealing the kinetics of Guinier-Preston zone formation in Al-Cu from atomic Monte Carlo — •TOBIAS STEGMÜLLER and FERDINAND HAIDER — University of Augsburg, Universitätsstr. 1, 86159 Augsburg, Germany

Guinier–Preston zones (GPZ) in Al–Cu, constituting the precipitate phase that was already responsible for the hardness increase in the first age-hardenable Alalloy about 115 years go, still attract attention first because of their special atomic mono- up to multilayer structure of Cu atoms and second due to their even at room temperature occurring formation, requiring an unexpected fast Cu diffusion.

To understand the origin of the GPZ structure, we performed Monte Carlo (MC) simulations mimicking precipitate growth by applying a Cluster Expansion (CE) for Al–Cu. From this we were able to identify an energy barrier above and below the layers of GPZ that is hardly overcome by migrating Cu. With this barrier we are able to explain the morphology of GPZ from a perspective focussing on the growth kinetics. On the one hand, the barrier guides migrating Cu to the layers' edges, supporting 2D growth. On the other hand, Cu atoms moving towards the layers' faces are stopped by the barrier, leading to nucleation of further Cu layers and explaining the multilayer shape.

To study the origin of the high Cu mobility, we recently included vacancies into simulations by switching from the CE based rigid lattice MC to a MC method allowing lattice relaxations by using a neural network interatomic potential. We present first results from this approach with regard to the interaction of vacancies with GPZ.

Atomic-scale observation of silver segregation in a high angle grain boundary in copper — •LENA FROMMEYER, TOBIAS BRINK, GERHARD DEHM, and CHRIS-TIAN LIEBSCHER — Max-Planck-Str. 1, 40213 Düsseldorf

Although it is well recognized that segregation to grain boundaries (GBs) influences mechanical and electrical properties of materials, the impact of segregation on individual GB phases is poorly understood on the atomic level. Thermodynamic models are established to describe equilibrium segregation, but the atomistic origins and direct observation of solute segregation inside the GB core structure are seldomly investigated since high resolution imaging and spectroscopy are required.

Lately, we were able to resolve the atomic structure of a symmetric  $\Sigma$  37c <111> {3 4 7} tilt GB in a Cu thin film using aberration-corrected high angle annular dark field scanning transmission electron microscopy (HAADF-STEM). By

depositing a 100 nm thin Ag layer on top of our 2  $\mu$ m-thick Cu thin film and subsequent annealing at 600°C, we could investigate the effect of Ag segregation on these GBs. Interestingly, the structure of the GB remains unchanged. Ag atoms solely substitute specific sites in the GB. If the Ag content in the GB is increased, one atomic column in the GB structure is filled up first, followed by four other columns. A combination of atomic resolution energy dispersive X-ray spectrometry, HAADF-STEM experiments and atomistic simulations were used to explore the underlying mechanisms leading to the observed Ag segregation pattern.

Grain boundary phase transitions and patterning in a copper tilt grain boundary — •TOBIAS BRINK¹, LENA FROMMEYER¹, RODRIGO FREITAS², TIM-OFEY FROLOV³, CHRISTIAN H. LIEBSCHER¹, and GERHARD DEHM¹ — ¹Max-Planck-Institut für Eisenforschung GmbH, Germany — ²MIT, USA — ³LLNL, USA

The atomic structure of grain boundaries (GBs) can exhibit different "phases" (also called complexions), which undergo thermodynamic phase transitions, but which have been observed in just a few simulation studies. Experimental confirmation often remains indirect. Here, we report on such a transition investigated by molecular dynamics computer simulations and supported by direct evidence from STEM imaging [1]. Two distinct atomistic structures could be found in a  $\Sigma 37c$  [111] tilt GB by a search with an evolutionary algorithm. Free energy calculations using the quasi-harmonic approximation predict a GB phase transition at 460 K. In the experiment, both phases also occur, but exhibit a pattern at room temperature in which the two phases alternate. We present a hypothesis to explain this thermodynamically unexpected phenomenon by elastic interactions of the phase junctions, which are line defects with partial dislocation character.

Structural and thermal characterisation of a AuGe alloy via electron microscopy and fast differential scanning calorimetry — •ŠTEFAN STANKO¹, JÜRGEN SCHAWE^{1,2}, and JÖRG LÖFFLER¹ — ¹Laboratory of Metal Physics and Technology, Department of Materials, ETH Zurich, 8093 Zurich, Switzerland — ²Mettler-Toledo GmbH, Analytical, 8606 Nänikon, Switzerland

A device combining scanning electron microscopy (SEM) and fast differential scanning calorimetry (FDSC) was developed to perform *in situ* characterisation of metastable phase transformations. The potential of this device is demonstrated on the example of a AuGe eutectic alloy. Upon rapid cooling, the alloy forms the metastable crystalline phases  $\beta$  and  $\gamma$  and an amorphous phase. A thin lamella for transmission electron microscopy (TEM) was produced from a sample prepared in FDSC to further characterise the microstructure of the alloy beyond the capabilities of the *in situ* device. *Ex situ* FDSC experiments were performed using cooling and heating rates of several 1000 K/s to characterise the thermal behaviour of the  $\beta$  and  $\gamma$  phase. The transformation kinetics of the metastable phases was investigated. Finally, we show that we can prepare the glassy phase in FDSC and determine its thermophysical properties.

**Phase decomposition in nanoporous Au-Pt** — •MAOWEN LIU^{1,2} and JÖRG WEISSMÜLLER^{1,2} — ¹Institute of Materials Mechanics, Helmholtz-Zentrum Hereon — ²Institute of Materials Physics and Technology, Hamburg University of Technology

Nanostructured Au-Pt system has attracted great attention for its broad applications in catalysis. Due to the miscibility gap for a large range of composition and temperature in bulk Au-Pt system, a comprehensive understanding of the structure transformation at various temperatures is necessitated. In the present work, nanoporous Au-Pt prepared by dealloying is selected for the investigation of the microstructure evolution during annealing. Dealloying transforms the homogeneous, ternary bulk solid solution Ag-Au-Pt into a nanoporous Au-Pt solution that would be immiscible at thermodynamic equilibrium. Remarkably, in view of the substantial atomic-scale rearrangement at the dissolution front, our experiments confirm a homogeneous Au-Pt solid solution. Upon annealing-induced coarsening, the phase structure evolves to semicoherent two-phase by way of an intermediate, coherent two-phase state.

Nanoscale analysis of Ti-modified Mo-Si-B alloy to elucidate solid solution and particle strengthening — •RESHMA SONKUSARE¹, TORBEN BOLL¹, JULIA BECKER², MARTIN HEILMAIER¹, and MANJA KRÜGER² — ¹Institute of Applied Materials and Karlsruhe Nano Micro Facility, Karlsruhe Institute of Technology, Germany — ²Institut für Werkstoff- und Fügetechnik, Otto-von-Guericke-Universität Magdeburg, Germany

Mo-Si-B alloys are attractive high-temperature structural materials due to their high melting point (>2000C), high-temperature strength and good oxidation resistance. We found that small additions of Ti to multi-phase Mo-Si-B lead to strengthening of alloy at intermediate and high temperatures. To understand the effect of Ti on microstructure and thus mechanical properties, we investigated powder metallurgically processed Mo-7.2Si-9.7B-1.7Ti. The microstructure consists of Mo solid solution phase, intermetallic silicide phases, nanoscale oxide and silicide particles. To analyze the composition of these nanoscopic particles, atom probe tomography is required. APT reveals Ti to cause an unexpected compositional change of Mo(SS) phase. This change and an analysis of the composition and distribution of other phases combined with an investigation of the particles and elemental segregations at the grain boundaries and inside the grains improve the understanding of the solid solution and particle strengthening in the alloy and hence the mechanical behavior.

Intrinsic room temperature ductilisation of lean rare-earth free ternary Mg **alloys** — •Wassilios Delis¹, Pia Huckfeldt¹, Bengt Hallstedt², Pei-Ling Sun¹, Dierk Raabe³, Sandra Korte-Kerzel¹, and Stefanie Sandlöbes- $\mathrm{Haut}^1 - {}^1\mathrm{Institute}$  for Physical Metallurgy and Materials Physics, RWTH Aachen, 52074 Aachen, Germany – ²Institute for Materials Applications in Mechanical Engineering, RWTH Aachen, 52062 Aachen, Germany — ³Max-Planck Institut für Eisenforschung, Max-Planck-Straße 1, 40237 Düsseldorf, Germany Mg is a lightweight structural material with a good specific strength. Unfortunately, it lacks good room temperature formability and therefore a wider commercial use of Mg is hindered. The preferred basal slip and strong basal-type texture were found to be the main reasons for the poor room temperature formability. For basal slip the von Mises' criterion is not fulfilled. Recent experimental and simulative studies tried to activate more slip systems without changing the mechanical properties with alloying approaches. Alloys containing Y and rareearth elements showed a highly increased room-temperature ductility. Since Y and rare-earth elements are costly further research has been carried out to identify similar acting alloy systems. For this purpose, the parameter I1 SFE has been used and the system Mg-Al-Ca was identified to have a similar I1 SFE. In experiments the system indeed showed the expected increased room temperature ductility. Further research of the effects of the chemical composition on the ductilisation has now been performed.

# MM 4.3 Mon 10:45 H46 PT phase transitions and spectral structure of the interacting Hatano-Nelson

**model** — •SONGBO ZHANG — Stetthachrrain 20, Zurich, Switzerland In this talk, I will discuss the Hatano-Nelson model, i.e., a one-dimensional non-Hermitian chain of spinless fermions with nearest-neighbour nonreciprocal hopping, in the presence of repulsive nearest-neighbour interactions. At halffilling, I will show two PT transitions, as the interaction strength increases. The first transition is marked by an exceptional point between the first and the second excited state in a finite-size system and is a first-order symmetry-breaking transition into a charge density wave regime. Persistent currents characteristic of the Hatano-Nelson model abruptly vanish at the transition. The second transition happens at a critical interaction strength that scales with the system size and can thus only be observed in finite-size systems. It is characterized by a collapse of all energy eigenvalues onto the real axis. I will also show that in a strong interaction regime, but away from half-filling, the many-body spectrum shows point gaps with nontrivial winding numbers, akin to the topological properties of the single-particle spectrum of the Hatano-Nelson chain.

Plasticity of the Ca(Al,Mg)2 phase with variable temperature and composition — •MARTINA FREUND¹, DOREEN ANDRE¹, PEI-LING SUN¹, NICOLAS J. PETER², and SANDRA KORT-KERZEL¹ — ¹Institut für Metallkunde und Materialphysik, RWTH Aachen University — ²Max-Planck-Institut für Eisenforschung GmbH, Düsseldorf

Magnesium is a promising lightweight material, but its application as cast alloys at elevated temperature is limited because of its low creep resistance. By alloying with Al and Ca different Laves phases form, which improve creep strength. While investigating largely unknown properties with respect to composition and temperature changes, a challenge is to physically relate and represent such results. Here, we explore - in addition to the specific findings - how this may be done in terms of defect phase diagrams. Due to their complex packing, Laves phases are brittle at low temperatures. In order to overcome this restriction and to study their mechanical properties and mechanisms of plasticity, we used nanomechanical testing. For the cubic CaAl2 phase, nanoindentation tests revealed a constant hardness of 5.9 +- 1.2 GPa and indentation modulus of 120.3 +- 17.9 GPa. Slip traces and cracks in the vicinity of indents were correlated with the crystal orientation and mostly corresponded to the {111} and {112} planes. Microcompression revealed deformation on {111} and {112} planes in <1-10> direction and the CRSS has been calculated as 0.97 +- 0.03 GPa and 0.96 +- 0.03 GPa, respectively. These planes and Burgers vectors were also confirmed by TEM using the g*b criterion.

MM 4.6 Mon 11:45 H46 Ab initio study of magneto-chemo-structural coupling at FeMn grain boundaries — •OMKAR HEGDE, JÖRG NEUGEBAUER, and TILMANN HICKEL — Max-Planck-Institut für Eisenforschung, Max-Planck-Strasse 1, 40227 Düsseldorf, Germany

Mn segregation at Fe grain boundaries is known to be a precursor for a variety of phenomena such as embrittlement, spinodal decomposition, phase transformation, etc [1,2]. Therefore, various heat treatments are performed in experiments to control Mn decoration at grain boundaries for *segregation engineering* [1], which could alter the local magnetic state. In this direction, a thorough understanding of the connection between the local magnetic state and segregation remains elusive. In the present work, we tackle this issue by studying segregation in both the ferromagnetic state (low-temperature) and paramagnetic state (high-temperature) using ab initio-based approaches [3]. We demonstrate that the Mn segregation profile is mainly modulated by local magnetic interactions, providing new opportunities for grain boundary segregation engineering. Finally, we

show that the formation of grain boundary and Mn segregation can, in turn, tune the local magnetic transition temperature, thereby revealing a complex coupling of structure, chemistry, and magnetism.

Sulphation kinetics of chloride particles, corrosion potential and effect of reactive additives — •SEBASTIAN PENTZ and FERDINAND HAIDER — Universität Augsburg, Institut für Physik, 86135 Augsburg

Chlorine induced high temperature corrosion leads to massive problems especially in waste-to-energy-plants, but also in biomass combustion. During the combustion process chloride containing particles are released and deposited on heat exchanger surfaces. There chlorides get converted into sulphates with a release of chlorine species which then lead to severe corrosion. In laboratory experiments we study the conversion kinetics under various conditions like temperature, particle size or gas composition. Both the sulphation reaction and the rate of subsequent corrosion show an Arrhenius dependency on temperature, a linear dependence on time, on particle surface and on partial pressure of SO2. The addition of reactive additives can strongly influence this reaction and consequently the release of chlorine species: Adding iron oxide (e.g. Fe₂O₃) results in a strong acceleration of the sulphation process due to catalysis of the reaction from SO₂ to SO3. On the other hand, a reduction of the sulphur content in the reaction atmosphere by desulphurising species like calcium oxide slows down the sulphation reaction and reduces the amount of released chlorine compounds.In lab experiments, chlorides (mixed with additives) are applied to 16Mo3 steel samples and exposed to a flowing reaction atmosphere in a tube furnace.Support by Federal Ministry for Economic Affairs and Climate Action on the basis of a decision by the German Bundestag.

Influence of oxygen and carbon on the chemistry at the niobium/alumina interface in a refractory composite material — •MICHAEL EUSTERHOLZ¹, TORBEN BOLL¹, ALEXANDER KAUFFMANN¹, RESHMA SONKUSARE¹, VINCENT OTT¹, JULIAN GEBAUER¹, BASTIAN KRAFT¹, ANJA WEIDNER², MICHAEL STÜBER¹, SVEN ULRICH¹, and MARTIN HEILMAIER¹ — ¹Karlsruhe Institute of Technology (KIT) — ²TU Bergakademie Freiberg (TUBAF)

High-temperature processes such as steel casting impose harsh conditions on materials, which thus require excellent properties, including creep strength and resistance to thermal shock. Composites based on coarse-grained refractory metals and refractory ceramics promise superior performances due to adjustable mechanical and electrical properties.

Conventionally sintered composites from technical grade raw materials of  $\alpha$ -Al₂O₃ and Nb include impurity elements that form carbides alongside oxides during synthesis. To understand the principles of formation, we investigate  $\alpha$ -Al₂O₃ substrates sputter-coated with Nb as model materials beside the technical grade material. As the latter is subjected to carbon and oxygen containing gases during sintering, we compare the effect of oxygen and carbon overexposure on the ceramic-metal interface and contrast these results with a heat treatment with

unaffected interface. Electron microscopy techniques elucidate the microstructure, while atom probe tomography advances the understanding of nano-scale phase formation at the phase boundary which are decisive for the material properties and corrosion resistance.

MM 4.9 Mon 12:30 H46

Oxidation mechanisms of SMART alloys and MAX phases — •ANICHA REUBAN^{1,2}, JESUS GONZALEZ-JULIAN^{1,2}, IVAN POVSTUGAR¹, ANDREY LITNOVSKY^{1,3}, and CHRISTIAN LINSMEIER¹ — ¹Forschungszentrum Jülich GmbH, 52425 Jülich, Germany — ²Institute of Mineral Engineering, RWTH Aachen University, 52064 Aachen, Germany — ³Moscow

Concentrated Solar Power (CSP) is a sustainable energy technology where sunlight is focused on a solar receiver and the thermal energy is used to generate electricity. The receiver must withstand temperatures greater than 1000 °C, be resistant to oxidation by air and/or corrosion by molten salts and and maintain its properties over time. Self-passivating SMART alloys, originally designed for the fusion reactor, are resistant to plasma sputtering and can suppress oxidation in case of an accident with air ingress, up to 1000 °C. MAX phases, a bridge between metals and ceramics, are lightweight, easily machinable materials, oxidation- and corrosion-resistant up to 1400 °C. To understand the oxidation mechanisms in these materials, it is important to obtain nanoscale information using advanced characterization techniques such as Atom Probe Tomography (APT). According to the APT analysis of the SMART alloy W-Cr-Y, Y segregates at oxide grain boundaries while in the alloy it forms Y-O precipitates. Further analyses are being performed to get more information about the role of Y in the oxidation process. Electron microscopy is used along with APT for a correlative approach to nanoscale characterization.

The focus of this work is the development of a new composite material, that has to withstand the immense heat and particle fluxes in future fusion reactors. The wall material is based on the element tungsten, which already shows a very high compliance with the requirement profile in its pure form. Pure tungsten is inherently brittle below the DBTT and cracks could lead to a complete failure of the wall material. To counter this problem, extrinsic strengthening mechanisms were tested with new fabric types, based on radially braided yarns with seven core- and 16 sleeve filaments. These yarns were coated with an Yttriumoxide interface by Magnetron-sputtering and then further processed with chemically vapor deposited tungsten in a six-layer structure to form a solid composite material. This sample was analysed optically and got mechanically tested in a three-point bending test.

**Vacancy transport in oxides exposed to high electric fields** — •REINER KIRCHHEIM — University of Goettingen, Goettingen, Germany — Max-Planck-Institute for Iron Research, Duesseldorf, Germany — I2CNER, Fukuoka, Japan Internal electrochemical redox reactions and accumulation of charge in oxides are treated. Internal reactions shall lead to electronic conduction in the reduced and oxidized regions near cathode and anode respectively. Several scenarios for the generation and transport of charged oxygen vacancies and the attainment of steady state are discussed. It will be shown that at high cell voltages the characteristic time for reaching steady state, also called incubation time, is smaller than the characteristic time for the growth of reacted regions. Then the incubation time is inverse proportional to the squared cell voltages or the voltage drop across the oxide, respectively. Examples were this relation is fulfilled are given for electromigration in integrated circuits, formation of memristors, flash sintering of ceramics and degradation of high-k materials. In addition, diffusion coefficients for vacancies evaluated from incubation times of yttria stabilized zirconia (YSZ) agree with extrapolated measured values. Internal reactions will also play a role in solid oxide fuel cell (SOFC) and solid oxide electrolysis cells (SOEC), where current densities may exceed the reaction rates with gases at the porous electrodes.

Unveiling the mechanisms of motion of synchro-Shockley dislocations in Laves phases – •ZHUOCHENG XIE¹, DIMITRI CHAURAUD^{2,3}, ACHRAF ATILA^{2,3}, ERIK BITZEK^{2,3}, SANDRA KORTE-KERZEL¹, and JULIEN GUÉNOLÉ⁴ – ¹Institute of Physical Metallurgy and Materials Physics, RWTH Aachen University, 52056 Aachen, Germany – ²Max-Planck-Institut für Eisenforschung GmbH, Max-Planck-Str. 1, 40237 Düsseldorf, Germany – ³Institute I: General Materials Properties, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany – ⁴Université de Lorraine, CNRS, Arts et Métiers ParisTech, LEM3, 57070 Metz, France

In Laves phases, synchroshear is the dominant basal slip mechanism. It is accomplished by the glide of synchro-Shockley dislocations. However, the atomic-scale mechanisms of motion of such zonal dislocations are still not well understood. In this work, using atomistic simulations, two 30° synchro-Shockley dislocations with different Burgers vectors and core structures and energies are identified. We demonstrate that nucleation and propagation of kink pairs is the energetically favorable mechanism for the motion of the synchro-Shockley dislocation. Vacancy hopping and interstitial shuffling are identified as two key mechanisms related to kink propagation and we investigated how vacancies and antisite defects assist kink nucleation and propagation, which is crucial for kink mobility. These findings provide insights into the dependency on temperature and chemical composition of plastic deformation induced by zonal dislocations in topologically close-packed phases.

**Macroscopic characteristics of plastic deformation described through dislocation mobility properties** — •SERGEI STARIKOV, ANTOINE KRAYCH, and MA-TOUS MROVEC — Ruhr University Bochum, ICAMS, Germany

Plastic deformation of bcc metals is a complicated phenomenon that links a behaviour of crystal defects with the macroscopic change of a sample shape. It is known that one of the basic mechanisms of plasticity is a motion of dislocations under applied stress. In this work, on the example of Mo and Nb, the study of plastic deformation in bcc metals was carried out with large-scale atomistic modelling. The temperature-dependent mobility functions of screw and edge dislocations were calculated from molecular dynamics simulation. The simulations of screw dislocation movement under applied shear stress revealed that the process can proceed in two different regimes: through thermally activated motion and athermal motion. Hence, the dislocation velocity depends on the shear stress in a non-trivial way. The calculated data provide a way to evaluate the basic macroscopic characteristics of plastic deformation at various temperatures and strain rates.

Analytic description of grain boundary segregation, tension, and formation energy in the copper-nickel system — TAMARA KRAUSS, FELIX FISCHER, and •SEBASTIAN EICH — Institut für Materialwissenschaft — Lehrstuhl für Materialphysik, Universität Stuttgart

In this atomistic study, a recently proposed segregation model [1] is applied to segregation data of an exemplary  $\Sigma 5$  grain boundary (GB), which is investigated using a copper-nickel embedded-atom method potential. Segregation in the semi-grandcanonical ensemble is systematically studied by varying the chemical potential in order to explore the full composition range for temperatures from 500 K to 1000 K. As a major thermodynamic feature, the mentioned segregation model avoids the usage of interface compositions, for which an arbitrary volume must be defined, but rather models the thermodynamically unambiguous solute excess. It was shown that the solute excess and the interface formation energy could be described very accurately over a wide range of temperatures and over the entire composition. Since the model was initially derived for systems without lattice mismatch, the copper-nickel system with a mismatch of roughly 2.7% is chosen in this study to further extend the segregation model by a linear-elastic theory to also account for the interface tensions. Using this extended model, it will be shown that the solute excess, GB tensions, and GB formation energies can be derived from an effective energy of segregation for all temperatures and over the whole composition range [2].

Impurity segregation at grain boundaries in bcc iron: large scale models based on machine learned interatomic potentials — •PETR ŠESTÁK¹, MONIKA VŠIANSKÁ^{1,2}, PAVEL LEJČEK^{1,3}, and MIROSLAV ČERNÝ¹ — ¹Central European Institute of Technology, CEITEC BUT, Brno University of Technology, Purkyňova 123, CZ-616 69 Brno, Czech Republic — ²Department of Chemistry, Faculty of Science, Masaryk University, Kotlářská 2, CZ-611 37 Brno, Czech Republic — ³Institute of Physics of the Czech Academy of Sciences, Na Slovance 2, CZ-182 21 Prague 8, Czech Republic Location: H44

In this work, we employed on the fly machine learning (ML) as it is implemented in the current version of the VASP to study segregation of Sn, P and Ge atoms at selected GBs (e.g.  $\Sigma3(112)$ ,  $\Sigma3(111)$ ,  $\Sigma5(310)$ ,  $\Sigma5(210)$ ,  $\Sigma13(510)$ ,  $\Sigma13(320)$ , etc.) in bcc iron. Segregation energies were obtained using small supercells (<100 atoms), medium cells (~400 atoms) and also larger cells (>1000 atoms). Data obtained from the small and medium cells were compared with results of ab initio calculations as well as with available experimental data and predictions. This comparison serves as a benchmark of the interatomic potentials received from ML. The comparison shows that the segregation energies and some other GBs characteristics obtained for small cells are very consistent with ab initio simulations which bring a proof of reliability of interatomic potentials. The obtained results revealed that using small simulation cells (leading to high concentrations of impurity atoms), typical for ab initio simulations, might not be sufficient to predict correct segregation energies.

#### MM 6.5 Mon 16:45 H44

An efficient method to access the grain boundary parameter space with atomistic simulations — •TIMO SCHMALOFSKI¹, MARTIN KROLL², REBECCA JANISCH¹, and HOLGER DETTE² — ¹ICAMS, Ruhr-University Bochum, 44780 Bochum, Germany — ²Department of Mathematics, Ruhr-University Bochum, 44780 Bochum, Germany

A grain boundary (GB) is a two dimensional defect in solids with significant influence on different material properties. It describes the interface between two grains with different orientations and is thus defined by five macroscopic degrees of freedom (DOF), 2 from the rotation axis, 1 from the misorientation angle and 2 from the grain boundary normal vector. The GB energy as a function of the DOF can be obtained e.g. by atomistic simulations. However, a systematic sampling of the 5D grain boundary parameter space, or even lower-dimensional subspaces of it, comes with several challenges. To overcome them, a sampling method is needed, which only needs a small number of data points and can automatically find the cusps (deep minima) in the energy while sampling. Recently we introduced a sequential sampling technique which fulfills both [1] in the 1D subspace of symmetrical tilt grain boundaries. Now this sequential sampling technique will be evaluated for a 2D analysis of the energy as a function of GB plane inclination for fixed misorientations. [1] Kroll, M., Schmalofski, T., Dette, H. and Janisch, R. (2022), Efficient Prediction of Grain Boundary Energies from Atomistic Simulations via Sequential Design. Adv. Theory Simul. 2100615.

Electronic band gap of  $Al_xSc_{1-x}N$ : a comparison of CPA and SQS – •JAN M. WAACK^{1,2}, MARKUS KREMER^{1,2}, MICHAEL CZERNER^{1,2}, and CHRISTIAN HEILIGER^{1,2} – ¹Institut für theoretische Physik, Justus-Liebig-Universität Gießen, Germany – ²Center for Materials Research (LaMa), Justus-Liebig-Universität Gießen, Germany

Calculating physical properties of random substitutional solid solutions such as  $Al_xSc_{1-x}N$  requires specific methods such as the coherent potential approximation (CPA)[1] and special quasi-random structures (SQS)[2]. We compare the CPA in the framework of the atomic sphere approximation (ASA) Korringa-Kohn-Rostoker (KKR) density functional theory (DFT) with the SQS using the plane-wave pseudopotential DFT to calculate the lattice parameters and electronic band structures of the face-centered cubic phase of  $Al_xSc_{1-x}N$  (with  $0 \le x \le 1$ ).

Using the low-computational-cost LDA-1/2 quasiparticle method[3] to calculate the electronic band structures within SQS and CPA, we present the first implementation of LDA-1/2 within the KKR DFT. We find that both the lattice parameter and the indirect band gap satisfy Vegard's law including a bowing parameter.

Using MD simulations to better understand and control self-propagating reactions in Al-Ni multilayers — •FABIAN SCHWARZ and RALPH SPOLENAK — Laboratory for Nanometallurgy, Department of Materials, ETH Zürich, CH-8093 Zürich, Switzerland

Reactive multilayers are capable of releasing large amounts of heat in a short time, making them a possible tool for energy storage or joining applications. Molecular Dynamics (MD) simulations can be used as a tool to study the front propagation, while varying certain system parameters. We study the influence of the crystal structure on the reaction front propagation in Al-Ni multilayers by looking at various microstructures, such as amorphous, single crystal or different grain structures. We found that crystallinity has a significant impact on the front propagation speed, which is likely related to different diffusion mechanisms. The more disordered the individual layers become, e.g., by increasing the grain boundary density, the higher is the resulting propagation speed. Furthermore, we study the influence of a premixed interlayer at the interface on the reaction propagation. For this, premixed interlayers with different, namely homogeneous, gradient and s-shaped profiles are studied and compared to existing experimental results. Beyond better understanding of the premixed interlayer, we show that it can be used to control the front propagation speed in reactive multilayers. Furthermore, we show that the heat of crystallization of amorphous AlNi to B2-AlNi alone is high enough for a self-propagating reaction to occur.

#### MM 6.8 Mon 17:45 H44

strong impact of spin fluctuations on the antiphase boundary energies of weak ferromagnetic Ni3Al — •XIANG XU^{1,2}, XI ZHANG², ANDREI RUBAN^{3,4}, SIEGFRIED SCHMAUDER¹, and BLAZEJ GRABOWSKI² — ¹Institute for Materials Testing, Materials Science and Strength of Materials, University of Stuttgart, Germany — ²Institute for Materials Science, University of Stuttgart, Germany — ³KTH Royal Institute of Technology, Stockholm, Sweden — ⁴Materials Center Leoben Forschung GmbH, Leoben, Austria

The antiphase boundary (APB) was believed to be crucial for explaining the anomalously increased yield stresses of  $L1_2$  Ni₃Al. However, an accurate temperature-dependent APB energy is still missing and the magnetic effect was often underestimated or even neglected. In this work, the influence of longitudinal spin fluctuations (LSF) as well as other thermal mechanisms were considered within the ab-initio framework up till the melting point. We found that the calculated *T*-dependent APB energies show a remarkable agreement with the experimental data despite the large discrepancy between different works. The LSF effect was determined to crucially increase APB energies, especially for (100)APB with a maximum of 50% over the nonmagnetic data. This significant contribution prompts to take serious consideration of LSFs when studying the paramagnetism, even for weak itinerant ferromagnetic materials. The accurate APB energy acquired in this work can be used to set up quantitative models for simulating dislocation motions and the elastic-plastic behavior for Ni-based superalloys on the macro scale.

Ab initio study on the phase stabilities of multi-component carbides in high-Mn steels — LEKSHMI SREEKALA¹, JÖRG NEUGEBAUER¹, and •TILMANN HICKEL^{1,2} — ¹Max-Planck-Institut für Eisenforschung, Düsseldorf, Germany — ²BAM Bundesanstalt für Materialforschung und -prüfung, Berlin, Germany

The high strength and ductility of advanced high Mn steels makes them suitable for lightweight applications in the transportation sector. A modification of their properties can be achieved by intentional or unintentional addition of further alloying elements, which is often connected with the formation of secondary phases. In particular, Cr addition improves corrosion resistance and, at the same time, inadvertently yields a substantial increase in the number of carbides precipitated, such as Fe3C and Fe23C6. Therefore, in the present work, we use density functional theory to determine the thermodynamic driving force for the formation of these multicomponent carbides by evaluating their phase stabilities. We study the free energy of formation at finite temperatures by considering the vibrational, electronic and magnetic contributions. While both Cr and Mn stabilize Fe-carbides, we found that the impact of Cr is higher than that of Mn for a typical host matrix composition of Fe, Cr and Mn. Further, we analyze the critical role of magneto-structural coupling for the phase stability of these compositionally complex carbides. Through this study, we demonstrate the predictive capability of ab initio thermodynamics to accurately describe the phase stabilities of chemically complex secondary phases in metallic alloys.

Atomistic simulation of diffusion in  $\gamma'$ -strengthened Co-based superalloys — •LIN QIN¹, JUTTA LOGAL^{2,3}, DOROTA KUBACKA⁴, and RALF DRATZ¹ — ¹ICAMS, Ruhr University Bochum, Bochum, Germany — ²Department of Chemistry, New York University, New York, United States — ³Department of Physics, Free University of Berlin, Berlin, Germany — ⁴Institute of Micro- and Nanostructure Research, FAU, Erlangen, Germany

The suppressed diffusion of Al in the strengthening  $\gamma'$  precipitates in Co-based superalloys is suspected to be one plausible reason to cause the selective formation of alumina in the early stage of oxidation above 900°C. In order to validate this assumption, the diffusion properties of Al, Co and W in a prototype structure of  $\gamma'$  phase, i.e. Ll₂-Co₃ (Al, W), are investigated with Density Functional Theory (DFT) and Kinetic Monte Carlo (KMC) simulations. DFT calculations reveal that the migration barrier of each element in Co sublattice is comparable with its respective barrier in pure Co. However, the crossover barriers of Al and W from their original positions to Co sublattice are much higher than the barriers for the reverse process. This large discrepancy in barriers constrains the site fraction of Al and W in Co sublattice, and therefore significantly suppresses the long-distance diffusion of Al and W in  $\gamma'$  phase. KMC results show that Al diffusivity in  $\gamma'$  phase is over two order of magnitudes lower than that in a solute  $\gamma$  phase (Co₇₅Al_{12.5}W_{12.5}) at 900°C, suggesting that the sluggish diffusion of Al in  $\gamma'$  can be a possible reason to cause the selective formation of alumina in Co-based superalloys.

Evolution of a particle in twisted bilayer optical potentials - •GANESH C. PAUL¹, PATRIK RECHER^{1,2}, and LUIS SANTOS³ - ¹Institut für Mathematische Physik, Technische Universität Braunschweig, 38106 Braunschweig, Germany ²Laboratory for Emerging Nanometrology, 38106 Braunschweig, Germany — ³Institut f
ür Theoretische Physik, Leibniz Universit
ät Hannover, Germany Very recently few theoretical proposals have been put forward to simulate twisted bilayers using cold atoms in state-dependent optical lattices, which can be used as an alternative platform to investigate twisted bilayers in solid-state experiments. We study the band structure of both square and hexagonal geometries in an optical lattice set-up, where the band structure can be tuned to be almost flat by proper implementation of interlayer Gaussian-type coupling. We examine the evolution of a particle in the twisted bilayer square-like potential, and find that the particle follows specific paths forming channels when the interlayer hopping is much stronger than the intralayer hopping strength. Due to the flexibility of controlling the inter- and intralayer coupling in optical lattices, our proposals should be easy to be realised in a cold atom set-up.

#### MM 7.2 Mon 16:00 H45

Phase transitions and phonon renormalization in CsPbBr₃ via a machine learning interatomic potential — •ERIK FRANSSON¹, FREDRIK ERIKSSON¹, PETTER ROSANDER¹, TERUMASA TADANO², and PAUL ERHART¹ — ¹Chalmers University of Technology, Gothenburg, Sweden — ²National Institute for Materials Science, Tsukuba, Japan

Here, we present a study on phase-transition and phonon renormalization in the metal halide perovskite CsPbBr₃ using a machine learning (ML) interatomic potential. The ML potential is a neuroevolution-potential constructed using the GPUMD software and is trained on atomic forces, energies and stresses obtained from DFT calculations. We find that the ML potential captures the correct phase-

transition from the orthorhombic phase to tetragonal phase and from tetragonal to cubic phase. The phase transition temperatures obtained are slightly underestimated compared to experimental studies, but in good qualitative agreement. These phase-transitions are connected to the so called tilt-modes at the R and M point in the brillouin zone, which corresponds to tilting of the PbBr₆ octahedra. The dynamics of these modes are studied with MD simulations and mode projections, and we find that they have are strongly anaharmonic and overdamped character. Furthermore, we investigate and benchmark how different self-consistent phonon methods work for these strongly anharmonic modes.

A particular EFG temperature dependence for 181-Ta(TiO2): An electrongamma TDPAC study — •IAN CHANG JIE YAP¹, JULIANA SCHELL^{2,3}, THIEN THANH DANG³, CORNELIA NOLL⁴, REINHARD BECK⁴, ULLI KÖSTER⁵, RONALDO MANSANO⁶, PETER BLÖCHL^{1,7}, and HANS CHRISTIAN HOFSÄSS¹ — ¹Georg-August Universität Göttingen — ²European Organization for Nuclear Research (CERN) — ³Institute for Materials Science and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen — ⁴Helmholtz-Institut für Strahlen- und Kernphysik, University of Bonn — ⁵Institut Laue-Langevin — ⁶Escola Politécnica, Universidade de São Paulo — ⁷Technische Universität Clausthal, Institute of Theoretical Physics

In this work, we report on the hyperfine parameters of the implanted 181Ta probe in the rutile structure of the single crystal TiO2 using the e - y time differential perturbed angular correlation (e - y TDPAC) technique. The experiments were performed under vacuum within the temperature range of 50 K - 427 K. The hyperfine parameters that are obtained from the e - y TDPAC spectroscopy agrees with that of the y - y TDPAC spectroscopy at room temperature, apart from a calibration factor, both from our experiments and literature. Surprisingly, we have detected a parabolic increase of Vzz with a concave curvature at the lowtemperature regime (50 K - 427 K), as opposed to the linear increase at the high-temperature regime (600 K - 1200 K) as found in the literature. Hence, we are performing DFT calculations on Ta-doped TiO2 over a broad temperature range to obtain deeper insights.

Since the discovery of charge disproportionation in  $Sr_3Fe_2O_7$  by Mössbauer spectroscopy >50 years ago, the spatial ordering pattern of the disproportionated charges has stayed "hidden" to conventional diffraction, despite numerous x-ray and neutron studies. Our neutron Larmor diffraction and Fe *K*-edge resonant x-ray scattering demonstrate checkerboard charge order in the FeO₂ planes that vanishes at a sharp second-order phase transition at 332 K. Stacking disorder of the checkerboard pattern due to frustrated interlayer interactions broadens their superstructure reflections, greatly reducing their amplitude, explaining the dif-

ficulty to detect them. We discuss implications of these findings for research on "hidden order" in other materials.

Band structure effects of a current-induced Mott-insulator to metal transition in Ca₂RuO₄ — •D. CURCIO¹, C. E. SANDERS², A. CHIKINA¹, M. BIANCHI¹, H. E. LUND¹, V. GRANATA³, M. CANNAVACCIUOLO³, P. DUDIN⁴, J. AVILA⁴, C. POLLEY⁵, B. THIAGARAJAN⁵, A. VECCHIONE⁶, and P. HOFMANN¹ — ¹Department of Physics and Astronomy, Aarhus University, Denmark — ²STFC Central Laser Facility, Harwell Campus, United Kingdom — ³Dipartimento di Fisica *E.R. Caianiello*, Università degli Studi di Salerno, Italy — ⁴Synchrotron SOLEIL, Gifsur-Yvette, France — ⁵MAX IV Laboratory, Lund University, Lund, Sweden — ⁶CNR-SPIN, c/o Università degli Studi di Salerno, Italy

The Mott insulator  $Ca_2RuO_4$  can be turned into a metal by the application of a weak electric field and a corresponding transport current. This transition affects the optical and magnetic properties of the material. However, because of the electric field's presence and the field-induced energy broadening, it is challenging to determine the electronic structure in the metallic state by angle-resolved photoemission spectroscopy (ARPES). Making use of the recently introduced approach to enable ARPES measurements of current-carrying devices by using a nano-scale light spot [1], we are able to measure ARPES data that tracks the current-induced phase transition in  $Ca_2RuO_4$  simultaneously with the electrical transport, revealing the spectral function of the current-induced state along with a potential map of the sample's surface.

Atomistic analysis of Li migration in  $Li_{1+x}Al_xTi_{2-x}(PO_4)_3$  (LATP) solid electrolytes — •DANIEL PFALZGRAF^{1,2}, DANIEL MUTTER², DANIEL URBAN^{1,2}, and CHRISTIAN ELSÄSSER^{1,2} — ¹Freiburg Materials Research Center (FMF), University of Freiburg, Stefan-Meier-Straße 21, 79104 Freiburg, Germany — ²Fraunhofer IWM, Wöhlerstraße 11, 79108 Freiburg, Germany

We present an examination of the ionic migration of Li in LATP  $[Li_{1+x}Al_xTi_{2-x}(PO_4)_3]$  solid electrolytes from an atomistic viewpoint based on density functional theory calculations [1]. In our study, we vary the Al content and investigate its effects on the crystal structure of LATP and on the migration energy landscape of interstitial Li ions. The energy profiles governing the Li diffusion are found to be systematically influenced by the position of Al ions in direct vicinity of the migration path, and we derive a simplified classification scheme of three universal energy profile shapes. The overall influence of the Al/Ti-ratio on the Li migration is analyzed by a separation into chemical and geometrical aspects. This work provides a solid basis for a resource-efficient computational examination of the ionic conductivity of Li in LATP with varying Al/Ti concentrations.

MM 8.3 Mon 16:15 H46

Li diffusion in perovskite materials for battery applications — •WEI WEI¹, JU-LIAN GEBHARDT^{1,2}, DANIEL URBAN^{2,3}, and CHRISTIAN ELSÄSSER^{1,2,3} — ¹Cluster of Excellence livMatS, University of Freiburg, Germany — ²Fraunhofer Institute for Mechanics of Materials IWM, Freiburg, Germany — ³Freiburg Materials Research Center (FMF), University of Freiburg, Germany

Metal halide perovskites are promising photovoltaic (PV) absorber materials, with the highest power conversion efficiency values currently exceeding 22%. Furthermore, unlike most of the traditional PV materials, hybrid perovskites have a strong ionic character. Therefore, these materials have recently been reported to have good ionic conductivity and lithium storage potential,  $^{\left[ 1\right] }$  allowing in principle the combination of a solar cell and a Li-ion battery in a single device. Here, we investigate this possibility by a Li-CsPbI3 model system. By means of density-functional-theory calculations, we consider two scenarios: 1) Li in the rigid cubic perovskite structure, and 2) Li in the perovskite structure with flexible tilted bonds, which is the more realistic scenario at room temperature. The results of our simulations show that in the less symmetric structure the interstitial Li sites become nondegenerate and Li ions migrate along more complicated paths and have to overcome higher barriers than in the cubic structure. Nevertheless, diffusing Li ions have to overcome only moderate energy barriers of 0.16-0.33 eV, corroborating the potential use of metal-halide perovskites as Liion conducting PV materials.

#### MM 8.4 Mon 16:30 H46

Analytical TEM studies of LiCoO₂ thin film electrode for Li-ion batteries — •ARDAVAN MAKVANDI¹, SANDRA LOBE², MICHAEL WOLFF², MARTIN PETERLECHNER¹, CHRISTOPH GAMMER³, SVEN UHLENBRUCK², and GERHARD WILDE¹ — ¹Institute of Materials Physics, University of Münster, Münster, Germany — ²Institute of Energy and Climate Research, Materials Synthesis and Processing (IEK-1), Forschungszentrum Jülich GmbH, Jülich, Germany — ³Erich Schmid Institute of Materials Science, Austrian Academy of Sciences, Leoben, Austria

LiCoO₂ is the mostly used cathode material in commercial Li-ion batteries. However, only half of its theoretical capacity can be used due to the structural and chemical instability of its surface at charge voltages higher than 4.2 V. In general, interfaces (e.g. active material/coating, electrode surface/electrolyte) determine the local Li-ion transport kinetics and finally the electrochemical performance. Therefore, it is necessary to study the structure and chemistry of electrodes and electrode/electrolyte interfaces. In this work, the structure and chemistry of the bulk and surface regions of LiCoO₂ thin film before and after cycling are studied using transmission electron microscopy (TEM). In this case, the effect of an Aldoped ZnO-coating layer on the stability of the electrode surface upon cycling at high charge voltage has been studied.

#### MM 8.5 Mon 16:45 H46

Investigation of volume changes in the colquiriite structure due to Li insertion from first principles — •ALJOSCHA BAUMANN^{1,2}, DANIEL MUTTER², DANIEL URBAN^{1,2}, and CHRISTIAN ELSÄSSER^{1,2} — ¹Freiburger Materialforschungszentrum, Stefan-Meier-Straße 21, 79104 Freiburg — ²Fraunhofer IWM, Wöhlerstraße 11, 79108 Freiburg

The long-term stability of lithium-ion batteries (LIB) is often negatively affected by mechanical stresses in the cathode material during charge/discharge cycles. Materials that show a zero-strain (ZS) behavior, i.e. their volume changes hardly during insertion or extraction of Li ions, are therefore of great interest. For individual compounds of the material class of colquiriites, LiA^{II}M^{III}F₆, ZS behavior has already been predicted theoretically and observed experimentally, e.g. for Li_{1+x}CaFeF₆, which exhibited a volume change of less than 0.5 % upon insertion of lithium ions up to x=0.8.

In order to identify the mechanism responsible for the ZS behavior we calculated the variation of the equilibrium volume due to varying Li concentration using density-functional theory (DFT). The analysis of the electronic and magnetic structure and local structure parameters at equilibrium volumes indicates that the total volume is influenced by a combination of expanding fluorine octahedra around the transition-metal ions due to the changing oxidation state, the distortion of octahedra around the Ca ions, and a decrease of repulsion between fluorine anions due to the inserted Li ions.

#### MM 8.6 Mon 17:15 H46

Cu2+ Intercalated Vanadium Pentoxide Grown on Carbon Cloth as Binder-Free Cathodes for Reversible Aqueous Zinc Ion Batteries — •PING HONG^{1,2}, YUDE WANG², HUAPING ZHAO¹, and YONG LEI¹ — ¹Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany — ²School of Materials Science and Engineering, Yunnan University, Kunming, People's Republic of China

Aqueous zinc batteries (ZIBs) with low cost, safety, environmentally friendly, and high theoretical capacity are a promising electrochemical energy storage technology. Vanadium based materials have been widely studied as cathode materials for ZIBs because of their safety, diverse crystal structure, abundant resources, low cost and high theoretical capacity. In the reported cathode materials, the mass loading of the cathode is usually less than 4 mg/cm2 is not sufficient enough for practical applications. Herein, Cu2+ intercalated vanadium pentoxide (CVOH@CC) with high loading (~7 mg/cm2) were directly grown on carbon cloth via hydrothermal method. The as-prepared CVOH@CC has a distinct 3D interconnected nested structure. When applying as binder-free cathode for ZIBs, CVOH@CC electrodes exhibited a high capacity of 223.4 mAh/g at 1.0 A/g and a long cycling performance of over 2000 cycles. The intercalation resulted in a better capacitive response and faster diffusion rate for the cathode compared to pure vanadium pentoxide (VOH@CC), which means better rate performance and cycling stability, providing a viable design proposal for the production of industrial grade ZIBs.

#### MM 8.7 Mon 17:30 H46

Reversible hybrid Na-CO2 batteries with low charging voltage and long-life — •CHANGFAN XU — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany — School of Metallurgy and Environment, Central South University, Changsha 410083, China — Faculty of Metallurgical and Energy Engineering, Kunming University of Science and Technology, Kunming 650093, China

A reversible and long-life hybrid Na-CO2 battery was proposed by using Na3Zr2Si2PO12 solid electrolyte as a separator, the saturated NaCl solution as an aqueous electrolyte, and nitrogen-rich graphitic carbon framework with well-defined morphology and dense bimetallic Fe-Cu sites (Fe-Cu-N-C) as cathodic catalyst. Besides having high Na+ ion conductivity, Na3Zr2Si2PO12 solid electrolyte also can prevent potential contamination from H2O and CO2 to sodium anode and avoid the internal short-circuit touch of Na dendrite with the cathode, thus improving the battery safety. The aqueous electrolyte can facilitate the dissolution of insulated discharge products, which overwhelmingly improves the reaction kinetics. The Fe-Cu-N-C cathodic catalyst can facilitate the fast evolution and degradation of flocculent discharge products. Finally, the hybrid Na-CO2 battery exhibited an excellent long-term cyclability with up to 1550 cycles (over 600 h). The reaction mechanism of Na-CO2 battery was revealed by in-situ Raman, SEM and XRD analyses.

#### MM 8.8 Mon 17:45 H46

Revisiting the storage capacity limit of graphite battery anodes: spontaneous lithium overintercalation at ambient pressure — CRISTINA GROSU^{1,2}, •CHIARA PANOSETTI¹, STEFFEN MERZ², PETER JAKES², SEBASTIAN MATERA¹, RÜDIGER-A. EICHEL², JOSEF GRANWEHR², and CHRISTOPH SCHEURER¹ — ¹Fritz-Haber-Institut, Berlin, Germany — ²IEK-9, Forschungszentrum Jülich, Germany

The market quest for fast-charging, safe, long-lasting, and performant batteries drives the exploration of new energy storage materials, but also promotes fundamental investigations of those already widely used. Presently, revamped interest in anode materials is observed - primarily graphite electrodes for Liion batteries. We focus on the upper intercalation limit in the morphologically quasi-ideal highly oriented pyrolytic graphite (HOPG), with a LiC₆ stoichiometry corresponding to 100% state of charge (SOC). We prepared a sample by immersion in liquid lithium at ambient pressure. Investigation by static ⁷Li nuclear magnetic resonance (NMR) resolves unexpected signatures of superdense intercalation compounds,  $\text{LiC}_{6-x}$ . These were ruled out for decades, since the highest geometrically accessible composition, LiC2, can only be prepared under high pressure. We thus challenge the widespread notion that any additional intercalation beyond LiC₆ is not possible under ambient conditions. We monitored the sample upon calendaric aging and employed ab initio calculations to rationalise the NMR results. The computed relative stabilities of different superdense configurations reveal that non-negligible overintercalation does proceed spontaneously beyond the currently accepted capacity limit.

#### MM 8.9 Mon 18:00 H46

The dielectric behaviour of Lithium intercalated graphite anodes as a function of the state of charge — •SIMON ANNIÉS^{1,2}, CHIARA PANOSETTI², MARIA VORONENKO¹, and CHRISTOPH SCHEURER² — ¹Theoretical Chemistry, Techni-

cal University Munich, Germany — ²Fritz Haber Institut, Berlin, Germany The dielectric behaviour of battery materials is a crucial piece of information for understanding atomistic mechanics and modelling diffusionand charging processes. However, for the most common anode material in today's Lithium ion batteries (Lithium intercalated graphite), literature results regarding this property are sparse, conflicting and only available for the empty state of charge (SOC).

Utilizing our recently developed DFTB parametrization (based on a machinelearned repulsive potential), we are - for the first time - able to compute the dielectric behaviour of Lithium intercalated graphite for the entire range of charge from 0% to 100%. Our results agree with experiments for 'empty' graphite, as well as for (bilayer-) graphene, which we use for an additional benchmark of our approach.

With increasing state of charge, we find a linear dependency of the dielectric constant, growing from around 7 at 0% SOC to around 29 at 100% SOC. With this, we lay an important piece of foundation for the understanding and multi-scale modelling of entire charging and discharging processes of Li-ion batteries.

#### MM 8.10 Mon 18:15 H46

**In-situ analysis of SEI formation and cycle behavior on Sn by combined QCM-CV** – •KE WANG and GUIDO SCHMITZ – Chair of Materials Physics, Institute for Materials Science, University of Stuttgart, Heisenbergstr. 3, 70569 Stuttgart, Germany

Sn (Tin) could in principle be a promising candidate for a lithium-ion battery anode since it offers larger capacity than commercially graphite. But, researchers are still confused about the capacity fade especially caused by the formation of solid electrolyte interface (SEI). Here, we perform an in-situ characterization to clarify the mechanisms of SEI formation. Cyclic voltammetry has been conducted in combination with a quartz crystal microbalance to measure the growth of the SEI. Beside the overall mass increase, evaluating the mass change per charge (MPE) even enables identification of the ab/desorbed species. In advanced analysis, we combine three different characteristics including mass spectra, real-time MPE and average MPE, for the different stages of the long-term SEI formation. Except the SEI layer formed in first cycle, the SEI is continuously affected by the formation of Li2O during lithiation and the oxidation of Sn during de-lithiation. In addition, the influence of the voltage window and the thickness of the electrodes on SEI formation are investigated. Remarkably, the SEI thickness reveals a linear relation to the electrode thickness which is linked to continuous cracking and major oxidization of Sn bulk. Particularly, the inorganic part of the SEI formed during lithiation in the specific voltage range of 0.36 - 0.27 V plays an important role on the microstructure of electrode and stabilizing the electrode.

# Topical TalkMM 9.1Mon 17:15H45Design of corrosion-free and highly active electrocatalysts and photocatalysts

via combinations of ab initio calculations and electrodynamics — •HEECHAE CHOI — Institute of Inorganic Chemistry, University of Cologne, Greinstr. 6, 50939, Cologne, Germany

Long enough lifetime of a catalyst is a very important, and frequently overlooked issue in catalyst design and development. For catalytic materials used in extreme conditions, corrosion resistance is the key factor to determine the lifetime and the steady performances over time. However, the theoretical design principle for the corrosion resistance of catalytic materials is lacking compared to the performance descriptor, which can give accurate predictions of catalytic activities of metallic materials. Recently, using the combinations of ab initio calculations and electrodynamics model, we proposed a new theoretical scheme to improve the catalytic activity and corrosion resistivity. Under the hypothesis that the resistance of corrosion is a function of adsorption energy of corrosive ions in aqueous phases, we attempted to install built-in electric fields on heterogeneous catalyst surfaces. As the results, the performances of TiO2 photoanode, Co/graphene Zn-air battery, and the water splitting by metal/carbon hetereojunctions were highly improved. In this talk, I will introduce the procedures of such materials design theory developments and the experimental verifications.

MM 9.2 Mon 17:45 H45 Understanding DC-induced abnormal grain growth in FeC-thin films -•THOMAS BREDE, MICHEL KUHFUSS, REINER KIRCHHEIM, and CYNTHIA VOLK-ERT — Institut für Materialphysik, Universität Göttingen, Deutschland The field of processing materials with magnetic or electric fields and currents in steadily growing, since it opens the door to more efficient ways of material treatment and former not achievable material modifications. In this scope, it was shown recently, that high DC electric current densities up to 4 MA/cm² can be used at elevated temperatures of 550°C to produce elongated ferrite grains with high aspect ratios in an otherwise nanocrystalline iron-carbon thin film. To understand the underlying mechanism we will present experiments in a wide range of process parameters. The samples were characterized by SEM and EBSD in different stages of the experiment. The results shown allow a detailed description of the underlying mechanism of the evolution of the abnormal grown structures. In addition they reveal a threshold linked to the electromigration-induced Cflux, below which no changes occur. A purely kinetic model will be presented to describe the observed behaviour and allow the prediction of similar effects at different process parameters and material systems.

Location: H45

MM 9.3 Mon 18:00 H45

**Cavity induced and influenced phases of matter** — •CHRISTIAN J. ECKHARDT^{1,2}, GIACOMO PASSETTI², MARIOS MICHAEL¹, FRANK SCHLAWIN¹, DANTE M. KENNES^{2,1}, and MICHAEL A. SENTEF¹ — ¹Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — ²RWTH Aachen University, Aachen, Germany

An optical cavity may be used to influence or induce phases of matter. We discuss how a charge-density wave phase in a 1-dimensional chain of spinless fermions is enhanced through the coupling to the quantized photon field. At the critical point between the Luttinger liquid and the charge-density wave, we find strong light-matter entanglement. Additionally, we ask in what ways photons can be used as pairing glue for superconductivity (SC). We show that a fingerprint feature of such cavity-induced SC is the pickup of a k-dependence of the gap in the electronic spectrum on the Fermi-surface.

MM 9.4 Mon 18:15 H45

Floquet engineering the band structure of materials with optimal control theory — •ALBERTO CASTRO^{1,2}, UMBERTO DE GIOVANNINI^{3,4}, SHUNSUKE SATO^{5,4}, HANNES HÜBENER⁴, and ANGEL RUBIO^{4,6} — ¹ARAID Foundation, Zaragoza (Spain) — ²Institute for Biocomputation and Physics of Complex Systems, University of Zaragoza, Spain — ³Universitá degli Studi di Palermo, Dipartimento di Fisica e Chimica - Emilio Segrè, Palermo, Italy — ⁴Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany — ⁵Center for Computational Sciences, University of Tsukuba, Tsukuba, Japan — ⁶Center for Computational Quantum Physics (CCQ), The Flatiron Institute, New York NY

We demonstrate that the electronic structure of a material can be deformed into Floquet pseudo-bands with tailored shapes. We achieve this goal with a novel combination of quantum optimal control theory and Floquet engineering. We illustrate this framework utilizing a tight-binding description of graphene. We show several examples focusing on the region around the K (Dirac) point of the Brillouin zone: creation of a gap with opposing flat valence and conduction bands, or closure of the gap when departing from a modified graphene model with a non-zero gap. We employ time periodic drives with several frequency components and polarizations, in contrast to the usual monochromatic fields, and use control theory to find the optimal amplitudes of each component that optimize the shape of the bands as desired.

MM 10.1 Mon 18:00 P2

Training Gaussian Approximation Potentials for Aqueous Systems — •NIKHIL BAPAT, MARTIN VONDRÁK, JOHANNES T. MARGRAF, HENDRIK H. HEE-NEN, and KARSTEN REUTER — Fritz-Haber-Institut der MPG, Berlin, Germany An accurate and efficient description of aqueous systems via atomistic computer simulations is of high relevance for many applications. Machine learning potentials (MLPs) trained on first principles data have demonstrated promising accuracy and computational efficiency for the length and time scales critical to the description of water. But even with the compelling advancements in MLPs, building a successful data-efficient atomistic model for complex aqueous systems remains a challenging task. The training of such MLPs can be notoriously difficult and so far required either negligence of chemical reactivity in the MLP or excessive amounts of training data.

In this work we propose an efficient training procedure specifically designed for aqueous systems. To that end, we employ the widely applicable Gaussian approximation potential MLP and leverage it with a workflow for generating training data which ensures systematic inclusion of the bulk water configuration space. We calculate and compare ensemble properties of bulk water like its equilibrium density and diffusion coefficient to validate the MLP. The resulting model, when coupled with an added stimuli from a solid surface, can provide insights into many technologically important solid-liquid systems which are difficult to simulate otherwise.

MM 10.2 Mon 18:00 P2 **Transfer learning on organic/inorganic interfaces for different substrates** — •ELIAS FÖSLEITNER, JOHANNES CARTUS, LUKAS HÖRMANN, and OLIVER T. HOF-MANN — Graz University of Technology, Graz, Austria Performing structure search of organic molecules on metallic surfaces requires finding the structure with the lowest energy. Using conventional density functional codes this proves to be a time-consuming task, since the number of possible configurations is large and individual calculations are expensive. For all-electron approaches, this becomes even more problematic when calculating molecules on metal substrates of higher nuclear charge number, e.g. on gold. To circumvent the computation of all possible configurations, machine learning techniques such as Gaussian process regression proved to be a useful tool to reduce the amount of calculated data.

In our work we further reduce the data requirements by using transfer learning from one substrate to another. To this end, we first train the system on substrate A, and use this information to accelerate the learning process of the system on another substrate B. This is done by using the energy predictions of substrate A as a prior for the machine learning model imposed on system B. By doing so, we can reduce the data requirements for the training of expensive systems to an extent that makes the investigation computationally feasible.

MM 10.3 Mon 18:00 P2

Large-scale molecular dynamics simulations using fourth generation neural network potentials — •EMIR KOCER¹, ANDREAS SINGRABER², TSZ WAI KO¹, JONAS FINKLER³, PHILIPP MISOF², CHRISTOPH DELLAGO², and JÖRG BEHLER¹ — ¹Georg-August University, Göttingen, Germany — ²University of Wien, Vienna, Austria — ³University of Basel, Basel, Switzerland

In the last decade, their proven success in bridging the gap between ab initio and classical molecular dynamics made machine learning potentials (MLP) very attractive. However, many MLPs are short-ranged and unable to capture interactions beyond a certain cutoff, which leads to inaccurate forces and energies in systems where long-range interactions are important. While MLPs including long-range electrostatic interactions based on local charges have been available for some years, only recently fourth generation MLPs have emerged that can take also global phenomena like non-local charge transfer into account. An example is the fourth generation high dimensional neural network potential (4G-HDNNP), which utilizes a global charge equilibration step. This study presents a modified version of 4G-HDNNPs, in which the matrix solution is replaced by a function minimization algorithm for an enhanced scalability on multi-core systems. The new potential has been implemented into the LAMMPS software and tested in large-scale molecular dynamics simulations.

#### MM 10.4 Mon 18:00 P2

Interatomic Potential Fitting in pyiron — •MARVIN POUL¹, NIKLAS LEIMEROTH², ALEXANDER KNOLL³, MARIUS HERBOLD³, and JOERG NEUGEBAUER¹ — ¹Max-Planck-Institut fuer Eisenforschung — ²Universitaet Goettingen — ³TU Darmstadt

Interatomic potentials have a key role in computational materials science bridging the gap between Ab-Initio methods and large-scale engineering applications. pyiron[1] is an IDE for computational materials science that allows for reproducible yet easy to write simulation protocols. Within its framework we have developed tools that allow for semi-automatic fitting and verifying of potentials. This includes wrappers for AtomicRex[2] (for classical potentials) and as well the machine-learned Moment Tensor Potentials (MTP[3]), high-dimensional neural network potentials (HDNNP[4]), and ACE potentials. In this work we introduce the facilities offered by our code on the examples of an Magnesium MTP and an EAM potential for Copper.

MM 10.5 Mon 18:00 P2 Effect of temperature pre-treatments on atomic dynamics in PdNiP studied with ECM — •OLIVIA VAERST, MARTIN PETERLECHNER, and GERHARD WILDE — Institute of Material Physics, University of Münster, Germany

Pre-treatments on amorphous PdNiP, such as annealing and treatments of thermo-mechanical kind, significantly influence the local structure, kinetic stability, and mechanical properties of this bulk metallic glass (BMG).

In the present work,  $Pd_{40}Ni_{40}P_{20}$  samples are pre-treated thermally by annealing them at different temperatures below the glass transition temperature. The resulting well-defined states are investigated via transmission electron microscopy (TEM) with electron correlation microscopy (ECM) at room temperature. ECM is used to study atomic rearrangements and dynamics in the material at nanometer spatial resolution [1,2]. The effect of thermal pre-treatments on ECM evaluation parameters is discussed. Such investigations of the atomic mobility in pre-treated PdNiP give further insight into underlying mechanisms and properties of the amorphous phase as well as on the local relaxation dynamics of a bulk metallic glass.

#### MM 10.6 Mon 18:00 P2

Investigating the short-range order of amorphous GeTe upon structural relaxation obtained by TEM diffractometry and RMC methods — •CHRISTIAN STENZ¹, JULIAN PRIES¹, T. WESLEY SURTA², MICHAEL W. GAULTOIS², and MATTHIAS WUTTIG¹ — ¹Institute of Physics IA, RWTH Aachen University, 52074 Aachen, Germany. — ²Faculty of Chemistry, University of Liverpool, Liverpool L7 3NY, United Kingdom.

New experimental insights into the structural changes during resistance drift in amorphous GeTe are presented. Selected area electron diffraction is performed on a-GeTe in five different annealing states to compute the pair distribution functions upon relaxation. Examination of the short-range order based on the order parameters  $S(q_2)/S(q_1)$  and  $r_2/r_1$  implies a continuous increase in the most prominent average bond angle by 1° towards 104.5°. This is consistent with the analysis of the bond angle distribution (RMC simulations) which reveals a shift of the main contribution (~ 103.5°) towards larger angles. A concomitant increase of intermediate geometries between tetrah. and octah. (~ 140°) is observed. Applying three different techniques to estimate the fraction of tetrahedral Ge atoms the three measures coherently suggest a decrease in tetrahedicity. We conclude that an enhancement of Peierls-like distorted/pyramidal motifs, *i.e.* an increase in the *PD*-ratio  $r_L/r_S$ , causes the increase of the average bond angle, resulting in a widening of the band gap. This structural relaxation ultimately leads to the resistance drift.

#### MM 10.7 Mon 18:00 P2

Influence of swift heavy ion irradiation on Pd-based metallic glasses — •SABA KHADEMOREZAIAN¹, MAXIMILLIAN DEMMING¹, MARILENA TOMUT^{1,2}, SERGIY DIVINSKI¹, and GERHARD WILDE¹ — ¹Institute of Materials Physics, University of Münster, Wilhelm-Klemm-Str. 10, 48149 Münster — ²GSI Helmholtzzentrum für Schwerionenforschung, 64291 Darmstadt, Germany

Bulk and ribbon samples of Pd40Ni40P20 in as-quenched and relaxed states were room-temperature irradiated with 4.8 MeV/u 179Au ions at the UNILAC accelerator. Ion beam-induced surface patterning associated with irradiation masks and smoothening of the surface were studied by laser scanning microscope and profilometry. Irradiation induces an out-of-plane swelling step of approximately 100 nm as measured at the boundary between the irradiated and non-irradiated areas and can be explained by additional free volume creation in the solidified ion tracks. The swelling and plastic flow mechanisms are analyzed. Changes in the relaxation enthalpy have been investigated using differential scanning calorimetry. Low-temperature heat capacity measurements substantiate prominent irradiation-induced changes of the Boson peak. Furthermore, changes in diffusivity with increasing fluence was found by post-irradiation tracer diffusion measurements. The evolution of mechanical properties was probed by nanoindentation measurements and the changes induced by irradiation are compared with those caused by mechanical rejuvenation.

#### MM 10.8 Mon 18:00 P2

Investigations on the relaxation of metallic glasses using fast scanning calorimetry — •MAXIMILIAN DEMMING, MARK STRINGE, MARTIN PETER-LECHNER, and GERHARD WILDE — Institut für Materialphysik, Westfälische Wilhelms-Universität Münster, 48149 Münster

During isothermal annealing below the glass transition, all glasses, and thus also metallic glasses, show relaxation effects that resemble the underlying trajectory in phase space towards metastable equilibrium. Using fast scanning calorimetry (FSC) it becomes feasible to investigate such phenomena over a wide range of rates and at very high controlled heating or cooling rates. The tremendous advantage of FSC in comparison to a conventional differential scanning calorimeter (DSC) is, that here one can reach cooling and heating rates up to several 10000 K/s, which makes in-situ quenching possible. Another advantage is that a large number of measurements can be performed in small time intervals. This makes the FSC quite interesting for experiments in thermic cycling with controlled heating and cooling rates. One special method is the so-called cryogenic cycling, which means, that a sample is periodically quenched and reheated between room and a cryogenic temperature. According to literature, this treatment, that has been termed as *cryogenic rejuvenation* could lead to markedly changed properties of the metallic glass. The materials investigated here are Au-CuSiAg and PdNiS due to their low glass transition temperature and melting point. In this work different relaxation states achieved by in-situ quenching via FSC are examined and compared to the relaxation behavior observed at conventional rates.

#### MM 10.9 Mon 18:00 P2

Investigation of thermoelectric transport through infrared spectroscopy of Heusler and Heusler-like compounds based on  $Fe_2VAI - \bullet$ SAHRA BLACK, MICHAEL PARZER, FABIAN GARMROUDI, ERNST BAUER, ANDREI PIMENOV, and EVAN CONSTABLE — Institute of Solid State Physics, Vienna University of Technology, 1040 Vienna, Austria

Thermoelectric materials have attracted much interest in recent years for their ability to convert a thermal gradient into an electric current, thereby acting as an electric power generator. Full and half Heusler compounds have attracted special interest in the growing field of thermoelectricity for several members with a high thermoelectric performance. One Heusler compound in particular Fe₂VAl was under investigation for its high power Factor *PF* and its high thermoelectric figure of merit *ZT*. And recently the element doped thin film Fe₂V_{0.8}W_{0.2}Al broke the world record for the highest thermoelectric figure of merit of roughly 5 ever recorded.

The purpose of the project was to investigate the dielectric response of the thermoelectric material class  $Fe_2VAl$  under different manufacturing methods with the usage of Fourier-transformed infrared (FTIR) spectroscopy. This led to a better understanding of the different contribution to the thermoelectric figure of merit *ZT*.

#### MM 10.10 Mon 18:00 P2

Atom probe tomography study of diffusion in Al-TiB2 and Al3Ta-TiB2 systems — •EVGENIIA VOLOBUEVA, PATRICK STENDER, JIEHUA LI, and GUIDO SCHMITZ — University of Stuttgart, Institute of Material Science, Heisenbergstr. 3, 70569, Stuttgart, Germany

To improve the quality of castings, grain refinement is a technique that can improve the overall qualities and properties of the material. For grain refinement in aluminum casting processes, TiB2 and Ta are added. It is well known, that Al and Ta form an Al3Ta phase inside the Al-based alloy. In order to gain insight into the process of grain refinement, the diffusion of Al3Ta and Al in TiB2 crystals was analyzed via Atom Probe Tomography (APT) in detail.

In this project, single crystals of TiB2 were used as raw material, glued on top of tungsten posts. Both pure aluminum layers and stoichiometric Al3Ta layers were deposited by sputter deposition on these crystals with a layer thickness of 200 nm. Subsequent annealing treatments were carried out to investigate segregation and diffusion phenomena at the crystal interface. To use the high spatial and chemical resolution of APT, the samples were sharpened to a final apex ra-

dius of 50 nm by azimuthal milling using a Focused Ion Beam Instrument (FIB). Observed segregation and determined diffusion coefficients will be presented.

MM 10.11 Mon 18:00 P2 **Highly conductive Graphite Intercalated Compounds** — •Leonhard Nie-MANN — Robert Bosch GmbH

Since its discovery, graphene has been a material of great research interest due to its promising properties of high electron mobility and electrical conductivity. However, the proposed applications have not yet been realized due to the complexity of fabricating high-quality, defect-free, large-area graphene films. Graphite, which consists of stacked graphene layers, does not have the same promising properties but is easier to fabricate. By intercalating Lewis acids between the graphene layers of graphite, the layers decouple and graphene like behaviour is achieved. The conductivity of these graphite intercalated compounds (GIC) is increased. Here, we report a gas-phase intercalation method for graphite films with AlCl3, resulting in GICs with 20 MS/m. These films exhibit good longterm thermal stability. It is noted that the final conductivity depends on the electrical conductivity of the untreated graphite films which is affected by defects in single graphene flakes and the flake size. Studies to increase the conductivity of non-intercalated graphite films are necessary to increase the conductivity of GICs. Therefore, further studies on graphenization of graphite films and defect healing are conducted and the results are presented.

MM 10.12 Mon 18:00 P2

**Flatbands and Nonlinear Transport in Nodal Line Semimetals** — •THOMAS BÖMERICH, JINHONG PARK, and ACHIM ROSCH — Institute for Theoretical Physics, University of Cologne, Germany

Ohm's law describes the linear dependence of the current on the electric field. Although deviations from this relation are quite small for usual metals we present a model of a semimetal with large non-ohmic conductivity. Motivated by recent experiments on  $ZrTe_5$  we study a low-energy Hamiltonian consisting of a single Dirac point which gets deformed into a nodal line by mirror symmetry breaking. Upon Landau quantization a zero energy state for a wide range of momenta emerges. For small densities the lowest Landau level can be reached at feasible magnetic fields making it possible to investigate the properties of the flatband.

While flatbands have generated growing interest because of their large density of states and the importance of interactions, we instead focus on their impact on nonlinear transport. Using the Boltzmann equation we obtain higher order conductivities and compare our results to a Dirac semimetal. We show that in the quantum limit, the nonlinear signal of the nodal line semimetal is five orders of magnitude larger than the Dirac semimetal. This enhancement of the nonlinear properties orginates from the emergence of the flat bands in the nodal line semimetal. Additionally we investigate the influence of disorder on the linear conductivity.

#### MM 10.13 Mon 18:00 P2

Towards an efficient formalism to calculate Electron-Phonon-coupling Self Energies and Transport properties from MD Simulation — •MARKUS KREMER^{1,2}, MICHAEL CZERNER^{1,2}, and CHRISTIAN HEILIGER^{1,2} — ¹Institut für Theoretische Physik, Heinrich-Buff-Ring 16, 35392 Gießen, Germany — ²Zentrum für Materialforschung Justus-Liebig-Universität Gießen, Heinrich-Buff-Ring 16, 35392 Gießen, Germany

Calculating transport properties for finite temperature systems has been a concern of research for a long time, with the semiclassical Lowest-order-variational approximation to the Boltzmann-equation (LOVA) being the most commonly used. Recently it was presented that within the KKR formalism more accurate results can be obtained for some materials by using a quantum mechanical Landauer-Büttiker approach incorporating phase-breaking scattering.

Here we want to investigate the possibility of obtaining transport properties at finite temperatures by using a classical MD Simulation and carrying out a transport calculation in the KKR formalism of a certain amount of randomly picked MD screenshots. This procedure is repeated for different lengths of the device to verify that the cell shows ohmic behaviour and obtain its specific resistance. Afterwards we can map this specific resistance to a self-energy.

#### MM 10.14 Mon 18:00 P2

Determination of interdiffusion coefficients for Pt-Pd binary system by Atom Probe Tomography and DFT calculations — •YOONHEE LEE¹, XI ZHANG², SE-BASTIAN MANUEL EICH¹, PATRICK STENDER¹, BLAZEJ GRABOWSKI², and GUIDO SCHMITZ¹ — ¹Department for Materials Physics, Institute for Materials Science, University of Stuttgart, Heisenbergstr. 3, 70569 Stuttgart, Germany — ²Department of Materials Design, Institute for Materials Science, University of Stuttgart, Pfaffenwaldring 55, 70569 Stuttgart, Germany

Understanding the diffusion behavior of different alloy components is fundamental and many systems are well evaluated with distinct diffusivities. However, despite its significant usage as a catalyst for many applications, the interdiffusion behavior of the Pt-Pd binary system has not yet been fully uncovered due to the remarkably slow atomic migration. In this work, interdiffusion coefficients have been determined from experimental data and compared with the results of DFT simulations. For the temperature range between 400 and 700°C, nano-sized multilayer samples were created by Ion-Beam Sputtering(IBS). After heat treatment, the samples are analyzed by Atom Probe Tomography (APT). Obtained composition profiles are fitted by a Fourier series approach and the respective interdiffusion coefficients are determined. For the temperature range between 800 and 970 °C, micron-sized Pt/Pd diffusion couples are used and analyzed using EDX. The respective interdiffusion coefficients are determined by the Boltzmann-Matano method. All interdiffusion coefficients are compared with DFT simulations.

#### MM 10.15 Mon 18:00 P2

**Imbibition- and Drying-Induced deformation of Nanoporous Solids** — •JUAN SANCHEZ¹, PATRICK HUBER¹, HOWARD STONE², LARS DAMMANN¹, and ZHUO-QUING LI¹ — ¹Hamburg University of Technology (TUHH), Hamburg, Germany — ²Princeton University, NJ, USA

We present time-dependent macroscopic dilatometry experiments on the deformation of nanoporous monoliths (Vycor glass) upon spontaneous, capillaritydriven infiltration of water as well as drying. We find two distinct dynamical regimes. One of them can be quantitatively traced to deformation originating in changes in the surface stress at the inner pore walls (dynamic Bangham's regime), whereas the second results from Laplace pressure effects. The interplay of both strain-inducing regimes allows to infer the water content in the pore space.

The theoretical framework used to describe our experimental data combines simple continuum mechanics and fluid dynamics on the macroscopic porous-solid scale, supported by molecular dynamics simulations on the singlenanopore scale. Our study demonstrates that it is possible to monitor imbibition and drying dynamics by simple dilatometry measurements, offering multiple potential applications.

 $MM\,10.16\quad Mon\,18:00\quad P2$  The Interplay of Spreading, Imbibition and Evaporation of Droplets at Nanoporous Surfaces — •LAURA GALLARDO^{1,2,3}, JUAN SÁNCHEZ^{1,2,3}, OLIVIER VINCENT⁴, and PATRICK HUBER^{1,2,3} — ¹Institute for Materials and X-Ray Physics, Hamburg University of Technology, 21073 Hamburg, Germany — ²Center for X-Ray and Nano Science CXNS, Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany — ³Center for Hybrid Nanostructures CHyN, University of Hamburg, 22607 Hamburg, Germany — ⁴CNRS & Univ. Lyon 1, Institute for Light and Matter (ILM), Villeurbanne, France

The dynamics of a droplet deposited on a porous substrate is a combination of three phenomena: spreading, imbibition and evaporation. Here we present a study on the interactions of droplets on nanoporous silicon prepared by electrochemical etching as a function of time. The evolution of the droplet volume is analyzed theoretically and experimentally considering the evaporation and the imbibition of the liquid into the porous substrate. Water is employed to illustrate the case of an evaporation-dominated regime [1]. For an imbibition-dominated regime squalane is employed. The very low vapor pressure of this fluid allows for the analysis of the imbibition process of a droplet into a porous substrate without the contribution of evaporation. The agreement between the experimental data and the theoretical predictions deepens the understanding of the structure of HF-etched porous silicon substrates and provides new insights into the fundamentals of fluid transport in nanoporous media.

MM 10.17 Mon 18:00 P2

Kinetic trapping in brittle crack opening — •TOBIAS MÜLLER and BERND MEYER — Interdisciplinary Center for Molecular Materials and Computer Chemistry Center, FAU Erlangen-Nürnberg, Germany

In the 1920s, Griffith introduced his continuum approach for fracture. Since then great efforts were made to describe crack propagation more precisely within continuum mechanics. Nevertheless, it is evident that the atomic structure of the crack tip itself plays a major role in crack advancement, thus making it necessary to extend the concept of Griffith to the discrete atomic level. This enables the possibility to investigate essential and material-specific processes, such as local bond rearrangements and path-dependent activation barriers. In general, crack opening is a complex chemical process on a multi-dimensional potential energy surface with many local minima and saddle points. The complexity even increases if parameters such as temperature, pressure or chemical environments are included. Here we discuss first DFT-based geometry optimizations for silicon to study brittle fracture mechanics. We show that cracks can propagate via a multitude of local energy minimum configurations connected by a variety of energy barriers. We highlight the complex nature of crack advancement and the complexity of modelling and finding the correct fracture pathway even for a material with a simple crystal structure such as silicon.

#### MM 10.18 Mon 18:00 P2

Comparison of Crack - Dislocation Interactions in fcc and bcc Metals — •BENEDIKT EGGLE-SIEVERS and ERIK BITZEK — Max-Planck-Institut für Eisenforschung GmbH, Max-Planck-Straße 1, 40237 Düsseldorf

The Interactions between Cracks and Dislocations are investigated by means of large scale atomistic simulations with EAM-potentials. Dislocations of differ-

ent character and Burgers vector are placed in the vicinity of a strain-controlled crack, resulting either in an attraction or repulsion of the dislocation. In the former case further interations can be observed in the course of the simulation, e.g. dislocation emission or crossslipping of screw parts. Depencies on the stress state, the crack system, dislocation character and distance between dislocation and crack tip are investigated in fcc and bcc crystals. The results are discussed in the framework of resolved shear stresses acting on the dislocations in the near field of the crack tip and for different dislocations characteristics in fcc and bcc.

#### MM 10.19 Mon 18:00 P2

Molecular dynamics analysis of point defects in ferroelectrics — •TAKAHIRO Tsuzuki¹, Dilshod Durdiev², Frank Wendler², Ryo Kobayashi¹, Masayuki Uranagase¹, Hikaru Azuma¹, and Shuji Ogata¹ – ¹Nagoya Institute of Technology, Nagoya, Japan — ²Friedrich-Alexander University of Erlangen-Nürnberg, Fürth, Germany

Ferroelectrics are used in many devices such as capacitors. Pb(Zr, Ti)O3 is the most used material in piezoelectric devices but it contains lead which is gradually prohibited using these days because lead is poisonous to human health. BaTiO₃, which is a very famous classical ferroelectric and lead-free, is newly focused on because its characteristics improve treated by containing defects. But the mechanism of the effects of the defects is not well understood.

We investigated the effects of point defects, monovacancies, and first and second neighbor divacancies on the domain growth of BaTiO3 with an applied electric field by molecular dynamics simulation using core-shell inter-atomic potential. We found that the first neighbor Ba-O divacancy is the most effective on the domain growth [1]. The sum of the electric field from the divacancy dipole and applied electric field, when they are in the same direction, strongly assist the domain growth.

Phase-field models are powerful tools to investigate ferroelectrics in mesoscale simulation. We obtained parameters, which contain the effect of vacancies mentioned above, for a phase-field model from the molecular dynamics simulation. [1] Tsuzuki T. et al., J. Appl. Phys. 131, 194101(2022).

#### MM 10.20 Mon 18:00 P2

Effect of increasing Mn content on generalized planar fault energies of Ni-**Mn-Ga alloys** — •MARTIN HECZKO¹, PETR ŠESTÁK², and MARTIN ZELENÝ¹ -¹Institute of Materials Science and Engineering, Faculty of Mechanical Engineering, Brno University of Technology, Brno, Czech Republic — ²Institute of Physical Engineering, Faculty of Mechanical Engineering, Brno University of Technology, Brno, Czech Republic

Giant magnetic field induced strain (MFIS) in martensitic phase of Ni-Mn-Ga ferromagnetic shape memory alloy makes this alloy promising for various applications. The reasons for existence of MFIS are the high mobility of twin boundaries combined with large magneto-crystalline anisotropy. We performed our calculations using the spin-polarized DFT method implemented in the Vienna Ab Initio Simulation Package (VASP) to reveal the effect of increasing concentration of excess Mn on formation and propagation of twin boundaries, which can be characterized by changes in generalized planar fault energy (GPFE) curves. Effects of excess Mn local arrangement in Ga sublattice on GPFE curves has been considered as well.

Our results show that the barriers for nucleation and grow of a twin rise with increasing content of Mn. It results in more difficult twin formation and propagation in compositions far from stoichiometry. This effect is even more enhanced if excess Mn atom in Ga sublattice is located exactly in the planar fault.

#### MM 10.21 Mon 18:00 P2

Influence of Twin Boundaries on the Mechanical Behavior of Nanowires Subjected to Bending — •SABA KHADIVIANAZAR^{1,2}, JONAS SCHICKEL¹, and ERIK BITZEK^{1,2} - ¹Friedrich-Alexander-Universität Erlangen-Nürnberg , Chair of General Materials Properties, Institute I, Martensstr. 5, Erlangen 91058, Germany — ²Max-Planck-Institut für Eisenforschung GmbH, Max-Planck-Straße 1 , Düsseldorf 40237, Germany

Metallic nanowires (NWs) display superior mechanical properties compared to their bulk counterparts and are regarded as promising building blocks for a variety of application such as touchscreen displays, flexible and stretchable electronic devices. Recently it has been observed that the multi twinned nanowires show higher yield stress and enhanced localized deformation compared to the single crystalline nanowires. Despite the importance of characterizing the deformation behavior under bending loads, most studies of metallic twinned NWs to date have been performed under tensile testing conditions.

Here we present recent results of atomistic simulations on bi-crystalline twinned nanowires under bending. Atomistic simulations allow for controlled variation of the material, size, morphology, the location of the twin boundary (TB), and loading conditions. We show that the presence of a TB not only influences the plastic deformation but also affects the stress state of nanowires. The critical resolved shear stress for dislocation nucleation was determined and the interactions of dislocations with TBs was studied in detail for varying twin boundary location and bending directions.

Benchmarking a Machine-Learning Enhanced Dimer Method for Transition State Search — •NILS GÖNNHEIMER, KING CHUN LAI, KARSTEN REUTER, and JOHANNES T. MARGRAF - Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany

The implementation of Machine-Learning (ML) surrogate models into established atomistic simulation types (e.g. molecular dynamics or geometry optimizations) offers the opportunity of significantly lowering their computational cost. The Dimer method for finding saddle points on high-dimensional potential surfaces is a prime example of this. This method is an important tool for locating transition states and exploring reaction mechanisms in heterogeneous catalysis, but applications are limited by its large computational cost. Jacobsen et al. recently showed that this can be overcome by combining Dimer search with a Gaussian Process Regression surrogate model in the Artificial Intelligence-Driven dimer (AID-TS) algorithm. To better understand the role of the ML surrogate in this method, we compare accuracy, efficiency and diversity of the found states, for AID-TS and conventional dimer search, using surface self-diffusion of Pd(100) as an example.

Al-Ge solid solubility prediction using machine-learned forcefield potentials and phonon calculations — • ONDŘEJ FIKAR and MARTIN ZELENÝ — Institute of Materials Science and Engineering, Faculty of Mechanical Engineering, Brno University of Technology, Brno, Czech Republic

This work is focused on a theoretical study of the phase stability of Al rich solid solution in Al-Ge alloy. The solubilities of the solid solution were first determined using temperature-dependent free energies of pure elements and solid solutions of various chemical compositions obtained from ab initio calculations based on density functional theory. All total energy calculations were performed by Vienna Ab initio Simulation Package (VASP) with the help of Projector Augmented-wave potentials. Contributions of vibrational free energy and electron free energy were obtained from Phonopy package. Subsequently, a forcefield potential for Al-Ge alloy using machine learning routines as implemented in the VASP package was created. The trained forcefield potential was then used to again carry out phonon calculations. The results were compared to the previous phonon calculations carried out without machine learning.

Simulation of long-term diffusion-based processes in Al and Ni -  $\bullet$ DARIA SMIRNOVA¹ and ERIK BITZEK^{1,2} — ¹Max-Planck-Institut für Eisenforschung GmbH, Düsseldorf, Germany – ²Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany

The study of coupled diffusive-displacive processes like dislocation climb at the atomic scale is inherently challenging due to the vastly different time scales involved in the individual processes. One way to address this challenge is to extend the possible simulation timescales while keeping proper atomistic description of a system by using diffusive molecular dynamics (DMD). The method combines classical atomistic interaction potentials in the variational Gaussian method with a numerical solver for the diffusion equation on a variable grid given by the atom positions. Recently, various computational implementations of DMD were presented. Here we describe in detail the different implementations of DMD and provide benchmarks for their efficiency using vacancy diffusion at defects in Al and Ni as model systems.

Ab initio study on novel precipitate-matrix interfaces in Al-Sc based alloys - •UJJAL SAIKIA¹, TILMANN HICKEL^{1,2}, SANKARAN SHANMUGAM³, SERGIY V. DIVINSKI⁴, and GERHARD WILDE⁴ — ¹Department of Computational Materials Design, Max-Planck-Institut für Eisenforschung GmbH $-\,^2\mathrm{BAM}$ Bundesanstalt für Materialforschung und -prüfung — ³Indian Institute of Technology Madras ⁴Institute of Materials Physics, University of Münster

The cube-on-cube orientation relationship (OR) with the Al matrix has been accepted as the orientation relationship for the coherent nano-scaled Al₃Sc-based particles in Al. Recently, in a severely cold-rolled and subsequently annealed Al-Sc-Zr-Ti alloy, atomic-scale investigations using high resolution scanning transmission electron microscopy (HRSTEM) reveals a novel type of precipitate/matrix coherency.

We performed density functional theory (DFT) based total energy calculations to understand the mechanism of formation of this new type of precipitate/matrix coherency between Al₃Sc and Al matrix and to compare it with the established interfaces. Our DFT results reveal that the newly observed interface corresponds to a local minimum of energy and there is an energy penalty for the interface boundary to 'escape' the particle. We also studied segregation behavior of Sc atoms to probe the initial stage of formation of the observed novel Al₃Sc/Al interface.

#### MM 10.26 Mon 18:00 P2

Ab initio study of point defects in disordered systems — •PAVEL PAPEZ¹, MAR-TIN FRIÁK², and MARTIN ZELENÝ¹ — ¹Institute of Materials Science and Engineering, Faculty of Mechanical Engineering, Brno University of Technology, Brno, Czech Republic — ²Institute of Physics of Materials, v.v.i., Czech Academy of Sciences, Brno, Czech Republic

This work is focused on a theoretical study of the influence of N and C interstitials in the equiatomic medium entropy alloy CoCrNi. These interstitials can be found in the alloy as contamination after preparation by powder-metallurgy techniques. The study was done by employing ab initio calculations based on the density functional theory and was performed by Vienna Ab initio Simulation Package (VASP) using the projector-augmented-wave formalism. The calculations were done on 6x6x2 supercells generated by using the special quasi-random structures approach (SQS) consisting of 216 atoms. The supercell consisted of 6 lattice planes {1 1 1} along the z-axis. The hcp structures were made from the fcc cells by moving the planes to create the hcp ABABAB stacking. Our results have shown which interstitial positions result in the lower enthalpy of formation. They are characterized by a higher amount of Cr and lower amount of Ni in their nearest neighbours (NN) shell with the most stable being the one with 2 Co, 3 Cr, and 1 Ni in its 1st NN shell. The stacking fault energy (SFE) was calculated using the first-order axial Ising model and by explicit stacking-fault calculations in two times larger fcc supercell. The results shown that interstitials always increase the SFE

Charge distribution and electronic structure of ZIF-8 and its derivatives from first principles — •Joshua Edzards¹, Holger-Dietrich Sassnick¹, Ana MARIA VALENCIA^{1,2} und CATERINA COCCHI^{1,2} -¹nstitut für Physik, Carl von Ossietzky Universität Oldenburg, 26129 Oldenburg -²nstitut für Physik and IRIS Adlershof, Humboldt-Universität zu Berlin, 12489 Berlin

Metal organic frameworks are novel materials with high potential in many fields of applications, ranging from gas storage and catalysis to optoelectronics. In spite of their growing popularity, there is still a lack of fundamental understanding of the physico-chemical properties of these materials, even in the most established subgroups such as the zeolitic imidazolate frameworks (ZIFs). To shed light into the nature of the chemical bonds in these systems, we performed a firstprinciples study based on density-functional theory investigating the charge distribution in ZIF-8 and its derivatives with Br, Cl, and H terminations replacing CH3. Our results indicate the presence of an ionic bond connecting the Zn atom to the organic scaffold, which is held together by covalent bonds. Control calculations performed on the building blocks of ZIF-8 indicate that the aforementioned characteristics are quantitatively influenced by the extended nature of the framework. The presence of halogen substituents, carrying around an excess of negative charge, leads only to a negligible redistribution of the charge density. On the other hand, the electronic structures computed for these systems indicate a reduction of about 0.5 eV of the band-gap in the Br- and Cl-terminated systems with respect to ZIF-8.

#### MM 10.28 Mon 18:00 P2

Recent progress in ICET — J. MAGNUS RAHM, •ERIK FRANSSON, PERNILLA EKBORG-TANNER, JOAKIM BRORSSON, MATTIAS ÅNGQVIST, and PAUL ERHART - Department of Physics, Chalmers University of Technology, Gothenburg, Sweden

Alloy cluster expansions (CEs) provide an accurate and computationally efficient mapping of the potential energy surface of multi-component systems that enables comprehensive sampling of the many-dimensional configuration space. In this contribution, we provide an update regarding recent developments and new features in the integrated cluster expansion toolkit (ICET). We have im-

Tuesday plemented a version of the constituent strain formalism in ICET, which enables treatment of long-ranged strain contributions. This approach is demonstrated for the Pd-H system in order to study coherent phase transitions via constrained Monte Carlo simulations. Furtermore, in CEs of low-dimensional systems, lack of symmetry leads to large numbers of independent effective cluster interactions (ECIs). We have made it possible to merge orbits, i.e., reduce the number of independent ECIs by considering local symmetries and merging parameters that are similar. This approach enables training of accurate models while requiring significantly fewer DFT calculations. This approach is employed to study surface segregation in AuPd and CuPd in environments ranging from vacuum to high pressures of hydrogen. Finally, we have added a number of additional features, including Wang-Landau sampling and extraction of long-range order parameters, and the code has undergone a thorough review that has resulted in a significant performance boost. MM 10.29 Mon 18:00 P2

Molecular dynamics simulations of porous silica networks - •HEMANGI PATEL¹, BARBARA MILOW^{1,2}, and AMEYA REGE¹ - ¹Institut für Werkstoff-Forschung, Abteilung Aerogele und Aerogelverbundwerkstoffe, Deutsches Zentrum für Luft- und Raumfahrt e.V. (DLR), Cologne, Germany -²Nanostructured Cellular Materials, Institut of Inorganic Chemistry, University of Cologne, Cologne, Germany

Molecular dynamics (MD) simulations offer a significant advantage over experimental procedures to investigate the nanoporous structure in silica-based systems because they present a detailed insight into the atomic-scale phenomena that underlie the formation of the materials* network. In this work, porous silica networks are modelled using MD simulations. α- quartz form of SiO2 is subjected to high temperature and equilibration followed by quenching to obtain amorphous silica structure  $\alpha$ - quartz form of SiO2 is subjected to high temperature and equilibration followed by quenching to obtain amorphous silica structure. The negative pressure rupturing approach is then used to obtain a fractal structure. Local minimum energy configuration is obtained using the conjugate gradient scheme for the formation of a stable porous network. The structural evolution of the silica backbone in the network is investigated. This technique is used to obtain porous networks of varying densities. The resulting model systems are investigated for their structural and mechanical properties. Uniaxial tensile and compressive simulations will be presented, and properties such as their Young's modulus will be quantified.

MM 10.30 Mon 18:00 P2

Magnetotransport properties of coupled nanowire arrays in LAO/STO • •RANJANI RAMACHANDRAN¹, DENGYU YANG¹, MUQING YU¹, ADITI NETHWEWALA¹, PATRICK IRVIN¹, JEREMY LEVY¹, and KI-TAE EOM² — ¹University of Pittsburgh, Pittsburgh, USA — ²University of Wisconsin-Madison, Madison, WI, USA

The ability to create and characterise an array of coupled nanowires is an important step towards understanding the physics of systems like stripe phase superconductors, sliding Luttinger liquids, anisotropic materials made up of quasi-1D chains, etc. Here, we create nanowire arrays using Ultra Low voltage Electron beam lithography. ULVEBL has been shown to create conducting nanostructures in the 2D electron system at the LAO/STO interface. We study the transport properties of this system at low temperatures and high magnetic fields. We show that it is possible to reversibly tune the interwire coupling using a back gate voltage and magnetic field. This can act as a tool to study the dimensionality cross over from 1D to 2D. This can potentially be extended further to create more complicated structures using ULV-EBL that can model the behaviour of other materials and lattice models.

Time: Tuesday 9:30-10:00

#### Invited Talk

MM 11.1 Tue 9:30 H44 Fast calorimetry: studying phase transitions in slow motion — •JÖRG F. LÖF-FLER — Laboratory of Metal Physics and Technology, Department of Materials, ETH Zurich, 8093 Zurich, Switzerland

Studying the details of phase transitions and metastable phase formation is generally difficult for metallic materials because of their rapid nucleation and growth kinetics. Bulk metallic glasses (BMGs), on the other hand, show very sluggish crystallization kinetics. By applying fast calorimetry to slowly transforming BMG-forming systems at heating and cooling rates of several 10,000 K/s, we are able to determine phase transitions more or less in slow motion. In this way, we can explore novel glass states [1], determine their stochastics of nucleation, and study metastable phase formation. During heating at low temperatures, BMGs generally form metastable crystals that transform into more stable modifications at higher temperatures. The classical interpretation is a direct solid-to-solid transformation, but by fast calorimetry we can show that this transition occurs via metastable melting [2]. Furthermore, while with classical calorimetry it is not possible to sufficiently characterize metastable phases owing to their structural changes upon slow heating, fast calorimetry allows for detailed measurements of their heat capacity and melting temperatures [3]. In this way, we are able to verify the existence of monotropic polymorphism and validate Ostwald's phase rule for many metastable phases. [1] J. E. K. Schawe, J. F. Löffler, Nat. Commun. 10, 1337 (2019). [2] S. Pogatscher et al., Nat. Commun. 7, 11113 (2016). [3] J. E. K. Schawe, J. F. Löffler, Acta Mater. 226, 117630 (2022).

# MM 12: Computational Materials Modelling: Physics of Ensembles 1

Time: Tuesday 10:15-13:00

MM 12.1 Tue 10:15 H44

**Pinpointing Hubbard corrections to tackle inhomogenous nl subshells: The DFT+U(m) method** — •ERIC MACKE¹, IURII TIMROV², LUCIO COLOMBI CIACCHI¹, and NICOLA MARZARI² — ¹Hybrid Materials Interfaces Group and Bremen Center for Computational Materials Science, MAPEX, University of Bremen, Am Fallturm 1, 28359 Bremen, Germany — ²Theory and Simulation of Materials (THEOS) and National Centre for Computational Design and Discovery of Novel Materials (MARVEL), Ecole Polytechnique Federale de Lausanne (EPFL), CH-1015 Lausanne, Switzerland

DFT+U remains a key tool in computational material science as it mitigates the DFT self-interaction error. While this simplistic approach often provides electronic and magnetic properties in fair agreement with literature, recent investigations revealed that DFT+U massively over-stabilizes high spin configurations of transition metal elements surrounded by strong ligand fields. In such compounds, the projection of occupied Kohn-Sham states onto the atomic basis frequently yields occupation numbers  $n_m^{\sigma} \approx 0.5$  for certain magnetic quantum numbers m, so that the penalizing Hubbard term  $E_U = \sum_{m,\sigma} \frac{U}{2} [n_m^{\sigma} (1 - n_m^{\sigma})]$  is maximized. We argue that if the occupation of a magnetic (spin-) orbital is dominated by the effect of hybridization with a ligand, Hubbard corrections should not be applied in the same way as for unaffected orbitals. To account for such inhomogeneous bonding regimes, we propose a more flexible scheme that enables the use of distinct Hubbard parameters U(m) for the same species, computable by means of *ab initio* methods.

MM 12.2 Tue 10:30 H44 Efficient computation of optical properties of large-scale heterogeneous systems —  $\bullet$ JOSEPH C. A. PRENTICE¹ and ARASH A. MOSTOFI² — ¹Department of Materials, University of Oxford, UK — ²Departments of Physics and Materials, Imperial College London, UK

The optical properties of large-scale (>1000 atoms) heterogeneous systems are of interest in several fields, from photovoltaics to biological systems. Computing such properties accurately from first principles, however, is challenging; even if only a small region is optically active, quantum mechanical environmental effects must often be included, and the cost of applying a quantitatively accurate level of theory is prohibitive. Here, I present recent work demonstrating how such calculations can be performed efficiently from first principles via two methods: an extension of the spectral warping method of Ge et al., and a novel combination of quantum embedding (specifically embedded mean-field theory) and linear-scaling (time-dependent) density functional theory. The accuracy and utility of these methods is demonstrated by applying them to systems including the molecular crystal ROY, chromophores in solution, and pentacene-doped p-terphenyl. The results pave the way for quantitatively accurate calculations to be performed on previously inaccessible large-scale systems.

#### MM 12.3 Tue 10:45 H44

**Converging tetrahedron method calculations for non-dissipative parts of spectral functions** — •MINSU GHIM^{1,2,3} and CHEOL-HWAN PARK^{1,2,3} — ¹Center for Correlated Electron Systems, Institute for Basic Science, Seoul 08826, Korea — ²Department of Physics and Astronomy, Seoul National University, Seoul 08826, Korea — ³Center for Theoretical Physics, Seoul National University, Seoul 08826, Korea

Integrations in k space are used to calculate many of the physical quantities in solid-state physics. Examples include various static or dynamical conductivity, self-energy of an electron, and electric polarizability. The integral usually takes the form of a product of proper matrix elements and  $1/[\hbar\omega - (\epsilon_{mk} - \epsilon_{nk}) + i\eta]$ , which is decomposed into the real part and the imaginary part, P $\{1/[\hbar\omega - (\epsilon_{mk} - \epsilon_{nk})]\}$  and  $-i\pi\delta[\hbar\omega - (\epsilon_{mk} - \epsilon_{nk})]$ , respectively. Here,  $\omega$  is the frequency,  $\epsilon_{mk}$  and  $\epsilon_{nk}$  are the energies of the valence and conduction electronic bands with Bloch wavevector **k**, respectively, and  $\eta = 0^+$ . Although the delta-function part has been widely calculated by the tetrahedron method, the non-dissipative principal value integral part has not. Tools to obtain matrix elements and energy eigenvalues from first principles have been actively developed, but there are technical difficulties in the tetrahedron method for the non-dissipative part. In this talk, we introduce an easy-to-implement, stable method to overcome those obstacles. Furthermore, our method is tested by calculating the spin Hall conductivity of fcc platinum.

#### MM 12.4 Tue 11:00 H44

**Self-consistency in GW**Γ **formalism leading to quasiparticle-quasiparticle couplings** — •CARLOS MEJUTO-ZAERA¹ and VOJTĚCH VLČEK² — ¹Scoula Internazionale Superiore di Studi Avanzati SISSA, Trieste, Italy — ²University of California Santa Barbara UCSB, USA

Many-body perturbation theory (MBPT) has become a tool of choice for the description of materials. Traditionally tied to the weakly-interacting limit, e.g. through the GW approximation, its expansion towards higher interactions is a

fundamental goal in the field. Existing attempts can rely on selected diagram resummation or downfolding, which involve some choice of expansion parameters typically reducing the approach's generality and flexibility. Despite this apparently intrinsic price, MBPT provides through Hedin's equations a formally exact path to describe any dynamically correlated system, regardless of interaction strength. We revisit this framework to disentangle how to systematically extend its practical validity beyond weak interactions, focusing on the structure of the interaction vertex  $\Gamma$  within self-consistent implementations. Using the Hubbard dimer at half-filling, we unveil the role of  $\Gamma$ 's functional derivative with respect

#### MM 12.5 Tue 11:15 H44

Automated Corrections for Materials Design of Ionic Systems: AFLOW-CCE —  $\bullet$ RICO FRIEDRICH^{1,2}, MARCO ESTERS¹, COREY OSES¹, STUART KI¹, MAXWELL J. BRENNER¹, DAVID HICKS¹, MICHAEL J. MEHL¹, CORMAC TOHER¹, and STEFANO CURTAROLO^{1,3} — ¹Center for Autonomous Materials Design, Duke University, USA — ²Helmholtz-Zentrum Dresden-Rossendorf, Dresden — ³Materials Science, Electrical Engineering, and Physics, Duke University, USA

to the Green's function, hitherto typically neglected, in generating diagrams that

can extend the reliability of MBPT towards high interactions [1].

Materials databases such as AFLOW [1] leverage *ab initio* calculations for autonomous materials design. The predictive power critically relies on accurate formation enthalpies — quantifying the thermodynamic stability of a system. For ionic materials such as oxides and nitrides, standard DFT leads to errors of several hundred meV/atom [2,3].

We have recently developed the "coordination corrected enthalpies" (CCE) method yielding highly accurate room temperature formation enthalpies with mean absolute errors down to 27 meV/atom [3]. Here, we introduce AFLOW-CCE [4] — our implementation of CCE into the AFLOW framework. It provides a tool where users can input a structure file and receive the CCE corrections, or even the CCE formation enthalpies if pre-calculated LDA, PBE or SCAN values are provided. The implementation features a command line tool, a web interface, and a Python environment.

MM 12.6 Tue 11:45 H44 Revealing the ambient and high-pressure phases of group IV monochalcogenides and monoxides with an evolutionary algorithm — •LONG NGUYEN and GUY MAKOV — Department of Materials Engineering, Ben-Gurion University of the Negev, Beer-Sheva, Israel

Group IV chalcogenides and oxides are candidates for incorporation into optoelectronic and thermoelectric conversion devices. These functional materials are mostly p-type semiconductors that provide low-cost, environmentally friendly, abundant, and high-efficiency. To expand the possible phases and study their stability upon compression, a combination of DFT modelling with evolutionary algorithm (EA) is applied to extensively investigate across the group IV monochalcogenides and oxides. We will report our results from the implementation of the EA to search for stable phases. In group IV monoxides, our results include multiple structural transitions of SnO and PbO upon compression. Two new high-pressure polymorphs are predicted, the orthorhombic Pbcm SnO and the octahedral monoclinic C2/m PbO. Weakening of the lone pairs and elastic instability are the main drivers for the structural transitions. Among the monochalcogenides, SnS and GeS phase families are examined together with their electronic and optical properties. At ambient conditions, GeS and SnS can present several polymorphs with bandgaps in the range from 0.3 to 1.6 eV, which can be attractive for a variety of optoelectronics applications. Upon compression, we found a similar convergence of SnS and GeS into the Cmcm and later the Pm3m phase. The transition mechanism is discussed through the lone pairs' influence on the structural distortion.

#### MM 12.7 Tue 12:00 H44

An Open-source Interface to MP2 and Coupled-Cluster Methods for Solids for Localized Basis Set Codes — •Evgeny Moerman¹, Felix Hummel², Andreas Irmler², Andreas Grün-eis², and Matthias Scheffler¹ — ¹The NO-MAD Laboratory at the FHI-MPG, Berlin — ²Inst. for Th. Phys., TU Wien, Vienna

Coupled cluster (CC) theory is often considered the gold standard of quantumchemistry. For solids, however, the available software is scarce ([1] and references therein). We present CC-aims[2], which can interface ab initio codes with

localized atomic orbitals and the CC for solids (CC4S) code by the group of A. Grüneis. CC4S features a continuously growing selection of wave function-based methods including perturbation and CC theory. The CC-aims interface was developed for the FHI-aims code[2] but is implemented such that other codes may use it as a starting point for corresponding interfaces. As CC4S offers treatment of both molecular and periodic systems, the CC-aims interface is a valuable tool, where DFT is either too inaccurate or too unreliable, in theoretical chemistry and materials science alike. In this talk we describe the CC-aims interface, the CC4S code, and demonstrate the application of CC and MP2 by investigating the relative stability of boron nitride phases. - This work received support from the European Union's Horizon 2020 research and innovation program under Grant Agreement No. 951786 (The NOMAD CoE).

#### MM 12.8 Tue 12:15 H44

Wannier function perturbation theory: localized representation and interpolation of wavefunction perturbation — •JAE-MO LIHM and CHEOL-HWAN PARK — Department of Physics, Seoul National University, Seoul, Korea

Wannier functions provide a localized representation of the electronic structure of solids and are thus finds wide application in condensed matter physics. However, the Wanneier function method is limited in that it cannot be used to represent the change of the wavefunctions due to perturbations. In this work, we introduce Wannier function perturbation theory (WFPT) [1], which overcomes this limitation by providing a localized representation of wavefunction perturbation which we term "Wannier function perturbation." Among the diverse possible applications of WFPT, we provide three examples. First, we calculate the temperature dependence of the indirect optical absorption spectra of silicon. Our calculation differentiates phonon-absorption and phononemission processes and includes the band-gap renormalization without arbitrary temperature-dependent shifts in energy at the same time, which is beyond reach of existing methods. Second, we develop a theory for calculating the shift spin current without any band-truncation error and apply it to monolayer WTe₂. Third, we apply WFPT to calculate the spin Hall conductivity of the same material, again without any band-truncation error. WFPT will open up a new way for studying the response properties of the electron states in real materials.

MM 12.9 Tue 12:30 H44

Boosting first-principles molecular dynamics with orbital-free density functional theory — •Lenz Fiedler¹, Zhandos A. Moldabekov¹, Xuecheng Shao², Kaili Jiang², Tobias Dornheim¹, Michele Pavanello², and Attila Cangi¹ — ¹Helmholtz-Zentrum Dresden-Rossendorf / CASUS — ²Rutgers University Newark

Kohn-Sham density functional theory (KS-DFT) is one of the most important simulation methods in materials science and quantum chemistry. Yet, standard DFT codes exhibit scaling behaviors in terms of system size and temperature that prohibit extended dynamical investigations of materials using DFT driven molecular dynamics simulations (MD), especially towards the warm dense matter regime (WDM). We present a practical hybrid approach that combines orbital-free density functional theory (DFT) with Kohn-Sham DFT for speeding up first-principles molecular dynamics simulations. Equilibrated atomic configurations are generated using orbital-free DFT for subsequent Kohn-Sham DFT molecular dynamics. This leads to a massive reduction of the simulation time without any sacrifice in accuracy. We show results across systems of different sizes and temperature, up to the warm dense matter regime. To that end, we use the cosine distance between the time series of radial distribution functions representing the ionic configurations. Likewise, we show that the equilibrated ionic configurations from this hybrid approach significantly enhance the accuracy of machine-learning models that replace Kohn-Sham DFT.

#### MM 12.10 Tue 12:45 H44

First-principles calculations of plasma frequency in an all-electron fullpotential framework — •MARIA K. POGODAEVA, SERGEY V. LEVCHENKO, and VLADIMIR P. DRACHEV — MOSCOW, Russia

We present a first-principles methodology to calculate plasma frequency of using density-functional theory in an all-electron full-potential framework implemented in FHI-aims. The results are compared to the results obtained with pseudopotential approaches and experimental data from photo-emission, absorption, and electron energy loss spectra. We test the approach on seven elemental metals: gold, silver, sodium, copper, palladium, platinum, and aluminum. Our results reproduce experimental values for plasma frequency within 0.1-0.3 eV accuracy compared to experiment for all metals except sodium. Calculated plasma frequency for sodium is consistently overestimated by 0.5 eV by VASP and FHI-aims. For other metals except gold FHI-aims and VASP are in a perfect agreement with each other and with experiment. For gold VASP underestimates plasma frequency by 0.6 eV compared to experiment, but FHI-aims calculates the value within 0.2 eV. Overall, the agreement between the two codes and the experiment is good. This validates our all-electron implementation and allows for further applications of the methodology to more complex systems

Topical TalkMM 13.1Tue 10:15H45Supercompatibility in ceramic micropillars of lanthanum niobate•OLIVIAA. GRAEVE and HAMED HOSSEINI-TOUDESHKIUniversity of California SanDiego, La Jolla, CA, USA

Superelastic materials represent a distinct family of compounds with the ability to manifest reversible deformation in response to an applied stress. Generally, superelastic materials are metallic in nature, and only very few ceramics have been shown to fully or partially display this response. Here, we describe exceptional superelasticity and enhanced reversibility on micropillars of LaNbO4 ceramic in response to compressive stresses up to 1100 MPa without fracture. The micropillars were prepared by focused ion beam machining from specimens consolidated by spark plasma sintering. The material response to stress is consistent with the theory of supercompatibility (cofactor theory) that has been reported to address the enhanced reversibility and low-hysteresis behavior (i.e., improved superelasticity) of certain shape memory metallic alloys. This makes LaNbO₄ a unique addition to the germane family of smart materials for applications as long-lived actuators impacting the automotive, energy and aerospace sectors, among many other technologically significant fields, especially in extreme conditions (i.e., higher temperatures or pressures) under which ceramics excel compared to metals.

Topical TalkMM 13.2Tue 10:45H45X-Ray Spectro(micro)scopy as analytics for field assisted deposition pro-cesses — •DAVID N. MUELLER — Peter Grünberg Institut, ForschungszentrumJülich

X-Ray absorption spectroscopy (XAS) is element specific, sensitive to the electronic structure around the Fermi level, and provides information about the short-range order in a material, and can be tuned to be surface sensitive. It therefore represents a versatile tool to assess the impact of external fields during synthesis of functional materials on the structure property relations required for optimizing functionalization. Providing spatial resolution on the sub micrometer scale with X-Ray photoemission electron microscopy (XPEEM) additionally allows identification of phase inhomogeneities and their peculiarities with respect to chemistry and structure.

In this presentation, we will use 3d transition metal based oxides of varying complexity to showcase how XAS and XPEEM can give valuable insights into the atomic and electronic structure and how those can be improved towards use in e. g. catalysis by using external fields during synthesis. It will furthermore be discussed how numerical methods such as principal component analysis can help analyzing spectromicroscopic data to unambiguously identify subtle lateral inhomogeneities in the spectroscopic signatures, providing information about phase formation and decomposition processes.

Magnetic Field-assisted Chemical Vapor Deposition of MgFe2O4 Films for Photoelectrochemical Water Splitting — HYENKWON LEE¹, •ZIYAAD TALHA AYTUNA¹, AMAN BHADRWAJ¹, MICHAEL WILHELM¹, KHAN LE¹, BENJAMIN MAY², DAVID MÜLLER², and SANJAY MATHUR¹ — ¹Greinstraße 6, 50939 Köln — ²Wilhelm-Johnen-Straße, 52438 Jülich

Single-phase magnesium ferrite films (MgFe2O4) were grown by magnetic field-assisted chemical vapor deposition (CVD) of mixed-metal precursor [MgFe2(OtBu)8] as a function of the applied field strength (B = 0.0, 0.5 and 1.0 T). The formation of monophase MgFe2O4 deposits was confirmed by X-ray diffraction and photoelectron spectroscopy. The cross-sectional analysis (FIB-SEM) of the film revealed an increased densification and crystal growth, upon application of the magnetic field when compared to zero-field deposition. The MgFe2O4 films deposited under zero-field and field-assisted conditions were used as electrodes in a photoelectrochemical (PEC) water-splitting reaction. All the three samples showed a stable performance and photocurrent values, how ever, the photocurrent was found to gradually decrease with increasing applied

magnetic field (0 T: 5.74  $\mu$ A/cm2, 0.5 T 2.33  $\mu$ A/cm2, and 1 T: 1.33  $\mu$ A/cm2 at 1.23 V (vs. RHE)), which is possibly due to change in absorption properties and crystal orientation, decreasing photo absorption intensity provided by the UV-vis results and the latter being evident in the disappearance of (220) peak in MgFe2O4 films grown under the influence of the external magnetic field.

**PECVD** carbon-coated electrospun vanadium pentoxide nanofibers as cathode material for photoresponsive batteries — •MICHAEL WILHELM, RUTH ADAM, AMAN BHARDWAJ, and SANJAY MATHUR — University of Cologne, Cologne, Germany

Harvesting and converting sunlight as the most sustainable energy source on earth is still challenging. Photo-rechargeable batteries represent a synergistic concept that integrates both energy harvesting and energy storage modalities based on dual-functional materials. Vanadium pentoxide nanofibers (VNF) as photoresponsive material was synthesized by electric field-assisted spinning technique and used as dual-action cathode material for photo-rechargeable lithium-ion batteries. A high discharge capacity was delivered, which could be increased under light illumination confirming the photoresponsive behavior. To minimize side reactions and to increase the stability of the electrodes, the VNF were carbon-coated by plasma-enhanced chemical vapor deposition (PECVD). Long-term stability tests showed that besides being a conductive shell, the carbon coating is also essential in retaining the structural instability of VNF. Higher capacity retention upon cycling compared to the non-carbon-coated VNF (after 300 cycles: 43.85 % capacity retention VNF and 61.13 % capacity retention for carbon-coated VNF). Further, the rechargeability of the material by light was demonstrated by illuminating with a UV lamp and afterward discharging the electrode material in the dark which delivered a photoconversion efficiency of 4.24 % for VNF and 5.07 % for carbon-coated VNF.

Structure and Morphology Engineering of Hexagonal Boron Nitride (h-BN) using Magnetic Field assisted CVD — •ANJA SUTORIUS, MICHAEL WILHELM, KHAN LÊ, ZIYAAD AYTUNA, and SANJAY MATHUR — University of Cologne, Cologne, Germany

The aim for two dimensional materials namely graphene, MoS2 and borophene has become a high interest due to their amazing properties (e.g. conductivity, flexibility, dimensionality) and demand for innovative electronic device applications. The large band gap material h-BN catches the attention of latest research due to its non-toxicity, environmentally friendly and chemical stability as well as its dielectric properties. The commonly preparation of h-BN often requires a gas phase deposition on catalytic metals at very high temperatures and is despite intense research very challenging. A new opportunity is provided using an external magnetic field during synthesis. Precursor molecules like amino borane (NH3BH3) or dimethyl amino borane (CH3)2NBH2 and h-BN itself exhibit a charge distribution and thus can be influenced by an applied field. Here, we would like to report about the thin film formation of h-BN with and without an external magnetic field on a variety of substrates ranging from catalytic metal substrates to non-catalytic dielectric silicon substrates. Results from infrared and x-ray photoelectron spectroscopy, as well as transmission and scanning microscopy.

#### MM 13.6 Tue 12:15 H45

Nanocrystalline CoCrFeNiGax (x = 0.5, 1.0) high entropy alloys: structural and magnetic features — •NATALIA SHKODICH, MARINA SPASOVA, and MICHAEL FARLE — Faculty of Physics and Center of Nanointegration (CENIDE), University of Duisburg-Essen, Duisburg, 47057 Germany

Nanocrystalline single fcc phase CoCrFeNiGax (x = 0.5, 1.0) high entropy alloy (HEA) powder particles with good structural and compositional homogeneity were successfully fabricated by high energy ball milling (HEBM). Characterization by XRD, SEM/EDX, and TEM/EDX shows that the fcc phase with the refined microstructure of nanosized grains (~10 nm) could be obtained after 190 min of HEBM at 900 rpm. We used HEBM powders to fabricate homogeneous nanocrystalline bulk HEAs by spark plasma sintering (SPS). SPS at 1073 K of the CoCrFeNiGa0.5 HEA powder increases the crystallinity of the fcc phase, while for the equiatomic CoCrFeNiGa powder a partial transformation of the fcc into the bcc phase is observed. The nanocrystalline HEA CoCrFeNiGax (x = 0.5, 1.0) powders show a paramagnetic behavior at room temperature and a Curie temperature (Tc) is of 127K-130K. After SPS, the CoCrFeNiGa bulk material is ferromagnetic up to Tc =775K. Its saturation magnetization Ms (300K) increases by a factor of 10 as compared to the HEA powder. The SPS of the CoCrFeNiGa0.5 HEA powder, however, does not change its paramagnetic nature at ambient temperature. This work has been supported by the Deutsche Forschungsgemeinschaft (DFG) within CRC/TRR 270, project S01 (project ID 405553726).

Topical TalkMM 13.7Tue 12:30H45Field-assisted processing of magnetic materials — •FERNANDO MACCARI andOLIVER GUTFLEISCH — Technical University of Darmstadt, 64287Darmstadt, 64287Germany

Optimization of materials requires a precise control of processing parameters to achieve a desired combination of phases and microstructural features. The application of an external fields during synthesis, going beyond the classical use of only temperature and time, can be used as additional degree of freedom to promote densification, solid state phase transformation, intermetallic compounds and precipitates formation. This combination opens new possibilities to obtain highly tailored microstructures and improved properties.

Focusing on magnetic materials, this talk will provide an overview on how different length scales can be manipulated using external magnetic and electric field assisted processing techniques to create materials with enhanced functional properties. Aspects related to induced magnetic anisotropy and phase formation in soft and hard magnetic materials will be covered. Additionally, field driven coupled magnetic and phase transition is going to be addressed and exemplified in ferromagnetic shape memory Ni-Mn-Ga Heusler compound.

How Important are Long-Range Electrostatics in Machine-Learning Potentials for Battery Materials? — •CARSTEN STAACKE¹, HENDRIK HEENEN¹, CHRISTOPH SCHEURER¹, GABOR CSANYI², KARSTEN REUTER¹, and JOHANNES MARGRAF¹ — ¹Fritz Haber Institut, Berlin, Germany — ²Engineering Department, Cambridge University, UK

All-solid-state Li-ion batteries promise gains in safety and durability by combining high Li-ion conductivity and mechanical ductility. In this respect, solid-state electrolytes (SSE) such as the  $\mathrm{Li}_7\mathrm{P}_3\mathrm{S}_{11}$  glass-ceramic have gained much attention. Modern machine learning (ML) potentials are increasingly being adopted as a tool for modeling SSEs at the atomistic level. However, the local nature of these ML potentials typically means that long-range contributions arising, e.g., from electrostatic interactions are neglected. To this end, we have combined short-ranged machine-learning potentials based on the Gaussian Approximation Potential (GAP) approach with a classical electrostatic model in the longrange (ES-GAP). We will present a first-principles validation of both, the pure GAP potential and the new ES-GAP for the LPS SSE. In particular, the role of Coulomb interactions in isotropic vs. non-isotropic system simulations will be evaluated. In standard isotropic simulation tasks, such as determining ionic conductivities, both GAP and ES-GAP yield similar results. In contrast, simulations on non-isotropic systems show the importance of ES contributions and provide new insights into interface stability of Li₇P₃S₁₁.

MM 14.2 Tue 10:30 H46 Oxygen Hole Formation Controls Stability in LiNiO₂ Cathodes: DFT Studies of Oxygen Loss and Singlet Oxygen Formation in Li-Ion Batteries — •ANNALENA GENREITH-SCHRIEVER^{1,3}, HRISHIT BANERJEE^{1,2,3}, CLARE P. GREY^{1,3}, and ANDREW J. MORRIS^{2,3} — ¹Yusuf Hamied Department of Chemistry, University of Cambridge, Cambridge, United Kingdom — ²School of Metallurgy and Materials, University of Birmingham, Birmingham, United Kingdom — ³The Faraday Institution, Harwell Science and Innovation Campus, Didcot,

Location: H46

United Kingdom Ni-rich cathode materials achieve both high voltages and capacities in Li-ion batteries but are prone to structural instabilities and oxygen loss via the formation of singlet oxygen. Using ab initio molecular dynamics simulations, we observe spontaneous O₂ loss from the (012) surface of delithiated LiNiO₂, singlet oxygen forming in the process. We find that the origin of the instability lies in the pronounced oxidation of O during delithiation, i.e., O plays a central role in Ni-O redox in LiNiO₂, as analysed with density-functional theory and dynamical mean-field theory calculations based on maximally localised Wannier functions. The O₂ loss route observed here consists of 2 surface O⁻ radicals combining to form a peroxide ion, which is oxidised to O₂, leaving behind 2 O vacancies and 2 O²⁻ ions: effectively 4 O⁻⁻ radicals disproportionate to O₂ and 2 O²⁻ ions. Singlet oxygen formation is caused by the singlet ground state of the peroxide ion, with spin conservation dictating the preferential release of ¹O₂.

#### MM 14.3 Tue 10:45 H46

Defects and Phase Formation in Non-Stoichiometric LaFeO₃: A Combined Theoretical and Experimental Study — •DANIEL MUTTER¹, ROLAND SCHIERHOLZ², DANIEL URBAN¹, SABRINA HEUER^{2,3}, THORSTEN OHLERTH^{2,3}, HANS KUNGL², CHRISTIAN ELSÄSSER^{1,4}, and RÜDIGER-A. EICHEL^{2,3} — ¹Fraunhofer IWM, Freiburg — ²Forschungszentrum Jülich, IEK-9 — ³RWTH Aachen, Institute of Physical Chemistry — ⁴FMF, Universität Freiburg

Defect engineering of perovskite compounds has become increasingly popular as it offers the possibility to influence their catalytic properties for applications in energy storage and conversion devices such as solid-oxide fuel- and electrolyser cells. We present results of a combined theoretical and experimental study exploring the feasibility for an active manipulation of the La stoichiometry, and thereby the valence state of Fe, in LaFeO3, which can be regarded as a base compound of the family of catalytically active  $La_{1-x}A_xFe_{1-y}B_yO_{3-\delta}$  compounds. Concentrations of point defects are presened, derived from formation energies which were calculated by first-principles DFT+U calculations as a function of experimental processing conditions, resulting in predictions of achievable stoichiometry ranges. In the experimental part, LFO was synthesized with a targeted La-site deficiency, and we analyzed the phases in detail by X-ray diffraction and various electron microscopy methods (STEM, EDS, EELS). Instead of a variation of the La/Fe ratio, a mixture of two phases, Fe₂O₃/LaFeO₃, was observed, resulting in an invariant charge state of Fe, which is in line with the theoretical results.

#### MM 14.4 Tue 11:00 H46

Can we improve thermoelectric properties by microstructural manipulations? — •LEONIE GOMELL¹, TOBIAS HAEGER², MORITZ ROSCHER¹, HANNA BISHARA¹, RALF HEIDERHOFF², THOMAS RIEDL², CHRISTINA SCHEU¹, and BAPTISTE GAULT¹ — ¹Max-Planck-Insitut für Eisenforschung GmbH, Düsseldorf, Deutschland — ²Institute of Electronic Devices, University of Wuppertal, Deutschland

Thermoelectric (TE) materials convert (waste) heat into electrical energy. Several material properties determine TE performance, with the influence of microstructure being the least understood. However, the microstructure plays a crucial role in the performance of TE materials. We present microstructural investigations of Fe₂VAl, synthesized via laser surface remelting. Scanning electron microscopy and atom probe tomography were used to bridge the scale from nanometer to micrometer. The local electrical resistivity was analyzed by an in-situ four-probe technique and the thermal conductivity by scanning thermal microscopy.

We observed a high dislocation density in the order of  $10^{13}$  m⁻² and small grains separated by low-angle grain boundaries. Segregation of V and N was found at grain boundaries and dislocations, observed by atom probe tomography. These defects scatter electrons and phonons, influencing their transport within the material.

We conclude that by manipulating the microstructure, we were able to improve the properties of Fe₂VAl. The combination of detailed microstructural analysis and local measurement of properties offers the possibility of understanding the microstructure-property relationship.

#### MM 14.5 Tue 11:15 H46

**Enhanced efficiency of graphene-silicon Schottky junction solar cell through inverted pyramid arrays texturation** — •JIAJIA QIU^{1,2}, HUAPING ZHAO¹, WEN-HUI MA², and YONG LEI¹ — ¹Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, TU Ilmenau, 98693 Ilmenau, Germany — ²State Key Laboratory of Complex Nonferrous Metal Resources Clean Utilization, Kunming University of Science and Technology, Kunming 650093, China

Recently, a growing interest of incorporating graphene (Gr) with silicon (Si) to develop Gr-Si Schottky junction solar cells is considered as a potential low-cost alternative to the conventional p-n junction silicon solar cells. In this work, silicon nanowries (SiNWs) and silicon inverted pyramid arrays (SiIPs) were introduced on surface of Gr-Si solar cell through silver and copper-catalyzed chemical etching, respectively. The effects of SiNWs and SiIPs on carrier lifetime, optical properties and efficiency of Gr-SiNWs/SiIPs solar cell were systematically analyzed. The results show that the inverted pyramid arrays have ability of balance of antireflectance and surface area simultaneously. Compared to the Gr-SiNWs solar cells, power conversion efficiency (PEC) and carrier lifetime of Gr-SiIPs devices increase by 62% and 34%, respectively. Finally, the Gr-SiIPs cell with efficiency of Gr-Si solar cells area simultaneously doping nitric acid. This work proposes a new strategy to introduce the inverted pyramid arrays for improving the performance of Gr-Si solar cells.

# MM 15: Hydrogen in Materials: Hydrogen Effects

Time: Tuesday 11:45-13:00

MM 15.1 Tue 11:45 H46

Atomistic study of hydrogen behavior in bcc and fcc Fe in presence of crystal defects — •DARIA SMIRNOVA¹, SERGEI STARIKOV², TAPASWANI PRADHAN², RALF DRAUTZ², and MATOUS MROVEC² — ¹Max-Planck-Institut für Eisenforschung GmbH, Düsseldorf, Germany — ²Ruhr University Bochum, ICAMS, Bochum, Germany

We apply atomistic simulations to consider hydrogen behavior in Fe in presence of the given lattice distortions, namely, crystal defects or lattice expansion/compression due to applied stresses. Simulations are based on a new interatomic potential developed by the authors of current work. Firstly, we consider segregation of hydrogen on typical defects of different complexity: from vacancies to grain boundaries (GBs). Estimated segregation energies obtained for different types of GBs generally agree with the existing DFT data. Moreover, performed classical atomistic simulations give information on several types of GBs, which, due to their complex structure and considerable model size, are inaccessible for ab initio modeling. High-temperature simulations of H diffusion in the presence of GBs also show that for bcc Fe hydrogen diffusion coefficient in the GB is much lower than in bulk. The same type of study is carried out for fcc Fe. Also, we discuss variations in zero-temperature hydrogen migration barriers in bulk bcc Fe with applied stress and compare them with the results of the finite-temperature H diffusion simulations. We see that while the variations in the lattice parameter change hydrogen migration barrier, they give no significant impact on the finite-temperature hydrogen diffusion.

#### MM 15.2 Tue 12:00 H46

Interplay of hydrogen with defects in Al alloys — •POULAMI CHAKRABORTY¹, HUAN ZHAO¹, BAPTISTE GAULT^{1,2}, TILMANN HICKEL^{1,3}, and JÖRG NEUGEBAUER¹ — ¹Max-Planck-Institut für Eisenforschung, Düsseldorf, Germany — ²Department of Materials, Royal School of Mines, Imperial College London, United Kingdom — ³BAM Federal Institute for Materials Research and Testing, Berlin, Germany

Al alloys are used as major structural material in the aviation and more recently, automobile industries. This demands detail research of microstructural defects generated while usage. We have performed density functional theory calculations to study the competition of microstructural features including grain boundaries and second phase particles. The results reveal second phases as better trapping sites since H has a higher solubility compared to the GBs. However, it is seen that certain solutes such as Mg enhances the chance of HE at the forming surface during crack initiation. This is further supported by experimental data where a high strength 7xxx Al alloy is charged by deuterium using atom probe tomography (APT). Subsequently, we have extended our study to several other alloying elements such as Sc, Sn and Zr, at the GB which are inevitably present as impurities in technical alloys. Interestingly, it is seen that Sn strongly binds with H at the GB without increasing the embrittling tendency. Based on these insights, effective alloying strategies can be developed to improve the resistance to hydrogen embrittlement.

Location: H46

Impact of H on Fe and Cr diffusion in pure Fe and FeCr alloy — •OLGA LUKIANOVA¹, ANTON CHYRKIN², VLADISLAV KULITCKII¹, JAN FROITZHEIM², SERGEI STARIKOV³, GERHARD WILDE¹, RALF DRAUTZ³, and SERGIY DIVINSKI¹ — ¹Institute of Materials Physics, University of Münster, Münster, Germany — ²Chalmers University of Technology, Department of Chemistry and Chemical Engineering, Division of Energy and Materials, Gothenburg, Sweden — ³ICAMS, Ruhr-Universitä Bochum, Bochum, Germany

The impact of hydrogen on the tracer diffusion of the Fe and Cr in pure iron and Fe-18wt.%Cr alloy was measured at 873 K. The annealing treatments were performed in purified argon (H-free) and Ar+H2 atmospheres. Volume diffusion of Cr was found not to be affected by the presence of H in both alpha-Fe and the FeCr alloy whereas volume diffusion of Fe was enhanced by an order of magnitude. On the contrary, grain boundary diffusion of Cr in the FeCr alloy was retarded, while it was not affected by hydrogen in pure iron. Grain boundary diffusion of Fe remains practically unchanged in both materials. The tracer data are compared with the predictions from atomistic simulations.

#### MM 15.4 Tue 12:30 H46

**Correlation of hydrogen diffusion behavior and in situ micromechanics during hydrogen charging of bcc Fe-Cr alloys** — •MARIA JAZMIN DUARTE CORREA, JING RAO, and GERHARD DEHM — Max-Planck-Institut für Eisenforschung, Düsseldorf, Germany

Hydrogen (H) is a strong candidate as energy carrier but it might cause material degradation through hydrogen embrittlement. Individual hydrogenmicrostructure interactions, can be studied by targeting analyses at the nano-/microscale during H exposure. We will present our novel *back-side* electrochemical H charging approach for nanoindentation related techniques. Hydrogen diffusion from the charged back-side towards the testing (front) surface is quantified by Kelvin probe permeation tests and unwanted corrosion is avoided. Our unique method allows differentiating between the effects of trapped and mobile H, and performing well controlled measurements with different H levels monitored over time to consider H absorption, diffusion and release through the metal. These aspects will be presented by nanoindentation and micropillar compression tests during H charging of Fe-Cr alloys (8-20 wt.%Cr). An enhanced dislocation nucleation is shown consistent with the defactant theory, and a hardening effect while increasing the Cr content and the H entry. The mechanical data is finally analyzed in terms of the diffusion behavior and used to develop a nanohardness-based H diffusion coefficient approach.

MM 15.5 Tue 12:45 H46 Role of hydrogen on the relative stability of the phases in steels — •Ali Tehranchi, Tilmann Hickel, and Jörg Neugebauer — Max Planck institute for Iron research, Max Planck Straße 1, 40237 Düsseldorf Tuesday

Hydrogen embrittlement (HE) is a persistent mode of failure in high-strength steels. During the service life of these steels phase transformations occur and are a key element that determines their response to the service loads. Thus the investigation of the role of H atoms in the relative stability of the phases present and forming in steels is of great interest. In this work, we studied the role of H on the relative stability of the fcc/bcc/hcp phases using the ab initio thermodynamics. The results indicate that at low hydrogen chemical potentials the stability of the fcc phase, which can be representative of retained austenite (RA) in steels, is slightly enhanced by the presence of H atoms. In contrast, at high hydrogen chemical potentials the bcc phase is stabilized by H. Moreover, since the excess volume of the hydrogen-rich bcc phase is significantly larger than that of the fcc phase, the presence of a stress field can change the relative stability of these phases in the coexistence regions of the phase diagram. This feature is particularly important for cyclic loading conditions: during loading cycles forward and reverse phase transformations occur and the H released by these transformations can damage the material.

co-electrodeposition of compositionally complex co-cr-fe-mo-ni alloy thin films — •HONGSHUAI LI, MARTIN PETERLECHNER, and GERHARD WILDE — Institute of Materials Physics, University of Münster, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany

Co-Cr-Fe-Mo-Ni, a compositionally complex alloy with a face-centered cubic structure, was successfully obtained by electrochemical deposition. To achieve a smooth morphology, an aqueous electrolyte with several additives was used as the solution for electrodeposition. Since the characterization of the sample requires a certain thickness, the electrodeposition time was set to 10 min. Characterization of the film deposited under a constant current density reveals the deposit is metallic with a face-centered cubic structure. The adhesion properties as well as the effective mechanical performance have also been tested by nano-scratch experiments, indicating a microscopically ductile behavior. The electrolytes developed in this study may be a promising approach for the electrodeposition of Co-Cr-Fe-Mo-Ni medium entropy alloys.

#### MM 16.2 Tue 14:15 H44

orientation dependence of the deformation mechanisms of cocrfeni high entropy alloys — •HAIHONG JIANG, MARTIN PETERLECHNER, and GERHARD WILDE — Westfälische Wilhelms-Universität Münster, Institut für Materialphysik, Wilhelm-Klemm-Str. 10, D-48149 Münster, Germany

The mechanical behavior of CoCrFeNi high entropy alloys in different deformation states have been analyzed by nanoindentation. Microhardness and Young's modulus values were determined at high accuracy as a function of the specified crystallographic orientations, which were measured by electron backscatter diffraction (EBSD). Modulus and Poisson's ratio values of polycrystalline CoCr-FeNi were calculated from experimentally determined ultrasonic velocities for comparison. This approach allows for in-depth analysis and comparison of the mechanical properties as function of the local orientations of the crystal lattice in dependence of the thermo-mechanical history.

#### MM 16.3 Tue 14:30 H44

Influence of crack tip radius on fracture toughness: an atomistic study — •TARAKESHWAR LAKSHMIPATHY¹ and ERIK BITZEK^{1,2} — ¹Department of Materials Science and Engineering, Institute I, Friedrich-Alexander-Universität

# Location: H44

Erlangen-Nürnberg (FAU), Germany — ²Department Computational Materials Design, Max-Planck-Institut für Eisenforschung, Germany

In fracture mechanics, initial cracks are typically assumed to be infinitely sharp, leading to a singularity in the crack tip stress field. However, on the atomic scale, crack tips have a radius of at least one atomic distance, which removes the singularity and leads to high, but finite stresses directly at the crack tip. Furthermore, cracks may blunt due to various reasons which leads to an increase in the macroscopic stress to reinitiate a sharp crack. Using harmonic "snapping spring" nearest-neighbor potentials which provide the closest match to linear elastic fracture mechanics (LEFM) on a discrete lattice, we show that the LEFM model for sharp cracks is insufficient to describe the boundary value problem (BVP) of blunted cracks at the atomic scale. We also show that the LEFM-based equations for blunted cracks are insufficient to describe the stress distribution ahead of atomically blunted cracks. We develop a semi-empirical scaling relation for blunted cracks using the LEFM-based equations for elliptical cracks by introducing a factor to account for the deviations. Furthermore, we identify a lower bound for the maximum crack tip radius at which this factor stops playing a role and a scaling model from the unmodified LEFM-based equations for elliptical cracks can be used.

Interplay of Cottrell atmosphere formation and carbon ordering in ferrite — •SAM WASEDA, TILMANN HICKEL, and JÖRG NEUGEBAUER — Max-Planck-Institut für Eisenforschung, Dusseldorf, Germany

In common steels, carbon atoms are purportedly or unintentionally added and alter mechanical properties of the steels. In ferrite, it is proposed that much of them does not stay as solid solution and ends up in the following possibilities: I, segregate to structural defects; 2, make an elastically favorable ordered structure (Zener-ordering); 3, diffuse to other phases or form a precipitate (austenite, cementite etc.). While they are individually well studied, the interplay between these different scenarios is hardly studied. In this work, we present a density-based diffusion model to study the chemical and elastic interactions between the formation of Cottrell atmospheres and the Zener-ordering.

Open system mechanical behavior of nanoporous palladium-platinumhydrogen solid solution near critical point — •SAMBIT BAPARI and JÖRG WEISSMÜLLER — Werkstoffphysik und technologie, Technische Universität Hamburg

Bulk nanoporous palladium is an ideal system for studying open system elasticity as palladium with randomly oriented nanometer size ligaments affords rapid equilibration of hydrogen between an environment and the materials bulk [1]. In this work, nanoporous palladium-platinum (5 at%) alloy was prepared by electrochemical dealloying. Transmission electron microscopy, oxygen adsorption*desorption methods were used to characterize the morphology and structure of the nanoporous alloy. The average ligament size of the as dealloyed nanoporous palladium-platinum alloy is 4 nm compared to 20 nm for nanoporous palladium. Hydrogen solubility isotherms show near critical point behavior in palladium-platinum-hydrogen solid solution at room temperature. Solute susceptibility and concentration-strain coefficient were determined to estimate the difference in compliance between open and closed systems. In situ quasistatic mechanical tests and strain rate jump tests were conducted to analyze the open system elastic and plastic deformations at near critical point.

#### MM 17.2 Tue 14:15 H46

Metal-organic frameworks for hydrogen isotope separation — •MICHAEL HIRSCHER — Max-Planck-Institut für Intelligent Systeme, Stuttgart, Germany One of the important operations in chemical industry is separation and purification of gaseous products. Especially  $H_2/D_2$  isotope separation is a difficult task since its size, shape and thermodynamic properties resemble each other. Porous materials offer two different mechanisms for separating hydrogen isotopes, either confinement in small pores, i.e., *kinetic quantum sieving*, or adsorption on strong binding sites, i.e., *chemical affinity quantum sieving*. The new class of metal-organic frameworks (MOFs) allows the exact tailoring of pore size and aperture as well as including open metal sites into the framework. Furthermore, if MOFs consist not of a static, but flexible framework, they can reversibly respond to external stimuli, which may even enhance the separation selectivity.

Experimentally, the measurement of the selectivity for hydrogen isotope separation is very challenging, since it requires low temperatures near the boiling point of the gases. Using low-temperature thermal desorption spectroscopy (TDS), we have developed a method for measuring directly the isotope selectivity after exposure to  $H_2/D_2$  mixtures.

Exemplarily, this talk will present experimental results on hydrogen isotope separation in MOFs.

#### MM 17.3 Tue 14:30 H46

Microstructural study of MgB₂ in the LiBH₄-MgH₂ composite by TEM — •OU JIN¹, YUANYUAN SHANG², XIAOHUI HUANG¹, XIAOKE MU¹, DOROTHÉE VINGA SZABÓ¹, THI THU LE², STEFAN WAGNER¹, CHRISTIAN KÜBEL³, CLAUDIO PISTIDDA², and ASTRID PUNDT¹ — ¹Karlsruhe Institute of Technology, Karlsruhe, Germany — ²Helmholtz-Zentrum hereon GmbH, Geesthacht, Germany — ³Technical University of Darmstadt, Darmstadt, Germany

The LiBH₄-MgH₂ composite is known as Reactive Hydride Composite for hydrogen storage that has an exceptional hydrogen storage capacity (up to ~ 12 wt%  $H_2$ ) and enhanced thermodynamic properties (down to ~ 45 kJ/mol  $H_2$ ). The main challenge that limits the extensive application of this material is its sluggish kinetic performance, which is primarily ascribed to the hampered nucleation of MgB₂ during decomposition. It was found that transition metal-based additives could facilitate the formation of MgB2 and accelerate the decomposition of LiBH₄-MgH₂. However, the additive effect on the kinetic improvement had not been fully understood until now. To unravel the uncertainties, the formation of MgB₂ in the decomposed LiBH₄-MgH₂ with and without the additive 3TiCl₃-AlCl₃ was studied using manifold transmission electron microscopy techniques. Varied MgB₂ morphologies have been determined, originating from different nucleation centers. Given the heterogeneous nucleation, the crystallographic orientation relationship of the relevant phases is in depth discussed. It turns out that atomic misfit plays a dominant role and directly affects the in-plane strain energy density, leading to varied kinetic performance.

#### MM 17.4 Tue 14:45 H46

ETEM studies on hydride precipitation and growth in Mg films — MAGNUS HAMM¹, MARIAN DAVID BONGERS¹, VLADIMIR RODATIS¹, STEFAN DIETRICH², KARL-HEINZ LANG², and •ASTRID PUNDT² — ¹Göttingen University, Institute of Materials Physics (IMP), Göttingen, Germany — ²Karlsruhe Institute of Technology (KIT), Institute for Applied Materials - Materials Science and Engineering (IAM-WK), Karlsruhe, Germany

Understanding solute-induced phase transformations is crucial in a variety of research fields such as catalysis, memory switching or energy storage. We present solute-induced phase transformations studied on the model system magnesium-hydrogen (MgH) which provides high lattice expansion during the phase transformation. In situ precipitation and growth of MgH₂ is studied in an environmental transmission electron microscope (ETEM), combining electron energy loss spectroscopy (EELS) and various imaging techniques. We observe that the Mg-hydride (MgH₂) formation proceeds through the formation of nanocrystals that are separated by low-angle grain boundaries. We attribute this microstructural change to large strains and stresses between the matrix and the MgH₂ created during the transformation. [1] M. Hamm et al., Int. J. Hydr. Energy 44 (2019) 32112.

Thermal transport properties of sodium superionic conductors from molecular dynamics simulations — •INSA DE VRIES, FREYA HALLFARTH, HELENA OSTHUES, and NIKOS DOLTSINIS — Institut für Festkörpertheorie, Westfälische Wilhelms-Unviersität Münster, Germany

Improvements of energy storage systems include the usage of sustainable and low-cost materials. In the case of electrolytes for solid state batteries, this is true for sodium superionic conductors due to the high availability of sodium especially compared to lithium based systems. A proper and safe integration of the electrolyte into battery cells also requires taking into account its thermal properties. Due to the ionic motion enabled by the open crystal structure of the electrolyte, in addition to electronic and phononic parts, a diffusive part also contributes to thermal transport. It is thus important to determine activation barriers for ionic motion and diffusion mechanisms, as they affect the thermal properties.

Equilibrium atomistic molecular dynamics simulations were performed of  $NaZr_2P_3O_{12}$  and  $Na_3Zr_2Si_2PO_{12}$  using a pair potential by Kumar and Yashonath [1]. Besides identifying ionic diffusion pathways, diffusion constants and thermal transport properties were calculated for various temperatures and compared to results from first principles molecular dynamics.

hiphive - Constructing and sampling higher order force constants for strongly anharmonic materials — •ERIK FRANSSON¹, FREDRIK ERIKSSON¹, JOAKIM BRORSSON¹, ZHEYONG FAN², and PAUL ERHART¹ — ¹Chalmers University of Technology, Gothenburg, Sweden — ²Aalto, University Helsinki Finland Higher order force constants (FCs) play a key role in lattice dynamics and are

crucial for the analysis of many thermodynamic materials properties. Typically FCs have been extracted using the finite displacement method, which suffers, however, from poor scaling with order and system size. In this contribution we present updates to and applications of the python package hiphive, a tool that allows the efficient extraction of FCs via a regression approach, both up to high order and for low symmetry systems. Higher order FCs can be used to directly run molecular dynamics (MD) simulations, however for strong anharmonic materials these models can become unstable. To overcome this obstacle, we present a self-consistent (iterative) approach for training higher order FCs and demonstrate its effectiveness for multiple strongly anharmonic materials. We have furthermore interfaced hiphive with the GPUMD software, which enables large scale molecular dynamics simulations using FC expansion potentials. This allows for sampling of, e.g., thermal conductivity via Green-Kubo techniques. This approach of extracting higher order FCs and sampling thermal conductivity is demonstrated for two very anharmonic materials, SnSe and BaGaGe. Lastly, we also demonstrate the application of this approach to study the complex dynamics of inorganic halide perovskites.

High-throughput calculations for proprety maps of solids — •DANIELA IVANOVA¹, DANIEL WORTMANN¹, STEFAN BLÜGEL¹, and MATTHIAS WUTTIG² — ¹Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich, Germany — ²Department of Physics, RWTH Aachen University, Aachen, Germany

Over the last two decades, high-throughput computation has become a vital pillar of the scientific research and development process in the field of computational science. In order to forecast material properties for a larger sets of atomic configurations, Density Functional Theory (DFT) as a widely utilized and highpredictive-power first-principles approach, has become increasingly frequent to be used robust and automated. In this work, the DFT open-source of an integrated suite of codes for electronic-structure calculations, Quantum ESPRESSO is used as connected and deployed through the open source Automated Interactive Infrastructure and Database for Computational Science AiiDA framework to achieve automation. Aside from the existence of (1) covalent, (2) metallic, and (3) ionic bonding, as well as the two weaker forms of (4) hydrogen and (5) van der Waals bonding, compelling evidence has been found that a new bonding mechanism prevails in crystalline phase change materials, termed as*(6)'metavalend bonding*. The materials data set chosen for high-throughput computing and calculation of the relevant materials properties supplies essential data for mapping distinctions between the bonding mechanisms. Such property maps can also lead to the conjecture of a sixth bonding mechanism (MVB).

High Perfomance Computing as enabler for condensed matter research — •ANDREAS STRAUCH, JENS FÖRSTNER, THOMAS KÜHNE, and CHRISTIAN PLESSL — Paderborn University, Paderborn, Germany

The availability of High Perfomance Computing ressources has enabled a wide range of high-impact science in the field of condensed matter physics in the last decades. We review the numerical research performed at the Paderborn Center for Parallel Computing ( $PC^2$ ) ranging from atomistic ab- initio-calculations to electromagnetic, optoelectronic, and quantum dynamical simulations. Combining in-depth knowledge on high performance computing and on heterogeneous hardware architectures with topical research has led to the development of high-level hardware-agnostic parallel-computing frameworks like HighPerMeshes [1] and to research on novel numerical methods, e.g. for molecular dynamics simulations [2,3].

Computational studies of liquid chromophores — •ERIC LINDGREN — Department of Physics, Chalmers University of Technology, Gothenburg, Sweden Liquid chromophores such as perylene and its derivatives constitute an important class of materials, with applications ranging as solvent-free dyes to increasing the efficiency of solar cells via photon conversion. Their structural and in particular dynamical behaviour on the molecular level is not very well known, yet crucial for their optical properties. In this work, we use molecular dynamics (MD) simulations to investigate the structural and dynamical properties of perylene and two of its derivatives (perylene-ethyl and perylene-diimide). Specifically, we extract the static and dynamical structure factors and the current correlation functions for various temperatures as well as for two different initial structural models of the systems, which in principle allows us to establish a direct link to experimental studies. Motivated by recent experimental work by Hultmark et al. (Science Advances 7.29 (July 2021)), we consider two structural models that differ with respect to the relative orientation of the molecules. Whereas in model 1 the molecules are more or less randomly oriented, model 2 features domains with pronounced pi-pi stacking. The latter configuration corresponds to a simplified representation of the supramolecular aggregates that some extended perylene derivatives have been observed to form experimentally. At the moment we have established our simulation protocol and verified the basic premise of this project. Next we will extend our study to derivatives with larger sidegroups and mixtures thereof.

#### MM 18.6 Tue 17:30 P2

Edge states in proximitized graphene ribbons and flakes in a perpendicular magnetic field: Emergence of lone pseudohelical pairs and pure spin-current states — •YAROSLAV ZHUMAGULOV, TOBIAS FRANK, and JAROSLAV FABIAN — Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany

Graphene influenced by the valley-Zeeman intrinsic spin-orbit coupling through proximity effects provides signatures of pseudohelical edge states. Analyzing the band structure of a zigzag graphene nanoribbon in the presence of proximity induced spin-orbit interaction and an external magnetic field, we have discovered the effect of stabilization of intervalley edge states and removal intravalley edge states by the external magnetic field. Stabilization of states is associated with the closing/reopening of the bulk bandgap between nonzero Landau levels. The magnitude of the external magnetic stabilization field was estimated both numerically and analytically. Finally, we have found that stabilized intervalley edge states in the presence or in the absence of a spin-flip hopping through the armchair edge form pseudohelical states or pure spin current states, respectively. The states of pure spin current are formed in wide graphene flakes and are protected from scattering by defects on the zigzag edges of graphene flakes. This work was supported by DFG SPP 2244, DFG SFB 1277 and EU Graphene Flagship.

#### MM 18.7 Tue 17:30 P2

**Modelling mechanical bond scission of amine cured Epoxy resins under stress** — •SAMPANNAI PAHI¹, MATTIA LIVRAGHI¹, CHRISTIAN WICK^{1,2}, and ANA-SUNCANA SMITH^{1,3} — ¹PULS Group, Institute for Theoretical Physics and Interdisciplinary Center for Nanostructured Films (IZNF), Friedrich-Alexander Universität Erlangen-Nürnberg (FAU), 91058 Erlangen, Germany — ²Competence Unit for Scientific Computing (CSC), FAU, 91058 Erlangen, Germany — ³Group of Computational Life Sciences, Division of Physical Chemistry, Ruder BosŎ1e9oviÕ107 Institute, 10000 Zagreb, Croatia

Epoxy resins are widely used thermoset polymers in manufacturing processes. Understanding of fracture propagation in cured epoxy resins is pivotal in determining the bulk level properties of the material. In this paper, a scale-bridging approach that links atomistic molecular dynamics(MD) simulations with DFT based Quantum Mechanical(QM) criterions has been implemented to model bond breakage in Quantum level. In our approach, we create smaller model systems for each bond and implement COGEF procedure to determine optimal bond breakage criterion. Furthermore, a hybrid on-the-fly QM/MM method is described and its ability to capture bond scission on cross linked polymer system with no predetermined fracture site is demonstrated. Using QM bond breakage criterion, bond scission in MD run is identified and checked using presence of spin contamination. Our study provides insights into the molecular mechanisms governing the fracture mechanism of epoxy resins and demonstrates the success of utilising atomistic molecular simulations towards predicting bulk properties.

#### MM 18.8 Tue 17:30 P2

Solvation effects on proton irradiation of DNA — •Daniel Muñoz-Santiburcio¹, Bin Gu², and Jorge Kohanoff¹ — ¹Instituto de Fusión Nuclear "Guillermo Velarde", Universidad Politécnica de Madrid, Spain $-\,^2 {\rm Department}$ of Physics, Nanjing University of Information Science and Technology, China Proton irradiation of DNA is of utmost importance for many fields, from radiation damage in space to medical applications for cancer treatment. Ab initio simulations are highly valuable tools for understanding such process, but they are cumbersome due to the required level of theory. These involve simulating the non-adiabatic propagation of the electronic subsystem of the target material, and to date have been restricted to DNA systems in absence of water, or at most with few solvating molecules. Here we present the results of large-scale ab initio (RT-TDDFT) simulations of proton irradiation of a realistic DNA system in bulk water, where we have determined different important aspects of the proton irradiation process such as the stopping power of the system, the spacial distribution of the holes in terms of the depopulations of the maximally localized Wannier functions, and more importantly the influence of the surrounding water. We will show that water is neither a mere spectator on the process nor a simplistic reducing or enhancing agent of the excitation process. Instead, water qualitatively changes the excitation landscape of the proton-irradiated DNA, making the hole population on the different atoms and bonds qualitatively different in the solvated vs. the dry DNA case.

#### MM 18.9 Tue 17:30 P2

**Resistometric determination of GP-zone formation and growth** — •FABIAN MILLER, JOHANNES BERLIN, TOBIAS STEGMÜLLER, and FERDINAND HAIDER — Universität Augsburg,Institut für Physik, 86135 Augsburg, Deutschland

Aluminium alloys are of crucial importance in todays economy, therefore the deeper understanding of their mechanical and electrical properties is important. These properties can be influenced by precipitate formation. In this work we focused in the Al*Cu system with samples containing around 4 wt.% of Cu. They were homogenized at the eutectic temperature and rapidly quenched to ambient temperature. Afterwards 4-point-resistance measurements were conducted during natural and artificial aging. Due to formation of Guinier Preston zones, the resistivity first increases, then slowly decreases, allowing to monitor the unmixing for different temperatures and for different quenching conditions. Further experiments with other alloying metals than Cu will be conducted and variations of the homogenisation temperature are planned to be inspected.

#### MM 18.10 Tue 17:30 P2

**Dealloying and nanoscale structure formation at crystal-melt coexistence** – •ZHONGYANG LI¹, NINA PETERSEN¹, LUKAS LÜHRS¹, and JÖRG WEISSMÜLLER^{1,2} – ¹Institute of Materials Physics and Technology, Hamburg University of Technology – ²Institute of Materials Mechanics, Hybrid Materials Systems, Helmholtz-Zentrum Hereon

Recent work on Ti-Ag alloy has shown that a bicontinuous microstructure can be formed via peritectic melting, which could further transform to open porous Ti or Ag networks through selective etching. Several factors including the large solubility difference of two alloy elements in liquid phase, large composition difference and the volume fraction of the solid and liquid phases are considered to be criteria for this phenomenon. However, the formation mechanism of this particular microstructure during peritectic dealloying is still not fully known.

#### Metal and Material Physics Division (MM)

In this work, alloy systems including Bi-Ni, Fe-Sn and Mn-Sn, are chosen, which satisfy part or all of the aforementioned criteria. With SEM and diffraction experiments of these samples after peritectic melting, we investigate the morphology of different phases, and discuss the dominant factor for the formation of bicontinuous structure. The effect of parameters for thermal treatment, including temperature and duration of heat treatment, are also studied using SEM, in order to find the optimized combination that could produce finer microstructure. With the research in these two aspects, we discuss the possibility of broadening the application of this new dealloying method from peritectic dealloying to dealloying at liquid-solid coexistence state.

#### MM 18.11 Tue 17:30 P2

Structural and Textural Transitions of Discotic Ionic Liquid Crystals in Nanoporous Solids — •ZHUOQING L1¹, PATRICK HUBER¹, SABINE LASCHAT², AILEEN RAAB², ANDREAS SCHÖNHALS³, and MOHAMED A. KOLMANGADI³ — ¹Institute for Materials and X-Ray Physics, Technische Universität Hamburg, Hamburg, Germany — ²Institut für Organische Chemie, Universität Stuttgart, Stuttgart, Germany — ³Bundesanstalt für Materialforschung und -prüfung (BAM), Berlin, Germany

Discotic ionic liquid crystals (DILCs) derived from 3,4- dihydroxyphenylalanine (DOPA) have synergetic properties of liquid crystals and ionic liquids. Driven by the  $\pi^*\pi$  interactions among the aromatic cores, DILCs may self-organize, leading to a hexagonal ordered columnar liquid crystalline mesophase. Embedding of DILCs in nanoporous solids allows one to design hybrid materials with 1-D ionic conductivity pathways on the single-nanopore scale and tailorable photonic properties. The structural organization of confined DILCs is determined by a interplay of geometrical constraints and interfacial interactions at the pore wall and thus depends on pore size, temperature treatment and molecular wall anchoring. The optical birefringence experiments and small angle X-ray scattering results indicate ordered liquid crystalline mesophases of different collective orientations as a function of anchoring of the DILC discs at the pore surface. In particular, these experiments suggest that depending on the pore size a transition from the formation of circular concentric ring structures to an arrangement, where the columns are aligned parallel to the pore axis occurs.

#### MM 18.12 Tue 17:30 P2 Laughlin topology on fractal lattices without area law entanglement — •MANI CHANDRA JHA — MPI-PKS

Laughlin states have recently been constructed on fractal lattices, and the charge and braiding statistics of the quasiholes were used to confirm that these states have Laughlin type topology. Here, we investigate density, correlation, and entanglement properties of the states on a fractal lattice derived from a Sierpinski triangle with the purpose of identifying similarities and differences compared to two-dimensional systems and with the purpose of investigating whether various probes of topology work for fractal lattices. Similarly to two-dimensional systems, we find that the connected particle-particle correlation function decays roughly exponentially with the distance between the lattice sites measured in the two-dimensional plane, but the values also depend on the local environment. Contrary to two-dimensional systems, we find that the entanglement entropy does not follow the area law if one defines the area to be the number of nearest neighbor bonds that cross the edge of the selected subsystem. Considering bipartitions with two bonds crossing the edge, we find a close to logarithmic scaling of the entanglement entropy with the number of sites in the subsystem. This also means that the topological entanglement entropy cannot be extracted using the Kitaev-Preskill or the Levin-Wen methods. Studying the entanglement spectrum for different bipartitions, we find that the number of states below the entanglement gap is robust and the same as for Laughlin states on two-dimensional lattices.

#### MM 18.13 Tue 17:30 P2

A study of the local fields in bismuth ferrite by using different radioactive tracer ions — •THANH T. DANG¹, JULIANA SCHELL^{1,2}, MARIANELA E-CASTILLO¹, DANIIL LEWIN¹, ASTITA DUBEY¹, ANDREA G. BOA^{2,3}, REINHARD BECK⁴, CORNELIA NOLL⁴, JOÃO N. GONÇALVES⁵, DMITRY ZYABKIN⁶, KONSTANTIN GLUKHOV⁷, IAN C. J. YAP⁸, ADELEH M. GERAM^{2,9}, KOEN V. STIPHOUT¹⁰, GEORG MARSCHICK¹¹, EDGAR M. S. D. REIS^{1,2}, SOBHAN M. FATHABAD¹, and DORU C. LUPASCU¹ — ¹University of Duisburg-Essen — ²European Organization for Nuclear Research — ³Technical University of Demmark — ⁴University of Bonn — ⁵Universität Göttingen — ⁹School of Particles and Accelerators — ¹⁰Georg-August-Universität Göttingen — ¹¹Vienna University of Technology

This work presents the study of the local electric and magnetic fields in multiferroic bismuth ferrite using Time Differential Perturbed Angular Correlation spectroscopy. The measurements were carried out at a wide range of temperatures up to 8500C, after the implantation of various radioactive tracer ions: 181Hf, 111In and 111mCd. The experimental results reflect the obedience to Landau theory and Brillouin-Weiss equation of local electric polarization and magnetization, respectively. Particularly, a huge coupling between local electric and magnetic fields has been investigated in anti-ferromagnetic order. With the support of ab-initio DFT simulations, we can conclude that 111mCd is located at Bi-atom, 181Hf and 1111n substitute Fe-atom.

#### MM 18.14 Tue 17:30 P2

**Partitioning of transition metals to the**  $\gamma$  and  $\gamma'$  phase of Co-based superalloys — •ISABEL PIETKA¹, ANDREAS FÖRNER², MANUEL KÖBRICH², STEF-FEN NEUMEIER², RALF DRAUT2¹, and THOMAS HAMMERSCHMIDT¹ — ¹Ruhr-Universität Bochum, Interdisciplinary Centre for Advanced Materials Simulation (ICAMS) — ²Friedrich-Alexander-Universität Erlangen-Nürnberg, Department of Materials Science & Engineering

Single-crystal Co-base superalloys are a promising class of materials in highpressure high-temperature applications such as blades of gas turbines or jet engines. The superior mechanical properties at high temperatures are a consequence of the underlying y/y' microstructure. The improvement of the mechanical properties of these alloys is therefore closely tied to an understanding of the influence of alloying elements on the microstructure. In this work, we describe the y/y' particioning of different alloying elements, i.e. their preference for the ymatrix or the y' particles of the microstructure. In particular, we determine the energy difference of nearly all 3d, 4d, 5d transition metals (TMs) in Co₃(Al/W) by density functional theory calculations. In very good agreement with results from wavelength-dispersive X-ray spectroscopy and atom probe tomography, we find a preference. We demonstrate that the findings can be rationalized in terms of band-filling and atomic size differences by moment analysis from bond order potential theory.

MM 18.15 Tue 17:30 P2

The oxidation of TNM alloy at 700°C and 760°C — •HENG ZHANG^{1,2} and YONGFENG LIANG² — ¹Institute of Materials Physics, University of Münster, Germany — ²State Key Laboratory for Advanced Metals and Materials, University of Science and Technology Beijing, Beijing, China

The TNM sample morphology and components of the oxides are measured with SEM, EDS and XPS after oxidation until 200 hours at 700°C and 760°C respectively. Al2O3 is the main oxides at 700°C combined with a little TiO2, MoO2 and MoO3, while the oxides are TiO2,MoO2 and MoO3 at 760°C, exhibiting a good oxidation resistance under 700°C.

#### MM 18.16 Tue 17:30 P2

Reactive Surface Corrosion of Stainless Steel studied with Atomic Force Microscopy and Kelvin Probe Force Microscopy – •Julian Cremer¹, SINAN KIREMIT², BERNHARD KALTSCHMIDT³, THOMAS KORDISCH², ANDREAS HÜTTEN³, and DARIO ANSELMETTI¹ – ¹Experimental Biophysics and Applied Nanoscience (BINAS), Bielefeld University – ²Bielefeld Institute for Applied Materials Research, Bielefeld University of Applied Sciences – ³Thin Films & Physics of Nanostructures, Bielefeld University

The pitting surface corrosion of three different stainless steels (1.4016, 1.4510 and 1.4301) used for industrial applications was investigated by exposition to oxidative liquids. Here, we focus on the investigation of the origin of the pitting using Kelvin probe force microscopy (KPFM) and on the prevention of corrosion by surfactants using high-resolution atomic force microscopy (AFM). KPFM allows to determine the work function of a sample with high spatial resolution. We found that the initiation of a pit can be caused by an abnormal anodic site (low work function) surrounded by a normal surface which acts as a cathode, or by the presence of an abnormal cathodic site (high work function) surrounded by a normal surface. In order to test whether KPFM can predict where and why pitting corrosion occurs, we use a micro corrosion liquid cell that allows live observation of the previously scanned area during corrosion inhibitors on stainless steels regarding adsorption dynamics and layer thickness in different temperature-controlled solutions.

#### MM 18.17 Tue 17:30 P2

**Reactive Surface Corrosion of Polypropylene studied with Atomic Force Microscopy** — •JULIAN CREMER¹, BERNHARD KALTSCHMIDT², ANDREAS HÜTTEN², and DARIO ANSELMETTI¹ — ¹Experimental Biophysics and Applied Nanoscience (BINAS), Bielefeld University — ²Thin Films & Physics of Nanostructures, Bielefeld University

The surface corrosion of various polypropylene samples used for industrial applications was investigated by exposition to oxidative liquids. The samples are formulated by different additive packages and include fillers such as talc or glass fibers for reinforcement. In particular, we study the aging and corrosion of these polypropylene samples in oxidative liquid media, analyzing the influence of temperature and oxidants. Contrary to aging induced by UV radiation, aging in oxidative liquids is rarely studied. Shedding some light on this research area, we placed the polypropylene samples in an oxidative test solution at 95°C, which was constantly renewed. In total, the samples were examined after ten different time steps up to 4000h. Mainly, we used atomic force microscopy (AFM) to image the samples and to determine the Young's modulus, which is a decisive parameter for the age of plastic materials. In some cases, we observe a growth of a fibrous structure on the surface covering nearly the whole sample. To determine the chemical composition of the bloomed structure and follow the aging on a chemical level, attenuated total reflection infrared spectroscopy was performed (ATR-FTIR). We present structural and chemical changes of aged industrial polypropylene as well as the consequence of additive blooming.

#### MM 18.18 Tue 17:30 P2

High-Pressure Torsion Deformed Magnesium: Microstructure Evolution and Hydrogen Diffusion — •SABINE SCHLABACH^{1,2,3}, BINGYU WU¹, GIOR-GIA GUARDI¹, STEFAN WAGNER¹, JULIA IVANISENKO^{2,3}, and ASTRID PUNDT¹ — ¹Karlsruhe Institute of Technology, Institute for Applied Materials, Karlsruhe, Germany — ²Karlsruhe Institute of Technology, Institute of Nanotechnology, Karlsruhe, Germany — ³Karlsruhe Institute of Technology, Karlsruhe Nano Micro Facility, Karlsruhe, Germany

Magnesium (Mg) is one of the materials considered as a solid state storage material for Hydrogen (H) as it is capable of storing up to 7.6 wt.% of H while forming magnesium hydride (MgH₂). However, the volume diffusion rate of H in MgH₂ is low, and thus the sorption rate of H is rather slow. As grain boundaries are suggested as fast diffusion paths, an increasing volume fraction of grain boundaries by reducing the grain size is aimed. Starting from polycrystalline bulk Mg, this can be done, e.g., by high-pressure torsion, one method of severe plastic deformation. The deformation induced microstructure evolution is investigated by using electron backscatter diffraction depending on different process parameters like imposed pressure and number of revolutions. Special attention is taken on local misorientations as a measure of dislocation density and their possible influence on H-diffusion. The related H loading capability of the deformed Mg samples is tested at room temperature utilizing gas volumetry. In a first step, H-diffusion in the  $\alpha$ -Mg phase is assessed as model system. Thus, the maximum H concentration is kept below the solid solution limit.

#### MM 18.19 Tue 17:30 P2

**Co(OH)2@FeCo2O4 as high-performance electrode material for supercapacitors** — •ZIDONG WANG^{1,2}, YUDE WANG², HUAPING ZHAO¹, and YONG LEI¹ — ¹Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany — ²School of Materials and Energy, Yunnan University, 6500504 Kunming, Peoples Republic of China

Spinel-type MCo2O4 (M = Zn, Ni, Fe, *) are regarded as a partial replacement of Co3O4 without crystal structure changes, and they provide advantages of lower cost and improved performance compared with Co3O4. Particularly, the variable valence of Fe in FeCo2O4 benefits the energy storage capability. However, previous works indicate that the attainable performance of FeCo2O4 is still limited. Herein, a 2D planar morphology design is proposed to optimize the performance of FeCo2O4 as active materials of supercapacitors. In this work, nanosized Co(OH)2 were composited on FeCo2O4 nanosheets skeleton by a simple one-step hydrothermal process. Due to the synergistic effect, the sample achieves outstanding performances with the specific capacitance of 1173.43 F g*1 at a current density of 1 A g*1 and 95.4% capacitance retention after 5000 cycles. It in dicates that nanostructured Co(OH)2@FeCo2O4 would have hopeful prospects in energy storage applications.

#### MM 18.20 Tue 17:30 P2

Quantitative investigation of reversible Li2O formation on Germanium battery anodes — •KE WANG and GUIDO SCHMITZ — Chair of Materials Physics, Institute for Materials Science, University of Stuttgart, Heisenbergstr. 3, 70569 Stuttgart, Germany

Lithium-ion batteries (LIB) serves as efficient energy storage devices in many aspects of our life. Anodes belonging to the Group IV (Si, Ge and Sn) are promising candidates to replace commercially applied graphite (372 mAh g-1) owing to their high theoretical capacity (3850 mAh g-1 for Si, 1570 mAh g-1 for Ge, and 990 mAh g-1 for Sn). But, the respective mechanisms of Li storage and the formation of solid electrolyte interface (SEI) are still not clearly. In this work, cyclic voltammetry has been conducted in combination with a quartz crystal microbalance to measure the SEI mass, and the amount of eventual reversibly processed species. Similar to Si and Sn, also with Ge anodes, the QCM mass spectroscopy identifies Li2O as a reversibly processed species that contributes a significant part to the electrochemical capacity. The amount of reversibly stored Li2O decreases weakly with increasing cycling rate, but increases significantly with the thickness of the Ge anodes. Interestingly, the amount of Li2O decreases if pronounced anode cracking appears, which is probably attributed to the fact that the fracture introduces short circuit transport paths deep into the volume of the Ge which accelerates lithiation. Thermodynamically, Li*2O should form before Li is inserted. But in the experiment simultaneously formation of Li*2O and LixSny is observed on Sn, probably attributed to lateral heterogeneity introduced by surface roughness.

#### MM 18.21 Tue 17:30 P2

Recycling of anode graphite from spent lithium-ion batteries and reused in heat transfer medium — •YU QIAO^{1,2}, ZHONGHAO RAO^{3,4}, HUAPING ZHAO¹, and YONG LEI¹ — ¹Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany — ²School of Electrical and Power Engineering, China University of Mining and Technology, 221116, Xuzhou, China — ³School of Energy and Environmental Engineering, Hebei University of Technology, 300401, Tianjin, China — ⁴Hebei Key Laboratory of Thermal Science and Energy Clean Utilization, Hebei University of Technology, 300401, Tianjin, China

Lithium-ion batteries (LIBs) have been widely employed in fast-growing mobile devices, stationary storage devices and electric vehicles. However, LIBs face a large wave of retirement because of a certain life. Graphite is the most common anode material in LIBs, amount of waste graphite will also be produced with the retirement of spent LIBs. Anode graphite (AG) from spent LIBs has the characteristics of large layer spacing and ease of being intercalated due to reducing the interlamination force after repeated charge and discharge cycles. In this study, two-dimensional graphite flakes (GFs) were prepared from spent AG through a freeze-thaw ultrasonic-assisted circulation method. The heat transfer ability of as-obtained GFs dispersed in ethylene glycol was investigated experimentally. The results indicated that GFs could enhance the heat transfer coefficient and the maximum enhancement is about 30%.

#### MM 18.22 Tue 17:30 P2

Mild-temperature solution-assisted encapsulation of phosphorus into ZIF-8 derived porous carbon as lithium-ion battery anode — •CHENGZHAN YAN¹, SHUN WANG², and YONG LEI¹ — ¹Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany. — ²Key Laboratory of Carbon Materials of Zhejiang Province, Institute of Materials and Industrial Technologies, Wenzhou University, Wenzhou, Zhejiang, 325027, China.

Phosphorus in the form of polyphosphides anions (PP) is encapsulated into ZIF-8 derived porous carbon through a solution-assisted etching diffusion process under a mild temperature, and the composites with a high phosphorous content of 30 wt% exhibit a high capacity, improved cycling stability as well as a good rate performance as a lithium-ion battery anode. Herein, a series of morphological and structural characterizations are applied to analyze the differences between individual MOF-derived carbon hosts with the whole body that has PP inside the pore. Subsequently, their electrochemical performance is also compared. The results of the above-mentioned material analysis and application practices jointly confirmed the superiority of this mild temperature solution-assisted encapsulation of phosphorus method. In summary, this work provides a new strategy to design and fabricate phosphorus-based electrodes for batteries beyond lithiumion batteries.

#### MM 18.23 Tue 17:30 P2

**Optimization of flash sintering input parameters for obtaining 8YSZ dense samples** — •FÁBULO R. MONTEIRO¹, GUSTAVO C. DACANAL¹, JOÃO V. CAMPOS², LILIAN M. JESUS², ADILSON L. CHINELATTO³, and ELIRIA M. J. A. PALLONE¹ — ¹University of São Paulo, Pirassununga, Brazil — ²Federal University of São Carlos, São Carlos, Brazil — ³University of Ponta Grossa, Ponta Grossa, Brazil

Flash sintering has been widely investigated due to its technological potential, since it allows very rapid densification of different ceramic materials. The literature still lacks studies assessing how the electrical parameters of the technique (electric field and current density) involved in the process affect material densification since these parameters may vary depending on furnace type and, especially, sample geometry. Thus, this study used the response surface technique to analyze and relate, in a multivariate way, a few flash sintering variables. A mathematical model was proposed to optimize the densification of 8YSZ cylindrical and dog-bone samples. For this, a complete second order factorial planning with three central points was used in combination with the response surface methodology. The results obtained allowed us to predict electric field and electric current density values to optimize the densification of 8YSZ samples in the two geometries used and to understand how electric field and electrical current density values affected onset and sample temperatures (estimated by the black body radiation model).

#### MM 18.24 Tue 17:30 P2

The effect of crystallinity of layered transition metal disulfide on the performance of potassium-ion batteries: The case of molybdenum disulfide — •YULIAN DONG, HUAPING ZHAO, and YONG LEI — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Layer-structured transition metal dichalcogenides (LS-TMDs) are being studied in potassium-ion batteries owing to their structural uniqueness and electrochemical mechanisms. In this work, the dependence of electrochemical performance on the crystallinity of LS-TMDs has been investigated. Taking MoS2 as an example, lower crystallinity can alleviate diffusional limitation in 0.5*3.0 V, where intercalation reaction takes charge in storing K-ions. Higher crystallinity can ensure the structural stability of the MoS2 layers and promote surface charge storage in 0.01*3.0 V, where conversion reaction mainly contributes. The low-crystallized MoS2 exhibits an intercalation capacity (118 mAh/g) and great rate capability (41 mAh/g at 2 A/g), and the high-crystallized MoS2 delivers a high capacity of 330 mAh/g at 1 A/g and retains 161 mAh/g at 20 A/g. It shows that when intercalation and conversion reactions both contribute to store K-ions, higher crystallinity ensures the structural stability of the exfoliated MoS2 basal layers and promotes surface-controlled charge storage.

#### MM 18.25 Tue 17:30 P2

**Magnetic Hardening of Nd-Fe-B Permanent Magnets** — •LUKAS SCHÄFER¹, KONSTANTIN SKOKOV¹, FERNANDO MACCARI¹, ILIYA RADULOV¹, DAVID KOCH², and OLIVER GUTFLEISCH¹ — ¹Functional Materials, Institute of Material Science, Technical University of Darmstadt, 64287, Darmstadt, Germany — ²Strukturforschung, Institute of Material Science, Technical University of Darmstadt, 64287, Darmstadt, Germany

Nd-Fe-B alloys used for permanent magnets provide highest performance and energy density and are therefore used in numerous energy and high-tech applications. The superior intrinsic properties of the hard magnetic  $Nd_2Fe_{14}B$  phase are translated by a controlled production processes leading to a specific micro- and grain boundary structure and high coercivity. In this work, we take a different approach and show a novel magnetic hardening mechanism in such materials. This mechanism has the potential to be incorporated into existing manufacturing processes and to be adapted to novel production routes for Nd-Fe-B permanent magnets such as Additive Manufacturing. As an example, we demonstrate how the microstructural transformation from metastable  $Nd_2Fe_{17}B_x$  phase to the hard magnetic  $Nd_2Fe_{14}B$  phase by controlled annealing leads to a significant increase in coercivity from 250 kAm⁻¹ to 700 kAm⁻¹ in  $Nd_{16}Fe_{bal-x-y-z}Co_xMo_yCu_zB_7$  alloys. This approach offers also a promising opportunity for the fabrication of nano composite magnets.

#### MM 18.26 Tue 17:30 P2

Spin fluctuations and Wigner thermal transport in thermoelectric skutterudites — •ENRICO DI LUCENTE¹, MICHELE SIMONCELLI², and NICOLA MARZARI¹ — ¹Theory and Simulation of Materials (THEOS) and National Centre for Computational Design and Discovery of Novel Materials (MARVEL), École Polytechnique Fédérale de Lausanne, Lausanne 1015, Switzerland — ²TCM Group, Cavendish Laboratory, University of Cambridge, 19 JJ Thomson Avenue, Cambridge, CB3 0HE UK

Skutterudites are highly promising functional materials due to their peculiar thermoelectric and magnetic properties. We elucidate the complex fenomenology that takes place in these materials both in terms of spin fluctuations and in the crossover from a Peierls-Boltzmann to a Wigner thermal transport regime, where tunneling of phonon wavepackets emerges. We first study the electronic structure using the state-of-the-art DFT+Hubbard theory to uncover multiple self-consistent magnetic and charge disproportionated configurations. While the lowest energy state is antiferromagnetic but metallic, paramagnetic fluctuations captured through a special quasi random structure open a small gap of 61 meV, in good agreement with experiments. Moreover, in going from the parent compound to the related filled skutterudite, a transition from a Peierls-Boltzmann to a Wigner thermal transport regime arises, where, at working temperature of the devices, the tunneling of phonon wavepackets becomes as relevant as the drifting diffusion.

#### MM 18.27 Tue 17:30 P2

**Freezing and melting of water in nanopores: A temperature-dependent X-ray scattering study** — •LARS DAMMANN^{1,2}, STELLA GRIES^{1,2}, MILENA LIPPMANN¹, and PATRICK HUBER^{1,2} — ¹Deutsches Elektronen-Synchrotron DESY, Notkestr. 85, Hamburg 22607, Germany — ²Hamburg University of Technology, Institute for Materials and X-Ray Physics, Eißendorfer Straße 42, Hamburg 21073, Germany

The crystallization of water in extreme spatial confinement of nanoporous media plays a pivotal role in many natural and technological processes, ranging from frost heave to modern materials processing. However, the induced interfacial stresses in the porous medium during melting and crystallization and the crystalline structures of nanoconfined water are still subject of scientific discussions. Here we present simultaneous temperature dependent small and wide angle Xray scattering (SAXS/WAXS) measurements of water in ordered silica nanopores of diameters around 3 nm and 7-8 nm in a temperature range from 300 K to 150 K. With SAXS we investigate the crystallization induced strain on the pore network and with WAXS the structure of water ice in nanoconfinement. A complete analysis of the measurements is yet to be conducted, however, promising first results of the SAXS measurements show a strong dependence of pore strain on freezing in the pores especially for the smaller pores. As a next step we aim to compare the SAXS data to the measured WAXS signal to investigate the structure of the crystallized confined water.

#### MM 18.28 Tue 17:30 P2

Liquids in Atom Probe Tomography — •TIM MAXIMILIAN SCHWARZ, HELENA SOLODENKO, JONAS OTT, GUIDO SCHMITZ, and PATRICK STENDER — .University of Stuttgart, Institute for Materials Science, Chair of Materials Physics, Heisenbergstr. 3, 70569 Stuttgart, Germany

Frozen liquids are challenging and rather new in the investigation by atom probe tomography. However, recent progress in instrumentation, especially the introduction of cryo transfer shuttles, and the development of the required preparation routes to shape nanometric needles of frozen liquids enable measurements of sufficient quality and size of data sets to discover the typical features of this material class. The field evaporation of liquids resembles more the behaviour of weakly cross-linked polymers than that of metals. So frozen liquids, stabilized by weak hydrogen or van der Waals bonds, typically evaporate in large molecular fragments which raises general questions about spatial resolving power and chemical sensitivity of the atom probe tomography. At the example of saturated glucose solutions, we investigate the accuracy of the chemical analysis and the spatial resolution in localizing dissolved molecules. The direct comparison to the field evaporation of solid bulk glucose demonstrates in water a matrix-assisted field desorption that enables the detection of the chemical structure of larger organic molecules. One step further natural honey, which is a supersaturated solution consiting of a mixture of different monosaccarides and higher sugars in water, can be investigated on the nanoscale.

#### MM 18.29 Tue 17:30 P2

**Fractal abnormal grain growth in nanocrystalline Pd-Au at the atomistic level** — •JOHANNES WILD¹, TORBEN BOLL¹, JULES DAKE², DOROTHÉE VINGA SZABÓ¹, STEFAN WAGNER¹, CARL E. KRILL², and ASTRID PUNDT¹ — ¹Karlsruhe Institute of Technology (KIT), Institute for Applied Materials - Materials Science and Engineering (IAM-WK), Karlsruhe, Germany — ²University of Ulm, Institute of Functional Nanosystems, Ulm, Germany

Nanocrystalline (NC) Pd-10 at.% Au (PdAu) prepared by inert gas condensation (IGC) shows an unconventional manifestation of abnormal grain growth upon heat treatment. This unusual growth mode leads to complex and highly convoluted boundaries resembling those of fractal shapes. Furthermore, the microstructure shows a bimodal grain size distribution with regions of NC grains bordering grains in the micron range. This phenomenon is unique to this NC PdAu as conventionally prepared samples showed normal grain growth for the same heat treatment. In this study, we investigate the abnormal grain boundaries of heat-treated IGC PdAu using atom probe tomography (APT) and field ion microscopy (FIM). The position-specific APT samples are produced by targeted sample preparation with focused ion beam lift-out methods at chosen regions of interest that are identified beforehand by high-resolution electron backscatter diffraction imaging. We also use FIM, which has a higher lateral resolution than APT. This research is financially supported by the Deutsche Forschungsgemeinschaft (DFG) via project number 461632490, DFG PU131/18-1, DFG KR1658/10-1 and Karlsruhe Nano Micro Facility (KNMFi).

#### MM 18.30 Tue 17:30 P2

Formation porous metal nanosystems under near-equilibrium condensation conditions in plasma-condensate system — •ANNA KORNYUSHCHENKO^{1,2}, VYACHESLAV PEREKRESTOV¹, and GERHARD WILDE² — ¹Sumy State University, Laboratory of Vacuum Nanotechnologies, Sumy, Ukraine — ²WestfälischeWilhelms-Universität, Institute of Materials Physics, Münster, Germany

It is known, that porous structures depending on morphology can possess unique physical properties which can determine areas of their application. In the proposed work a new technique for synthesizing metal porous micro- and nanostructures has been developed. This approach is based on the phase transition of sputtered substances into the condensed state under conditions close to thermodynamic equilibrium. The low dimensional metal systems (Cr, Zn, Cu, Ti, Ni, Al) have been obtained in the different morphological forms, such as network structures, nanowires, agglomerations of weakly-bound crystals, columnar structures consisting of prolonged crystals with approximately identical habitus, etc. The results confirm the important new opportunities for size, shape and physical property tuning of nanostructured materials that are given by deposition near thermodynamic equilibrium conditions. It has been established that the growth mechanism under conditions close to thermodynamic equilibrium possesses principally new peculiarities and possibilities in comparison with traditional methods of condensation from vapor state and consequently can contribute to a new zone in the structure zone model.

#### MM 18.31 Tue 17:30 P2

Self-detachment and sub-surface densification of dealloyed nanoporous thin films — •GIDEON HENKELMANN¹, DIANA WALDOW¹, MAOWEN LIU¹, LUKAS LÜHRS¹, and JÖRG WEISSMÜLLER^{1,2} — ¹Institute of Materials Physics and Technology, Hamburg University of Technology, Hamburg, Germany — ²Institute of Materials Research, Materials Mechanics, Helmholtz-Zentrum Geesthacht, Geesthacht, Germany

This work highlights experimental observations showing microstructural gradients at interfaces in nanoporous gold, and it explains those observations as a consequence of gradients in a laterally averaged mean curvature of the pore surfaces. Nanoporous gold can be covered by a densified layer at its external surfaces. Furthermore, as we report, thin films of the material often spontaneously detach from massive gold base layers that are intended to enhance adhesion to the substrate. Those phenomena appear intrinsic to the material, as they are naturally reproduced by our kinetic Monte Carlo (KMC) simulation of dealloying and of the subsequent microstructure evolution. Our results suggest that spontaneous densification or decohesion at interfaces may be generic features of nanoscale porous network materials that evolve by curvature-driven surface diffusion.

#### MM 18.32 Tue 17:30 P2

Structural-mechanical property correlation in hierarchical nanoporous gold — •LUKAS RIEDEL¹, SHAN SHI^{1,2}, JÜRGEN MARKMANN¹, and JÖRG WEISSMÜLLER^{1,2} — ¹Institute of Materials Mechanics, Helmholtz-Zentrum Hereon, Geesthacht, Germany — ²Institute of Material Physics and Technology, Hamburg University of Technology, Hamburg, Germany

Implementing a structural hierarchy in nanoporous metals has been demonstrated as an efficient way to achieve lightweight and enhanced mechanical performance. So far, several aspects of the correlation between structure and mechanical behavior are not clearly proven. Here, hierarchical nanoporous gold (HNPG) with tunable ligament size at each hierarchy level is synthesized out of Ag90Au10 via a dealloying-coarsening-dealloying strategy. The structural analysis is conducted with scanning electron microscopy, small-angle X-ray scattering (SAXS) and ultra small-angle X-ray scattering (USAXS). We demonstrate that SAXS and USAXS are valued as advantageous methods for the determination of the structural size of HNPG. In particular, USAXS is very useful for the description of nanoporous structures with a ligament size of several hundred nanometers. It is observed that the mechanical behavior of HNPG is highly dependent on the ligament size at both the upper and the lower hierarchy level. Moreover, HNPG made out of Ag90Au10 shows improved stiffness in comparison to HNPG made out of Ag93Au7 even though they have similar feature sizes. The results represent an evidence for the development of the connectivity during coarsening in relation to the solid fraction.

#### MM 18.33 Tue 17:30 P2

Hierarchical-structural effect on creep of nanoporous gold — •HANSOL JEON¹, SHAN SHI^{1,2}, JÜRGEN MARKMANN^{1,2}, and ERICA LILLEODDEN³ — ¹Helmholtz-Zentrum Hereon, Institute of Materials Mechanics, 21502 Geesthacht — ²Hamburg University of Technology, Institute of Materials Physics and Technology, 21073 Hamburg — ³Fraunhofer Institute for Microstructure of Materials and Systems, 06120 Halle (Saale)

Nanoporous gold (NPG), a bi-continuous structure composed of ligaments and pores, is highly attracting attention in application fields due to its high surface area and chemical inertness. In addition, hierarchical nested-network nanoporous gold (N3PG) has been developed as an even lighter and faster functional material. With respect to mechanical properties, the research on the timedependent deformation as called creep for NPG and N3PG is scarce while there have many studies of tension, compression, and nanoindentation. In this study, we performed compressive creep tests for NPG and N3PG pillars in order to investigate the creep behavior under control of the electrochemical potential. We prepared N3PG samples with the same higher-level ligament size and with different lower-level ligament-sizes and a non-hierarchical NPG sample according to the higher-level ligament size so that we analyzed the effect of lower-level ligament-size on N3PG as well as the effect of the hierarchical structure itself on creep. In addition, by controlling the electrochemical potential, we controlled the surface status in order to check on the size effect of the relationship between creep behavior and surface state.

#### MM 18.34 Tue 17:30 P2

Fabrication of hierarchical porous silicon and amorphous silica by means of silver nanoparticle catalyzed chemical etching — •STELLA GRIES^{1,2,3}, MANUEL BRINKER^{1,2,3}, and PATRICK HUBER^{1,2,3} — ¹Institute for Materials and X-Ray Physics, Hamburg University of Technology, 21073 Hamburg, Germany — ²Center for X-Ray and Nano Science CXNS, Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany — ³Center for Hybrid Nanostructures CHyN, University of Hamburg, 22607 Hamburg, Germany

Many biological tissues and materials exhibit a multiscale porosity with small, often nanoscale pores as well as large, macrosocpic pores or capillaries in order to achieve simultaneously large inner surfaces in combination with an optimized mass transport capability. Achieving such a hierarchical porosity in artificial porous media is a very active research field. Here we present a novel approach based on silver nanoparticle-assisted chemical etching (MACE) of electrochemically fabricated macroporous silicon for the synthesis of wafer-scale, singlecrystalline silicon with a bimodal pore size distribution. With MACE macroporous silicon membranes can be porosified into hierarchical porous silicon (hp-Si). The resulting semiconducting material offers good hydraulic permeabilities and simultaneously a large inner surface for potential applications in energy harvesting or conversion or for on-chip sensorics and actuorics. Finally, the hp Si membranes can be transformed by thermal oxidation at temperatures above 800°C to hierarchical porous amorphous silica a material that could be of particular interest for opto-fluidic and photonic applications in the visible.

#### MM 18.35 Tue 17:30 P2

In situ X-ray spectroscopic and scattering studies on the emergence of CoO nano-assemblies in solution - •CECILIA ZITO¹, LUKAS GROTE^{1,2}, KILIAN FRANK³, ANN-CHRISTIN DIPPEL², PATRICK REISBECK³, KRZYSZTOF PITALA⁴, KRISTINA KVASHNINA⁵, STEPHEN BAUTERS⁵, BLANKA DETLEFS⁵, OLEH IVASHKO², PALLAVI PANDIT², MATTHIAS REBBER¹, SANI HAROUNA-MAYER¹, BERT NICKEL³, and DOROTA KOZIEJ¹ — ¹University of Hamburg, Germany $-^2$ Deutsches Elektronen-Synchrotron, Hamburg, Germany $-^3$ Ludwig-Maximilians-Universität München, Germany $-^4$ AGH, University of Science and Technology, Faculty of Physics and Applied Computer Science, Krakow, Poland — ⁵European Synchrotron Radiation Facility ESRF, Grenoble, France The key to fabricating complex, hierarchical materials is the control of chemical reactions at various length scales. The classical crystallization theory is insufficient to properly describe the chemical reaction leading to monomer formation, the evolution of small primary particles, and how they assemble into superstructures. Here, we illustrate how the combination of advanced X-ray spectroscopic and scattering in situ studies probe length scales all the way from atomic to macroscopic, and shed light on the formation mechanism of CoO nanocrystal assemblies in solution. Utilizing HERFD-XANES, we directly access the molecular level of the nanomaterial synthesis. We reveal that initially Co(acac)3 rapidly reduces to square-planar Co(acac)2 and coordinates to two solvent molecules. Furthermore, we track subsequent structural changes with in situ total X-ray scattering and atomic pair distribution function analysis, pinning down the transition from the dissolved Co complex to crystalline CoO. Ultimately, SAXS uncovers the assembly process of the crystallites into distinct spherical superstructures. The concomitant growth and assembly of crystallites into a superstructure differentiates the investigated pathway from a classical mechanism. The combination of X-ray spectroscopy and scattering can elucidate the emergence of assemblies in solution with a broad perspective.

#### MM 18.36 Tue 17:30 P2

Hierarchical materials mimicking mechanical behaviour of human bone synthesized by additive manufacturing and dealloying. — •ALEKSANDR FILIMONOV¹, LUTZ MÄDLER^{1,2}, and LIYA OKULOV^{1,2} — ¹Faculty of Production Engineering, University of Bremen, Badgasteiner Str. 1, 28359 Bremen, Germany — ²Leibniz Institute for Materials Engineering-IWT, Badgasteiner Str. 3, 28359 Bremen, Germany

The close match between the elastic properties of an implant material and bone is crucial to avoid the stress-shielding effect. Therefore, low modulus biomaterials are desirable for biomedical implants that ensure rapid healing of hard tissue. Due to its complex hierarchical structure, bone features moderate strength similar to some metals and low elastic modulus like polymers. Implant materials for bone fixation should be several times stronger compared with that of bone. However, the general relation between strength and elastic modulus of man-made materials suggest that stronger materials typically possess higher elastic modulus including metals - usual candidates for bone fixation. In this work, novel hierarchical metal-polymer composite materials "breaking" the general trend between strength and elastic modulus were synthesized by additive manufacturing and liquid metal dealloying. The large digital porosity of metallic scaffold was synthesized by additive manufacturing and its fine porosity is a result of materials self-organization upon dealloying. The results suggest that these novel composite materials mimicking the structure and mechanical behaviour of bone are potential candidates for biomedical applications.

#### MM 18.37 Tue 17:30 P2

Peculiarities of electron transport and resistive switching in point contacts on TiSe2 and TiSe5. — DMYTRO BASHLAKOV¹, •OKSANA KVITNITSKAYA¹, YULIIA SHEMERLIUK², SAICHARAN ASWARTHAM², DMITRI EFREMOV², BERND BÜCHNER^{2,3}, and YURII NAIDYUK¹ — ¹B. Verkin Institute for Low Temperature Physics and Engineering, NAS of Ukraine, Kharkiv, Ukraine — ²Institute for Solid State Research, IFW Dresden, Dresden, Germany — ³Institut für Festkörper- und Materialphysik and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, Dresden, Germany

We report resistive switching in voltage biased point contacts (PCs) based on the transition metals chalcogenides TiSe2 and TiSeS. The switching is taking place between a low resistive *metallic-type* state and a high resistive *semiconducting-type* state by applying bias voltage (<0.4V), while reverse switching takes place by applying voltage of opposite polarity. The difference in resistance between these two states can reach of about two orders of magnitude at helium temperature. The origin of the effect can be attributed to the electric field induced change of stoichiometry in PC core due to drift of Se vacancies. Additionally, we demonstrated, that heating takes place in PC core, which can facilitate the electric field induced effect. At the same time we did not found any evidence for CDW spectral features in our PC spectra for TiSe2. The observed resistive switching allows to propose TiSe2 and TiSeS as the promising materials, e.g., for non-volatile resistive random access memory (ReRAM) engineering.

#### MM 18.38 Tue 17:30 P2

Electron-phonon interaction and point contact enhanced superconductivity in trigonal PtBi2 — DMYTRO BASHLAKOV¹, •OKSANA KVITNITSKAYA¹, GRIG-ORY SHIPUNOV², SAICHARAN ASWARTHAM², OLEG FEYA^{2,3}, DMITRI EFREMOV², and BERND BÜCHNER^{2,4} — ¹B. Verkin Institute for Low Temperature Physics and Engineering, NAS of Ukraine, Kharkiv, Ukraine — ²Institute for Solid State Research, IFW Dresden, Dresden, Germany — ³Kyiv Academic University, Kyiv, Ukraine — ⁴Institut für Festkörper- und Materialphysik and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, Dresden, Germany

PtBi2 is a Weyl semimetal, which demonstrates superconductivity with low critical temperature Tc ~ 0.6 K in the bulk. Here, we report our study of electronphonon interaction (EPI) in trigonal PtBi2 by the Yanson point contact (PC) spectroscopy and presenting the observation of PC enhanced superconductivity. We show, that the Yansons PC spectra display a broad maximum around 15 meV, indicating, apparently, EPI mechanism of Cooper pairing in PtBi2. Moreover, we discovered a substantial increase of Tc up to ~ 3.5 K in PCs. The observed Tc is sufficiently higher than the bulk value, as well as detected at hydrostatic pressure. We calculated the phonon density of states and Eliashberg EPI function in PtBi2 within the framework of the density functional theory. A comparison of experimental data with theoretical calculations showed acceptable agreement. The theoretical Tc is 3.5 K, which corresponds to the experimental value.

#### MM 18.39 Tue 17:30 P2

Quantification of intrinsic surface charges on MgO nanocubes using offaxis electron holography — •YAN LU^{1,2}, FENGSHAN ZHENG¹, QIANQIAN LAN¹, MICHAEL SCHNEDLER¹, PHILIPP EBERT¹, and RAFAL E. DUNIN-BORKOWSKI¹ — ¹Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons (ER-C 1) and Peter Grünberg Institute (PGI 5), Forschungszentrum Jülich, Jülich, Germanz — ²Beijing Key Lab and Institute of Microstructure and Properties of Advanced Materials, Beijing University of Technology, Beijing, China

Metal oxide nanoparticles exhibit outstanding catalytic properties, believed to be related to the presence of oxygen vacancies at the particle surface. However, little quantitative is known about concentrations of point defects inside and on surfaces of these nanoparticles due to the challenges in achieving an atomically resolved experimental access. By employing off-axis electron holography, we demonstrate exemplarily using MgO nanoparticles as a methodology, which allows us to discriminate between mobile charges induced by electron beam irradiation and immobile charges associated with deep traps induced by point defects as well as distinguish between bulk and surface point defects. Counting the immobile charges provides a quantification of the concentration of  $F^{2+}$  centers induced by oxygen vacancies at the MgO nanocube surfaces.

#### MM 18.40 Tue 17:30 P2

**3D Printed One Piece Surface Alteration Sensor with Galvanic Isolation** — •MICHAEL FEIGE and SONJA SCHÖNING — Bielefeld Institute for Applied Materials Research (BIFAM), Bielefeld University of Applied Sciences, Department of Engineering Sciences and Mathematics

More recently it is possible to combine conductive and non-conductive materials in one 3D print process. This allows printing of complex structures like PCBs, 3D coils, transformers, capacitors or high frequency components like antennas or transmission lines. Furthermore it is possible to combine those components to build highly specialized sensors in one production step.

We developed a concept for a sensor which, in its specialized form, could be used for detection of mechanical, chemical or biological alteration of surfaces such as abrasion, material degradation or separation. The detection method is based on an electrical, inductive readout while maintaining a sufficient galvanic isolation between the sensing area and the readout circuit.

In this contribution an actual sensor device capable of detecting corrosion is presented, which was designed, printed and tested with successful results. The sophisticated design outweighs the lack of high electrical conductivity and high magnetic permeability within the range of printable materials by the ability of the printer to precisely integrate the conductive material into the insulating material.

#### MM 18.41 Tue 17:30 P2

A first study on the current-controlled flash sintering experiments on 3YSZ-Ni composites — •PRANAV RAI and DEVINDER YADAV — Department of Metallurgical and Materials Engineering, Indian Institute of Technology Patna, Bihta, Patna 801106, India Flash sintering involves densification of ceramic bodies in few seconds at relatively low furnace temperatures. The normal flash sintering experiments are characterized by a non-linear rise is the electrical conductivity of the sample. In the present work, flash sintering experiments were conducted in the currentcontrolled mode where the current is made to increase linearly through the sample at a constant rate. The sample sinters progressively as the current increases. Composites of 3YSZ and Ni, with different Ni contents (5wt.%, 10wt.%, and 20wt.%) were flash sintered at a constant current rate of 600 mA/min with a target current density of 100 mA/mm2, at a furnace temperature of 900°C. The total span of the experiments was 50 s. The extent of densification decreased with increase in Ni content. In addition, the samples with higher Ni content started to densify at a higher current density. XRD revealed oxidation of Ni in all the samples, post flash sintering. However, complete oxidation of Ni to NiO in conventional sintering of the same composites occurred at 1450°C after a hold time of 2 hours. The flash sintered microstructure of 3YSZ phase was characterized by relatively fine grains with narrow grain size distribution. The 3YSZ-20Ni samples exhibited a microstructure with percolating network of the NiO phase. The processed samples can have possible applications in designing the anode materials for solid oxide fuel cells.

MM 18.42 Tue 17:30 P2

Electrospun Electroluminescent CsPbBr3 Fibers: Flexible Perovskite Networks for Light-Emitting Application — •KHAN LÊ¹, FLORIAN VON TOPERCZER², FERAY ÜNLÜ¹, THOMAS FISCHER¹, KLAS LINDFORS², and SANJAY MATHUR¹ — ¹Institute of Inorganic Chemistry, University of Cologne, Greinstr. 6, 50939 Cologne, Germany — ²Institute of Physical Chemistry, University of Cologne, Greinstr. 4-6, 50939 Cologne, Germany

Organic-inorganic and all-inorganic lead halide perovskites (APbX3) have continuously attracted research interest and went through significant improvements towards highly efficient photovoltaic technologies and LEDs. Most lead-halide perovskite devices are based on thin films or quantum dots while reports on alternative morphologies are scarce. We prepared CsPbBr3@polymer composite nanofibers by one-step electrospinning and characterized them by scanning electron microscopy, transmission electron microscopy, X-ray diffractometry, UV/vis and photoluminescence spectroscopy. As a proof-of-concept, we subsequently integrated the fiber mats as active layers in electrically driven light emitting devices. While the synthesis of perovskite nanofibers is not new, to the best of our knowledge we would be the first to report on electroluminescence of such fibers. In addition, all preparations were conducted under ambient atmosphere and the perovskite precursor ink was prepared with low toxicity solvents (H2O/EtOH/ionic liquid). This work could pave the way towards cost effective and flexible optoelectronic fiber- or yarn-based lead-halide perovskite devices by an up-scalable method.

**Raman spectra of Arsenopyrite: Experiment and Theory** – •NEBAHAT BULUT¹, AYBERK ÖZDEN¹, CAMELIU HIMCINSCHI¹, ESTEBAN ZUNIGA PUELLES², ROMAN GUMENIUK², and JENS KORTUS¹ – ¹TU Bergakademie Freiberg, Institute of Theoretical Physics – ²TU Bergakademie Freiberg, Institute for Experimental Physics, Germany

Arsenopyrite (FeAsS) is a semiconductor with a small bandgap and a common source for arsenic (As) mineral. Chemical and structural information on this material is still of interest. The crystal structure is, monoclinic with space group  $P_{2_1/c}$ , derived from orthorhombic marcasite (FeS₂) [1]. Here we present a combined experimental and theoretical study on the vibrational properties of arsenopyrite, which have to our knowledge not yet been reported. Raman spectra have been recorded experimentally by means of a LabRam HR800 spectrometer from HORIBA Jobin Yvon using 633 nm laser as the excitation source. Additionally, Raman spectra were calculated using Quantum Espresso [2] with normconserving pseudopotential and PZ exchange-correlation functional. The comparison of experimental and theoretical data shows good agreement and allows for symmetry assignment of the Raman peaks.

Microstructural evolution of severely deformed nanocomposite high entropy alloys irradiated by swift heavy ions — •SHABNAM TAHERINIYA¹, CHRIStian Gadelmeier², Harald Rösner¹, Martin Peterlechner¹, Christoph GAMMER³, MARILENA TOMUT^{1,4}, SERGIY V. DIVINSKI¹, UWE GLATZEL², and GERHARD WILDE¹ – ¹Institute of Materials Physiks, University of Münster, Germany — ²Metals and Alloys, University of Bayreuth, Bayreuth, Germany ³Erich Schmid Institute of materials Science, Austrian Academy of Science, Leoben, Austria — ⁴GSI Helmholtz Center for Heavy Ion Research, Darmstadt, Germanv

Structural modifications induced by the processing of high entropy alloys (HEAs) under non-equilibrium conditions are investigated to shed light into the stability of such advanced materials. The nanocomposite HEAs are produced by the room-temperature high pressure torsion (HPT) of stacked single-phase equiatomic FCC CoCrFeMnNi (Cantor) and BCC HfNbTaTiZr (Senkov) alloys. Solely Cantor and Senkov alloys were HPT-processed under the similar conditions, too. Cross-sections of the HPT-processed disks were subjected to high fluences of Au swift-heavy-ion irradiation at ambient and cryogenic temperatures. Deformation and irradiation-induced microstructural changes were examined in detail applying scanning and transmission electron microscopies with respect to evolution of chemical composition and local microstructure. A combination of nano-beam diffraction with angular correlation was utilized to provide information about the resolved crystal structures and strain fields in the different HEA phases.

#### MM 20.2 Wed 10:30 H44

Impact of high-pressure torsion and post-deformation annealing on CoCr-FeMnNi high-entropy alloy with carbon content — •SANDRA HECHT, SERGIY V. DIVINSKI, and GERHARD WILDE — Institute of Materials Physics, University of Münster, Münster, Germany

The well-known Cantor alloy CoCrFeMnNi provides attractive mechanical properties and strength-ductility combinations, which can be improved by further alloying of small amounts of carbon.

In the present work, the impact of high-pressure torsion (HPT) and postdeformation annealing on equiatomic Cantor alloy and nearly-equiatomic (C alloyed (4.4 at.%)) Cantor alloy, produced via arc-melting and subsequent homogenization at 1373 K for 3 days under pure Ar, is examined. The thermal, mechanical and microstructural properties of the initially coarse-grained samples were investigated before and after deformation at room temperature (5 rotations at 8 GPa) and afterwards post-deformation annealing treatments using differential-scanning calorimetry (DSC), X-ray diffraction (XRD), scanning and transmission-electron microscopy (SEM & TEM) as well as micro-hardness measurements. Impact of the interstitial carbon and in particular the carbides Cr₂₃C₆ on the mechanical response and microstructure evolution is examined.

#### MM 20.3 Wed 10:45 H44

Phase Stability and Ordering in Ta-Mo-Cr-Ti-Al Refractory High Entropy Al- $\mathsf{loys}-\mathsf{\bullet}\mathsf{Yilun}\,\mathsf{Gong}^1,\mathsf{Alexander}\,\mathsf{Shapeev}^2,\mathsf{Fritz}\,\mathsf{Koermann}^{1,3},\mathsf{and}\,\mathsf{Joerg}$ Neugeвauer¹ — ¹Max-Planck-Institut für Eisenforschung GmbH, Germany - 2 Skolkovo —  3 Delft University of Technology, The Netherlands

Predictive capabilities of phase stability and ordering in multi-component systems are critical to designing better alloys. This is particularly important for properties which are difficult to be quantified by traditional experimental techniques.

In the present work, a class of body-centered-cubic (bcc) refractory high en-

proach, various mechanisms and concepts proposed in the literature have been tested: Besides lattice distortions, stacking-fault energies (SFEs) have been successfully used as a descriptor to link atomistic simulations to the macroscopic deformation mechanisms that are behind the su- perior mechanical performance. Interstitial alloying with C reveals, e.g., large fluctuations in solution energies depending on the specific local chemical environment and its impact on SFEs can be even qual- itatively different depending on alloy composition. We also discuss BCC-HCP stability as promising descriptor to identify mechanically appealing refractory HEAs and the critical role of lattice distortions therefore. Based on these computationally highly expensive computa- tions easy-to-use materials de-

sign rules will be derived and discussed for the various examples.

# Location: H44

tropy alloys was studied. In contrast to its superior high-temperature behaviour, it shows less-satisfying ductility below 600 °C. As origin of the poor mechanical performance long-range B2-ordering at low temperatures has been proposed but is still controversially discussed due to contradicting experimental findings. To predict and to quantify the temperature-dependent stable structure, we employed on-lattice machine-learning interatomic potentials (namely low-rank potentials). This type of potentials is capable of accurately describing chemical interactions in multi-component systems used in subsequent Monte Carlo simulations. Systematic studies of training qualities, statistical uncertainties and impact of local lattice distortions were conducted. Computed ordering sequence, site occupancies, short-range order parameters and alloying with interstitial O will be discussed.

MM 20.4 Wed 11:00 H44

Stabilities and Mechanical Properties of Mg-based Light Metal Multi-**Principal Alloys** — •Wernfried Mayr-Schmölzer¹, Johannes Kirschner², Ceramics, TU Hamburg -²Institute of Solid State Physics, TU Vienna -³USTEM, TU Vienna -⁴LKR, Austrian Institute of Technology GmbH

Compositionally Complex Alloys (CCAs) consist of four or more elements alloyed in approximately equal fractions and often crystallize in a simple crystal lattice. In many cases, their mechanical properties like structural stability or ductility exceed that of common modern alloys. Usually, they mainly contain heavy d-Orbital metals, and investigations into low density light metal CCAs have been rare due to the complex binding modes of their constituents.

We use both a Cluster Expansion approach with stochastic prescreening steps and neural network based pair potentials to scan the large configuration space of the Mg-Al-Cu-Zn system for stable phases. Training data was generated using DFT calculations implemented in the VASP code. In conjunction with experiments, we find that addition of Cu into the Al-Mg-Zn system inhibits phase separation by formation of a stable cubic phase, reflected in an increase of the calculated bulk modulus. Furthermore, we evaluate the predictive power of these screening methods and their ability to provide insights into simulation of physical properties of these complex multicomponent alloys.

In-situ Nanoalloying by Laser Powder Bed Fusion: Molecular Dynamics Simulations of Cantor-Alloy Formation in a Powder Blend - •YULIA Klunnikova¹, Arne J. Klomp², and Karsten Albe³ - ¹klunnikova@mm.tudarmstadt.de —  2 klomp@mm.tu-darmstadt.de —  3 albe@mm.tu-darmstadt.de Laser powder bed fusion (LPBF) is an additive manufacturing technology involving a gradual build-on of layers to form a complete component typically starting with prealloyed particles. Alternatively, one can also start with a power blend and initiate in-situ alloying by the laser beam. In this context, multi-component systems, including high entropy alloys, are of particular interest. In this contribution we show results of molecular dynamics simulations of high-entropy nanoalloys formed by LBPF. We use the Cantor alloy as model system and explore the possibility to create the FeCrCoMnNi alloy from powder blends under farfrom-equilibrium conditions and compare to the case of pre-alloyed nanopowders. By varying parameters (temperature field, melt pool, substrate type, etc.) we explore the correlation to microstructural features. In the case of the powder blend the elemental components mix in the liquid phase and solidify partially in crystalline and glassy states. Depending on the parameters of the laser (irradiation temperature, laser spot size) we see varying amounts of crystal defect, such as stacking faults, twinning, and vacancies. The results show that the result-

ing structures are delicately depending on the interplay of laser parameters, heat transport, interdiffusion and geometric factors. We acknowledge the NHR4CES for the computing time.

Phase stability and formation energies of stacking faults in intermetallic  $Mg_xAl_{2-x}Ca$  Laves phases — •ALI TEHRANCHI, TILMANN HICKEL, and JÖRG NEUGEBAUER — Max Planck institute for Iron research, Max Planck Straße 1, 40237 Düsseldorf

The intermetallic Laves phases that form in Mg-based alloys at higher alloying concentrations have a significant impact on their mechanical properties. For example, they can enhance the creep resistance of the alloys and extend their application to higher temperature domains. However, the mechanisms of deformation of these phases are not fully understood. In this work, at first the formation energies of the different realizations of C14, C15, and C36 Laves phases in the composition domain,  $Mg_xAl_{2-x}$  with 0<x<2, using the ab initio simulations is calculated. Using these formation energies, the phase diagram of the phases of interest is constructed. The effect of the strain fields on the relative stability of these phases is included. In addition, using the analytic Axial Next-Nearest Neighbor Ising (ANNNI) type model, the basal stacking faults in each phase and composition are calculated. The results of the analytic models are in good accordance with the results of the direct DFT simulations of the stoichiometric stacking faults. The gamma surface of certain realizations of the C36 phase is also investigated and explain the experimentally observed planar defects in the C36 phase.

#### MM 20.7 Wed 12:00 H44

**Rational design of bimetallic nanoparticles** — •SAMUEL BALTAZAR^{1,2}, JAVIER ROJAS^{1,2}, PAMELA SEPULVEDA², and RAFAEL FREIRE² — ¹Physics Department, Universidad de Santiago de Chile, Chile — ²Center for the development of Nanoscience and Nanotechnology, Universidad de Santiago de Chile, Chile

The study of bimetallic nanoparticles (BNP) has recently attracted increasing attention from researchers worldwide due to their potential for technological applications in the electronic and environment fields. This study will be carried out through a theoretical framework to identify the fundamental atomic-scale mechanisms for BNP such as FeCu, AgCu, and FeNi. It is therefore necessary to determine the structural, electronic, and magnetic properties of the nanostructures with two or more elements, where the interplay between both metallic elements can be used to limit the oxidation of iron or the electron transfer between elemnts. This can be done based on some of the characteristics of these systems, such as (i) the surface-volume ratio, (ii) the shape of nanoparticles as an interesting aspect due to the physico-chemical properties at their surface, (iii) Concentration and (iv) distribution of elements. We performed molecular dynamics simulations under the NVT canonical ensemble to further deepen our study. The results pointed out that AgCu and FeNi BNP with a core shell and janus like morphologies are some of the most stable configurations, with a competition between them for FeCu as a function of the concentration and size of each element. These results were compared with experimental data for BNP, evidencing a good agreement among these approaches.

Atomic cluster expansion for the Ag-Pd system — •YANYAN LIANG, MATOUS MROVEC, YURY LYSOGORSKIY, and RALF DRAUTZ — ICAMS, Ruhr-Universität Bochum, Germany

Alloys of noble metals, such as silver and palladium, have been regaining attention in recent years due to their importance in nanotechnology and catalysis. However, for the binary Ag-Pd system reliable and efficient interatomic potentials that provide an accurate description of structural and thermodynamic properties are lacking. In this work, we developed a new atomic cluster expansion (ACE) parametrization for both elements Ag and Pd as well as their binary compounds by fitting to a large training set of ab initio data. The resulting ACE potential provides an accurate description for a wide range of fundamental properties, including the equations of states of various phases, elastic moduli, phonon frequencies, transformation paths, and defect energies. The excellent computer efficiency and linear scaling of ACE enable to carry out large-scale molecular dynamics and Monte Carlo simulations to evaluate complex phenomena, such as thermal expansion, melting, diffusion and phase diagrams. Examples of these simulations will be provided to demonstrate the outstanding predictive power of ACE.

#### MM 20.9 Wed 12:30 H44

Atomistic modelling of hybrid organic-inorganic nanocomposites — KAI SELLSCHOPP¹, WERNFRIED MAYR-SCHMÖLZER¹, ROBERT MEISSNER², and •GREGOR VONBUN-FELDBAUER¹ — ¹Institute of Advanced Ceramics, TU Hamburg, Germany — ²Institute of Polymers and Composites, TU Hamburg, Germany

Novel hybrid materials like supercrystalline nanocomposites from nanobuilding blocks promise excellent properties and functions for diverse applications. One realization are inorganic nanoparticles (NP) from transition-metal oxides which are functionalized with organic ligands and then assembled on different levels of hierarchy. In this contribution atomistic modelling based on density functional theory (DFT) calculations is used to shed light on the first level of hierarchy. Particularly, the interfacial properties of different ligands and effects in the interphase between the NP are addressed. For modelling interfaces, the configuration space is a challenge and here the program CodeRed (Configuration space determination and Reduction) is presented which allows to sample the adsorption configuration space and to select configurations as input for DFT calculations using unsupervised machine learning approaches. The results are further facilitated to obtain mechanical properties using DFT, and as input for molecular dynamics simulations as a first step towards multi-scale modelling to allow for an accurate description of larger and more complex systems.

**Ab initio investigation of Mg alloy corrosion in water** — •JING YANG, MIRA TODOROVA, and JÖRG NEUGEBAUER — Max-Planck-Insitut für Eisenforschung GmbH, Düsseldorf, Germany

Magnesium alloys have great potential as structural materials for the automotive and aerospace industries, as well as bio-implants due to their low density and non-toxic nature. However, intrinsically poor ductility and poor corrosion resistance limit their practical application. In this work, we focus on the solid solution of Al and Ca in Mg, an alloying system which has shown improved ductility and corrosion resistance. In particular, we elucidate the effect of Al and Ca alloying on the aqueous corrosion process of Mg metal by ab initio molecular dynamics simulation of the metal/water system. We analyze the segregation behavior of the alloying elements, their impact on the interfacial water structure and dynamics, and the subsequent implication on corrosion kinetics. By combining our DFT calculations with thermodynamics, we construct interface phase diagrams for the Mg-Al-Ca system to elucidate the influence of the environment on surface structure and composition. We consider both implicit and explicit water calculations, which allows us to analyze the impact the water-modelling approach has on the constructed interface phase diagrams. We show that such ab initio molecular dynamics studies strongly improve our understanding on microscopic corrosion processes at realistic conditions.

Time: Wednesday 10:15-13:00

MM 21.1 Wed 10:15 H45

Computational modeling of extremely anisotropic van der Waals thermal conductors — Shi En Kim¹, Fauzia Mujid¹, Akash Rai², •Fredrik Eriksson³, Joonki Suh¹, Preeti Poddar¹, Ariana Ray⁴, Chibeom Park¹, Erik Fransson³, Yu Zhong¹, David A. Muller⁴, Paul Erhart³, David G. Cahill², and Jiwoong Park¹ — ¹Uni. of Chicago, USA. — ²Uni. of Illinois UC, USA. — ³Chalmers, Sweden. — ⁴Cornell Uni., USA.

Materials with thermal conduction anisotropy can provide innovative thermal management strategies in integrated circuits. However, artificially engineered material lacks the anisotropy ratios seen in nature. Here, we report extremely anisotropic thermal conductors based on large-area van der Waals thin films with random interlayer rotations, which produce a room-temperature thermal anisotropy ratio close to 900 in  $MoS_2$ , one of the highest ever reported. This is enabled by the interlayer rotations that impede the through-plane conductivity,

while the long-range intralayer crystallinity maintains high in-plane onductivity. In this contribution we will present the computational analysis of the measured ultralow thermal conductivities in the through-plane direction for  $MoS_2$  (57 ± 3 mW m⁻¹ K⁻¹). Using molecular dynamics simulations we quantitatively explain these values and reveal a one-dimensional glass-like thermal transport. Conversely, the in-plane thermal conductivity in these  $MoS_2$  films is close to the single-crystal value. Our work establishes interlayer rotation in crystalline layered materials as a new degree of freedom for engineering-directed heat transport in solid-state systems. Nature 597, 660-665 (2021)

#### MM 21.2 Wed 10:30 H45

Searching and Finding Thermal Insulators via ab initio Green-Kubo Simulations — •FLORIAN KNOOP^{1,2}, THOMAS A.R. PURCELL¹, MATTHIAS SCHEFFLER¹, and CHRISTIAN CARBOGNO¹ — ¹The NOMAD Laboratory at the FHI-MPG and HU, Berlin, Germany — ²Department of Physics, Chemistry and Biology (IFM), Linköping University, Sweden

We present a first-principles search for thermal insulators in material space, covering hundreds of compounds in seven space groups, including simple rocksalt and zinc blende structures up to complex perovskites. Using the highthroughput framework *FHI-vibes* [1] and a recently developed measure for the strength of anharmonicity, [2] we identify 120 experimentally known materials with potential for ultra-low thermal conductivity <2 W/mK at room temperature, i.e., comparable to those of thermoelectrics such as SnSe. For the 60 most promising candidates, we perform non-perturbative, fully anharmonic *ab initio* Green-Kubo simulations [3] to include all anharmonic effects. Besides revealing seven ultra-insulating compounds, these calculations shed light on the importance of strong anharmonic effects not accessible in perturbative phonon formalisms, e.g., short-lived metastable configurations and precursors of phase transitions.

#### MM 21.3 Wed 10:45 H45

A spatially resolved optical method to measure thermal diffusivity — •FeI Sun¹, SIMLI MISHRA¹, PHILIPPA H MCGUINNESS¹, ZUZANNA H FILIPIAK¹, IGOR MARKOVIC¹, DMITRY A SOKOLOV¹, NAOKI KIKUGAWA², JOSEPH W ORENSTEIN^{3,4}, SEAN A HARTNOLL⁵, ANDREW P MACKENZIE^{1,6}, and VERONIKA SUNKO^{1,3} — ¹Max Planck Institute, CPfS, Dresden, Germany — ²NIMS, Ibaraki, Japan — ³UC Berkeley, California, USA — ⁴LBNL, California, USA — ⁵Univ. of Cambridge, Cambridge, UK — ⁶Univ. of St Andrews, St Andrews, UK

We introduce an optical method to directly measure thermal diffusivity across a broad range of temperatures. Two laser beams are used, one as a source to locally modulate the temperature, and the other as a probe of the reflectivity. Thermal diffusivity is obtained from the phase delay between two beams. Combining the technique with a microscope setup allows for spatially resolved measurements. The in-plane diffusivity can be obtained when overlapping the two laser beams instead of separating them in the traditional way, which further enhances the spatial resolution. We demonstrate on two ruthernates:  $Sr_3Ru_2O_7$ and  $Ca_3Ru_2O_7$ . The spatial resolution allowed us to study the diffusivity in single domains of the latter, and we uncovered a temperature-dependent in-plane diffusivity anisotropy. Finally, we used the enhanced spatial resolution to study the Ti-doped  $Ca_3Ru_2O_7$ . We observed large variations of transition temperature over the same sample, originating from doping inhomogeneity, and pointing to the power of spatially resolved techniques in accessing inherent properties.

#### MM 21.4 Wed 11:00 H45

Investigation of temperature dependent thermal transport in Sr₂RuO₄ and Sr₃Ru₂O₇ over a wide temperature range — FEI SUN¹, •SIMLI MISHRA¹, UL-RIKE STOCKERT¹, RAMZY DAOU², NAOKI KIKUGAWA³, ROBIN S PERRY⁴, SEAN A HARTNOLL⁵, ANDREW P MACKENZIE^{1,6}, and VERONIKA SUNKO^{1,7} — ¹Max Planck Institute - CPfS, Dresden, Germany — ²CRISMAT,ENSICAEN, UNI-CAEN, Normandie Université, Caen, France — ³NIMS, Ibaraki , Japan — ⁴LCN, University College London, London, UK — ⁵DAMTP, University of Cambridge, Cambridge, UK — ⁶School of Physics and Astronomy, University of St. Andrews, UK — ⁷Department of Physics, University of California, Berkely, USA

We use optics to study thermal transport by modifying a typical laser pumpprobe technique. A direct measurement of thermal conductivity is very challenging at high temperatures. In contrast, our method measures temperature dependent diffusivity over a wide range of temperature (10K up to 330K). As thermal diffusivity is the ratio of the thermal conductivity to the heat capacity, we can access the higher temperature thermal conductivity by an optical measurement of diffusivity and standard heat capacity measurement. We have used this technique to measure thermal diffusivity of two strongly correlated metals, Sr₂RuO₄ and Sr₃Ru₂O₇. This temperature dependent thermal transport combined with the resistivity measurements offers an insight into the electronic and phononic contributions to the quasiparticle scattering.

#### MM 21.5 Wed 11:15 H45

Simultaneous measurement for the complete characterization of thermoelectric materials - real experiment and its digital twin — •SEVERIN KOPATZ¹, ECK-HARD MÜLLER^{1,2}, and PAWEL ZIOLKOWSKI¹ — ¹Institute of Materials Research, German Aerospace Center, Cologne, Germany — ²Institute of Inorganic and Analytical Chemistry, Justus Liebig University Gießen, Gießen, Germany

Thermoelectric (TE) materials directly convert thermal energy into electric energy. Their efficiency depends on the figure of merit zT ( $zT = S^2 \sigma/\kappa$ ). Commonly, the individual transport properties, mainly the electrical conductivity ( $\sigma$ ), the Seebeck coefficient (S), and the thermal conductivity ( $\kappa$ ) are measured in

separate measurement set-ups. Here, we report on the 'Combined ThermoElectric Measurement' (CTEM) apparatus, which provides temperature-dependent measurements of the aforementioned transport properties on a single TE sample such as Co-doped FeSi₂ simultaneously. The measurements are carried out in a temperature range between room temperature and 600 °C. Since experimental CTEM results deviate from reference values, we introduce a digital twin of the CTEM. In combination with the real experiment, the numerical model allows to study possible error sources. One of the examples discussed in this talk concerns radiative effects which have to be considered especially at high temperatures above 300 °C and affect the measurement of the thermal conductivity in particular.

MM 21.6 Wed 11:45 H45

Appearance of non-equilibrium grain boundaries in additively manufactured high-entropy CoCrFeMnNi alloy — •NURI CHOI^{1,2}, VLADISLAV KULITCKII¹, JOSUA KOTTKE¹, BENGÜ TAS¹, JUNGHO CHOE³, JI HUN YU³, SANG-SUN YANG³, JOO HYUN PARK², JAI SUNG LEE², GERHARD WILDE¹, and SERGIY DIVINSKI¹ — ¹Institute of Material Physics, University of Münster, Germany — ²Dep. of Mat. Sci. & Chem. Eng., Hanyang University, South Korea — ³Center for 3D Printing Materials Research, KIMS, South Korea

Additive manufacturing process with laser melting includes the repetitive melting/solidification, which generates residual thermal stresses in the bulk material, alongside with creation of various defects, including point defects, dislocations and numerous grain boundaries. How far the kinetic properties of these interfaces are modified by the processing remains an open issue, that is of fundamental importance for such phenomena as creep, phase transformation and precipitation. In the present study, grain boundary diffusion in additively manufactured CoCrFeMnNi high-entropy alloys is measured using the radiotracer technique. Since the additive manufacturing results in a hierarchical microstructure, grain boundary diffusion is examined in different samples prepared via different scan/build strategies. A non-equilibrium state of a fraction of high-angle grain boundaries is discovered. The non-equilibrium state is shown to relax after annealing at low temperatures without measurable microstructural changes. The grain boundary diffusivities of the 3D printed alloys are discussed with respect to those for fully homogenized cast or severe plastically deformed alloys.

#### MM 21.7 Wed 12:00 H45

Grain boundary diffusion and segregation of Cr in high-purity Ni bicrystals with a  $\Sigma 11$  grain-boundary – •D. GAERTNER¹, S. V. SEVLIKAR¹, G. M. MURALIKRISHNA¹, D. COZLIN², D. IRMER², D. SCHREIBER³, B. TAS¹, M. VAIDYA¹, T. BRINK⁴, V. E. ESIN², C. DUHAMEL², G. DEHM⁴, V. RAZUMOSKII³, G. WILDE¹, and S. V. DIVINSKI¹ – ¹Institute of Materials Physics, University of Münster, Münster, Germany – ²MINES ParisTech, PSL University, Centre des Matériaux, Évry, France – ³Materials Center Leoben Forschung GmbH (MCL), Austria – ⁴Max-Planck-Institut für Eisenforschung GmbH, Düsseldorf, Germany

Grain-boundary diffusion of Cr in a Ni near  $\Sigma 11(113)[110]$  bi-crystal is measured in an extended temperature interval between 503 K and 1303 K using the radiotracer technique. The grain boundary diffusion coefficients,  $D_{\rm gb}$ , and the triple products, P are determined in the C- and B-type kinetic regimes, observing a strong deviation from the otherwise linear Arrhenius-type temperature dependence above 1000 K. The present results substantiate that the segregation factor of Cr in Ni is about unity, being in agreement with the preliminary findings in polycrystalline counterparts measured by SIMS and are fully supported by DFT-based calculations. Extensive MD simulations with empirical interatomic potentials substantiate an extreme stability of the  $\Sigma 11$  grain-boundary structure in Ni from 0 K up to melting point. The non-linear Arrhenius temperature dependence is interpreted in terms of pronounced anharmonic contributions to defect formation at elevated temperatures.

#### MM 21.8 Wed 12:15 H45

grain boundary melting phase transition in Ni-Bi system — •BAIXUE BIAN¹, BORIS STRAUMAL², SERGIY DIVINSKI¹, and GERHARD WILDE¹ — ¹Institute of Materials Physics, University of Münster, Wilhelm-Klemm-Str. 10, 48149 Münster, Gemany — ²Chernogolovka

Grain boundary segregation may drastically decrease the strength of structural materials. The intermediate temperature embrittlement of Ni-based alloys is a classical example of a catastrophic matrix degradation caused by solute segregation, in particular by Bi. In this work, the impact of grain boundary segregation of Bi in dilute polycrystalline Ni-Bi alloys on Ni grain boundary diffusion was systematically studied as function of temperature and composition. The radio-tracer technique was used applying the 63Ni radioisotope and measuring grain boundary diffusion in both B- and C-type kinetic regimes after Harrison*s classification. An abrupt increase of the grain boundary diffusivities by about two orders of magnitude was observed at certain Bi contents which are unequivocally in the single-phase region of the corresponding bulk phase diagram. The present results unambiguously prove the occurrence of a pre-melting grain boundary

Location: H46

phase transition in the Ni-Bi system.

Investigation of Phase Transitions in Polycrystalline Tungsten Trioxide Films during Ion Insertion and Extraction by in Situ Transmission and Raman Spectroscopy — •MARKUS S. FRIEDRICH^{1,2}, ALEXANDER G. STRACK^{1,2}, PAUL K. TUCHECKER^{1,2}, JAN L. DORNSEIFER^{1,2}, and PETER J. KLAR^{1,2} — ¹Institute of Experimental Physics I, Giessen, Germany — ²Center for Materials Research, Giessen, Germany

The International Energy Agency stated in its "European Union 2020 Energy Policy Review" that in 2016 in the European Union alone 152 TWh where consumed for air conditioning (AC), despite only six percent of the global stock of AC units is operated in the EU. So called "smart windows", e.g. windows based on electrochromic materials, such as tungsten trioxide, are promising candidates to reduce this kind of energy consumption. The coloration and bleaching of the EC material is based on the reversible insertion and extraction of small ions inside the material. Ion diffusion plays a key role in this process and therefore needs to be understood in depth in order to enable the optimization of future devices. Burkhardt et al. found, that the diffusion coefficient in this material is dependent on the concentration of already incorporated ions. We suggest, that this originates from changes in the crystal structure of the thin films. To substantiate this suggestion spatially and temporally resolved in situ transmission and Raman spectroscopic experiments were performed during potentiostatic ion insertion and extraction to correlate the diffusion of small ions inside the material with changes of its crystal structure.

# MM 21.10 Wed 12:45 H45

Self-diffusion in ge2sb2te5 thin films — •QINGMEI GONG, SERGIY DIVINSKI, and GERHARD WILDE — University of Münster, Institute of Materials Physics, Wilhelm-Klemm-str. 10, 48149 Münster, Germany

Phase change memory devices (PCM) are considered as one of the most mature technologies among the emerging non-volatile memories and are based on the reversibility of the amorphous-to-crystalline transition within a nanosecond timescale. Ge2Sb2Te5 is the most widely studied composition. In this work, the self-diffusion in Ge2Sb2Te5 thin films is measured using secondary ion mass spectroscopy (SIMS) and applying the highly enriched natural 122Te isotope. A 200 nm thick layer of Ge2Sb2Te5 was deposited on a Si substrate by DC magnetron sputtering at room temperature. Subsequently, a thin layer of 122Te was deposited on as-prepared Ge2Sb2Te5/Si samples using physical vapor deposition. In the as-deposited state, Ge2Sb2Te5 was amorphous as confirmed by XRD and transmission electron microscopy. The Te diffusion coefficients in Ge2Sb2Te5 were estimated from SIMS measurements after annealing at different temperatures below crystallization onset.

# MM 22: Data Driven Materials Science: Experimental Data Treatment and Machine Learning

Time: Wednesday 10:15-13:00

# Topical TalkMM 22.1Wed 10:15H46Ingredients for effective computer-augmented experimental materials science- •CHRISTOPH T. KOCH, MARKUS KÜHBACH, SHERJEEL SHABIH,<br/>BENEDIKT HAAS, and SANDOR BOCKHAUSER — Humboldt-Universität zu Berlin,<br/>Department of Physics & IRIS Adlershof, Berlin, Germany

Experimentally exploring the properties and uses of materials and improving them for particular purposes has been a major driving force for advancing the way people live over the last millennia. Experimental materials characterization techniques have now reached the level of detail that makes them converge with ab-initio computations based on fundamental building blocks: atoms and the electrons they share. During the last decades computers have surpassed the capacity of humans in the extraction of patterns in large amounts of data. It is thus a very natural consequence to involve their strengths also in further accelerating experimental materials science. In this talk we will use modern transmission electron microscopy as an example to illustrate current and future ways of how the process of linking the properties of materials to their fundamental structure can be supported computationally and by the availability of FAIR experimental and theoretical data sets. Along the way the contributions of the NFDI-project FAIRmat to this process will be highlighted, illustrating the importance of defining well-documented metadata catalogues, as well as providing community-specific online data processing capabilities.

#### MM 22.2 Wed 10:45 H46

A materials informatics framework to discover patterns in atom probe tomography data — •ALAUKIK SAXENA, NIKITA POLIN, BAPTISTE GAULT, CHRISTOPH FREYSOLDT, and JÖRG NEUGEBAUER — Max-Planck-Institut für Eisenforschung GmbH, Düsseldorf 40237, Germany.

Atom probe tomography (APT) is a unique technique that provides 3D elemental distribution with near-atomic resolution for a given material. However, the large amount of data acquired during the experiment and the complexity of the 3D microstructures poses a challenge to fully quantify APT data. Here, taking APT measurements corresponding to a Fe-doped Sm-Co alloy as an example, we present an approach based on unsupervised machine learning to extract different phases in the data. On top of this method, we have built a PCA-based workflow to reduce secondary phase precipitates with complex morphology into simpler plate-like morphologies thus enabling the quantification of in-plane compositional and thickness fluctuations, and relative orientations of the precipitates. The labeled data acquired from the PCA-based approach is used to train a U-NET to perform the same task on different APT samples of the same material automatically. The composition and thickness-related insights are expected to help understand the contribution of the particles to the confinement of the magnetic domains of the dominant 2:17 bulk phase, providing further indications to guide the design of future permanent hard magnets.

#### MM 22.3 Wed 11:00 H46

Correcting density artifacts in Atom Probe reconstructions: A tip shapecorrected volume reconstruction approach — •PATRICK STENDER¹, DANIEL BEINKE¹, FELICITAS BÜRGER², and GUIDO SCHMITZ¹ — ¹Institute for Materials Science, University of Stuttgart — ²Fakultät für Mathematik, Universität Regensburg, D-93040 Regensburg, Germany Atom Probe Tomography enables the chemical investigation of nanometric volumes with single atomic sensitivity in 3D. The tip shape sample is evaporated atom by atom. From the obtained data sequence, the respective volume is reconstructed.

Conventionally, this reconstruction is performed with the assumption of a hemispherical tip apex. This practice can lead to serious volume distortions (local-magnification effect). Instead of using in-situ correlative microscopy to discover the evolution of the tip shape during the measurement, we extract the emitter shape numerically from the event statistics on the 2D detector plane.

The method is based on the fundamental postulate that the detected density of events is linked to the local Gaussian curvature of the tip apex. Knowing the variation of this curvature, the surface profile is determined by a finite difference scheme. Except for convexity, no further restriction is imposed on the possible tip shapes.

Different simulated and experimental data sets of complex tip shapes will be discussed and compared. The method largely suppresses the local magnification effects appearing at interfaces between materials of contrasting evaporation thresholds.

MM 22.4 Wed 11:15 H46

Neural networks trained on synthetically generated crystals can classify space groups of ICSD powder X-ray diffractograms — •HENRIK SCHOPMANS^{1,2}, PATRICK REISER^{1,2}, and PASCAL FRIEDERICH^{1,2} — ¹Institute of Theoretical Informatics, KIT, Karlsruhe, Germany — ²Institute of Nanotechnology, KIT, Eggenstein-Leopoldshafen, Germany

Machine learning techniques have successfully been used to extract structural information such as the crystal space group from powder X-ray diffraction (XRD) patterns. However, training directly on simulated patterns from databases like the ICSD is problematic due to its limited size, class-inhomogeneity, and bias toward certain structure prototypes. We propose an alternative approach of generating random crystals with random coordinates by using the symmetry operations of each space group. Based on this approach, we present a highperformance distributed python framework to simultaneously generate structures, simulate patterns, and perform online learning. This allows training on millions of unique patterns per hour. For our chosen task of space group classification, we achieve a test accuracy of 60.4% on new ICSD structure prototypes not included in the statistics dataset guiding the random generation. Instead of space group classification, the developed framework can also be used for other common tasks, e.g. augmentation and mixing of patterns for phase fraction determination. Our results demonstrate, using the domain of X-ray diffraction, how state-of-the-art models trained on large, fully synthetic datasets can be used to guide the analysis of physical experiments.

#### MM 22.5 Wed 11:45 H46

Physics guided machine learning tools in analytical transmission electron microscopy — •CECILE HEBERT^{1,3}, HUI CHEN¹, and ADRIEN TEURTRIE^{1,2} — ¹LSME - IPHYS Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland — ²Unité Matériaux et Transformations, Université de Lille, France — ³Institut de Matériaux, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

Modern transmission electron microscopes are capable of recording large datasets containing both structural and chemical information on a scale ranging from sub-micrometer to atomic resolution. Operated in scanning TEM mode, two kind of chemical information can be obtained: either via energy dispersive X-Ray spectroscopy of via electron energy loss spectroscopy. On modern instruments, both signals can be acquired at the same time. Turning this huge amount of information (datasets can weight up to several Gb) into segmented quantitative information representing the different phases of the specimen is a real challenge. Pure statistical analysis like principal component analysis generally fails because of two main reasons: artifacts linked to the detection chain and/or non uniqueness of a statistical decomposition. The task is generally complicated by the overlap of phases in the specimen thickness and the presence of the same elements in different phases

With the introduction of physical constraints, like a modelling of the spectrum based on prior knowledge, both on the specimen and on the physical process leading to the spectra, it is possible to obtain a physically meaningful spatial segmentation of the data and to proceed with chemical analysis.

**Motif Extraction from Crystalline Images in Real Space** — •AMEL SHAM-SELDEEN ALI ALHASSAN and BENJAMIN BERKELS — AICES Graduate School, RWTH Aachen University, Germany

Using modern transmission and scanning transmission electron microscopes ([S]TEM), atomic resolution images are readily available. In particular, the amount of data produced is so large that automatic analysis tools are needed.

During the last decade, automatic data analysis methods concerning different aspects of crystal analysis have been developed, for example, unsupervised primitive unit cell extraction and automated crystal distortion and defects detection. However, an automatic, dedicated motif extraction method is still called for by experimentalists. While previous works on motif extraction did good work in, for example, finding the plane symmetries and restoring smeared out features or finding positions in atomic columns, they were either not automated enough, not applicable to atomic scale images, or required special calibration.

Here, we propose and demonstrate a novel method for automatic direct mo-

tif extraction from crystalline images based on variational methods. Given an atomic resolution crystalline image, our method employs unit cell extraction to find the atomic structure then solves a minimization problem involving the unit cell projection operator to find the motif. The method was tested on various synthetic and experimental data sets. The results are a representation of the motif in form of an image, primitive unit cell vectors and a denoised reconstruction of the input image.

Analysis of acoustic emission spectra for structural health monitoring — •KLAUS LUTTER, VIKTOR FAIRUSCHIN, and THORSTEN UPHUES — Institute for Sensor and Actuator Technology, Coburg, Germany

Today, the analysis of vibration and acoustic emission spectra is routinely used for health monitoring of gears in industrial production. Recent developments of extended IIoT networks provide even fleet comparison and optimization of required field service.

Here, we present an extended approach to utilize acoustic emission spectra to monitor the structural health of machining tools like mills or drills to extract degradation and lifetime information from the acoustic emission. A successful application of a spectral analysis will provide a huge impact on production quality as well as tool quality according to different production parameters which are transferred into related spectral properties. Furthermore we follow an experimental approach using contact microphones. Our diagnostic approach is a detailed analysis of the corresponding frequency spectra and in particular the existing harmonic frequencies during milling processes.

We demonstrate the classification of different process parameter sets according to different dominant frequencies via classification algorithms. The retrieved classes of spectra are used for a classical regression model assisted by neural networks to analyse characteristics changes over time. From an industrial perspective this type of analysis is a non-invasive and versatile approach and easily implementable, even in existing production machinery.

Electronic structure of the non-centrosymmetric antiferromagnetic delafossite AgCrSe₂ — •SEO-JIN KIM¹, HAIJING ZHANG¹, MARCUS SCHMIDT¹, MICHAEL BAENITZ¹, GESA SIEMANN², CHIARA BIGI², PHIL D. C. KING², and HELGE ROSNER¹ — ¹Max Planck Institute for Chemical Physics of Solids, D-01187 Dresden, Germany — ²School of Physics and Astronomy, University of St. Andrews, St. Andrews KY16 9SS, United Kingdom

We present the theoretical studies of the electronic structure and the anomalous Hall effect in AgCrSe₂ based on density functional theory together with experimental results. AgCrSe₂ is a layered triangular lattice system that lacks inversion symmetry, and exhibits a ferromagnetic coupling in layer and an antiferromagnetic coupling between Cr adjacent layers. The comparison of the Cr partial DOS determined from the photoemission measurements and the magnetic LDA+U calculations with a value of U = 0.75 eV shows a good agreement, revealing that this compound is weakly correlated due to a strong hybridization with the ligands. The Se 4p states are dominating near the Fermi energy, resulting the sizable band split of the order of 300 meV induced by the SOC. Our recent work demonstrates that this system shows an unconventional anomalous Hall effect driven by the Rashba-like spin-orbit coupling due to the non-centrosymmetric structure. The anomalous Hall conductivity was calculated based on the Berry curvature using an effective tight-binding model constructed by the Wannier function approach. The calculated  $\sigma_{xy}$  shows a good agreement to the experimental measurement.

MM 23.3 Wed 16:15 H44 **Magnetically-textured superconductivity in elemental Rhenium** – GABOR CSIRE¹, JAMES F ANNETT², •JORGE QUINTANILLA³, and BALAZS ÚJFALUSSY⁴ – ¹ICN2, Barcelona, Spain – ²University of Bristol, Bristol, United Kingdom – ³University of Kent, Canterbury, United Kingdom – ⁴Wigner Research Centre for Physics, Budapest, Hungary

Recent  $\mu$ SR measurements revealed remarkable signatures of spontaneous magnetism coexisting with superconductivity in elemental rhenium. Here we provide a quantitative theory that uncovers the nature of the superconducting instability by incorporating every details of the electronic structure together with spin-orbit coupling and multi-orbital physics. We show that conventional swave superconductivity combined with strong spin-orbit coupling is inducing even-parity odd-orbital spin triplet Cooper pairs, and in presence of a screw axis Cooper pairs* migration between the induced equal-spin triplet component leads to an exotic magnetic state.

**Magnetic bond-order potential for iron-cobalt alloys** — •ALEKSEI EGOROV, APARNA SUBRAMANYAM, RALF DRAUTZ, and THOMAS HAMMERSCHMIDT — ICAMS, Ruhr-Universität Bochum, Bochum, Germany

We present a general-purpose analytic bond-order potential for large-scale simulations of magnetic FeCo alloys. The model is based on a *d*-valent orthogonal tight-binding Hamiltonian in two-center approximation and an embedding term to account for the s electrons. The BOP is a physical model and therefore requires only a comparably small set of reference data and only a small number of parameters to be optimized. It still provides good transferability to properties of FeCo that we did not include in the fit. We demonstrate the transferability of the FeCo BOP for defect formation energies, vibrational properties, and elastic constants. Due to the explicit treatment of magnetism, our BOP can reproduce the main features of the electronic structure of magnetic and nonmagnetic phases. The predictive power of the FeCo BOP yields a reasonable estimate of the order-disorder transition temperature of magnetic B2-FeCo. Our FeCo BOP also reproduces the dense sequence of stable structures for Fe-rich FeCo compounds.

Ab-initio High-Throughput Screening for Magnetic MAX Phases — •ALI MUHAMMAD MALIK, JOCHEN ROHRER, and KARSTEN ALBE — Materials Modelling, Technical University of Darmstadt, Germany

MAX phases are layered ternary transition metal carbides and nitrides that combine both metallic and ceramic properties such as high toughness and strength at elevated temperatures. So far about ~80 single-M containing MAX phases have been synthesised. But very few of these phases, have long-range magnetic order and are mostly based on Cr and/or Mn. It is expected that magnetically ordered MAX phases will be promising in spintronics and magnetocaloric applications. In this work, we systematically search for stable MAX phases with a focus on magnetic properties, by screening about 1200 potential compositions. The thermodynamic stability is based on relative formation enthalpy compared to known competing phases that are present in M-A-X ternary phase diagram obtained from online databases e.g. Materials Project. Based on the evaluation of relative formation enthalpy, we have predicted around ~170 new MAX phases that are potentially synthesisable. However, out of these predicted phases, only 2 in total, based on Cr or Mn, were found to have long-range magnetic order. Finally, it is concluded that the incorporation of a late-transition metal into the MAX structure by alloying or unconventional post-synthesis routes, is the way forward for achieving magnetic long-range order.

**Energetic and electronic properties of CsK₂Sb surface facets: An** *ab initio* **study** — •RICHARD SCHIER^{1,2}, HOLGER-DIETRICH SASSNICK², and CATERINA COCCHI^{2,1} — ¹Humboldt-Universität zu Berlin and IRIS Adlershof — ²Carl von Ossietzky Universität Oldenburg

For the efficient generation of ultra-bright electron beams, the microscopic understanding of the electronic structure of the photoemitting materials is crucial. Ternary alkali antimonides have been proposed as a promising class of photocathodes [1-4]. However, still little is known about their surface properties. We fill this gap with an ab initio study of the energetic and electronic properties of 7 CsK₂Sb surface facets of low Miller index. We investigate formation energies as a function of chemical potential to quantify the stability of these systems at varying concentration of the atomic species. We find that the (111)-surfaces terminated with K on top of Sb are generally the most stable, except for very high (low) concentrations of Cs (K). Calculated values for the work functions range from 2.33 eV for (100)-surfaces to 3.50 eV for (111)-surfaces terminated with a Sb layer. From the analysis of the band structures we find 4 out of 7 surfaces to be semiconducting. Metallic surfaces are formed upon an excess of metal atoms at the interface with vacuum.

**Modeling Temperature-Dependent Electronic Structure of Semiconductors** with a Dynamic Tight-Binding Approach — •MARTIN SCHWADE, MAXIMILIAN SCHILCHER, and DAVID EGGER — Department of Physics, Technical University of Munich, Garching, Germany

For theoretical calculations of large-scale system sizes or longer time-scale phenomena the computational costs of typical density functional theory can present a steep barrier, which needs to be tackled by development of alternative approaches. Here, we propose an extension of the tight-binding (TB) formalism which allows for the calculation of macroscopic and temperature-dependent properties of semiconductors with little computational effort. In contrast to previous formulations, we fit TB parameters to first-principles energy eigenvalues using machine learning techniques. Furthermore, our TB approach employs hybrid orbital basis functions and addresses the problem of distance-dependent matrix elements by numerical integration of these orbitals. With this, we can maintain the average symmetry of the system as best as possible but still account for dynamic changes to that symmetry, e.g., by lattice distortions and other thermal effects. Our method is particularly helpful for getting an accurate solution of the electronic-structure problem for semiconductors at finite temperatures.

#### MM 23.8 Wed 17:45 H44

**Coupled electronic and lattice degrees of freedom in excitonic insulator candidate Ta2NiSe5 and Ta2NiS5** — •BANHI CHATTERJEE, JERNEJ MRAVLJE, and DENIS GOLEŽ — Jozef Stefan Institute, Jamova 39, SI 1000, Ljubljana, Slovenia The origin of phase-transition from a high temperature orthorhombic phase to a low temperature monoclinic phase in Ta2NiSe5 is debatable. There are two competing scenarios, namely, a structural instability with a B2g zone center optical phonon and electronic order parameter of excitonic nature breaking the discrete set of lattice symmetries [1-3]. We defined a theoretical description which takes both scenarios on equal footings based on realistic modeling using DFT as a starting point and describe electronic and lattice correlation on a Hartree Fock level. We have identified both excitonic instability and the B2g phonon mode in our calculations and investigate the effect of electron-phonon coupling. Within our methods we have further identified spectroscopic signatures showing the lack of excitonic ordering in the auxiliary compound Ta2NiS5 which is in agreement with the experimental ARPES observations [4].

Supermetal-insulator transition in a non-Hermitian network model — •HuI LIU¹, JHIH-SHIH YOU², SHINSEI RYU³, and ION COSMA FULGA¹ — ¹IFW Dresden and Würzburg-Dresden Cluster of Excellence ct.qmat, Helmholtzstrasse 20, 01069 Dresden, Germany — ²Department of Physics, National Taiwan Normal University, Taipei 11677, Taiwan — ³Department of Physics, Princeton University, Princeton, New Jersey, 08540, USA

We study a non-Hermitian and non-unitary version of the two-dimensional Chalker-Coddington network model with balanced gain and loss. This model belongs to the class  $D^{\dagger}$  with particle-hole symmetry^{$\dagger$} and hosts both the non-Hermitian skin effect as well as exceptional points. By calculating its twoterminal transmission, we find a novel contact effect induced by the skin effect, which results in a non-quantized transmission for chiral edge states. In addition, the model exhibits an insulator to "supermetal" transition, across which the transmission changes from exponentially decaying with system size to exponentially growing with system size. In the clean system, the critical point separating insulator from supermetal is characterized by a non-Hermitian Dirac point that produces a quantized critical transmission of 4, instead of the value of 1 expected in Hermitian systems. This change in critical transmission is a consequence of the balanced gain and loss. When adding disorder to the system, we find a critical exponent for the divergence of the localization length v = 1, which is the same as that characterizing the universality class of two-dimensional Hermitian systems in class D.

**Dynamical mean-field theory on the high-temperature superconductivity for cerium hydrides under extreme pressure** — •YAO WEI and CEDRIC WEBER — King's College London, London, UK

Hydrogen-rich superhydrides are promising high-Tcsuperconductors, with superconductivity experimentally observed near room temperature, as shown in recently discovered lanthanide superhy- drides at very high pressures, e.g. LaH10 at 170 GPa and CeH9 at 150 GPa. Superconductivity is believed to be closely related with the high vibrational modes of the bound hydrogen ions. Here we study the limit of extreme pressures (from 200 to 500 GPa or higher) where lanthanide hydrides with large hydrogen content have been observed. We focus on CeH10, the prototype candidate for achieving a large electronic contribution from hydrogen in the electron-phonon coupling. In this work, we use a first-principles calculation platform with the inclusion of many-body corrections to evaluate the detailed physical properties of the Ce-H system and to understand the structure, stability and superconductivity of these systems at ultra-high pressure. We provide a DMFT approach to further investigate conventional superconductivity in hydrogen rich superhydrides.

# Topical TalkMM 24.1Wed 15:45H45Electromigration effects on the atomic ordering process in hard magneticL10intermetallic phases• DANIEL URBAN^{1,2}and CHRISTIAN ELSÄSSER^{1,2}-¹Fraunhofer-Institut für Werkstoffmechanik IWM, Wöhlerstraße 11, 79108Freiburg-²Freiburger Materialforschungszentrum, Stefan-Meier-Straße 21, 79104Freiburg-

High-performance permanent magnets are needed for many applications in energy and information technology. The L1₀ phase of FeNi is a promising candidate for a sustainable material that is free of rare-earth elements. However, on earth FeNi can only be found in the disordered A1 crystal structure, although the layered L1₀ structure is lower in energy. By contrast, the latter was found in meteorites, proving the astronomical long timescales required for the dynamical ordering of the material.

We investigate the atomic migration processes in binary intermetallic  $L1_0$  phases within the framework of density functional theory. Our main objectives are (i) to develop a thorough understanding of the possibilities to enhance the thermally activated diffusion processes at the atomic scale by electric fields and currents and (ii) an assessment in how far electromigration effects can be effective in processing hard magnetic materials. We extend the scope to the hard magnetic L1₀ phases of FePt, FePd, MnAl and MnGa as well as ternary Fe(Pt,Ni). These alloys cover a wide range of thermal ordering time scales and related experimental feasibilities.

**Deriving Macroscopic Diffusivity from a Microscopic Master Equation Approach** — •DANIEL PFALZGRAF^{1,2}, DANIEL URBAN^{1,2}, and CHRISTIAN ELSÄSSER^{1,2} — ¹Freiburg Materials Research Center (FMF), University of Freiburg, Stefan-Meier-Straße 21, 79104 Freiburg, Germany — ²Fraunhofer IWM, Wöhlerstraße 11, 79108 Freiburg, Germany

We present our generalisation of a model formalism that allows the derivation of macroscopic diffusion properties of a crystalline material from jump rates of individual atoms or ions. This work is based on a mathematical formalism modelling the uncorrelated motion of particles on a lattice by a Markov chain, from which a master equation in time and space is constructed. This approach is discussed, reformulated, and generalised to be applicable to any three-dimensional crystal system. Specifically, it is capable of describing the diffusion and drift of particles in a tilted potential landscape, as e.g. induced by electric fields. We sketch multiple use cases for systems involving point defects and grain boundaries and use the derived framework to discuss the diffusion of oxygen vacancies in strontium titanate.

# MM 24.3 Wed 16:30 H45

Atomistic calculations of charged point defects at grain boundaries in SrTiO₃ — •CONG TAO¹, DANIEL MUTTER¹, DANIEL URBAN¹, and CHRISTIAN ELSÄSSER^{1,2} — ¹Fraunhofer IWM, Freiburg, Germany — ²University of Freiburg, FMF, Germany

Oxygen vacancies have been identified to play an important role in accelerating grain growth in polycrystalline perovskite-oxide ceramics. To advance the fundamental understanding of growth mechanisms at the atomic scale, we performed classical atomistic simulations to investigate the atomistic structures and oxygen vacancy formation energies at grain boundaries in the prototypical perovskite-oxide material SrTiO₃ [1]. We focus on two symmetric tilt grain boundaries, namely  $\Sigma 5(310)[001]$  and  $\Sigma 5(210)[001]$ . Electrostatic potentials are present in supercells containing alternatingly charged lattice planes and grain boundaries. We derive analytic solutions for these potentials for both open and periodic boundary conditions and apply them to our atomistic model structures. In this way, simulation artifacts resulting from the interaction of the electrostatic potential with charged point defects can be corrected, leading to physically reasonable defect energies. We report calculated formation energies of oxygen vacancies on all possible sites across boundaries between the two misoriented grains, and we analyze the values with respect to local charge densities at the vacant sites. The developed calculation procedure can be transferred to more complicated interfaces such as asymmetric tilt grain boundaries [2].

Field assisted sintering of piezoelectric-bioactive scaffolds for bone tissue engineering — •ABDULLAH RIAZ¹, CHRISTIAN POLLEY¹, EBERHARD BURKEL², and HERMANN SEITZ¹ — ¹Chair of Microfluidics, Faculty of Mechanical Engineering and Marine Technology, University of Rostock, Rostock, Germany — ²Institute of Physics, University of Rostock, Rostock, Germany

The treatment of critical size bone defects is still a challenge. The external ma-

terial is often needed to support bone and guide tissue regeneration by physical stimulation. Promising effects of electrical stimulation on bone cell growth have led to an interest in using piezoelectric ceramics for tissue repair. Nevertheless, it is still concerning due to the toxicity of ceramics, which exhibit ion dissolution in biological fluids. In this study, nanostructured pure and doped calcium titanate is prepared by sol-gel synthesis and field assisted sintering. The piezoelectric behaviour is observed in calcium titanate, which is also a non-cytotoxic compound. This behaviour is referred to as pseudo-piezoelectricity since it is generated by the distorted structure which is formed during densification by field assisted sintering. Additionally, piezoelectric barium titanate-45S5 bioactive glass composites are combined with titanium alloy Ti6Al4V for the potential implantation of piezoelectric-bioactive scaffolds in load-bearing areas. For the engineering of these bulk scaffolds, electron beam melting is utilized for manufacturing metallic load-bearing lattice structures and combined with piezoelectric-bioactive composites for the joint processing via field assisted sintering.

From Uncovering the Mechanisms of Flash Sintering to Realizing Ultrafast Sintering without Electric Fields and Discovering Electrochemically Driven Microstructural Evolution — •JIAN LUO — University of California San Diego, U.S.A.

This talk will first review our recent studies on understanding the scientific questions and technological opportunities of flash sintering [Scripta 146: 260 (2018); MRS Bulletin 46: 26 (2021)]. We originally proposed that flash sintering generally starts a thermal runaway [Acta 94:87 (2015)], but it can also be activated by bulk phase and grain boundary complexion transitions [Acta 181:544 (2019)]. We further proved that ultrafast densification is enabled by ultrahigh heating rates of ~100 K/s [Acta 125:465 (2017)]. Subsequently, a generic ultrafast high-temperature sintering was reported in a collaborative study [Science 368:521 (2020)]. Other related technologies include water-assisted flash sintering (WAFS) to flash ZnO at room temperature [Scripta 142:79 (2018)] and two-step flash sintering (TSFS) to densify ceramics with suppressed grain growth [Scripta 141:6 (2017)]. Recent research discovered electrochemically induced grain boundary transitions that can cause enhanced or abnormal grain growth [Nature Communications 12:2374 (2021)]. Subsequently, I will discuss a series of on-going studies to further investigate electrochemically controlled microstructural evolution and tailor the microstructural evolution with applied electric fields in various systems and schemes [Yan et al., unpublished work].

Electric fields effects in ionic conductors during flash sintering and ion exchange — •MATTIA BIESUZ, GIAN DOMENICO SORARU, and VINCENZO MARIA SGLAVO — University of Trento, Trento, Italy

Electric fields can drive ceramic ionic conductors out of the equilibrium dictated by temperature, composition, and pressure. These phenomena can be used to promote ceramics sintering or ion exchange.

Herein, we explore flash sintering in oxygen ionic conductors (YSZ and GDC) evidencing the presence of some electrochemical effects producing alterations

of the defect chemistry and activating n-type electronic conductivity. This enhances the conductivity of the green sample, increases the electric power dissipation and contributes to the activation of the flash leading to sudden densification of ceramics. The pivotal role of electrochemical reduction during DC-flash sintering impacts the thermal history of the flashed samples generating strong thermal gradients between the cathode and anode which can be enhanced or removed by changing the quality and type of the used electrodes. The electro-

Wednesday

Location: H46

chemical description of flash sintering in oxygen ion conductors well explains the electrode configuration and atmosphere effects on the flash processes.

Electrochemical phenomena are, however, pivotal also in other ionic conductor systems subjected to flash-like processes. It is shown that the electrode material choice strongly affects the flash behavior and modifies the glass composition in the vicinity of electrodes. Hence, electric fields can be to modify the surface glass or ceramics composition improving mechanical and functional properties.

# Topical TalkMM 25.1Wed 15:45H46Automated atomistic calculation of thermodynamic and thermophysical data- •JAN JANSSEN^{1,2}, TILMANN HICKEL^{1,3}, and JÖRG NEUGEBAUER¹ - ¹Max-Planck-Institut für Eisenforschung, Düsseldorf, Germany - ²Los Alamos Na-tional Laboratory, Los Alamos, USA - ³Bundesanstalt für Materialforschung

und -prüfung (BAM), Berlin, Germany A major challenge in predicting the properties of materials at realistic conditions is the accurate inclusion of finite temperature effects. Doing this on an ab initio level often requires complex simulation protocols. These complex protocols, which often couple several specialized codes, make a quantitative description of error propagation and uncertainty quantification a critical issue.

To handle this high level of complexity we have developed an integrated development environment (IDE) called pyiron - http://pyiron.org. pyiron has been specifically designed to scale simulation protocols from the interactive prototyping level up to the high throughput level, all within the same software framework.

We highlight two recent success stories towards automated calculation of phase diagrams: We first discuss with the automated convergence for all key parameters in DFT codes, followed by the calculation of melting points with a guaranteed precision of better than 1K. These fully automated high-precision tools allow us to study trends over the periodic table in an efficient and systematic way. Examples how such high-throughput screenings allow to develop new strategies in designing materials will be given.

Efficient parameterization of the atomic cluster expansion — •ANTON BOCHKAREV, YURY LYSOGORSKIY, MATOUS MROVEC, and RALF DRAUTZ — Atomistic Modelling and Simulation, ICAMS, Ruhr-Universität Bochum, D-44801 Bochum, Germany

The atomic cluster expansion (ACE) is a machine learning model with a complete basis set representation that can be used for constructing interatomic potentials. These potentials can be both, general-purpose as well as potentials designed for a specific application. The former are usually more reliable and accurately describe materials in various conditions, but building such models often requires a materials specific expertise and extensive training datasets. Purpose-specific potentials have only limited ranges of applicability, but are also less demanding in terms of training data. Here we demonstrate a complete, efficient and largely automated framework for constructing quantum accurate ACE models for various applications. Our framework includes automated data generation, model parameterization and validation. Efficient implementations on CPU and GPU hardware enable large scale simulations.

# MM 25.3 Wed 16:30 H46

Atomic cluster expansion for Mg: From defects to phase diagrams — •ESLAM IBRAHIM, YURY LYSOGORSKIY, MATOUS MROVEC, and RALF DRAUTZ — ICAMS, Ruhr Universität Bochum, 44780 Bochum, Germany

In this work, we developed a general-purpose parametrization of the atomic cluster expansion (ACE) for Mg. The model shows an outstanding transferability over a broad range of atomic environments and is able to capture physical properties of bulk as well as defective Mg phases in excellent agreement with reference first-principles calculations. We demonstrate the computational efficiency and the predictive power of ACE by calculating the phase diagram covering temperatures up to 3000 K and pressures up to 80 GPa using state-the-art thermodynamic integration techniques implemented in the CALPHY software package. The ACE predictions are compared with those of common interatomic potentials, such as the embedded atom method or the angular-dependent potential, as well as a recently developed neural network potential. The comparison reveals that ACE is the only model that is able to predict both qualitatively and quantitatively correctly the phase diagram in close experiment with experimental observations. MM 25.4 Wed 16:45 H46 Learning design rules for selective oxidation catalysts from high-throughput experimentation and artificial intelligence — •LUCAS FOPPA¹, CHRISTOPHER SUTTON¹, LUCA M. GHIRINGHELLI¹, SANDIP DE², PATRICIA LÖSER³, STEPHAN SCHUNK^{2,3}, ANSGAR SCHÄFER², and MATTHIAS SCHEFFLER¹ — ¹The NOMAD Laboratory at the Fritz Haber Institute of the Max Planck Society, Germany — ²BASF SE, Germany — ³hte GmbH, Germany

The design of heterogeneous catalysts is challenged by the complexity of materials and processes that govern reactivity and by the very small number of good catalysts. Here, we show how the subgroup-discovery (SGD) artificialintelligence *local* approach[1] can be applied to an experimental plus theoretical data set to identify constraints or *rules* on key physicochemical parameters that exclusively describe materials and reaction conditions with outstanding catalytic performance.[2] By using high-throughput experimentation, 120 SiO₂-supported catalysts containing Ru, W and P were synthesized and tested in propylene oxidation. As candidate descriptive parameters, the temperature and ten calculated parameters related to the composition and chemical nature of elements in the catalyst materials, were offered. The temperature, the P content, and the composition-weighted electronegativity are identified as key parameters describing high yields of value-added oxygenate products. The SG rules reflect the underlying processes associated to high performance, and guide catalyst design. [1] B.R. Goldsmith, *et al.*, *New. J. Phys.* **19**, 013031 (2017).

Topical TalkMM 25.5Wed 17:15H46Understanding Dislocation Flow and Avalanches in High Entropy Alloysby Machine Learning-based Data Mining of In-Situ TEM Experiments —•STEFAN SANDFELD — FZJ/IAS-9, 52068 Aachen, Dennewartsstr. 25-27

This talk will give an overview over recent developments in the field of material informatics and materials data science, in particular over current, state-of-theart machine learning and data-mining techniques in the context of TEM experiments.

As a main example, the goal is to understand some of the many open questions concerning the underlying structure-property relations in High Entropy Alloys (HEAs). Although in-situ Transmission Electron Microscopy (TEM) allows high-resolution studies of the structure and dynamics of moving dislocations and – in a way – makes the local obstacle/energy "landscape" visible through the geometry of dislocations; a 3D analysis and high-throughput datamining of the resulting data is still not possible.

We introduce a novel data-mining approach that is based on spatio-temporal coarse graining of TEM dislocation data, making ensemble averaging of a large number of snapshots in time possible. Using dislocations as "probes" we investigate the effect of pinning points on the dislocation glide behavior of CoCr-FeMnNi alloy during in-situ TEM straining. Additionally, we use our Deep Learning-based dislocation extraction and 3D reconstruction to analyze the strain avalanche statistics of in-situ TEM recordings and discuss the dependency of the power law exponent based on 3D dislocation dynamics simulations.

Phase stability and short range order in CrCoNi medium entropy alloy — •SHEULY GHOSH¹, VADIM SOTSKOV², ALEXANDER SHAPEEV², FRITZ KOERMANN^{1,3}, and JOERG NEUGEBAUER¹ — ¹Max-Planck-Institut für Eisenforschung GmbH — ²Skolkovo Institute of Science and Technology — ³Delft University of Technology

One of the key components in the design and exploration of multicomponent alloys is the knowledge about its phase stability. The solid solution of multicomponent alloys are often assumed to be ideally random. However, short-range order, which is challenging to quantify by experiments, is known to affect the mechanical properties of alloys. An important issue to address is therefore to quantify the degree of local chemical ordering as function of temperature and its chemical nature.

In the present work, we have investigated short-range order (SRO) and its impact on phase stability in CrCoNi medium entropy alloy. This alloy is known for its cryogenic damage tolerance and general mechanical superiority. For this purpose, we have employed a recently proposed computationally efficient onlattice machine-learning interatomic potential called low-rank potentials. These potentials are capable of accurately representing interactions in a system with many chemical components which is used in subsequent Monte Carlo simulations. The potentials are trained on DFT supercell calculations and thus allow to systematically include the impact of local lattice distortions. The computed short-range order parameters and observed ordering are discussed in view of recent simulation and experimental works.

Inverse Design of Multicomponent Crystalline Materials — TENG LONG^{1,2} and •HongBin Zhang¹ - ¹Institute of Materials Science, Technical University of Darmstadt, Darmstadt 64287, Germany — ²School of Materials Science and Engineering, Shandong University, Jinan 250061, China

Autonomous materials discovery with desired properties is one of the ultimate goals of materials science. In this work, we implemente and apply constrained crystal deep convolutional generative adversarial networks to design unreported (meta-)stable crystal structures. The essential continuous latent space is obtained based on the voxel construction of crystal structures, resulting in an image-based latent space which is proven to be a robust descriptor for forward inference of various physical properties. This also allows prediction of new crystal structures based on generative adversarial network. Furthermore, taking the formation energy as an example, it is demonstrated how the physical properties can be optimized automatically in the latent space while exploring a big chemical space to predict novel phases. Such an approach has been successfully applied on binary (e.g., Bi-Se) and multicomponent systems, which paves the way to achieve the inverse design of crystalline materials via multi-objective optimization.

# MM 25.8 Wed 18:15 H46

Databases for Machine Learning of Grain Boundary Segregation -•Alexander Reichmann¹, Christoph Dösinger¹, Daniel Scheiber², Oleg PEIL², VSEVOLOD RAZUMOVSKIY², and LORENZ ROMANER¹ – ¹Department of Materials Science, Leoben, Austria — ²Materials Center Leoben Forschung GmbH. Leoben, Austria

The chemical and structural state of grain boundaries (GBs) is of great importance for the design and performance of many technologically relevant materials. On the basis of atomistic simulations, the relevant quantities of GB, in particular the segregation energy has been calculated for many materials. On the experimental side, the concentration of solute elements at the GBs can be measured with a variety of techniques including in particular Auger spectroscopy or Atom Probe Tomography. When comparing calculated segregation energies with segregation energy gained from experimental excess data, good agreement is not always observed. In this talk we will present our current and planned activities regarding creation of segregation databases and application of data driven models. One of these is the Bayesian inference framework, which we used in combination with Markov chain Monte Carlo simulations for uncertainty quantification and model evaluation. These activities shall lead to a better understanding of the deviation between DFT-calculated and experimentally determined GB excess.

MM 27.1 Thu 9:30 H44 Crystal rotation kinematics during the tribological loading of high-purity copper — •CHRISTIAN GREINER — Karlsruher Institut für Technologie (KIT), Kaiserstrasse 12, 76131 Karlsruhe

Friction, wear and the associated energy dissipation are major challenges from nanoelectromechanical systems, over hip implants to offshore wind turbines. Already in 1950, Bowden and Tabor pointed out that in metallic tribological contacts the majority of the dissipated energy is spend to change the contacting materials' microstructures. This - in part - explains why most metals show a highly dynamic subsurface microstructure under the shear load imposed by a sliding contact. In order to understand these processes, the elementary mechanisms accommodating the shear strain and acting in the material need to be revealed and understood. One key process involved therein is the reorientation of the crystal lattice, or crystal rotation, due to the shear load imposed by the sliding contact. Our work sheds light on the early stage, fundamental mechanisms of tribologically induced lattice rotation kinematics. Using a high-purity copper bicrystal and a sapphire sphere, unlubricated, single-pass sliding tests were conducted. Electron backscatter diffraction (EBSD) performed directly on the wear track reveals a crystal rotation process around the transverse direction at the heart of tribologically induced lattice rotation, irrespective of sliding direction, grain orientation and normal load. A detailed analysis corroborates that surprisingly, changing the sliding direction merely alters the precise accommodation of crystal rotations, but not their fundamental nature.

# MM 28: Transport in Materials: Diffusion / Electrical Transport & Magnetism

Time: Thursday 10:15-11:30

# MM 28.1 Thu 10:15 H44

Electrical resistivity of magnetron-sputtered  $Fe_{l-x}O$  thin films – •SIMON Evertz¹, Nina Nicolin¹, Daniel Primetzhofer², James P. Best¹, and Gerнако Deнм¹ — ¹Max-Planck-Institut für Eisenforschung GmbH, Max-Planck-Str. 1, 40237 Düsseldorf, Germany — ²Department of Physics and Astronomy, Uppsala University, S-75120 Uppsala, Sweden

 $Fe_{1-x}O$  (wüstite) is a critical phase for a number of applications in the future hydrogen economy, such as photochemical materials for H₂ production by watersplitting. Hence, charge transport is crucial for the applicability of  $Fe_{1-x}O$  in electrode materials. To probe the charge transport of close-to-stoichiometric  $Fe_{1-r}O$ , thin films were synthesized by reactive magnetron sputtering with systematically varied O₂ gas flow. The phase formation and chemical composition was correlated to the electrical resistivity and mechanical properties, as measured in a van-der-Pauw-setup and nanoindentation, respectively. The charge transport mechanism is shown to change from thermally activated hopping of charge carriers - typical for a semiconductor - to metallic-like behavior as a function of the phase purity of the films. By correlative analysis of phase purity, microstructure and mechanical properties, it is shown that already small amounts of Fe as impurity phase are decisive for changing the charge transport mechanism. These significant changes in charge transport are further compared to the hardness and Young's modulus of these films.

MM 28.2 Thu 10:30 H44

Electronic structure and transport properties of NdTe3 - KIRSTINE J DALGAARD¹, SHIMING LEI¹, CLAUDIUS MÜLLER², STEFFEN WIEDMANN², MAR-TIN BREMHOLM³, and •LESLIE M SCHOOP¹ – ¹Department of Chemistry, Princeton University, Princeton, NJ, USA – ²High Field Magnet Laboratory (HFML-EMFL), Radboud University, Nijmegen, Netherlands – ³Department of Chemistry, Aarhus University, Aarhus, Denmark

The delocalized, hypervalent bonding in some main group element square-net materials have been linked to fascinating phenomena, including band inversions with high charge carrier mobility, and topologically nontrivial band structures. The family of rare earth tritellurides crystalize in a van der Waals structure with double tellurium square-nets, where the tellurium p orbitals form the Fermi energy crossing bands, and the partly filled 4f orbitals give rise to a rich spectrum of magnetic properties. The tellurium square-nets also undergo incommensurate charge density wave transitions affecting the band structure in ways that are yet to be fully understood. In this work, we studied the electronic structure of neodymium tritelluride through quantum oscillation and transport measurements. A remarkably high electron mobility for a magnetic van der Waals material was found, suggesting steeply dispersed bands, along with thus far unreported deviations from conventional Lifshitz-Kosevich behavior.

Non-coplanar magnetism, topological density wave order and emergent symmetry at half-integer filling of moiré Chern bands — •PATRICK WILHELM¹, THOMAS LANG¹, MATHIAS SCHEURER¹, and ANDREAS LÄUCHLI^{1,2,3} — ¹Institut für Theoretische Physik, Universität Innsbruck, 6020 Innsbruck, Austria — ²Laboratory for Theoretical and Computational Physics, Paul Scherrer Institute, 5232 Villigen, Switzerland — ³Institute of Physics, École Polytechnique Fédérale de Lausanne (EPFL), 1015 Lausanne, Switzerland

We study the impact of Coulomb interactions at half-integer filling of the moiré Chern bands of twisted double-bilayer graphene and twisted mono-bilayer graphene, using unbiased exact diagonalization comple-mented by unrestricted Hartree-Fock calculations. For small intra-sublattice tunneling, wAA, a non-coplanar magnetic state is found which has the same symmetries as the tetra-hedral antiferromagnet of the triangular moiré lattice and can be thought of as a skyrmion lattice commensurate with the moiré scale. The antiferromagnetic order competes with a set of ferromagnetic, topological charge density waves, which are favored for larger wAA and are associated with an approximate emergent O(3) symmetry, 'rotating' the different charge density wave states into each other. Exhibiting a finite charge gap and Chern number C=[1], the formation of charge density wave order which is intimately connected to a skyrmion lattice phase is consistent with recent experiments on these systems.

# MM 28.4 Thu 11:00 H44

**Interference effects in one-dimensional moiré crystals** — •NILS WITTEMEIER¹, MATTHIEU J. VERSTRAETE^{2,4}, PABLO ORDEJÓN¹, and ZEILA ZANOLLI^{3,4} — ¹Catalan Institute of Nanoscience and Nanotechnology, ICN2 (CSIC, BIST), Bellaterra, Spain — ²NanoMat/Q-Mat/CESAM, Université de Liège (B5), Liège, Belgium — ³Chemistry Department & Debye Institute for Nanomaterials Science, Utrecht University, Utrecht, the Netherlands — ⁴ETSF

This work [1] investigates interference effects in finite sections of 1D moiré crystals using the Landauer-Büttiker formalism within the tight-binding approximation. We explain interlayer transport in double-wall carbon nanotubes and demonstrate that wave function interference is visible at the mesoscale: in the strong coupling regime, as a periodic modulation of quantum conductance and emergent localized states; in the localized-insulating regime, as a suppression of interlayer transport, and oscillations of the density of states. The interlayer transmission between strongly coupled metallic nanotubes is limited to either  $1G_0$  or  $2G_0$ . Our results could be exploited to design quantum electronic devices, e.g. nonelectric switches based on chiral nanotubes. Most importantly, we clarify the origin of the so-far unexplained  $1G_0$  quantum conductance measured in multi-wall carbon nanotubes [2, 3].

MM 28.5 Thu 11:15 H44

On correlations between local chemistry, distortions and kinetics in high entropy nitrides: an ab initio study — •DAVID HOLEC¹, GANESH K. NAYAK¹, ANDREAS KRETSCHMER², PAUL H. MAYRHOFER², MARCUS HANS³, and JOCHEN M. SCHNEIDER³ — ¹Department of Materials Science, Montanuniversität Leoben, Leoben, Austria — ²Institute of Materials Science and Technology, TU Wien, Vienna, Austria — ³Materials Chemistry, RWTH Aachen University, Aachen, Germany

High entropy alloys (HEAs) have triggered significant scientific interest due to their unusual structural stability combined with excellent mechanical and other functional properties. Recently, exploration of materials used as protective coatings has also entered this room by exploring high entropy borides, oxides, carbides, and nitrides. These chemically complex systems provide huge combinatorial space for tuning the composition, hence making the experimental exploration tedious. High-throughput simulations based on unbiased ab initio calculations provide an ideal tool to guide the experiments.

We will show that for high entropy nitrides (HENs), strain is equally important for the stabilization as entropy. Our predictions were validated by experimental investigations on the thermal stability of selected HEN coatings. The predicted structures are further characterized in terms of their local distortions, one of the core effects of HEAs. Another core effect is sluggish bulk diffusion. Therefore, in the second part of the talk, we will explore correlations between migration barriers for bulk diffusion, local chemical compositions, and local distortions.

Lithium-sulfur (Li-S) batteries have been regarded as promising energy storage systems with ultra-high theoretical energy density. During a charging cycle Li₂S is converted to S₈ and vice-versa, where intermediate Li polysulfides (LiPS) are formed in a complex reaction mechanism which is still under debate. The theoretical exploration of the involved Li-S chemistry is challenged by an extended reaction network making it intractable for first principles methods. In contrast, machine learning interatomic potentials (MLIPs) which potentially retain predictive accuracy at a fraction of the computational cost are ideally suited for this task.

Here, we establish a training protocol for a Gaussian approximation potential (GAP) to simulate the chemistry of LiPS. Our training is based on a constrained on-the-fly exploration of the LiPS chemical space. In that, we enumerate the connectivity of (poly)cyclic LiPS and explore their stability via global optimization procedures with iteratively refined MLIPs. We use the final, sufficiently accurate MLIP to sample the LiPS phase space and to compute charging/discharging curves which we can directly compare to experimental data. Our MLIP calculations are expected to provide more fundamental insights into the LiPS conversion mechanism in Li-S batteries.

Uncertainty Modelling for Property Prediction of Double Perovskites — •SIMON TESHUVA¹, MARIO BOLEY¹, FELIX LUONG¹, LUCAS FOPPA², and MATTHIAS SCHEFFLER² — ¹Monash University, Melbourne, Australia — ²Fritz Haber Institute, Berlin, Germany

Statistical predictive models for double perovskite properties are of high interest, because the perovskite structure allows relatively accurate property prediction and at the same time provides enough flexibility to yield a huge number of different materials of which some are likely relevant for important applications. Existing results published for this class of materials typically refer only to the predictive performance as, e.g., measured by the root mean squared error. However, active learning strategies for effective materials screening also rely on adequate uncertainty estimates as provided by probabilistic models.

Here, we study the predictive performance of two popular machine learning models, Gaussian processes and random forests, together with the quality of their uncertainty estimates. This study is based on a dataset of over 800 single (ABO_3) and double (A_2BB'O_6)cubic perovskite oxides with computed bulk modulus, cohesive energy, and bandgap. We show that Gaussian processes, while providing sound Bayesian uncertainty estimates, can have inferior performance when their assumption of isometric smoothness of the target property is not met. In this case, as exemplified by the double perovskite bandgaps, random forests provide a better alternative, despite their rather ad-hoc uncertainty estimates. Improving these estimates thus appears to be a promising direction for future research.

# MM 29.4 Thu 11:00 H45

Automated effective Hamiltonian construction and active sampling of potential energy surface by Bayseian optimization — •MIAN DAI, YIXUAN ZHANG, and HONGBIN ZHANG — Institute of Materials Science, Technical University of Darmstadt, Darmstadt, 64287, Germany

A first-principles effective Hamiltonian method can be used to simulate the phase transition sequences. In practice it is quite tedious to express the total energy surfaces and estimate reasonable parameters for high-order polynomials. We implemented Bayesian optimization (BO) to sample the total energy surfaces based on active learning and fit the set of parameters for constructing the effective Hamiltonians. Taking BaTiO₃ as a case study, we found that less than 30 sampling configurations with automated generated structures by BO are enough to determine a new set of parameters. The hyperparater in our BO process is tuned to show the improvement of the convergence for all fitted parameters. Using the new set of parameters, we perform Monte Carlo simulations which produce comparable phase transition temepratures with experimental values and previous results. Our BO algorithm has a great potential for future application in construction the effective Hamiltonians with more complicated subspace and effective atomic potentials describing the full lattice dynamics.

MM 29.5 Thu 11:15 H45

**Predicting oxidation and spin states by high-dimensional neural networks** — •KNUT NIKOLAS LAUSCH¹, MARCO ECKHOFF¹, PETER BLÖCHL², and JÖRG BEHLER¹ — ¹Georg-August-Universität Göttingen, Institut für Physikalische Chemie, Theoretische Chemie, Göttingen, Germany — ²Technische Universität Clausthal, Institut für Theoretische Physik, Clausthal-Zellerfeld, Germany Machine learning potentials (MLP) such as high-dimensional neural network potentials (HDNNP) provide first-principles quality energies and forces enabling large-scale molecular dynamics simulations at low computational costs. However, most current MLPs do not provide any information about the electronic structure of the system, which is often important for a detailed understanding of complex systems such as transition metal oxides. The lithium intercalation compound  $\text{Li}_x \text{Mn}_2 \text{O}_4$  ( $0 \le x \le 2$ ), a commercially used cathode material in lithium ion batteries, is such a system since the manganese ions adopt different oxidation states based on the lithium content and distribution. Here, we propose a high-dimensional neural network (HDNN) that can predict atomic oxidation and spin states as a function of the local atomic environments in  $\text{Li}_x \text{Mn}_2 \text{O}_4$ . The HDNN can complement HDNNP-driven MD simulations giving insights into the underlying electronic processes that give rise to complex phenomena such as a charge ordering transition, and electrical conductance.

Controlling the degree of rejuvenation and strain-hardening in metallic glasses — •DANIEL  $OPU^{1,2}$ , XUDONG YUAN¹, and JÜRGEN ECKERT^{1,3} — ¹Erich Schmid Institute of Materials Science, Leoben, Austria — ²Technische Universität Darmstadt, Germany — ³Montanuniversität Leoben, Austria

The correlation between the degree of rejuvenation and strain-hardening in metallic glasses (MGs) is investigated using molecular dynamics simulations. By randomly removing atoms from the glass matrix, free volume is homogeneously generated and glassy states with different degrees of rejuvenation are designed and further mechanically tested. The highest rejuvenated state is defined by the dynamic balance between free volume generation and annihilation. The highest degree of rejuvenation correlates to the flow strain of the materials and the structure is similar to that found in shear bands. The free volume in the rejuvenated glasses can be annihilated under tensile or compressive deformation that consequently leads to structural relaxation and strain-hardening. Loading-unloading cycling tensile tests are simulated and the atomic-scale mechanism of strain-hardening in the highly rejuvenated MGs is highlighted.

# MM 30.2 Thu 10:30 H46

Revealing the impact of Sulfur addition on the medium-range order and relaxation dynamics of metallic glasses — •HENDRIK VOIGT¹, NICO NEUBER², HARALD RÖSNER¹, MARTIN PETERLECHNER¹, RALF BUSCH², and GERHARD WILDE¹ — ¹Institut für Materialphysik, Westfälische Wilhelms-Universität Münster, Münster, Germany — ²Chair of Metallic Materials, Saarland University, Saarbrücken, Germany

The addition of Sulfur as an alloying element has been shown to enable or improve the glass forming ability of certain glasses drastically [1]. Despite growing knowledge of the impact that Sulfur has on the mechanical properties, the underlying structure and its dynamics are still not fully understood [2].

In this contribution the sample system Pd31Ni42S27 has been investigated with respect to medium-range order (MRO). For the MRO analysis multiple series of nanobeam diffraction patterns with varying probe sizes were acquired in order to conduct variable resolution Fluctuation Electron Microscopy (FEM). Furthermore, Electron Correlation Microscopy (ECM) was employed to analyse relaxation dynamics by the acquisition of a tilted dark-field time series. By the combination of these two techniques it appears that the size of the regions displaying strongly decelerated dynamics at room temperature correlate with the detected MRO. The results are discussed with respect to current models.

Glass Formation and Shear Banding in High-Entropy Metallic Glasses: A Molecular Dynamics Study — •MARIE J. CHARRIER, DANIEL T. UTT, ARNE J. KLOMP, and KARSTEN ALBE — Fachgebiet Materialmodellierung, Institut fuer Materialwissenschaft, Technische Universitaet Darmstadt Location: H46

Bulk metallic glasses (BMGs) and High-Entropy Alloys (HEAs) both comprise a large number of elements but deviate strongly in their mechanical properties. BMGs are strong but brittle and usually derived from crystalline binary subsystems with deep eutectics and intermetallic phases. HEAs, on the other hand, show remarkable ductility, a small heat of mixing, and are thus typically not glass formers. The open question is whether a classically crystalline random solid solution HEA can be transformed into a BMG using appropriate processing. In this work, we use atomistic computer simulations to study the combination of the two materials classes, HE-MGs. Here, we are able to kinetically suppress crystallization in the CrMnFeCoNi alloy, which in the real world remains a crystalline single-phase solid solution using conventional quench rates. First, we investigate the thermodynamics of the glass transition and its dependence on quench rate. Second, the phase stability of the HE-MG is compared to the crystalline HEA. Third, the atomic-level structure is characterized in terms of chemical and structural short- and medium-range order. Last, we perform compressive and tensile testing on HE-MG samples to assess failure by homogeneous deformation or shear localization and compare the mechanical properties against a CoCrFeMnNi nanocrystal.

# MM 30.4 Thu 11:00 H46

Cyclical structural relaxation of PdNiP and micro-alloyed PdNiPFe and PdNiPCo glasses — •MANOEL W. DA SILVA PINTO, MARK STRINGE, KATHARINA SPANGENBERG, HARALD RÖSNER, and GERHARD WILDE — Institut für Materialphysik, WWU Münster

Relaxation phenomena in  $Pd_{40}Ni_{40}P_{20}$  bulk metallic glasses (BMG) as well as in micro-alloyed forms of Co and Fe addition were investigated by calorimetry. The BMGs were submitted to different thermal treatments by varying temperatures and times. In order to identify distinct signatures of relaxation, the thermal and temporal evolution of enthalpic contributions to calorimetric signals were analyzed using different kinetic models. A possibility was found to control the formation and depletion of an endothermic signature before the glass transition by quenching and annealing procedures. From the evolution of the enthalpies with annealing time and from isothermal heat flow, time constants related to structural relaxation were obtained and supplemented by dynamical and structural TEM analyses. The obtained results are discussed with respect to existing models for glass relaxation.

MM 30.5 Thu 11:15 H46

Enhancing ductility and strain hardening by modulating residual stresses in metallic glasses — •XUDONG YUAN¹, DANIEL ŞOPU^{1,2}, and JÜRGEN ECKERT^{1,3} — ¹Erich Schmid Institute of Materials Science, Leoben, Austria — ²Technische Universität Darmstadt, Darmstadt, Germany — ³Montanuniversität Leoben, Leoben, Austria

The correlation between the deformation behavior and the residual stress modulation in metallic glasses (MGs) is investigated using molecular dynamics simulations. Particularly, the influence of residual compressive stress and stress heterogeneity on the tensile deformation behavior of amorphous Cu64Zr36 alloys is investigated. Strain hardening together with enhanced tensile ductility in monolithic MGs can be attained by only modulating the internal stress without changing their local structure. The stress heterogeneity changes the shear band dynamics leading to the formation and interaction of multiple shear bands, which consequently enhances the macroscopic ductility. Additionally, the residual compressive stress offsets the external tensile stress, which delays shear band formation and enables strain hardening in uniaxial tensile tests.

### MM 30.6 Thu 11:45 H46

**Origin of the Invar effect in Fe-based bulk metallic glasses** — •ALEXANDER FIRLUS¹, MIHAI STOICA¹, STEFAN MICHALIK², ROBIN E SCHÄUBLIN¹, and JÖRG F LÖFFLER¹ — ¹1 Laboratory of Metal Physics and Technology, Department of Materials, ETH Zurich, 8093 Zurich, Switzerland.2 — ²Diamond Light Source Ltd., Harwell Science and Innovation Campus, Didcot, Oxfordshire OX11 0DE, UK

Generally, metals, including most ferromagnetic ones, have a constant coefficient of thermal expansion (CTE). However, a few magnetic alloys show an anomalously low CTE below their Curie temperature. At the Curie temperature it increases abruptly by up to one order of magnitude. This effect is known as the Invar effect. While it is rare in crystalline alloys, it is universally observed in ferromagnetic Fe-based bulk metallic glasses (BMGs). To this day, it is still unclear in which way the amorphous atomic arrangement creates the Invar effect and how it manifests at the atomic scale.

In this work we studied BMGs with only one magnetic atom species, Fe, by in-situ high-energy X-ray diffraction. This allows us to measure the thermal expansion at the atomic scale and to associate it with specific atomic pairs. Fe-Fe pairs are found to be responsible for the Invar effect at the atomic scale. Moreover, also full atomic shells, which contain all atomic species, show an abrupt increase in their thermal expansion. This proves that the Invar effect is not just a macroscopic effect but has clear origins at the atomic scale.

MM 30.7 Thu 12:00 H46 Coupling deformation mechanisms in metallic glass-high entropy alloy nanolaminates — •QI XU¹, DANIEL ŞOPU¹, and JÜRGEN ECKERT^{1,2} — ¹Erich Schmid Institute of Materials Science, Leoben, Austria — ²Montanuniversity leoben, Leoben, Austria

The uniaxial tensile deformation behavior of metallic glass (MG) - high entropy alloy (HEA) nanolaminates is explored through molecular dynamics simulations. The combination of glassy and crystalline nanolayers results in misfit stresses at the interface that drive the partial crystallization of amorphous phase and the nucleation of short dislocations. Upon loading, the further stressinduced crystallization facilitates the nucleation and growth of dislocations along the interfacial regions and across the HEA plate, which advances the yielding of MG-HEA nanolaminate. The dislocations are absorbed into the amorphous plate via slip transfer across glass-crystalline interface that in turn triggers the activation of homogeneously distributed STZs. The co-deformation mechanism suppresses the formation of critical shear bands and increases the resistance to dislocation motion that, consequently, promotes enhanced ductility in MG-HEA nanolaminate. The strength combination of HEA and MGs and the complex deformation behavior may overcome the typical strength-ductility trade-off and make MG-HEA laminates promising candidates for a variety of structural and functional applications.

# MM 30.8 Thu 12:15 H46

**Tracer diffusion of Fe and Zr in CuZr nanoglasses** — •CHRISTIAN AARON RIGONI¹, HENDRIK VOIGT¹, EVGENIY BOLTYNJUK², BONNIE TYLER³, SERGIY DIVINSKI¹, HORST HAHN², and GERHARD WILDE¹ — ¹Institute of Materials Physics, University of Münster, Germany — ²Institute of Nanotechnology, Karlsruhe Institute of Technology, Germany — ³Physikalisches Institut, University of Münster, Germany

Metallic nanoglasses consist of nanometer-sized amorphous regions separated by amorphous interfaces. According to the current knowledge, the amorphous structure of these interfaces is different from that of the amorphous grains. This rather new class of material shows a different behaviour in comparison to conventional homogenous metallic glasses, e.g. a reduced density, a reduced number of nearest neighbor atoms, a different electronic structure, an increase in the ferromagnetic transition temperature and an increased thermal stability were reported. In the present work, tracer diffusion in CuZr nanoglasses and their homogenous amorphous counterparts is measured. For the investigation, a radiotracer technique via ion beam sputtering (89Zr and 55Fe radioisotopes) is applied as well as SIMS profiling using stable isotopes. The tracer diffusion measurements are demonstrated to represent a specific and sensitive probe of the structure modifications, and the results are compared to the observations made by TEM and APT.

MM 30.9 Thu 12:30 H46 Anomalous Liquids on a New Landscape: from Water to Phase-Change Materials — •SHUAI WEI — Aarhus University, Aarhus, Denmark

A liquid that is cooled below its melting temperature, referred to as a supercooled liquid, can solidify into an amorphous rigid state (i.e., glass), if cooling is fast enough and crystallization is avoided. The phenomenology of supercooled liquids has been in general established. However, there are pronounced exceptions (e.g., water) which do not fall into the class of "normal" liquids but exhibit a transition behavior in their liquid states. The latest advances connect the unusual aspect of liquids to the properties of Phase-Change Materials (PCMs) that are the basis for non-volatile memory and neuromorphic technologies. Here we demonstrate that the "water-like" liquid anomalies exist in many alloys based on group-IV, V, VI elements including technologically important PCMs. Heat capacity, density, and thermal expansivity maxima were observed in the (supercooled) liquid states of those alloys. Structural changes were monitored using in-situ X-ray scattering and femtosecond X-ray diffractions. Dynamic properties were characterized by quasi-elastic neutrons scattering. Their anomalous behaviors can be rationalized in terms of liquid-liquid (metal-semiconductor, and fragile-strong) transitions. These transition behaviors have important implications for understanding the unusual phase switching behaviors in PCMs, in which amorphous phase can crystallize rapidly within tens of nanoseconds at an elevated temperature, while it retains excellent amorphous stability for 10 years at room temperature.

MM 30.10 Thu 12:45 H46 Thermophysical study of anomalies and transitions in liquid Bi-Ga and Ga-**In systems** – •Yuri Kirshon¹, Shir Ben-Shalom¹, Moran Emuna², Yaron Greenberg², Eyal Yahel², and Guy Makov¹ – ¹Department of Materials Engineering, Ben-Gurion University of the Negev, Beer-Sheva 84105, Israel — ²Physics Department, Nuclear Research Centre-Negev, Beer-Sheva 84190, Israel Interest in the properties and applications of liquid metals has been reignited and leading to innovative new pathways. Work on low-melting alloys provided new products such as Galinstan liquid metal thermometers, self-healing electronic devices and cooling systems for high-temperature reactors. However, due to the experimental challenges, study of thermophysical properties of liquid binary systems remains limited. In particular, Bi-Ga and Ga-In alloys have attracted scientific interest due to possible changes in their liquid structure, reported recently [Q.Yu (2017), Z.Wang (2017), Y.Kirshon (2019)]. In the present contribution, we report on thermophysical measurements conducted on Bi-Ga and Ga-In alloys. Custom table-top resistivity and differential thermal analysis (DTA) setups are presented, including a demonstration of their capability to capture subtle transitions in the melts. We observed evidence of liquid-liquid crossover in the liquid Ga-In, measured both systems at a temperature range in good agreement with previous density measurements. In the Bi-Ga system, we probed the liquid-liquid miscibility gap and were able to obtain the latent heat and resistivity change during the liquid de-mixing process. Both results were in good agreement with previous reports.

**Making low-scaling GW accurate** – •JAN WILHELM¹ and DOROTHEA GOLZE² – ¹Institute of Theoretical Physics, University of Regensburg – ²Faculty of Chemistry and Food Chemistry, TU Dresden

In standard GW implementations, the computational cost is growing as  $O(N^4)$  in the system size N, which prohibits their application to many systems of interest. I present a GW algorithm in a Gaussian-type basis with a computational cost that scales with  $N^2$  to  $N^3$ . It will be shown that large minimax grids and resolution of the identity with the truncated Coulomb metric improve the accuracy of Location: H44

the low-scaling GW algorithm to  $<0.01~\rm eV$  for the GW100 test set. Large-scale applications of low-scaling GW will be discussed.

MM 31.2 Thu 12:00 H44 Atomic cluster expansion parametrization of carbon for a fast, accurate and transferable interatomic potential — •MINAAM QAMAR, MATOUS MROVEC, YURY LYSOGORSKIY, ANTON BOCHKAREV, and RALF DRAUTZ — Interdisciplinary Centre for Advanced Materials Simulation (ICAMS), Ruhr-University Bochum, Germany We present a parametrization of the atomic cluster expansion (ACE) for carbon that can be employed in large-scale atomistic simulations of complex phenomena. The ACE model is parametrized over an exhaustive dataset of important carbon structures at extended volume and energy ranges, computed using highly accurate density functional theory (DFT). Dispersion corrections are explicitly added to properly account for long-ranged van der Waals interactions. A rigorous validation against DFT data reveals that ACE predicts accurately a broad range of properties of both crystalline and amorphous C phases while being significantly more computationally efficient than other popular machine learning models. We demonstrate the predictive power of ACE on two distinct applications: (1) brittle crack propagation in diamond at finite temperature, and (2) evolution of amorphous carbon structures at different densities and quench rates.

Design and analysis of scattering data driven molecular dynamics simulation on the example of water and selected crystals — •VERONIKA REICH¹, SE-BASTIAN BUSCH¹, and MARTIN MÜLLER² — ¹German Engineering Materials Science Centre (GEMS) at Heinz Maier-Leibnitz Zentrum (MLZ), Helmholtz-Zentrum Hereon, Lichtenbergstr. 1, 85748 Garching bei München, Germany — ²Helmholtz-Zentrum Hereon, Max-Planck-Str. 1, 21502 Geesthacht, Germany Molecular dynamics simulations are an indispensable tool to preinvestigate neutron scattering experiments. For many systems reliable force fields have been established and yield to significant simulations. On the other hand a lot of systems still don't have a satisfactory agreement between experiment and simulation.

In this work we compare experimental data to different liquid water model simulations and give an outline to crystal simulations.

We simulate the samples using molecular dynamics simulations using the program LAMMPS. Subsequently we calculate the coherent and incoherent scattering signals using the program SASSENA. Ensuing we compare the outcomes to already existing experimental data and evaluate changes in the underlying force fields in terms of their impact on the behaviour of the simulation. Finally we compare the incoherent calculations to mathematical models, which in turn we later fit to the simulation.

The aim of our work is to create a simple to use workflow of molecular dynamics simulations for scattering experiments.

Effects of post anodization processes on the surface stability of anodic aluminum oxide — •Lydia Daum, Stefan Ostendorp, and Gerhard Wilde — Westfälische-Wilhelms-Universität, Münster, Germany

The wide spectrum of different aluminum alloys enables the industry an economically advantageous material with the desired mechanical properties. In contrast to high-purity aluminum, the formation of a thin protective alumina layer is suppressed, which leads to a lower chemical corrosion resistance. Here anodization and the generation of anodic aluminum oxides (AAOs) are mandatory to obtain a necessary protective coating. The participating alloying elements are obstacles for mechanical stresses inside the AAOs which promotes the formation of nano- and microcracks at the surface. Thus, chemical attacks of the aluminum alloy are more favorable.

The use of post anodization processes will densify the pores and flatten the surface, which enhances the chemical resistance. A combination of nanoindentation studies and electron microscopy measurements are analyzing the surface stability of AAOs. By varying the methods in duration and medium, different wear, hardness and ductility characteristics are visible.

Surfaces of nanoporous gold: rough and faceted? — •Stefan A. Berger¹, Ulrike Dette^{1,2}, Lingzhi Liu³, Jürgen Markmann^{1,2}, and Jörg WEISSMÜLLER^{2,1} — ¹Helmholtz Zentrum Hereon — ²Technische Universität Hamburg — ³Shenyang National Laboratory for Materials Science

Nanoporous gold is an interesting model system for studying the impact of surfaces on the properties of nanomaterials. The surface morphology, faceted or rough, is of interest in that context. Scanning electron micrographs almost invariably show smoothly curved surfaces at the scale of the ligament size, suggesting roughness as opposed to faceting. Here, we show that proper imaging conditions to reveal facets, suggesting that the roughness may be an artifact of is often ignored in finite temperature atomistic simulations. Formulations to estimate quantum anharmonic effects precisely, such as the path integral method, are computationally demanding. Although various acceleration approaches allowing quantum effects to be fully accounted for in systems of hundreds of atoms have been proposed over the last two decades, they can fall short when it comes to modeling defects in solids, which can require significantly larger system sizes. We present a new approach for approximating nuclear quantum effects, exploiting a temperature map between the quantum system and its best classical surrogate. This map is constructed using the internal energies of classical and quantum harmonic oscillators within the Debye model. To a good approximation, our approach captures the impact of quantum effects on lattice constants, internal energies, and heat capacities with almost no additional cost compared to purely classical molecular dynamics simulations. Results for diamond cubic carbon and silicon are in good agreement with available literature values, which use full path integral Monte-Carlo simulations. We also show how this approach can be used to predict phase transition temperatures, e.g. the FCC to BCC transition for calcium.

Sharp phase-field modeling of isotropic solidification with a super efficient spatial resolution — •MICHAEL FLECK and FELIX SCHLEIFER — University of Bayreuth, 95447 Bayreuth, Germany

The phase-field method provides a powerful framework for microstructure evolution modeling in complex systems, as often required within the framework of integrated computational materials engineering. However, spurious grid friction, pinning and grid anisotropy seriously limit the resolution efficiency and accuracy of these models. The energetic resolution limit is determined by the maximum dimensionless driving force at which reasonable model operation is still ensured. This limit turns out to be on the order of 1 for conventional phasefield models. Grid friction and pinning can be eliminated by a the restoration of Translational Invariance (TI) in the discretized phase-field equation. This is called the sharp phase-field method, which allows to choose substantially coarser numerical resolutions of the diffuse interface without the appearance pinning. We propose an accurate scheme to restore TI locally in the local interface normal direction. The new model overcomes grid friction and pinning in three dimensional simulations, and can accurately operate at dimensionless driving forces up to the order of 10⁴. At one-grid-point interface resolutions, exceptional degrees of isotropy can be achieved, if further the inhomogeneous latent heat release at the advancing solid-liquid interface is mitigated. Imposing a newly proposed source term regularization the new model captures the formation of isotropic seaweed structures without spurious dendritic selection by grid anisotropy.

imaging. We find that the roughness is most pronounced after annealing in oxygen atmosphere. While low index facets are expected to prevail on gold, we regularly also observe high index facets.

Understanding of the underlying field evaporation mechanism of pure water **tips in high electric fields** — •TIM MAXIMILIAN SCHWARZ¹, GUIDO SCHMITZ¹, NICO SEGRETO², JOHANNES KÄSTNER², and PATRICK STENDER¹ – ¹University of Stuttgart, Institute for Materials Science, Chair of Materials Physics, Heisenbergstr. 3, 70569 Stuttgart, Germany - ²University of Stuttgart, Institute for Theoretical Chemistry, Pfaffenwaldring 55, 70569 Stuttgart, Germany

Frozen liquids are challenging and rather new in the investigation by atom probe tomography. However, recent progress in instrumentation, especially the introduction of cryo transfer shuttles, and the development of the required preparation routes to shape nanometric needles of frozen liquids enable measurements of sufficient quality and size of data sets to discover the typical features of this material class. In this talk, we present the fragmentation behaviour of bulk frozen water as an important matrix for biomolecules or solvent of electrolytes. The obtained mass spectra are complex. However, this support of DFT calculations of the molecule stabilities, we identify a systematic series of protonated (H2O)nH3O+ events that represent a clear "fingerprint" for the existence of water. Remarkably, tailing and the exact mass position of the two series differ, which provides evidence that the protonated fragments are permanently positively charged and therefore, slightly drawn out of the dielectric surface before the evaporation event.

# MM 32.4 Thu 12:30 H45

Synthesis of superparamagnetic iron oxide nanoparticles by electron beam irradiation — •JOHANNES DIETRICH^{1,2} and STEFAN MAYR^{1,2} — ¹Leibniz-Institut für Oberflächenmodifizierung e.V. (IOM), Permoserstraße 15, 04318 Leipzig — ²Universität Leipzig, Fakultät für Physik und Geowissenschaften, Abteilung Oberflächenphysik, Linnéstraße 5, 04103 Leipzig

Nanoparticles based on iron oxides are a highly versatile material used in a broad range of applications, for instance embedding magnetic particles in polymer matrices to create ferrogels. A common procedure is to synthesize the particles in separate processes, add them to the gel and crosslink the polymer chains with nanoparticles by electron beam treatment. Combining synthesis and crosslinking would offer the possibility to create ferrogels by an one-step process.

In our work, we show a procedure to synthesize superparamagnetic nanoparticles with a narrow size distribution and an average size of approximately 5 nm directly by electron beam irradiation. The formation of small amounts of nanoparticles could already observed for doses of 50 kGy, but these particles showed a low crystallinity and a higher percentage of amorphous particles. For higher doses increasing crystallinity and yield could be observed, which is also reflected in the higher saturation magnetization for samples irradiated with higher doses. Additionally, particles irradiated with doses starting from 150 kGy show a tendency to form bigger cluster with sizes from 34 nm to 73 nm.

Probing the oxide formation on Pt, Pd and Pt/Pd catalysts during NO oxidation by Atom Probe Tomography (APT) — •YOONHEE LEE¹, DANIEL DOBESCH², UTE TUTTLIES², PATRICK STENDER¹, ULRICH NIEKEN², and GUIDO SCHMITZ¹ — ¹Institute of Materials Science, University of Stuttgart, Heisenbergstr. 3, 70569 Stuttgart, Germany — ²Institute of Chemical Process Engineering, University of Stuttgart, Böblinger Str. 78, 70199 Stuttgart, Germany *Yoonhee.lee@mp.imw.uni-stuttgart.de

Inverse hysteresis behavior of Pt, Pd and PtPd alloy catalysts during NO conversion can be attributed to the formation of metal oxides. Even though there were many efforts to study the oxidation of these noble metals experimentally, still the surface change of the pure catalyst has not been observed yet. In this work, NO conversion measurements were carried out with nanoparticles of Pt, Pd and Pt/Pd alloy, produced by spark discharge method, in an isothermal flatbed reactor. The catalyst was subjected to alternating heating and cooling ramps in conditions prone to surface oxide formation. Besides, the oxygen content formed on the surface of catalyst was determined during Temperature-Programmed Reduction(TPR) in H2 atmosphere. The same conditions (gas concentration, heating and cooling rate) of the NO conversion experiments have been achieved in a reaction chamber directly connected to the Atom Probe Tomography (APT) under ultra-high vacuum conditions. The samples were exposed to the gas and measured in APT. The 3D chemical structure was reconstructed and the effective thickness of formed oxides was determined.

How to Speed up First-Principles Based Geometry Optimization with Small Numerical Basis Sets — •ELISABETH KELLER, JOHANNES T. MARGRAF, and KARSTEN REUTER — Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany

First-principles based geometry optimizations are often the most expensive part of high-throughput virtual screening studies for functional materials. This is particularly true for large systems, i.e. when studying complex surface reconstructions or nanoparticles. Here, the computational cost is strongly influenced by the size of the basis set. Large, converged basis sets result in precise equilibrium geometries, yet demand high computational cost and thus limit the simulation scale. Semiemprical methods using minimal basis sets offer a much lower computational cost, but may yield unacceptably large and uncontrolled errors. Furthermore, the availability of adequate parameterizations is rather sparse across the periodic table.

In this presentation, we will discuss the potential of using near-minimal basis sets for accelerating and enabling large-scale geometry optimizations at the DFT level. For this purpose, we studied how the size of the numeric atom-centered orbital (NAO) basis set in FHI-aims impacts the accuracy of bulk geometries. We recover equilibrium geometries at a nearly converged level with a highly compact basis by employing a simple short-ranged pair-potential correction. We show the scheme's ability to treat different systems across the periodic table ranging from small molecules and clusters to large-scale bulk and surface structures as well as complex molecule-surface interactions.

### MM 33.2 Thu 16:00 H44

A machine-learned interatomic potential for crystalline and amorphous silica – •LINUS ERHARD¹, JOCHEN ROHRER¹, KARSTEN ALBE¹, and VOLKER DERINGER² – ¹Institute of Materials Science, Technische Universität Darmstadt, Otto-Berndt-Strasse 3, 64287 Darmstadt, Germany – ²Department of Chemistry, Inorganic Chemistry Laboratory, University of Oxford, Oxford OX1 3QR, United Kingdom

Fitting an interatomic potential for silicon oxide that can be used for both the amorphous and numerous crystalline phases has proven to be difficult. This is already shown by the large number of interatomic potentials published in the last decades. Here, we present a machine-learned interatomic potential for silica, which is highly transferable between different crystalline polymorphs and the amorphous phase. It predicts the thermodynamics of the system accurately and is able to generate low-defect amorphous models by melt and quench simulations. We also discuss the importance of choosing an appropriated exchangecorrelation functional for density-functional data input, which is particularly Location: H44

important for silica. Since the generation of realistic amorphous structure models by melt-quench simulations is highly dependent on the quench rate, we show new ways via hybrid simulations that combine the speed of classical interatomic potentials with the accuracy of machine-learning potentials. We also investigate the extrapolation behavior of our machine-learning potential using highpressure simulations. Finally, we show first steps towards an interatomic potential for mixed Si-SiO2 systems.

# MM 33.3 Thu 16:15 H44 **An all-functionals automatic workflow for IR and Raman spectra** – •LORENZO BASTONERO^{1,2} – ¹University of Bremen, Bremen, Germany – ²EPFL, Lausanne, Switzerland

IR and Raman spectroscopies are among the best methods for the characterisation of materials at small scales, thanks to their fast measurement and high sensibility to local composition and configuration. Theoretical calculations are fundamental for the interpretation of experimental results and for the assessment of thermal properties. DFT has been employed in the last decades as a reliable tool for the analysis of these spectra, although the calculation of vibrational properties has been limited to the use of few functionals. Here, we devise an automatic user-friendly workflow for IR and Raman calculations within the AiiDA infrastructure, which exploits the finite displacements and finite fields to allow application to any complex functional. The package provides at the same time easy access and full customisability, relevant both for less experienced users and more elaborate purposes such as high-throughput searches.

### MM 33.4 Thu 16:30 H44

A Workflow for Obtaining Robust Density Functional Tight Binding Parameters Across the Periodic Table — •MENGNAN CUI, JOHANNES T. MARGRAF, and KARSTEN REUTER — Fritz-Haber-Institut der MPG, Berlin, Germany

The Density Functional Tight Binding (DFTB) approach allows electronic structure based simulations at length and time scales far beyond what is possible with first-principles methods. This is achieved by using minimal basis-sets and empirical approximations. Unfortunately, the sparse availability of parameters across the periodic table is a significant barrier to the use of DFTB in many cases.

In this contribution, we therefore propose a workflow which allows the robust and consistent parameterization of DFTB across the periodic table. Importantly, the approach requires no element-pairwise parameters and can thus easily be extended to new elements. Specifically, the parameters defining the band energy and repulsive potential are obtained via Bayesian Optimization on a set of elemental solids. In this way, robust baseline parameters can be obtained for arbitrary element combinations. The transferability of the parameters and appli-

ChemiTEM - optimized solutions and workflows for electron microscopy in materials science and chemistry — •WALID HETABA^{1,2}, ROBERT IMLAU³, LISETH DUARTE-CORREA², MAXIMILIAN LAMOTH², STEPHAN KUJAWA³, and THOMAS LUNKENBEIN² — ¹Max-Planck-Institut für Chemische Energiekonversion, Mülheim/Ruhr, Deutschland — ²Fritz-Haber-Institut der MPG, Berlin, Deutschland — ³Thermo Fisher Scientific, Eindhoven, Niederlande

Transmission electron microscopy (TEM) is an important and versatile method for investigating materials on the nanoscale. Information about the elemental composition and electronic structure can be obtained while imaging the sample with atomic resolution. Such investigations are usually performed by TEMexperts. However, enabling non-expert TEM users to perform such measurements would tremendously improve the efficiency of TEM investigations in both, materials science and chemistry. We therefore developed ChemiTEM: a set of standardized workflows for data acquisition and analysis which are integrated in an app for tablets and smartphones to provide easy access for all TEM users, irrespective of their level of experience. We tested the ability of ChemiTEM in helping non-expert TEM users to collect high quality data by having non-expert and expert TEM users investigate the same sample. Using ChemiTEM, the data acquired by the non-expert users were of similar quality to that of the data recorded by the TEM-expert. Thus, we were able to show that using the ChemiTEM app, TEM can be made available to everyone working in materials science.

 $MM \ 33.6 \quad Thu \ 17:15 \quad H44$  Determination of Formation Energies and Phase Diagrams of Transition Metal Oxides with DFT+U — •DANIEL MUTTER¹, DANIEL URBAN¹, and CHRIS-TIAN ELSÄSSER^{1,2} — ¹Fraunhofer IWM, Freiburg, Germany — ²Freiburger Materialforschungsinstitut (FMF), Freiburg, Germany

Knowledge about formation energies of compounds is essential to derive phase diagrams of multicomponent phases with respect to elemental reservoirs. The determination of formation energies using (semi-)local exchange-correlation approximations of the density functional theory exhibits well-known systematic errors if applied to oxide compounds containing transition metal elements. We generalize and reevaluate a set of approaches proposed and widely applied in the literature to correct for errors arising from the over-binding of the O2 molecule and from correlation effects of electrons in localized transition-metal orbitals. The DFT+U method is exemplarily applied to iron oxide compounds, and a procedure is presented to obtain the U values, which lead to formation energies and electronic band gaps comparable to the experimental values. Using such corrected formation energies, we derive phase diagrams for LaFeO3, Li5FeO4, and NaFeO₂, which are promising materials for energy conversion and storage devices. A scheme is presented to transform the variables of the phase diagrams from the chemical potentials of elemental phases to those of precursor compounds of a solid-state reaction, which represents the experimental synthesis process more appropriately. The workflow and methods can directly be applied to other transition metal oxides.

# MM 33.7 Thu 17:30 H44

A comparative study of the bulk properties of iron oxides calculated using empirical potentials and ab-initio calculations — •AHMED ABDELKAWY, MIRA TODOROVA, and JÖRG NEUGEBAUER — Max-Planck-Institut für Eisenforschung, Max-Planck-Str.1, 40470 Düsseldorf

Striving toward a green economy requires re-evaluating industrial processes and looking for new routes to, e.g., obtaining iron from iron ore. This necessitates understanding the steps involved in the reduction of iron oxides and leading to several phase transitions the final product of which is iron. The optimization of the involved processes will hugely benefit from an atomistic level understanding. Atomistic simulation techniques are versatile but are dependent on the quality of the used underlying empirical potentials. We therefore first evaluate the applicability of interatomic potentials for this study by comparing them to ab initio calculations. Specifically, we focus on a reactive forcefield (ReaxFF) parametrized for these materials, which accounts for the different oxidation states of each species (Fe and O) and enables their variation depending on the local environment and coordination, bond breaking, and making. We assess the reliability of the force field by assessing various bulk properties of the relevant iron as compared to density functional theory calculations. We find that a universal force-

field that is able to accurately describe the three main iron oxides (Magnetite, Hematite, and Wüstite) is difficult to obtain.

# MM 33.8 Thu 17:45 H44

Uncertainty in Predicting Thermodynamic Properties of TiO2 Polymorphs — •Olga Vinogradova, Pin-Wen Guan, Siying Li, and Venkatasubramanian Viswanathan — Carnegie Mellon University, Pittsburgh, USA

Polymorphism of crystals directly leads to materials with vastly different chemical and physical properties. However the lowest energy polymorphs often differ by only small amounts of energy. This makes it challenging to predict relative properties using first-principles density functional theory (DFT), which is significant in designing a material for the desired application. In this work we apply computational uncertainty within DFT to quantify the accuracy of stability and phase transition predictions under finite temperature and pressure. We study six polymorphs of TiO2 using a set of six exchange-correlation functionals to present a detailed sensitivity analysis using uncertainty capabilities within the Bayesian Error Estimation Functional. We show that a prediction confidence metric is particularly important for comparing the stability of numerically close predictions. We show how the choice of functional significantly affects predictions of phase transitions and identify which structures and properties that have inherently large uncertainties. From the trends observed in stability, finitetemperature, and phase transition pressure predictions we propose that uncertainty quantification provides a valuable insight in problems where drawn conclusions are highly sensitive to the choice of the functional.

Self-consistent phonon calculations of lattice dynamical properties in cubic EuTiO3 comparing with experimental thermal conductivity — •CHEN SHEN¹ WENJIE XIE¹, XINGXING XIAO¹, ANKE WEIDENKAFF¹, TERUMASA TADANO², and  ${\rm HongBin}\,{\rm Zhang}^1-{}^1{\rm nstitute}~{\rm of}~{\rm Materials}~{\rm Science},~{\rm Technical}~{\rm University}~{\rm Darm-}$ stadt, Darmstadt 64287, Germany – ²Research Center for Magnetic and Spintronic Materials, National Institute for Materials and Science, Tsukuba, Japan We investigate the role of the quartic anharmonicity in the lattice dynamics and thermal transport of the cubic EuTiO3 by combining ab initio self-consistent phonon theory combined with compressive sensing techniques experimental thermal conductivity determination measurement. The antiferromagnetic Gtype magnetic structure is used to mimic the para-magnetic EuTiO3. We find that the strong quartic anharmonicity of oxygen atoms plays an essential role in the phonon quasiparticles free from imaginary frequencies in EuTiO₃, causing the hardening of vibrational frequencies soft modes. The hardened modes thereby affect calculated lattice thermal conductivity significantly, resulting in an improved agreement with experimental results, including the deviation from  $\kappa_L \propto T^{-1}$  at high temperature. The calculated thermal conductivity of 8.2 W/mK at 300 K matched the experimental value of 6.1 W/mK. When considering the boundary scattering, the calculated thermal conductivity is reduced to 6.9 W/mK at 300 K, which agrees better with the experiment.

### MM 33.10 Thu 18:15 H44

Simulated indentation on graphene oxide — •JAVIER ROJAS-NUNEZ¹, SAMUEL BALTAZAR¹, EDUARDO BRINGA², and ALEJANDRA GARCIA³ — ¹Physics Department and CEDENNA, Universidad de Santiago de Chile (USACH), Santiago, Chile — ²Laboratorio de síntesis y modificación de nanoestructuras y materiales bidimensionales, Centro de Investigación en Materiales Avanzados, Nuevo León, México — ³CONICET & Facultad de Ingeniería, Universidad de Mendoza, Mendoza, Argentina

The better understanding of nanomaterial properties will be a key factor to tailor and enhance properties of new materials. Graphene oxide in particular can be synthesized with different oxidation levels in order so gain similar properties to its deoxidized counterpart, graphene. Through the molecular dynamic simulations, the atomistic behavior of a tri-layer graphene membrane under mechanical indentation will be studied in this work.

This work will study a highly oxidized graphene oxide tri-layer that will be indented with a repulsive spherical indentator. The modeling of the membrane will generate single layer graphene oxide candidates to pick the lowest energy configuration and later stack this layer over itself. The final tri-layer was used for the indentation simulation, where the young modulus was reproduced with decent similarity to experimental results.

The atomistic analysis of the indentation process suggest an important role of epoxide groups in the mechanical deformation of the membrane.

**Constructing Training Sets for Transferable Moment Tensor Potentials: Application to Defects in Bulk Mg** — •Marvin Poul, Liam Huber, Erik Bitzek, and JOERG NEUGEBAUER — Max-Planck-Institut fuer Eisenforschung

Machine learned interatomic potentials promise to bring quantum mechanical accuracy to system sizes that are inaccessible with traditional QM approaches. Here, we present a set of unary Mg Moment Tensor Potentials[1] with different speeds and accuracies in the range of 100–5 meV/atom. We focus on understanding the role of the training data in the fitting process. We discuss several ways in which the structural complexity of the training structures and a physical understanding of them helps to design an efficient training set construction. The resulting potentials are verified on out-of-fold structures, like vacancies, surfaces, and high-symmetry grain boundaries. This work is implemented as a pyiron[2] workflow and we identify challenges and opportunities of a fully automated setup to fit machine-learned potentials.

Active learning and uncertainty quantification for atomic cluster expansion models — •YURY LYSOGORSKIY, ANTON BOCHKAREV, and RALF DRAUTZ — Atomistic Modelling and Simulation, ICAMS, Ruhr-University Bochum, D-44801 Bochum, Germany

Interatomic potentials (IP) are widely used in computational materials science, in particular for simulations that are too computationally expensive for density functional theory (DFT). Recently the atomic cluster expansion (ACE) was proposed as a new class of data-driven IP with basis set completeness. Development of any IP requires numerous iterations and careful selection of training data. Thus automation of both construction of training dataset as well as IP validation would significantly speed up the development process. In this work we apply the Maxvol algorithm for training dataset selection and study the extrapolation grade metric (Podryabinkin and Shapeev, 2017) in the context of ACE and compare it to the query-by-committee approach for uncertainty estimation. These methods allow us to introduce extrapolation control in ACE models and to design different exploration automated protocols for accurate interatomic potentials development.

# MM 34.3 Thu 16:15 H45

Take Two:  $\Delta$ -Machine Learning for Molecular Co-Crystals — •Simon Wengerr^{1,2}, Gábor Csányi³, Karsten Reuter¹, and Johannes T. Margraf¹ — ¹Fritz Haber Institut der MPG, Berlin, Germany — ²TU Munich, Germany — ³University of Cambridge, UK

Co-crystals are a highly interesting material class, as varying their components and stoichiometry in principle allows tuning supramolecular assemblies towards desired physical properties. The in silico prediction of co-crystal structures represents a daunting task, however, as they span a vast search space and usually feature large unit-cells. This requires theoretical models that are accurate and fast to evaluate, a combination that can in principle be accomplished by modern machine-learned (ML) potentials trained on first-principles data. Crucially, these ML potentials need to account for the description of long-range interactions, which are essential for the stability and structure of molecular crystals. In this contribution, we present a strategy for developing  $\Delta$ -ML potentials for co-crystals, which use a physical baseline model to describe long-range interactions. The applicability of this approach is demonstrated for co-crystals of variable composition consisting of an active pharmaceutical ingredient and various co-formers. We find that the  $\Delta$ -ML approach offers a strong and consistent improvement over the density-functional tight binding baseline. Importantly, this even holds true when extrapolating beyond the scope of the training set, for instance in molecular dynamics simulations at ambient conditions.

**Magnetic Atomic Cluster Expansion and application to Iron** – •MATTEO RI-NALDI, MATOUS MROVEC, and RALF DRAUTZ — Interdisciplinary Centre for Advanced Materials Simulation (ICAMS)

The atomic cluster expansion  $(ACE)^{[1,2,3]}$  has proven to be a valuable tool to parametrize complex energy landscapes of pure elements and alloys. However, its application to potential energy surfaces determined also by additional degrees of freedom, such as magnetic moments, has been still lacking. In particular, ferromagnetic materials cannot be tackled with the original ACE formalism, where the single-site energies depend parametrically only on interatomic distances and chemical species, since these descriptors cannot distinguish between atoms with different magnetic moments. The solution of this issue was given theoretically by Drautz^[4], where the ACE formalism was extended to take into account additional labels of the atomic sites of scalar, vectorial and tensorial nature by including them in the definition of the atomic neighbor density. We have employed this formalism to parametrize a magnetic ACE for the prototypical ferromagnetic element Fe using a dataset of both collinear and non-collinear magnetic structures calculated with spin density functional theory. We will show that the new ACE model is able to describe correctly not only various magnetic phases of Fe at 0 K but also their finite temperature properties in good agreement with the reference *ab-initio* and experimental values.

MM 34.5 Thu 16:45 H45 Kernel Charge Equilibration: Learning Charge Distributions in Materials and Molecules — •Martin Vondrak, Nikhil Bapat, Hendrik H. Heenen, Johannes T. Margraf, and Karsten Reuter — Fritz-Haber-Institut, Berlin, Germany

Machine learning (ML) techniques have recently been shown to bridge the gap between accurate first-principles methods and computationally cheap empirical potentials. This is achieved by learning a systematic relationship between the structure of molecules and their physical properties. However, the modern ML models typically represent chemical systems in terms of local atomic environments. This inevitably leads to the neglect of long-range interactions (most prominently electrostatics) and non-local phenomena (e.g. charge transfer), which can lead to significant errors in the description of polar molecules and materials (particularly in non-isotropic environments). To overcome these issues, we recently proposed a ML framework for predicting charge distributions in molecules termed Kernel Charge Equilibration (kQEq). Here, atomic charges are derived from a physical model using environment-dependent atomic electronegativities. These models can be trained to reproduce electrostatic properties (e.g. dipole moments) of reference systems, computed from first principles. The impact of different fitting targets on predicted charge distributions is compared. Furthermore, strategies for fitting to energies are discussed, including combination of Gaussian Approximation Potential (GAP) with kQEq.

Machine Learning of ab-initio grain boundary Segregation Energies – •CHRISTOPH DÖSINGER¹, DANIEL SCHEIBER², OLEG PEIL², VSEVOLOD RAZUMOVSKIY², ALEXANDER REICHMANN¹, and LORENZ ROMANER¹ – ¹Montanuniversität Leoben, Department of Materials Science, Leoben, Austria – ²Materials Center Leoben Forschung GmbH, Leoben, Austria

Grain-boundary (GB) segregation is an important phenomenon in alloys, where the resulting GB excess can strongly influence their properties, for example induce intergranular fracture or lead to phase transformations. A fundamental quantity that uniquely describes the propensity of a solute towards GB segregation is the segregation energy. It determines the tendency of a solute atom to enrich or deplete at the GB. This quantity can be directly calculated from first principles. However, such calculations are computationally expensive and can become computationally unfeasible as the complexity of the GB crystal structure increases. The aim of this work is to reduce the computational cost of GB segregation energies by applying machine learning methods trained at series of representative DFT calculations and expanding them to more complex GB structures. The atomic structure, together with the segregation energies are used to train a model, which then is employed to predict the segregation energy for arbitrary segregation sites and GB types. In our work we apply this method to tungsten alloys. The results show, that this approach indeed gives reliable results for the segregation energies and can be used to get a complete description of segregation profiles.

Stability of binary precipitates in Cu-based alloys investigated through active learning and quantum computing — •ANGEL DIAZ CARRAL¹, XIANG XU², AZADE YAZDAN YAR¹, SIEGFRIED SCHMAUDER², and MARIA FYTA¹ — ¹Institute for Computational Physics (ICP), Universität Stuttgart, Allmandring 3, 70569, Stuttgart, Germany — ²Institut für Materialprüfung, Werkstoffkunde und Festigkeitslehre (IMWF), Pfaffenwaldring 32 70569, Stuttgart, Germany

Understanding the structure of thermodynamically stable precipitates is of great interest in material science as they can affect the electrical conductivity and mechanical properties of the matrix to a great degree. In this work, we use a relaxation-on-the-fly active learning algorithm in order to scan all possible binary candidates, for different types and concentrations of alloy elements (mainly Cu, Si, and Ni). Quantum-mechanical calculations are performed on a small number of candidates to train and improve the machine-learned potential. The model is then used to predict the enthalpy of formation of all candidates. The

stability of binary precipitates, based on predicting the convex hull, is further assessed by the phonon density of states analysis calculated by classic and quantum computing.

MM 34.8 Thu 17:45 H45

How to teach my deep generative model to create new RuO₂ surface structures? — •Patricia König, Hanna Türk, Yonghyuk Lee, Chiara PANOSETTI, CHRISTOPH SCHEURER, and KARSTEN REUTER - Fritz-Haber-Institut der MPG, Germany

Many widely used catalyst systems still hold complicated longstanding structural puzzles that hamper their full atomistic understanding and thus further knowledge based progress. Here, we address the well-known RuO₂ catalyst for the oxidative conversion of CO exhaust gases in combustion processes.

To explore the chemical space of RuO₂ surface structures, we trained a Generative Adversarial Network (GAN) that is capable of cheaply generating diverse structural guesses for novel surface structures. For the training set, 28,903  ${\rm RuO}_2$  surface terminations were created with a grand-canonical basin hopping method. The atomic positions of these structures were mapped to Gaussian densities on a three-dimensional grid to generate the GAN input. We demonstrate how two-dimensional images of cuts through RuO2 structures with inferred lattice lengths and energy conditioning can be created as a first step to realistic three-dimensional surface structures.

Data-Driven Design of Two-Dimensional Non-van der Waals Materials -•RICO FRIEDRICH^{1,2,3}, MAHDI GHORBANI-ASL¹, STEFANO CURTAROLO², and ARKADY V. KRASHENINNIKOV^{1,4} — ¹Helmholtz-Zentrum Dresden-Rossendorf, Dresden — ²Duke University, Durham, USA — ³TU Dresden — ⁴Aalto University, Aalto, Finland

Two-dimensional (2D) materials are traditionally associated with the sheets forming bulk layered compounds bonded by weak van der Waals (vdW) forces. The weak inter-layer interaction leads to a natural structural separation of the 2D subunits in the crystals, giving rise to the possibility of mechanical and liquidphase exfoliation as well as enabling the formulation of exfoliability descriptors. The unexpected experimental realization of non-vdW 2D compounds, for

which the previously developed descriptors are not applicable, opened up a new direction in the research on 2D systems [1]. Here, we present our recent datadriven search for representatives of this novel materials class [2]. By screening the AFLOW database according to structural prototypes, 28 potentially synthesizable candidates are outlined. The oxidation state of the surface cations is found to regulate the exfoliation energy with low oxidation numbers giving rise to weak bonding — thus providing an enabling descriptor to obtain novel 2D materials. The candidates showcase a diverse spectrum of appealing electronic, optical and magnetic features.

Robust recognition and exploratory analysis of crystal structures via Bayesian deep learning — • ANDREAS LEITHERER, ANGELO ZILETTI, and LUCA M. GHIR-INGHELLI — The NOMAD Laboratory at the Fritz Haber Institute and at the Humboldt University of Berlin, Germany

Atomic-resolution studies are routinely being performed in modern materialsscience experiments. Artificial-intelligence tools are promising candidates to leverage this valuable - yet underutilized - data in unprecedented, automatic fashion to discover hidden patterns and eventually novel physics. Here, we introduce ARISE (Nat. Commun. 2021, https://doi.org/10.1038/s41467-021-26511-5), a crystal-structure-identification method based on Bayesian deep learning. As a major step forward, ARISE is robust to structural noise and can treat more than 100 crystal structures, a number that can be extended on demand. While being trained on ideal structures only, ARISE correctly characterizes strongly perturbed single- and polycrystalline systems, from both synthetic and experimental sources. The probabilistic nature of the Bayesian-deep-learning model yields principled uncertainty estimates, which are found to be correlated with crystalline order of metallic nanoparticles in electron-tomography experiments. Application of unsupervised learning to the internal neural-network representations reveals grain boundaries and (unapparent) structural regions sharing interpretable geometrical properties. This work enables the hitherto hindered analysis of noisy atomic structural data from computations or experiments.

MM 35.1 Thu 15:45 H46

Structural and Electronic Reconstruction of Hexagonal Boron Nitride Interlayers Steps — •Subakti Subakti^{1,2}, Mohammadreza DaqiqShirazi³, Felix Kern^{1,2}, Daniel Wolf¹, Thomas Brumme³, Bernd Büchner^{1,2}, and Axel Lивк¹ — ¹Leibniz Institute for Solid State and Materials Research Dresden, Helmholtzstraße 20, 01069 Dresden, Germany — ²Institut für Festkörperphysik, TU Dresden, D-01062 Dresden, Germany — ³Chair of Theoretical Chemistry, Technische Universität Dresden, Bergstrasse 66, 01069 Dresden, Germany

The electrostatic potential of condensed matter provides not only atomic structure, but also the electronic structure that underlies the chemical bonding formation of atoms within one molecule. Off-axis electron holography (EH) technique allows us to probe the volume-averaged electrostatic potential (in crystalline materials over the unit cell) of the specimen with respect to a vacuum reference region. Therefore, a conjunction EH medium and high resolution data analysis and electrostatic potential based ab-initio calculation will be powerful for simultaneous atomic scale reconstruction and imaging. Visible projected potential jump at the edges of two adjacent monolayers hexagonal boron nitride (h-BN) will be addressed here as our data analysis suggest that it could be signature for the increased charge delocalization due to the formation of an additional covalent bond of the 2p orbitals in the rolled-up edge.

### MM 35.2 Thu 16:00 H46

Atom Probe Study of self-assembled Monolayers — •HELENA SOLODENKO, PATRICK STENDER, and GUIDO SCHMITZ — University of Stuttgart, Institute for Materials Science, Heisenbergstr. 3, 70569 Stuttgart

Atom probe tomography is a well-established characterization technique for metals, semiconductors, oxides and minerals. However, measurement of organic matter and biological materials is still challenging. Field evaporation of organic species leads to detection of CxHy groups, instead of single atoms. The fragmentation of the molecules possibly depends on the applied electric field strength and the nature of chemical bonding. Self-assembled monolayers (SAMs) represent a suitable model system to study the fundamental questions about field evaporation of such systems, since they represent a well-defined molecular film with a limited number of possible molecular fragments. Furthermore, a chemical bond is formed between substrate surface and the headgroup the SAM. By variation of the field strength, we expect to learn more about the field evaporation process and thus about the binding energies of the SAMs. We present measurements

of alkane-thiolates on Pt and silanes on ZnO by laser-assisted APT. The backbone evaporates in the form of small hydrocarbon fragments consisting of one to four C atoms, while S evaporates exclusively as single ions. With increasing laser power, a significant trend towards larger fragment sizes is observed. Furthermore, comparison with liquid alkanes and cross linked alkane networks is insightful which demonstrates a continuous transition from evaporation of complete molecules to single atoms.

# MM 35.3 Thu 16:15 H46

Tuning the Electronic Properties of Mesocrystals - •STEFAN MANUEL SCHUPP¹, CHRISTIAN JENEWEIN², BING NI², LUKAS SCHMIDT-MENDE¹, and HELMUT CÖLFEN² — ¹Unitversity of Konstanz, Department of Physics, Universitätsstraße 10, 78462 Konstanz, Germany — ²Unitversity of Konstanz, Department of Chemistry, Universitätsstraße 10, 78462 Konstanz, Germany

Colloidal crystals consisting of periodically aligned nanocrystalline building blocks, so-called mesocrystals, are promising candidates for nanostructured metamaterials. The high degree of order of the nanoparticles in the crystal results in a well-defined facet-to-facet distance which is determined by the used capping agents. In this work, we were able to grow micrometer-sized platinum nanocube-based mesocrystals with various capping agents and perform electrical measurements on individual crystals with a nanoprobing system. The extracted resistances increase with larger interparticle distances which can be attributed to the predominantly thermally activated tunneling mechanism in these superstructures. However, an additional annealing step leads to a decrease in resistance by seven orders of magnitude due to formed mineral bridges. After this treatment, the electronic properties are mainly determined by the nanomaterial itself. Finally, we were able to transfer these findings onto multi component superstructures consisting of platinum and iron oxide nanocubes. In these binary mesocrystals the ratio of the nanoparticle types can be varied to tune the electrical conductivity even further while simultaneously allowing to combine properties of both nanomaterials.

# MM 35.4 Thu 16:30 H46 Direct Visualization of Ordered Mesoporous Silica Using Atom Probe Tomography — •KUAN MENG and GUIDO SCHMITZ — University of Stuttgart, Institute for Materials Science, Heisenbergstr. 3, 70569, Stuttgart, Germany Inspired by enzyme catalytic reaction, heterogeneous catalysis with mesoporous support materials is considered as the fundamental for modern chemical syn-

Location: H46

^[2] R. Friedrich et al., Nano Lett. 22, 989 (2022).

thesis. However, the synergistic interplay between the catalysts and the pores is still unknown. To realize this, the structure of the mesoporous supports needs characterizing at first. Atom Probe Tomography, due to its subatomic resolution, strong chemical mapping power and direct visualization capability, is becoming a great candidate for mesoporous structure characterization. Yet to unfold its charm, pores must be filled.

In this work, Ordered Mesoporous Silica (OMS) filled with two different polymers, CDEAB and DCPD, was investigated. Firstly, both obtained mass spectra can be intepreted as a plausible combination of signature peaks between silica and polymers. Secondly, the porous network of OMS was visualized using neighboring analysis and the pore size turned out in the mesoporous range. Especially in the case of OMS filled with DCPD, the visualized network appeared to be regularly hexagonal, showing great resemblence with TEM images from similar pore orientations. Last, the obtained data were compared with the result of TAPsim simulations in order to understand the flaws in the visualization and to improve the understanding of the reconstructions.

MM 35.5 Thu 16:45 H46 plastic deformation of nanoporous gold modified with organic layers: a TEM study — •XIN ZHANG and NADIIA MAMEKA — Institute of Materials Mechanics, Helmholtz-Zentrum hereon, 21502 Geesthacht, Germany

As a result of their large specific surface area, strength of high-specific area materials must be sensitive to environment and surface chemistry. This notion is confirmed, e.g., by the enhanced flow stress found in single metal nanowires [1] and metallic networks like nanoporous metals when their surface is modified by adsorbed layers or surface coatings [2]. Yet, experimental studies of microstructural origins of the surface constraints impact on small-scale plasticity is still in its infancy. Here, were examine a defect structure of plastically deformed nanoporous gold (NPG) via ex-situ transmission electron microscopy. We exploit self-assembled monolayers (SAM) to modify a surface of NPG as inspired by a substantial flow stress increase due to SAM adsorption reported in [3]. In bare NPG deformed by rolling, we reveal higher density of twins consistent with [4]. In the deformed NPG with SAM, the formation of twins is strongly suppressed near the surface. Meanwhile, the existence of the organic layer apparently increases the density of twins in NPG. In the contribution, we discuss the TEM observations and link them to the findings from mechanical tests of the SAM-modified NPG. [1] Shin et al, Acta Mat. 166 (2019) 572e586. [2] Wu et al, Mater. Electrochemical actuation and tunable stiffness of hierarchical nanoporous gold via surface modification — •OLGA MATTS and NADIIA MAMEKA — Helmholtz-Zentrum Hereon, Geesthacht, Germany

Recently developed dealloying strategies towards nanoporous metals with structural hierarchy [1] open up new opportunities for functional behavior of this class of materials. The larger pores at the higher hierarchical level (characterized by diameters around 200 nm) of the hierarchical nanoporous metals (hc np) can promote fast mass exchange, while nanopores at the lower hierarchy level (below 30 nm) provide a large surface area. To explore the notion we employ electroactive self-assembled monolayers and conductive polymer polypyrrole for surface functionalization of hc np Au and np Au with unimodal pore size. Actuation and Young*s modulus behavior of the hybrid materials were then analyzed in situ in a dynamical mechanical analyzer and dilatometer upon potential cycling in aqueous electrolytes. We revealed pronounced variations in the macroscopic length change as well as elastic modulus in response to the voltage-induced redox reactions of the organic films at the np electrodes. In the contribution, we discuss the origin of the observations and compare the functional performance of both types of the hybrids based on np Au.

Laser-Ultrasonics Reveals the Complex Mechanics of Nanoporous Silicon – •Marc Thelen¹, NICOLAS BOCHUD², MANUEL BRINKER¹, CLAIRE PRADA³, and PATRICK HUBER^{1,4,5} – ¹MXP, TUHH, Hamburg, Germany – ²MSME, CNRS UMR 8208, UPEC, Univ Gustave Eiffel, Creteil, France – ³Institut Langevin, ESPCI Paris, Université PSL, CNRS, Paris, France – ⁴CXNS, DESY, Hamburg, Germany – ⁵CHyN, UHH, Hamburg, Germany

Nanoporosity in silicon leads to completely new functionalities of this mainstream semiconductor with numerous discoveries in fields ranging from nanofluidics and biosensorics to drug delivery, energy storage and photonics. Nevertheless, the mechanical properties, critical for a variety of applications, remain difficult to characterise comprehensively. The study presented here aims to address this problem by utilising laser-excited elastic guided waves, detected in dry and liquid-infused porous silicon. Among other things, the experiments reveal that the self-organised formation of 100 billions of parallel nanopores per square centimetre cross section results in an effective stiffness reduction of about 80 %, a nearly isotropic elasticity perpendicular to the pore axes and a higher stiffness along the pore axis, altogether leading to significant deviations from bulk silicon. This thorough assessment of the wafer-scale mechanics of nanoporous silicon and recent breakthroughs in laser ultrasonics therefore open up entirely new frontiers for in-situ, non-contact and non-destructive mechanical characterisation of complex porous material systems [1].

Fabrication and compressive behavior of monolithic nanoporous niobium at macroscale — •SEOYUN SOHN^{1,2}, SHAN SHI^{2,1}, JÜRGEN MARKMANN^{1,2}, and JÖRG WEISSMÜLLER^{2,1} — ¹Institute of Materials Mechanics, Helmholtz-Zentrum hereon, Geesthacht, Germany — ²Institute of Materials Physics and Technology, Hamburg University of Technology, Hamburg, Germany

Studying the mechanical performance of nanoporous (np) metals allows us to understand nanoscale solids as well as to design functional applications. However, the majority of studies have been confined to face-centered cubic noble metals such as gold and palladium due to high electronegativity which facilitates preparation by dealloying. Since the electrochemical or chemical dealloying involves a selective dissolution of less noble constituent(s) in an electrolyte solution, the remaining constituent should be nobler to form a bicontinuous porous structure. Niobium (Nb) on the other hand is less noble than gold, has higher stiffness and lower ductility, and its crystal lattice is body-centered cubic. In this work, np Nb was fabricated out of Ni75Nb25 by liquid metal dealloying; the ligament size could be controlled from 400 nm to more than 1 um by adjusting dealloying time and temperature. Each sample body is a few mm in size and freestanding, which allows us to perform conventional macro-compression tests to measure the strength and stiffness of the nano-ligament scaffold. Our observations support that the material strength is enhanced with smaller ligaments. More interestingly, our np Nb shows extremely anomalous compliance.

Maximal Anderson Localization and Suppression of Surface Plasmons in Two-Dimensional Random Au Networks — •JOHANNES SCHULTZ¹, KARL HIEKEL², PAVEL POTAPOV¹, PAVEL KHAVLYUK², ALEXANDER EYCHMÜLLER², and AXEL LUBK¹ — ¹Leibniz Institute for Solid State and Materials Research Dresden, Helmholtzstraße 20, 01069 Dresden, Germany — ²Chair of Physical Chemistry, TU Dresden, Zellescher Weg 19, 01069 Dresden, Germany

2D random metal networks possess unique electrical and optical properties, such as almost hundred percent optical transparencies and low sheet resistance, which are closely related to their disordered structure and may be exploited in various applications. Here we present a detailed experimental and theoretical investigation of their plasmonic properties, revealing Anderson (disorder-driven) localized surface plasmon (LSP) resonances of large quality factors and spatial localization close to the theoretical maximum. The LSPs typically consist of multiple field hotspots with a well-defined correlation distance. Moreover, they disappear above a geometry-dependent threshold at ca. 1.6 eV in the investigated networks, explaining their large transparencies in the optical spectrum. Electron energy loss spectroscopy in combination with scanning transmission electron microscopy was applied for the experimental studies. Both, the high spatial (≈1 nm) and spectral (≈50 meV) resolution allows to study the variety of LSP modes in terms of excitation energy and spatial localization. The theoretical study is based on a coupled dipole model, which allows modeling of large plasmonic systems by exploiting Babinet's principle.

Laterally aligned nanowires: Targeted process design and alignment control — •JASMIN-CLARA BÜRGER, SEBASTIAN GUTSCH, and MARGIT ZACHARIAS — Laboratory for Nanotechnology, Department of Microsystems Engineering -IMTEK, University of Freiburg, Georges-Köhler-Allee 103, 79110 Freiburg, Germany

For sensors, tin oxide nanowires (NWs) have shown superior properties due to their unique geometry, which allows for high sensitivities. NWs are often grown in freestanding mode for which metallization via standard lithography techniques is not applicable. In the production of single NW-based sensors, a multistep process has to be applied and an individual contacting of the NWs by, e.g., e-beam lithography becomes mandatory. Here, the use of planar NWs, i.e., laterally aligned NWs, is of advantage since the removal step from the growth substrate can be skipped and the NWs can be grown at defined positions. Due to their epitaxial contact with the monocrystalline growth substrate, the NWs are self-aligned towards the substrate lattice. However, the parameter space of these NWs is even smaller than for freestanding NWs. Based on finite element simulation and thermodynamic considerations, we developed a model for the growth of laterally aligned NWs.[1,2] The simulations and theory are supported by experimental results. Following, the preparation of longitudinal TEM lamella of individual NWs and AFM measurements allowed us for nanoscopic insight into the NW alignment on the growth substrate.[2]

Laser-excited electrons: how hot are they? — •BAERBEL RETHFELD — Department of Physics and Research Center OPTIMAS, TU Kaiserslautern, Germany Hot electrons play an important role in surface science. They are responsible for the functionalization of solar cells and the emission of intense THz beams, they drive chemical reactions at surfaces and are utilized in biosensing methods. Excitation and decay as well as transport of laser-excited electrons are fundamentally studied in pump-probe experiments using photoemission methods.

The term "hot electrons" is, however, not well-defined. It is used for single laser-excited electrons, for non-equilibrium electron distributions, and for Fermi distributions at elevated temperature. In all cases, the relaxation of such electrons towards an equilibrated situation is of interest. Its dynamics may be complex, since several scattering mechanisms act on different timescales. Therefore, athermal electron distributions as well as highly excited electrons can exist much longer than the single-electron lifetime predicts.

In this presentation, I introduce the calculation method of Boltzmann collision integrals, allowing to study the effect and mutual influence of different scattering mechanisms. I further show how such intertwined relaxation processes affect measurable macroscopic quantities on ultrafast timescales, particularly in multiband materials. Examples include the electrical conductivity in highly excited noble metals, spin and charge transport in magnetically ordered systems and the nonthermal electron-phonon coupling strength in metals and dielectrics.

Floquet Dressing and Multiphoton Photoemission on Metal Surfaces - • YUN Yen^{1,2} and MICHAEL SCHÜLER² – ¹Condensed Matter Theory Group, Paul Scherrer Institute, CH-5232 Villigen PSI, Switzerland — ²Ecole Polytechnique Fédérale de Lausanne (EPFL), CH-1015 Lausanne, Switzerland

Floquet engineering allows us to realize the control of quantum materials and explore exotic properties from light-matter interaction. Along with the development of various ultrafast experimental techniques, non-equilibrium quantum systems have gained more interests.

Metal surfaces such as Cu(111) or Ag(111) are considered as benchmarks for photoemission spectroscopy with nonlinear optical responses. The interplay between Shockley surface states (SS), image potential states (IP), and the related dressed bands can be studied with ultrafast pump-probe pulses. Starting from model potential, we utilize real space time-dependent surface flux method and non-equilibrium Green*s function to simulate the non-equilibrium dynamics on the metal surfaces. We calculate the interferometric-time-resolved multiphoton photoemission (ITR-mPP) spectrum. The Fourier analysis of the simulated ITRmpp spectrum shows the optical dressing of the surface electronic structures. Our approach successfully reproduce the previous experimental data, which allows us to investigate the origins of these signatures.

O 2.2 Mon 10:45 H3

Femtosecond orbital tomography of exciton dynamics in  $C_{60}$  thin films • •G. S. Matthijs Jansen¹, Wiebke Bennecke¹, Ralf Hemm², Andreas Windischbacher³, David Schmitt¹, Jan Phillip Bange¹, Chris-tian Kern³, Daniel Steil¹, Sabine Steil¹, Marcel Reutzel¹, Martin Aeschlimann², Peter Puschnig³, Benjamin Stadtmüller^{2,4}, and Stefan Mатні $as^1 - {}^1$ I. Physikalisches Institut, Georg-August-Universität Göttingen — ²Department of Physics and Research Center OPTIMAS, University of Kaiserslautern — ³Institute of Physics, University of Graz — ⁴Institute of Physics, Johannes Gutenberg-University Mainz

Time-resolved photoemission orbital tomography promises to be a unique probe of out-of-equilibrium electronic wavefunctions at the Ångström level and with femtosecond time resolution. Particularly interesting is the application to excitons, quasiparticles consisting of a bound electron and electron hole that govern the opto-electronic response of organic semiconductors. Here, we consider the prototypical organic semiconductor C₆₀, for which it has been proposed that the exciton cascade involves the two-step decay of a delocalized charge-transfer exciton into a localized Frenkel excitonic state. We will discuss how the combination of multi-dimensional photoemission spectroscopy with calculations within the many-body perturbation theory framework of the Bethe-Salpeter equation can shed light on the real-space femtosecond electron dynamics, and in particular show how the delocalization of excitons in  $C_{60}$  evolves on the femtosecond timescale.

# O 2.3 Mon 11:00 H3

Anisotropic carrier dynamics in a laser-excited Fe/(MgO)(001) heterostructure from real-time TDDFT — •ELAHEH SHOMALI, MARKUS ERNST GRUNER, and ROSSITZA PENTCHEVA - Department of Physics and Center for Nanointegration, CENIDE, University of Duisburg-Essen, Germany

The interaction of a femtosecond optical pulse with a  $Fe_n/(MgO)_m(001)$  (n=1,3,5 and m=3,5,7) metal/oxide heterostructure is addressed using time-dependent density functional theory (TDDFT) calculations in the real-time domain. We systematically study electronic excitations as a function of laser frequency (around and higher than the bulk MgO band gap). We find a marked anisotropy in the response to in- and out-of-plane polarized light, which changes its character qualitatively depending on the excitation energy: the Fe-layer is efficiently addressed at low frequencies by in-plane polarized light, whereas for frequencies higher than the MgO band gap, we find a particularly large sensitivity of MgOlayers to cross-plane polarized light. Moreover, the interface plays an important role, as it mediates transitions from the valence band of MgO into the 3d states of Fe closely above the Fermi-level and transitions from the Fe-states below the Fermi level into the conduction band of MgO. As these transitions can occur simultaneously without altering the charge balance of the layers, they could potentially lead to an efficient transfer of excited carriers into the MgO part [1]. Funding by SFB 1242, project C02, is gratefully acknowledged. [1] E. Shomali, M. E. Gruner, R. Pentcheva, Phys. Rev. B, in press, arXiv:2205.03178.

# O 2.4 Mon 11:15 H3

Ultrafast electron transport across interfaces in Au/Fe/MgO(001) heterostructures — Yasın Beyazit¹, Florian Kühne¹, Markus Heckschen¹, Björn Sothmann¹, Elaheh Shomali¹, Markus Gruner¹, Rossitza PENTCHEVA¹, PING ZHOU¹, DETLEF DIESING², and •Uwe BOVENSIEPEN¹ ¹Universität Duisburg-Essen, Fakultät für Physik, 47048 Duisburg -²Universität Duisburg-Essen, Fakultät für Chemie, 45141 Essen

The dynamics of electronic excitations at buried interfaces is decisive in electron transfer and carrier multiplication in heterostructures. Following recent developments in time-resolved two-photon photoemission spectroscopy the relaxation dynamics of optically excited, hot electrons can be distinguished in the individual layers of Au/Fe/MgO(001) by analysis of the Au thickness dependent relaxation times [Beyazit et al., PRL 125, 076803 (2020)]. Here we report on recent experimental results and the separation of the primary, optically excited electrons and the secondary, relaxed and propagating electron distribution. This study is complemented by calculations using the Boltzmann transport equation for the propagation through the Au layer and density functional theory calculations resolving the interface contribution.

Funding by the Deutsche Forschungsgemeinschaft through SFB 1242 is gratefully acknowledged.

# O 2.5 Mon 11:30 H3

Non-equilibrium carrier dynamics of different surface reconstructions of Sn on SiC(0001) — •MAXIMILIAN STECHER¹, MARIA-ELISABETH FEDERL¹, NIKLAS HOFMANN¹, LEONARD WEIGL¹, JOHANNES GRADL¹, NEERAJ MISHRA^{2,3}, STIVEN FORTI², CAMILLA COLETTI^{2,3}, and ISABELLA GIERZ¹ — ¹Department of Physics, University of Regensburg, 93040 Regensburg, Germany - ²Center for Nanotechnology Innovation @NEST, Istituto Italiano di Tecnologia, 56127 Pisa, Italy ³Graphene Labs, Istituto Italiano di Tecnologia, 16163 Genova, Italy

Sn on SiC(0001) forms different surface reconstructions in the monolayer coverage regime, among them a Mott insulating phase with a  $(\sqrt{3}) \times \sqrt{3} \times \sqrt{3}$ ture. We grow these structures and characterize them with low-energy elec-

Location: S054

Location: H3

tron diffraction (LEED), X-ray photoemission spectroscopy (XPS), and angleresolved photoemission spectroscopy (ARPES). We then investigate their lightinduced non-equilibrium carrier dynamics with time- and angle-resolved photoemission spectroscopy, looking for possible photo-induced phase transitions and metastable transient states. These preliminary studies then pave the way towards dynamical control of the electronic properties of Sn/SiC(0001) via resonant excitation of the IR-active phonon modes of the substrate that will modulate the atomic positions of the covalently bound Sn layer coherently.

# O 2.6 Mon 11:45 H3

ultrafast carrier dynamics of graphene - 2D Sn van der Waals interface — •MARIA-ELISABETH FEDERL¹, NIKLAS HOFMANN¹, LEONARD WEIGL¹, JO-HANNES GRADL¹, TIM WEHLING^{2,3}, NIKLAS WITT³, NEERAJ MISHRA⁴, CAMILLA COLETTI^{4,5}, STIVEN FORTI⁴, and ISABELLA GIERZ¹ — ¹Department of Physics, University of Regensburg, 93040 Regensburg, Germany — ²Institute for Theoretical Physics, University of Bremen, 28359 Bremen, Germany — ³Institute for Theoretical Physics, University of Hamburg, 22607 Hamburg, Germany — ⁴Center for Nanotechnology Innovation @NEST, Instituto Italiano di Tecnologia, Piazza San Silvestro 12, 56127 Pisa, Italy — ⁵Graphene Labs, Instituto Italiano di Tecnologia, 16163 Genova, Italy

The interface between epitaxial graphene and SiC(0001) is a confined space that allows for the growth of novel two-dimensional materials (2DMs) and thus graphene/2DM heterostructures. The electronic properties of these heterostructures are usually more complex than those expected from the sum of the individual layers as hybridization between the layers opens up band gaps in the electronic structure and produces electronic wavefunctions that are localized on both rather than individual layers of the heterostructure. We use time- and angle-resolved photoemission spectroscopy to reveal important differences between the non-equilibrium carrier dynamics of quasi-freestanding graphene and graphene proximity-coupled to a 2D metallic Sn layer that we interpret in terms of doping, scattering phase space, and ultrafast charge transfer with the help of ab initio band structure calculations.

# O 2.7 Mon 12:00 H3

tr-ARPES experiment with mid-infrared excitation for dynamical band structure engineering — •LEONARD WEIGL¹, NIKLAS HOFMANN¹, JOHANNES GRADL¹, NEERAJ MISHRA^{2,3}, STIVEN FORTI², CAMILLA COLETTI^{2,3}, and IS-ABELLA GIERZ¹ — ¹Department of Physics, University of Regensburg, 93040 Regensburg, Germany — ²Center for Nanotechnology Innovation @NEST, Istituto Italiano di Tecnologia, 56127 Pisa, Italy — ³Graphene Labs, Istituto Italiano di Tecnologia, 16163 Genova, Italy

The band structure of a solid is mainly determined by the orbital overlap between neighboring atoms. Therefore, electronic properties are commonly controlled via the chemical composition that determines structural parameters such as bond angles and lengths. Recently, control of the effective orbital overlap has been achieved by periodic modulation of solids with strong mid-infrared (MIR) light fields. The ideal probe for investigating driving-induced band structure changes is time- and angle-resolved photoemission spectroscopy (tr-ARPES). We have built a tr-ARPES setup that combines a strong-field wavelength-tunable MIR pump source with extreme ultraviolet probe pulses providing access to the band structure of driven solids across the complete first Brillouin zone with sub 100meV energy and sub 250fs temporal resolution. We present first results on driven graphene, analyze the MIR pump-induced carrier dynamics, and discuss the possible formation of photon-dressed states. The excellent performance of the setup now paves the way for the future investigation of light-induced superconductivity as well as light-induced topological phase transitions.

# O 2.8 Mon 12:15 H3

Anisotropic response to optical excitations in naturally layered delafossite  $PdCoO_2$  from time-dependent DFT — •MIKE J. BRUCKHOFF, MARKUS E. GRUNER, and ROSSITZA PENTCHEVA — Faculty of Physics and Center of Nanointegration, CENIDE, University of Duisburg-Essen, 47048 Duisburg, Germany In the framework of time-dependent density functional theory (TDDFT), we investigate the layer-resolved dynamics of the electronic structure of the metallic delafossite  $PdCoO_2$  after optical excitations.  $PdCoO_2$  can be conceived as a

natural multilayer system consisting of highly conductive Pd layers separated by insulating  $CoO_6$  octahedra. We calculate the responses to optical pulses with two polarization directions, multiple frequencies, different pulse durations and laser fluences within the real-time approach (RT-TDDFT) and compare the results to optical absorption spectra obtained within the linear-response regime (LR-TDDFT). We observe a strong anisotropy of the electronic response to different polarization directions and particular frequencies of the incident electric field, which corresponds to the strong anisotropy visible in the absorption spectra. In particular, we see a significant charge redistribution and time-dependent changes of occupation numbers, which depend on the orbital character of the involved *d*-orbitals. Analogies to previous studies for a Fe₁/(MgO)₃(001) heterostructure [1] are discussed. Funding by DFG within SFB1242 is gratefully acknowledged.

 $O \ 2.9 \ Mon \ 12:30 \ H3$ **Far-from-equilibrium electron-phonon interactions in optically-excited graphene** - •MARCO MERBOLDT¹, MARTEN DÜVEL¹, JAN PHILIPP BANGE¹, MICHAEL STELLBRINK¹, HANNAH STRAUCH¹, KLAUS PIERZ², HANS WERNER SCHUMACHER², DAVOOD MOMENI², DANIEL STEIL¹, G. S. MATTHIJS JANSEN¹, SABINE STEIL¹, DINO NOVKO³, STEFAN MATHIAS¹, and MARCEL REUTZEL¹ - ¹I. Physikalisches Institut, Georg-August-Universität Göttingen, Göttingen, Germany - ²Physikalisch-Technische Bundesanstalt, Braunschweig, Germany - ³Institute of Physics, Zagreb, Croatia

Comprehending far-from-equilibrium many-body interactions is one major goal of current ultrafast condensed matter physics research. A particularly interesting but barely understood situation occurs during strong optical excitation, where electron and phonon systems are significantly perturbed from their equilibrium and cannot be described by Fermi-Dirac or Bose-Einstein distributions, respectively.

Here, we use time- and angle-resolved photoelectron spectroscopy (trARPES) to study such situation for the prototypical material graphene. We show that upon optical excitation, it exhibits a complex non-equilibrium many-body response by evaluating the Dirac state linewidth and thus the imaginary part of the quasiparticle self-energy Im $\Sigma$  from spectrally deconvoluted trARPES data. By employing first-principles theoretical modeling, we find that the observed experimental features are caused by ultrafast NEQ scatterings between optical phonons and photoexcited charge carriers, active on timescales well below 100 fs. Düvel, Merboldt *et al.*, Nano Letters, accepted.

# O 2.10 Mon 12:45 H3

Coherent Time-Resolved Above-Threshold Plasmoemission from the Au(111) Shockley Surface State — •PASCAL DREHER, DAVID JANOSCHKA, ALEXANDER NEUHAUS, MICHAEL HORN-VON HOEGEN, and FRANK MEYER ZU HERINGDORF — Faculty of Physics, University of Duisburg-Essen, 47048 Duisburg, Germany

Strong nonperturbative interactions of an intense driving light field with the electronic band structure in a solid can result in exotic material properties that do not exist under equilibrium conditions. For suitable driving conditions, Floquet theory predicts that the originally unperturbed electronic structure is modified by the formation of light-dressed electron states in strong fields. Observing such dressing requires electronic state resolution as well as precise control over the intense periodic driving field to overcome intrinsic dissipation and decoherence in the solid.

Here, we explore nano-focusing of femtosecond surface plasmon polariton (SPP) pulses on flat surfaces as a possible route towards strong-field control over electronic states within a solid using time- and angle-resolved photoemission spectromicroscopy. We observe above-threshold electron emission from the Au(111) Shockely surface state by the absorption of up to seven SPP quanta. Two-dimensional time-resolved photoelectron spectroscopy using a birefringent delay line provides us with direct access to the coherent and incoherent dynamics of the electron emission process with attosecond precision. The presented results clearly indicate the coherent nature of the interaction of the intense SPP nano-focus with the band structure of the material.

# O 3: Focus Session: Single Atom Catalysis 1

The field of single atom catalysis has emerged rapidly in recent years out of the desire to utilize less and less precious metals, and remarkable successes have been reported in thermo-, electro-, and photo-catalysis. While much of the early focus was on establishing synthesis routes to achieve atomic dispersion, it has become clear that "single atom" systems cannot be considered as the smallest possible nanoparticle. Because isolated adatoms are stabilized by chemical bonds to the support, they have much more in common with mononuclear complexes used in homogenous catalysis. Thus, the focus has now changed towards understanding the role of coordination of the active site, and developing ways to tailor it toward specific processes. This has led to much interest in fundamental work, which opens up a tremendous opportunity for surface science to contribute to a hot topic in catalysis.

Organizer: Gareth Parkinson (Technical University Vienna), Matthias Meier (University of Vienna)

Time: Monday 10:30-12:45

**Topical Talk** 

# O 3.1 Mon 10:30 H4

Rational design of single atom electrocatalysts: handle with care — •GIANFRANCO PACCHIONI — Dipartimento di Scienza dei Materiali, Università Milano-Bicocca, Milano, Italy

One of the objectives of electronic structure theory is to predict chemical and catalytic activities. This is a challenging target due to the large number of variables that determine the performance of a heterogeneous catalyst. The complexity of the problem has reduced considerably with the advent of single atom catalysts (SAC) and, in particular, of graphene-based SACs for electrocatalytic reactions such as the oxygen reduction (ORR), the oxygen evolution (OER) and the hydrogen evolution (HER) reactions. In this context we assist to a rapidly growing number of theoretical studies based on density functional theory (DFT) and of proposals of universal descriptors that should provide a guide to the experimentalist for the synthesis of new catalysts. In this talk we critically analyze some of the current problems connected with the prediction of the activity of SACs based on DFT: accuracy of the calculations, neglect of important contributions in the models used, physical meaning of the proposed descriptors, inaccurate data sets used to train machine learning algorithms, not to mention some severe problems of reproducibility. It follows that the 'rational design' of a catalyst based on some of the proposed universal descriptors or of the DFT screening of large number of structures should be considered with great caution.

O 3.2 Mon 11:00 H4 Single atom co-catalyst dispersion on KTaO3 (001) by surface polarity compensation. — •AJI ALEXANDER¹, JESÚS REDONDO¹, DOMINIK WRANA¹, LUKÁŠ FUSEK¹, VIKTOR JOHÁNEK¹, JOSEF MYSLIVEČEK¹, and MARTIN SETVIN^{1,2} — ¹Department of Surface and Plasma Science, Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic — ²Institute of Applied Physics, TU Wien, Vienna, Austria

Redox chemistry on perovskite surfaces attracts attention due to these materials* promising catalytic properties, good ability to separate electron-hole pairs in light-harvesting, and the presence of ferroelectricity in many perovskites. This work focuses on enhancing catalytic activity achieved by activating the perovskite surface with extrinsic metals. Combined STM/AFM measurement together with XPS data shows the tendency of the cobalt atoms to disperse in the form of single adatoms on the polarity uncompensated KTaO3 (001) surface [1]. The interaction of cobalt with KTO surfaces was studied under various reducing and oxidizing conditions, as well as a function of temperature. This, in turn, will allow characterization of the metallic, oxide, and hydroxide phases of cobalt in dependence on the environment. The work was supported by projects GACR 20-21727X and GAUK Primus/20/SCI/009. [1] M. Setvin, M. Reticcioli, F. Poelzleitner et al., Science 359, 572 (2018)

Comparison study of different transition metals on two TiO2 model supports: anatase TiO2(101) and rutile TiO2(110) — •LENA PUNTSCHER¹, KEVIN DANINGER¹, PANUKORN SOMBUT^{1,2}, MATTHIAS MEIER², MICHAEL SCHMID¹, CESARE FRANCHINI², ULRIKE DIEBOLD¹, and GARETH S. PARKINSON¹ — ¹Institute of Applied Physics, TU Wien, Austria — ²Faculty of Physics, University of Vienna, Vienna, Austria

Single-atom catalysis (SAC) offers an opportunity to minimize the amount of precious catalyst material required for traditional heterogeneous catalysis and to heterogenize reactions presently requiring homogeneous catalysis. Unravelling how metal atoms bind to oxide supports is crucial for a better understanding of the SACs catalytic properties. Using STM and XPS, we compare the adsorption geometry and stability of several transition metals (Pt, Rh, Ir and Ni) on TiO2 model supports: anatase TiO2(101) and rutile TiO2(110), and the influence of water on the dispersion of these systems. While most of the metals rapidly sinter on both surfaces, there are a few exceptions: Ir forms stable adatoms on the anatase support. Ni is much more dispersed when water vapor is added to the deposition and a very low coverage of Pt single atoms can be stabilized in oxygen vacancies formed on rutile (110), which are only stable in UHV conditions. This

study points out the importance of metal-support interaction and the surprisingly different behaviour of the transition metals on TiO2 model supports.

Methane Activation by Free Tantalum Cluster Cations: When the Atomic System is Different — •MARTIN TSCHURL, JAN ECKHARD, and UELI HEIZ — Physical Chemistry, Department of Chemistry and Catalysis Research Center, Technical University of Munich

The efficient conversion of methane into valuable chemicals represents a challenge in chemistry in general. It also carries the potential of becoming a key technological process, given the availability of the substance from fossil, as well as agricultural, sources. Despite decades of research, only steam reforming is used today on commercially relevant scales. Nevertheless, the interest in the topic remains steadily strong, in particular in heterogeneous catalysis. Studies of ion-molecule reactions have already provided substantial contributions to the field and enabled the identification of fundamental reaction pathways and key properties governing them. We use of this approach in order to reveal pathways and reaction kinetics in the C-H bond activation in methane. This way, we comprehensively elucidate the size-dependent reactivity of different cluster cations of tantalum - a metal, which has already been noted as a prospective candidate in the activation of C-H bonds. One of our main finding, in the combined experimental and theoretical study, reveals a significant difference in the reaction of single atoms compared to that of larger clusters. The single atom is the only size that facilitates an often-desired C-C coupling, which further suggests a possible intrinsic benefit of single atoms over clusters in the catalytic conversion of methane.

Assessing the environmental benefit of palladium-based single-atom heterogeneous catalysts for Sonogashira coupling — •DARIO FAUST AKL¹, DARIO POIER^{1,2}, SHARON MITCHELL¹, ROGER MARTI², GONZALO GUILLÉN-GOSÁLBEZ¹, and JAVIER PÉREZ-RAMÍREZ¹ — ¹Institute of Chemical and Bioenginnering, ETH Zurich, Switzerland — ²ChemTech, HEIA Fribourg, Switzerland

The Pd-Cu catalyzed Sonogashira coupling of terminal alkynes and aryl halides is a cornerstone organic transformation. A cradle-to-gate life cycle analysis (LCA) reveals a two orders of magnitude potential improvement in process footprint when replacing an organometallic Pd catalyst with a heterogeneous analogue. The latter could be easily separated permitting full Pd recovery and catalyst reuse. Heterogeneous catalysts based on isolated metal atoms (single-atom catalysts, SACs) demonstrate promising potential to synergize the benefits of solid and molecular catalysts for efficient Pd utilization. By anchoring Pd atoms on nitrogen-doped carbon we achieve full recovery of the metal, allowing catalyst reuse over multiple cycles. A hybrid process using the Pd-SAC with a homogeneous CuI cocatalyst is more productive than a fully heterogeneous bimetallic Pd-Cu SAC, which deactivates severely due to copper leaching. In some scenarios, the LCA-based metrics demonstrate the process footprint of the hybrid SAC system is leaner than the purely homogeneous counterpart already upon single reuse. Combining LCA with experimental evaluation could guide the design of reusable catalysts for more sustainable organic transformations.

Nature of the active species in low-temperature CO oxidation over Pt-CeO2 model catalysts — •Alexander Simanenko¹, Maximilian Kastenmeier¹, Lesia Piliai², Tomáš Skála², Yuliia Kosto², Nataliya Tsud², Sascha Mehl³, Mykhailo Vorokhta², Iva Matolínová², Yaroslava Lykhach¹, and Jörg Libuda¹ — ¹Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — ²Charles University, Prague, Czech Republic — ³Elettra-Sincrotrone Trieste SCpA, Basovizza-Trieste, Italy

The low-temperature CO oxidation has wide applications in energy production and exhaust gas cleaning. Pt-CeO2 catalysts with high Pt content allow achieving 100% CO conversion below room temperature. We investigated the nature of active sites on Pt-CeO2 catalysts under the conditions of low-temperature CO oxidation by means of synchrotron radiation photoelectron spectroscopy, resonant photoemission spectroscopy, and near ambient pressure XPS. Model Pt-CeO2 systems were prepared by reactive physical vapor co-deposition and annealed in UHV or O2 in order to obtain different types of platinum species on the surface. These included mainly Pt2+ species accompanied by a small number of Pt4+ species that were reduced to Pt2+ or metallic Pt during annealing. Exclusively, stable Pt4+ species were formed on a thick Pt-CeO2 catalyst with high Pt content after annealing in oxygen at NAP conditions. The results of our study showed that there is no reduction or oxidation of the Pt-CeO2 catalysts by CO below 450 K. These observations suggest that low-temperature CO oxidation on Pt-CeO2 catalyst does not follow a Mars-Van Krevelen mechanism.

Adsorption sites and thermal stability of Pt adatoms on  $Fe_2O_3(1\overline{1}02) - \bullet$ Ali RAFSANJANI ABBASI, FLORIAN KRAUSHOFER, LENA HAAGER, MORITZ EDER, JIRI PAVELEC, GIADA FRANCESCHI, MICHELE RIVA, MICHAEL SCHMID, ULRIKE DIEBOLD, and GARETH S. PARKINSON — Institute of Applied Physics, TU Wien, Austria

Oxide-supported Pt catalysts offer superior performance because of their high activity and/or selectivity for many important chemical reactions. However, the high cost of Pt and its susceptibility to CO poisoning are two drawbacks to its role as a catalyst. Downsizing catalyst clusters to single atoms is an effective way to reach maximum efficiency, and so-called "single-atom catalysis" is now an important field of research [1]. Nevertheless, stabilizing single Pt atoms on oxide supports without compromising catalytic activity is still a key challenge. Here, we present a surface science study to investigate the local binding environment of Pt adatoms deposited on Fe₂O₃(1 $\overline{102}$ ) – (1 × 1) under UHV conditions. Ex-

tensive STM and XPS studies at different Pt surface coverages on Fe₂O₃(1 $\overline{1}02$ ) revealed that Pt single atoms are highly stable at room temperature. STM images showed that Pt single atoms are adsorbing at two distinct sites with different apparent heights. Through an atom-by-atom analysis, the relative contributions of two types of Pt adsorption sites were determined for different surface coverages. Moreover, thermally induced sintering of the Pt single atoms is traced by means of XPS and STM.

**Comparison of Single Metal Atoms on a Fe2O3 Model Support** — •GARETH PARKINSON¹, ALI RAFSANJANI-ABBASI¹, LENA PUNTSCHER¹, FLO-RIAN KRAUSHOFER¹, PANUKORN SOMBUT¹, CHUNLEI WANG¹, MATTHIAS MEIER^{1,2}, MORITZ EDER¹, JIRI PAVELEC¹, GIADA FRANCESCHI¹, MICHELE RIVA¹, MICHAEL SCHMID¹, CESARE FRANCHINI^{2,3}, and ULRIKE DIEBOLD¹ — ¹TU Wien, Vienna, Austria — ²University of Vienna, Vienna, Austria — ³Università di Bologna, Bologna, Italy

Understanding how the local environment of a "single-atom" catalyst affects stability and reactivity remains a significant challenge. Fe2O3 is the most common iron-oxide support material utilized for SAC, but little is known about how metal adatoms bind at its surfaces. In this talk, I will compare and contrast the behavior of Pt, Rh, and Ir atoms on the flat, well-ordered (1x1) termination of Fe2O3(1-102). Using a combination of scanning probe microscopy and spectroscopic data, as well as theoretical calculations, I will demonstrate significant differences between the adsorption site and thermal stability of the metals, as well as differences in their interaction with water and CO.

O 4.1 Mon 10:30 H6

**Tracing a Weyl Nodal Line in 3D-k-space via ARPES** — •TIM FIGGEMEIER¹, MAXIMILIAN ÜNZELMANN¹, PHILIPP ECK², JAKUB SCHUSSER¹, JENNIFER NEU^{3,4}, THEO SIEGRIST^{3,5}, DOMENICO DI SANTE⁶, GIORGIO SANGIOVANNI², HENDRIK BENTMANN¹ und FRIEDRICH REINERT¹ — ¹EP VII, Universität Würzburg, Germany — ²TP I, Universität Würzburg, Germany — ³NHMFL, Tallahassee, FL, US — ⁴Nuclear Nonproliferation Division, ORNL, Oak Ridge, Tennessee 37831, US — ⁵FAMU-FSU, Tallahassee, FL, US — ⁶Center for Computational Quantum Physics, Flatiron Institute, New York 10010, US

In contrast to the more conventional Dirac nodal lines, Weyl nodal lines (WNL) are only twofold-degenerate and this degeneracy is robust against strong spinorbit coupling [1]. The occurance of WNL is guaranteed by the combination of a glide plane and time-reversal symmetry (TRS).

In this talk we will present a soft x-ray angle-resolved photoemission (ARPES) study where we will trace a WNL in 3D k-space throughout the Brillouinzone over a wide range of photon energies. The experimental results are compared to density functional and photoemission calculations. By utilizing dichroic ARPES experiments, we will moreover address the characteristics of the electronic wave functions around the WNL.

[1] M. Hirschmann et al.; Symmetry-enforced band crossings in tetragonal materials: Dirac and Weyl degeneracies on points, lines, and planes; Phys. Rev. Mat 5; 054202 (2021)

# O 4.2 Mon 10:45 H6

An intriguing property of Weyl semimetals (WSM) is that they feature topologically protected crossings of the spin-polarized valence and conduction bands in their three-dimensional bulk band structure. These crossing points – the Weyl points (WP) – can be considered as 'magnetic' monopoles, which, however, are not located in real space but rather in momentum space. The topological (monopole) character manifests itself in the momentum-dependence of the electronic wave functions, which is investigated in the paradigmatic WSM TaAs, using bulk-sensitive soft X-ray angle-resolved photoelectron spectroscopy combined with spin-resolved measurements and circular dichroism (CD) [1]. The latter addresses the local orbital angular momentum (OAM), which exhibits a non-trivial winding around the WP, similar to the Berry curvature, i.e., the *k*-space magnetic field. The momentum-dependent modulation of the OAM around the WP – observed in density functional theory calculations and CD-ARPES – thus denotes a direct signature for the Berry flux monopoles in TaAs.

O 4.3 Mon 11:00 H6 Lifting the Spin-Momentum Locking in Ultra-Thin Topological Insulator Films — Arthur Leis¹, Jonathan Hofmann¹, Michael Schleenvoigt², Vasily Cherepanov¹, Felix Lüpke¹, Peter Schüffelgen², Gregor Mussler², Detlev Grützmacher², •Bert Voigtländer¹, and F. Stefan Tautz¹ — ¹Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, 52425 Jülich, Germany — ²Peter Grünberg Institut (PGI-9), Forschungszentrum

Jülich, 52425 Jülich, Germany 3D topological insulators are known to carry 2D Dirac-like topological surface states in which spin-momentum locking prohibits backscattering. When thinned down to a few nanometers, the hybridization between the topological surface states at the top and bottom surfaces results in a topological quantum phase transition, which can lead to the emergence of a quantum spin Hall phase. Here, the thickness-dependent transport properties are studied on the example of BiSbTe3 films, with a four-tip scanning tunneling microscope. The findings reveal an exponential drop of the conductivity below the critical thickness. The steepness of this drop indicates the presence of spin-conserving backscattering between the top and bottom surface states, effectively lifting the spin-momentum locking and resulting in the opening of a gap at the Dirac point. Moreover, we probe the edge state conductance these films. The experiments provide a crucial step toward the detection of quantum spin Hall states in transport measurements.

Simultaneous AFM and STM measurements of native point Defects in the topological insulator  $Bi_2Se_3 - \cdot$ CHRISTOPH SETESCAK, ALEXANDER LIEBIG, ADRIAN WEINDL, and FRANZ J. GIESSIBL — Institute of Experimental and Applied Physics, University of Regensburg, Regensburg, Germany

The main properties of topological insulators (TIs) can be derived from the fact that their band structure is "twisted" compared to normal insulators, leading to the creation of gapless states at the surface. To observe these states and make them viable for application in novel technologies it is crucial that the materials delicate electronic structure is not disturbed by defects. So far, experimental characterization of the native point defects relies on scanning tunneling microscopy (STM) and accompanying density functional theory [1]. Here, we present simultaneous atomic force microscopy (AFM) and STM measurements of surface and subsurface defects in Bi₂Se₃. We find not only rarely-observed single Se surface vacancies, but also larger defects that are composed of multiple surface vacancies. The AFM channel furthermore allows us to determine the relative relaxation of surface defects by means of Kelvin probe force spectroscopy. This is especially valuable as surface Se vacancies contribute to unwanted charge doping of the TI. [1] J. Dai et al., PRL 117, 106401 (2016)

O 5.1 Mon 10:30 S051

Molecular nanostructures on metals vs. graphene — •MEIKE STÖHR Zernike Institute for Advanced Materials, University of Groningen, Netherlands To preserve the (functional) properties of either individual adsorbates or wellordered molecular assemblies upon adsorption on solid surfaces, the molecule substrate interactions have to be generally relatively weak. This can be achieved by introducing a decoupling layer between (metallic) surface and molecules. Among others, graphene has been shown to be a good choice towards this end due to its low density of states around the Fermi level [1]. For two different organic molecules, the similarities and changes will be discussed when adsorbed on metals and graphene, respectively [2]. In the second part, the formation of chevron-like graphene nanoribbons (GNRs) using Ullmann-type coupling will be presented in dependence of the substrate used. [3] While for Cu(111) and Ag(110) 1D metal-coordinated polymers were obtained GNR formation was successful on Au(111). The electronic properties of the GNRs were observed to display both a length and symmetry dependence. References: [1] S. Maier et al., Beilstein J. Nanotechnol. 12 (2021) 950. [2] J. Li et al., J. FRANKE¹ — ¹Freie Universität Berlin, Germany — ²MPI for the Structure and Dynamics of Matter, Hamburg, Germany — ³Carl von Ossietzky Universität Oldenburg, Germany — ⁴Humboldt-Universität zu Berlin, Germany

The combination of transition-metal dichalcogenides (TMDCs) and organic molecules into hybrid inorganic-organic systems is a field gathering much interest in recent years. The use of submonolayers of the TMDC MoS₂ as a decoupling layer in an STM junction is already well established and allows highly resolved dI/dV spectra. But 2D materials also have drawbacks: Their properties are highly dependent on their local structure, because defects influence their properties severely. Here we utilise these defects by anchoring the thiol-based molecule CF3-3P-SH (trifluoromethyl-*p*-terphenyl-thiol) into purposely created top-layer sulphur point defects in  $MoS_2$  on Au(111). One end-group of the anchored molecule is bound to the defect, allowing it to rotate around the anchoring point. On such molecules we observe a Kondo resonance. *Ab initio* molecular state near  $E_F$  depending on the configuration of the molecule with respect to the surface, which in turn gives rise to the observed Kondo resonance.

Disentangling the Complex Electronic Structure of an Adsorbed Nanographene: Cycloarene C108 — •JOSE MARTINEZ-CASTRO¹, RUSTEM BOLAT¹, QITANG FAN², SIMON WERNER², HADI AREFI¹, TANER ESAT¹, JÖRG SUNDERMEYER², CHRISTIAN WAGNER¹, J. MICHAEL GOTTFRIED², RUSLAN TEMIROV^{1,3}, MARKUS TERNES^{1,4}, and F. STEFAN TAUTZ¹ — ¹Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, 52425 Jülich, Germany — ²Department of Chemistry, Philipps-Universität Marburg, 35032 Marburg, Germany — ³II. Physikalisches Institut, Universität zu Köln, 50937 Köln, Germany — ⁴II. Institute of Physics, RWTH Aachen University, D-52074 Aachen, Germany.

We combine low-temperature scanning tunneling spectroscopy, CO functionalized tips and algorithmic data analysis to investigate the electronic structure of the molecular cycloarene C108 (graphene nanoring) adsorbed on a Au(111) surface. We demonstrate that CO functionalized tips enhance the visibility of molecular resonances, both in differential conductance spectra and in real-space topographic images. Comparing our experimental data with ab-initio density functional theory reveals a remarkably precise agreement of the molecular orbitals and enables us to disentangle close-lying molecular states only separated by 50 meV at an energy of 2 eV below the Fermi level. We propose this combination of techniques as a promising new route for a precise characterization of complex molecules and other physical entities which have electronic resonances in the tip-sample junction.

Tuning of structure of cyano-porphyrin self-assemblies on surfaces: from metals to bulk insulators — MAXIMILIAN AMMON¹, MIRUNALINI DEVARAJULU¹, YI LIU¹, MARTIN GURRATH², DOMINIK LUNGERICH³, •BINBIN DA¹, NORBERT JUX³, BERND MEYER², and SABINE MAIER¹ — ¹Department of Physics, FAU Erlangen-Nürnberg, Erlangen, Germany. — ²Interdisciplinary Center for Molecular Materials and Computer Chemistry Center, FAU Erlangen-Nürnberg, Erlangen, Germany. — ³Lehrstuhl für Organische Chemie II, FAU Erlangen-Nürnberg, Erlangen, Germany.

We discuss the adsorption and binding motifs in self-assembled Zn-pCNTPP networks on Au(111), KBr(001), and MgO(001) using low-temperature STM and nc-AFM combined with DFT. Zn-CNTPPs adopt a planar adsorption geometry with the macrocycle parallel to the surface on all three surfaces and assemble in well-ordered islands. While a global minimum structure is found on KBr due to a strong CN···K interaction, multiple and energetically nearly equivalent adsorption sites occur on MgO and Au. Therefore, commensurate adsorption over molecule-surface interactions is more important on MgO and Au, which the STM and nc-AFM data experimentally evidence.[1] However, since the interaction of porphyrins with Au(111) is stronger than on MgO(001), the phenyl rings are more inclined toward the surface, resulting in larger unit cells on Au(111) and also the binding motif of the cyanophenyl groups changes. [1] Ammon, M. et al., Surface Science, 723, 122097, 2022.

O 5.7 Mon 12:15 S051

**Comparing adsorption of triphenylene derivatives: metallic vs. graphitic surfaces** — •JORIS DE LA RIE¹, MIHAELA ENACHE¹, QIANKUN WANG¹, WENBO LU¹, NICO SCHMIDT¹, MILAN KIVALA², and MEIKE STÖHR¹ — ¹Zernike Institute for Advanced Materials, University of Groningen — ²Institute of Organic Chemistry, University of Heidelberg

Thin films of organic molecules show great promise for applications in future (nano)electronic devices, such as solar cells, light emitting diodes and transistors. A major factor in the performance of these films is the interface between substrate and molecular film. The interfacial properties depend on the balance between intermolecular and molecule-substrate interactions. Herein, we present a comparative study on self-assembled monolayers (SAMs) of a triphenylene-based donor molecule (HAT) on three substrates: Ag(111), graphene/Ir(111)

Location: S051

and graphene/Ni(111). We studied the structure of the SAMs by means of scanning tunneling microscopy and low-energy electron diffraction, and their interaction with the substrates by X-ray and ultraviolet photoelectron spectroscopy. On each substrate, HAT formed a close-packed hexagonal network that is commensurate with the substrate. From the photoelectron spectroscopy measurements we only found a weak (physisorptive) interaction between molecules and substrates. This goes against the established belief for SAMs on metal surfaces, where commensurate networks are principally formed on strongly interacting surfaces where the molecules chemisorb.

# The Number of KCl layers counts:

O 5.8 Mon 12:30 S051

**Thickness dependent Growth of Quinacridone on KCl on the Ag(100) surface** — •NIKLAS HUMBERG¹, RÉMI BRETEL², and MORITZ SOKOLOWSKI¹ — ¹Institut für Physikalische und Theoretische Chemie der Universität Bonn, Germany — ²University of Paris-Saclay, Institut des Sciences Moléculaires D'Orsay, France The epitaxial growth of the prochiral molecule quinacridone (QA) on a insulating KCl layer on the Ag(100) surface was investigated by STM. If QA is deposited onto a complete KCl layer, then the growth of QA structures is strongly dependent on the thickness of the KCl layer. For small amounts of QA on thin KCl layers small domains of parallel molecular chains were observed. The structure of these chains is identical to the chains that were previously observed on the Ag(100) surface. However, the repulsive substrate mediated interaction between neighboring chains that was observed on the Ag(100) surface cannot be observed on such KCl layers. Interestingly, depositing larger amounts of QA on such KCl layers leads to the formation of three-dimensional chain-like structures that show some similarities with the bulk crystal structures of QA.

Contrary to this, on thick KCl layers on the Ag(100) surface that are five or

more monolayers high dewetting of the molecules and a formation of threedimensional QA clusters was already observed for very small amounts of QA. These effects are explained by the interaction between the QA molecules and the silver substrate which still plays a role for thin layers but is suppressed by thick KCl layers.

# O 5.9 Mon 12:45 S051

Growth of chiral heptahelicene molecules on ferromagnetic Co and Fe thinfilm substrates — •MOHAMMAD REZA SAFARI, FRANK MATTHES, DANIEL E. BÜRGLER, and CLAUS M. SCHNEIDER — Peter Grünberg Institut (PGI-6), Forschungszentrum Jülich, 52425 Jülich, Germany

The discovery of chirality-induced spin selectivity effects [1,2], which result from an interaction between the electron spin and the handedness of chiral molecules, has sparked interest in surface-adsorbed chiral molecules due to potential applications in spintronics, enantioseparation, and chemical sensing. Here, we report growth studies of chiral heptahelicene molecules on two monolayers Fe on W(110), Co bilayer nano-islands on Cu(111), and for comparison on Cu(111) by low-temperature spin-polarized scanning tunneling microscopy. In all cases, the molecules remain intact, adsorb in a flat configuration, and exhibit specific in-plane orientations that reflect the symmetry of the substrate lattices. The Co and Fe layers remain out-of-plane magnetized after molecular adsorption. In addition, we are able to determine the helicity of individual molecules adsorbed on the highly reactive Fe and Co surfaces in a similar manner as previously reported for the less reactive Cu(111) surface [3]. These observations pave the way for further investigations of CISS effects in well-defined molecule-substrate systems on the single-molecule scale as a basis for theoretical modeling.

Autonomous non-contact molecular manipulation of nanocars based on reinforcement learning — •BERNHARD R. RAMSAUER¹, GRANT J. SIMPSON², LEONHARD GRILL², OLIVER T. HOFMANN¹, and ANDREAS JEINDL¹ — ¹Institute of Solid State Physics, NAWI Graz, Graz University of Technology, Petersgasse 16, 8010 Graz, Austria — ²Institute of Chemistry, NAWI Graz, University Graz, Heinrichstraße 28/IV, 8010 Graz, Austria

At the world's first race of nanocars at the CEMES-CNRS, in France, participants had to direct a nanocar across a specific *racetrack* [1]. In order to control their nanocar, they have to manipulate it via an STM-tip, without being in direct contact with the nanocar. The physics that govern the molecule*s movement and rotation is complex and involves the interaction between the tip and the molecule as well as the molecule and the substrate [2]. Thus, it requires time and effort for humans to be able to maneuver a molecule with a reasonable success rate. However, predicting the outcome of a performed action is unintuitive and often hard to predict for humans. Therefore, we developed an artificial intelligence (AI) based on reinforcement learning (RL) and show how it can be implemented to manipulate single molecules. The AI utilizes an off-policy learning algorithm known as Q-Learning. Our results can be the basis for more sophisticated techniques of non-contact molecular manipulations. This allows to identify and manoeuvre single molecules at will, building the basis for future bottom-up constructions of nanotechnology. [1] G. Rapenne et al., Nature Rev. Mater. 2, 17040 (2017) [2] G. J. Simpson et al., Nature Nanotech. 12, 604 (2017)

O 6.3 Mon 11:00 S052

Electronic and magnetic properties of an on-surface synthesized 2D metal organic framework — •AMINA KIMOUCHE^{1,2}, ROBERTO ROBLES³, NOEMI CONTRERAS¹, DANIEL RUIZ¹, and AITOR MUGARZA^{1,4} — ¹Institut Català de Nanociència i Nanotecnologia, Barcelona, Spain — ²Institut für Physik und Astronomie, Universität Potsdam, Potsdam, Germany — ³Centro de Fisica de Materiales CFM/MPC (CSIC-UPV/EHU), Donostia-San Sebastián, Spain — ⁴ICREA Institució Catalana de Recerca i Estudis Avançats, Barcelona, Spain 2D MOFs constitute a new class of designer materials where the coexistence of Dirac electrons and flat bands can lead to rich physical phenomena and to the realization of quantum phases such as topological or quantum anomalous Hall insulators.

Following the concepts of coordination chemistry, based on a surface-assisted self-assembly of the metal and organic components, we have carried out synthesis of Iron-hexaiminotriphenylene (HITP) MOFs on Au(111) substrate and characterized their electronic structure using scanning tunnelling spectroscopy (STS). On the other hand, ab-initio calculations of the observed structures indicate the presence of strong ferromagnetic interactions that persist under the influence of the Au substrate, indicating that the interaction with the Au substrate stabilizes even further the FM state on Fe3(HITP)2. We relate such strong magnetic interactions to the formation of a radical spin at the ligand that mediate the inter-ionic interactions.

Host guest chemistry and supramolecular doping in triphenylamine-based covalent frameworks on Au(111) — CHRISTIAN STEINER¹, LUKAS FROMM², JU-LIAN GEBHARDT², YI LIU¹, ALEXANDER HEIDENREICH², NATALIE HAMMER², •HEXIA SHI¹, ANDREAS GÖRLING², MILAN KIVALA³, and SABINE MAIER¹ — ¹Department of Physics, Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany — ²Department of Chemistry and Pharmacy, Friedrich-Alexander Universität Erlangen-Nürnberg, Erlangen, Germany — ³Organisch-Chemisches Institut & Centre for Advanced Materials, Ruprecht-Karls-Universität Heidelberg, Heidelberg, Germany

We report the host-guest interaction in triphenylamine-based covalently-linked macrocycles and networks on Au(111) using low-temperature scanning tunneling microscopy in combination with density-functional theory. Tripheny-lamine precursors formed macrocycles and 2D networks featuring carbonyl- and hydrogen-functionalized pores, creating preferred adsorption sites for trimesic acid (TMA) and halogen atoms. TMA binds through hydrogen bonds to the carbonyl sites while halogens selectively adsorb between two carbonyl groups

at Au hollow sites. Band structure calculations reveal that TMA adsorption reduces the electronic band gap of the triphenylamine covalent frameworks due to charge transfer, while the interaction of the halogens leads to a slight downshift of the bands.^[1].

O 6.5 Mon 11:30 S052

**Carbon-carbon coupling on inert surfaces via a radical deposition source proof-of-concept, challenges and perspective** – •GIANLUCA GALEOTTI¹ and MARKUS LACKINGER^{1,2} – ¹Deutsches Museum, Museumsinsel 1, 80538 Munich, Germany – ²Technische Universität München, James-Franck-Str. 1, 85748 Garching, Germany

The realization of one-atom thin C-C-bonded nanostructures is an ongoing challenge of nanotechnology. Those are, however, almost exclusively synthesized on metal surfaces, taking advantage of the catalytic activity to lower the required temperature for monomer activation below the desorption threshold. The development of methods for the direct synthesis on inert and insulating surfaces would be a milestone in the field, enabling studies of nearly unperturbed covalent nanostructures with unique electronic properties, such as graphene nanoribbons and-conjugated 2D polymers. Here, we will describe the development of a Radical Deposition Source (RaDeS) for the direct deposition of radicals onto inert surfaces for subsequent coupling into C-C bonded polymers. The radicals are generated en route by indirect deposition of halogenated precursors through a heated reactive tube, where the dehalogenation reaction proceeds. As a model system for inert surfaces, we use Ag(111) passivated with a closed monolayer of chemisorbed iodine. We will first illustrate the proof-of-concept with the synthesis of poly-para-phenylene from iodinated terphenyl precursors. Subsequently, we show how this approach can be used to overcome limitations of the conventional on-surface synthesis imposed by desorption, opening additional pathways for the synthesis of nanostructures.

O 6.6 Mon 11:45 S052 Carbon-based low-dimensional materials from first principles — •Niklas ENDERLEIN, ROLAND GILLEN, SABINE MAIER, and JANINA MAULTZSCH — Friedrich-Alexander-Universität Erlangen-Nürnberg

Bottom-up synthesis of carbon-based networks from molecular precursors offers a promising path to material design, where the structural, electronic, optical and vibrational properties, in principle, can be tailored through the choice of the precursor structures and functionalization. Prominent examples for this method are chevron-type graphene nanoribbons with defined topology [1] and highly controllable nitrogen incorporation [2], or multifunctional nanoporous graphene [3]. Considering the vast number of possible carbon-based networks, density functional theory (DFT) is a powerful tool for the preselection and design of promising molecular precursors based on the computational prediction of their intrinsic physical properties.

In this spirit, we present the results of recent DFT simulations on potentially interesting carbon-based networks that lend themselves to on-surface bottomup synthesis through Ullmann coupling of well-defined molecular precursors. We show how the electronic properties are significantly affected by the network topology and the structure of the molecular building blocks, potentially giving rise to novel phenomena. Our results inspire further efforts in the direction of molecular precursor design.

O 6.7 Mon 12:00 S052 Covalently linked molecules as 1D materials — •SAMUEL VASCONCELOS and MICHAEL ROHLFING — University of Münster

We performed first-principles calculations to address the problem of the formation and characterization of covalently linked structures with molecules as building blocks. We show that upon pressure a re-hybridization process takes place which leads to one-dimensional compounds resembling nanothreads, in which carbon atoms are all 4-fold coordinated and possess remarkable mechanical properties. We show that for porphyrins, the resulting 1D nanostructures have metallic character. Moreover, in the case of porphyrin-metal complexes, we find that the covalently linked structures may be a platform for the stabilization of straight metallic wires. We extend the methodology for the kekulene family, that throughout the same processes forms sp3 nanotubes.

# O 6.8 Mon 12:15 S052

**Peierls distortion and charge density waves in novel exfoliable 1D materials** — •CHIARA CIGNARELLA¹, DAVIDE CAMPI², and NICOLA MARZARI¹ — ¹THEOS and MARVEL, EPFL, Lausanne, Switzerland — ²Universita di Milano Bicocca, Milano, Italy

One-dimensional materials are extremely attractive due to their unique electronic properties and potentialities in next-generation applications. A highthroughput screening has provided a portfolio of more than 800 novel 1D/quasi-1D materials exfoliable from the 3D Van der Waals compounds, out of which we select a dataset of metallic chains as possible candidates for vias and interconnects. Often, their low-dimensional nature leads to dynamical instabilities in the form of Peierls distortions or charge density waves (CDW), which drive structural phase transitions at finite wavevectors. Here, we analyse the stability of this novel class of materials, identifying the reconstructed stable superstructure from the phonon modes. In order to get more insight into the mechanism of the CDW, we then investigate the nesting function and the critical role of the electron-phonon coupling, still unexplored in real quasi-1D systems.

O 6.9 Mon 12:30 S052

**Emulating organic molecular orbitals with artificial atoms on a surface** – •E. SIERDA, D. BADRTDINOV, B. KIRALY, E. J. KNOL, X. HUANG, M. I. KATSNEL-SON, G. C. GROENENBOOM, D. WEGNER, M. RÖSNER, and A. A. KHAJETOORIANS – Institute for Molecules and Materials, Radboud University, Nijmegen, The Netherlands

Bottom-up strategies to emulate the orbital structure of organic compounds is an exciting prospect, especially for molecules that are complex, unstable or hard to isolate, e.g. cyclobutadiene or triangulene. A successful implementation of such an emulator requires creating and coupling artificial atoms with multi-orbital character and possibility for orbital hybridization, on a platform that does not couple to the emulated structure. We emulate the electronic structure of planar organic molecules, using coupled, bottom-up constructed quantum dots (QDs) composed of atomic ions. We illustrate that compact clusters of ions, created via atom manipulation, exhibit a well pronounced state, localized within the semiconductor bulk band gap. For a pair of such QDs, we observe two states and identify them as bonding and anti-bonding via spatial maps. Linear chains of QDs exhibit emulated linear combinations of atomic orbitals with both sand p-like character. Furthermore, we construct artificial structures resembling sp2-hybridized organic molecules. A rich electronic structure with pronounced states is found in tunneling spectroscopy. By comparing their spatial maps with quantum-chemical simulations of the organic compound, we can identify the states as emulated organic orbitals, providing evidence for sp2 hybridization present in the artificial structures.

O 6.10 Mon 12:45 S052

Substrate-mediated polymorphism in monolayer self-assembly at liquidsolid interfaces — •ARASH BADAMI BEHJAT¹, WOLFGANG HECKL^{1,2}, MICHAEL SCHMITTEL³, and MARKUS LACKINGER^{1,2} — ¹Technical University of Munich, James-Franck-Str. 1, 85748 Garching, Germany — ²Deutsches Museum, Museumsinsel 1, 80538 Munich, Germany — ³Universität Siegen, Adolf-Reichwein-Str. 2, 57068 Siegen, Germany

Scanning-Tunneling Microscopy (STM) studies of molecular self-assembly at liquid-solid interfaces require atomically flat, chemically inert, and electrically conductive substrates, hence are almost exclusively carried out on graphite. Here, we demonstrate that Au (111) passivated with a monolayer of chemisorbed iodine (I-Au(111)) constitutes a viable alternative for fundamental studies. By using aromatic homologues of tricarboxylic acids as a versatile model system, and by a direct comparison between graphite and I-Au (111), we experimentally study and demonstrate the decisive influence of molecule-surface interactions. We present three cases of a novel substrate-mediated polymorphism. On I-Au(111), we consistently find polymorphs with lower packing density and optimized intermolecular binding-a clear indication for diminished molecule-surface interactions. This hypothesis was corroborated by probing the monolayer's thermodynamic stability in variable temperature STM experiments.

**Coherent Noise Removal for Scanning Probe Microscopy** — JENS OPPLIGER, DANYANG LIU, and •FABIAN DONAT NATTERER — Department of Physics, University of Zurich, Winterthurerstrasse 190, CH-8057, Switzerland

Despite the best efforts to isolate the weak signals in scanning probe microscopes from sources of noise, white and coherent noise remain major nuisances. While the presence of Gaussian white noise can be handled with temporal averaging, the influence of high-Q coherent noise, such as coming from ground-loops or mechanical resonances, is less straightforward to delete when rastering along the surface. Such noise leads to characteristic streaks and spurious Bragg peaks in the Fourier transform of two-dimensional data. Here we demonstrate a straightforward method to remove coherent noise using data-labelling and exemplify its working for quasiparticle interference and topographic imaging.

O 7.3 Mon 11:15 S053

General, Strong Impurity-Strength Dependence of Quasiparticle Interference — •SEUNG-JU HONG¹, JAE-MO LIHM^{1,2,3}, and CHEOL-HWAN PARK^{1,2,3} — ¹Department of Physics and Astronomy, Seoul National University, Seoul 08826, Korea — ²Center for Correlated Electron Systems, Institute for Basic Science, Seoul 08826, South Korea — ³Center for Theoretical Physics, Seoul National University, Seoul 08826, South Korea

Quasiparticle interference patterns induced by impurities contain information about electronic structures in momentum space. In this presentation, we show that the interpretation of quasiparticle interference patterns is not trivial and needs special care. Even in the simple case of a single-site impurity on the square lattice, the pattern is strongly dependent on the strength of impurity potential. For example, the wave vector with the strongest scattering differs by about 16% in spin-dependent JDOS and exact QPI computations. We also showed that this dependence can be analyzed by decomposing the pattern into the impurity-dependent T-matrix part and momentum-dependent Green function part. We applied our formalism to TaAs, an archetype Weyl semimetal with first-principles calculations. We find that the strong dependence on impurities is also present in TaAs. Thus, our work demonstrates that these quasiparticle interference patterns must be analyzed with care and needs more attention.

# O 7.4 Mon 11:30 S053

Real-space sub-femtosecond imaging of quantum electronic coherences in molecules — MANISH GARG¹, •ALBERTO MARTIN-JIMENEZ¹, MICHELE PISARRA², YANG LUO¹, FERNANDO MARTIN^{2,3,4}, and KLAUS KERN^{1,5} — ¹Max Planck Institute for Solid State Research, Stuttgart, Germany — ²Instituto Madrileño de Estudios Avanzados en Nanociencia (IMDEA Nano), Madrid, Spain — ³Universidad Autonoma de Madrid (UAM), Madrid, Spain — ⁴Condensed Matter Physics Center (IFIMAC), Universidad Autónoma de Madrid, Madrid, Spain — ⁵Institut de Physique, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

Tracking electron motion in molecules is the key to understand and control chemical transformations. Contemporary techniques in attosecond science have the capability to generate and trace the consequences of this motion in real time, but not in real space. Scanning tunnelling microscopy (STM), on the other hand, can locally probe the valence electron density in molecules, but cannot provide by itself dynamical information at this ultrafast time-scale. Here we show that, by combining STM and attosecond technologies, quantum electronic coherences induced in molecules by < 6 femtosecond long carrier-envelope-phase (CEP) stable near-infrared laser pulses can be directly visualized with angstrom-scale spatial and sub-femtosecond temporal resolutions. We demonstrate concurrent real-space and real-time imaging of coherences involving the valence orbitals of perylenetetracarboxylic dianhydride (PTCDA) molecules, and full control over the population of the involved orbitals.

### O 7.5 Mon 11:45 S053

Femtosecond Tip-Enhanced Coherent Anti-Stokes Raman Spectroscopy of a Single Graphene Nanoribbon — •Yang Luo¹, Alberto Martin-Jimenez¹, MANISH GARG¹, and KLAUS KERN^{1,2} — ¹Max Planck Institute for Solid State Research, Stuttgart, Germany — ²Institut de Physique, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

By integration of ultrashort laser pulses with a scanning tunneling microscope (STM) one can study the electronic and carrier dynamics with very high spatial and temporal resolution. Nevertheless, molecular vibrational modes at the single-molecule level are difficult to track, owing to the lack of energy resolution. To overcome this barrier, we have now integrated a local spectroscopic tool, combining ultrafast laser pulses with an STM-based tip-enhanced Raman spectroscopy (TERS). By performing TERS with femtosecond laser pulses, we have tracked vibrational coherences and phonon dephasing dynamics in a single graphene nanoribbon (7-GNR). The decoherence time (T2/2  $\sim$  440 fs) of

the phonons in a GNR has been obtained from the time-resolved coherent anti-Stokes Raman spectra. Temporal evolution of vibrational coherences (beatings) between different phonon modes in the GNR has been measured, which evolve on time scales as short as  $\sim 100$  fs. This work lays the foundation for investigating intramolecular vibrational coherences and vibronic dynamics with utmost spatial, temporal and energy resolutions, simultaneously.

O 7.6 Mon 12:00 S053

Coherent phonon spectroscopy on the nanoscale — SHUYI LIU¹, ADNAN HAMMUD¹, IKUTARO HAMADA², MARTIN WOLF¹, •MELANIE MÜLLER¹, and TAKASHI KUMAGAI³ — ¹Fritz-Haber-Institut, Berlin, Germany — ²College of Materials Science and Engineering, Hunan, China — ³Institute for Molecular Science, Okazaki, Japan

Coherent phonon (CP) spectroscopy is a powerful tool to monitor ultrafast lattice dynamics under nonequilibrium conditions, providing insight into microscopic interactions that dictate macroscopic material properties. In imperfect crystals, the excitation and relaxation of CPs will be susceptible to the nanoscale environment, calling for real-space observation of ultrafast lattice dynamics. We demonstrate nanoscale coherent phonon spectroscopy by means of ultrafast laser-induced scanning tunneling microscopy (STM) in a plasmonic junction. Comparison of the CP spectra with tip-enhanced Raman spectroscopy allows us to identify the involved phonon modes. In contrast to the Raman spectra, the relative CP intensities exhibit strong nanoscale spatial variations, which correlate with changes in the local density of states recorded via scanning tunneling spectroscopy. Our work introduces a new approach to study the ultrafast structural response at solid surfaces using optical STM.

O 7.7 Mon 12:15 S053

Construction of a dry low temperature STM — •SIMON GERBER¹ and WULF WULFHEKEL² — ¹Physikalisches Institut, Karlsruhe Institute of Technology — ²Physikalisches Institut, Karlsruhe Institute of Technology

Driven by rising helium prices, we design a dry, low temperature Scanning Tunneling Microscope with a closed helium cycle. We designed a compact dry four stage cryostat with an integrated dilution refrigerator which is cooled using helium from a 400 mW cold head. The STM is connected to the dilution refrigerator and allows measurements down to millikelvin temperatures. The system is mechanically decoupled at several points to minimize vibrations from the cold head reaching the STM. The microscope is positioned inside a split-coil magnet with magnetic fields up to 4T. Optical Access to the STM is possible in the parked position and allows fast tip and sample exchange. The tips and samples can then be prepared under UHV conditions. The complete cryostat and and the STM are home-built.

O 7.8 Mon 12:30 S053

**Probing tunneling processes into YSR states with microwaves** — •JANIS SIEBRECHT¹, HAONAN HUANG¹, PIOTR KOT¹, SUJOY KARAN¹, CIPRIAN PADURARIU², BJÖRN KUBALA², JOACHIM ANKERHOLD², ALFREDO LEVY YEYATI³, JUAN CARLOS CUEVAS³, and CHRISTIAN R. AST¹ — ¹Max-Planck-Institut für Festkörperforschung, Stuttgart, Germany — ²Institut für Komplexe Quantensysteme and IQST, Universität Ulm, Ulm, Germany — ³Departamento de Física Teórica de la Materia Condensada and Condensed Matter Physics Center (IFIMAC), Universidad Autónoma de Madrid, Madrid, Spain

Microwaves are an important tool in the manipulation of multi-level systems such as single spins on a surface, nitrogen vacancies in diamond or double quantum dots. Here we use a scanning tunneling microscope (STM) at a base temperature of 0.56 K to probe the intrinsic YSR states in a Vanadium tip in contact with a V(100) surface. The addition of an E-Band (60-90 GHz) microwave antenna at the junction opens the possibility to study the behavior of YSR states with AC driving- a scenario which has been subject to many theoretical but very few experimental studies. Using microwave-assisted tunneling, we gain insight into how the excited state participates in the tunneling process and how this is related to Andreev processes and parity conservation. Our results point at a new path, namely microwave manipulation of YSR states, which could be an important step towards using YSR states as qubits.

# O 7.9 Mon 12:45 S053

**Compressed fingerprint spectroscopy based on scanning microscopy** – •Bernd Kästner¹, Manuel Marschall¹, Arne Hoehl¹, Andrea Hornemann¹, Gerd Wübbeler¹, Selma Metzner¹, Piotr Patoka², Eckart Rühl², and Clemens Elster¹ – ¹Physikalisch-Technische Bundesanstalt, Berlin, Germany – ²Freie Universität Berlin, Germany

The infrared spectral region between 400 and 4000  $\rm cm^{-1}$  is called the fingerprint region, because the absorption features are unique to individual organic substances. Such a spectrum usually contains many peaks, making it difficult to link individual peaks to the substance. Consequently, the spatial mapping of substances requires spectral imaging, where at each point in space a complete spectrum needs to be recorded. Usually this can be achieved by spectrometers equipped with array detectors. Recently, scanning methods based on the optical nearfield and local thermal expansion with nanoscale spatial resolution have been developed allowing sub-diffraction spectral imaging. However, the inherently serial recording severely limits their imaging application due to long acquisition times involved and the resulting stability issues. In this work we demonstrate different strategies to significantly reduce the measurement time in spectral imaging measurement by compressing the measurement combined with a low-rank matrix reconstruction. Several examples from different fields of application will be discussed.

O 8.1 Mon 10:30 S054

**Dynamic structure changes of bare and modified Cu(111) during CO and** water activation — •ANDREA AUER¹, NICOLAS HÖRMANN², MIE ANDERSEN³, KARSTEN REUTER², and JULIA KUNZE-LIEBHÄUSER¹ — ¹Institute of Physical Chemistry, University of Innsbruck, Austria — ²Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany — ³Aarhus Institute of Advanced Studies, Denmark

CO is a key intermediate in the electro-oxidation of energy carrying fuels. Singlecrystal Cu(111) model catalysts efficiently electro-oxidize CO in alkaline media, under strong and continuous surface structural changes that lead to simultaneous strengthening of the CO and weakening of the OH binding, which makes the observed high activity possible.

Cu(111) modified with Ni(OH)₂ and Co(OH)₂ reveals strong morphological changes upon adatom deposition, which lead to a significant enhancement in the rate of the alkaline hydrogen evolution reaction (HER), one of the most important processes in the development of hydrogen-based energy conversion devices. Adatom modification influences the charge distribution at the solid/liquid interface by a decrease of the electric field strength negative of the potential of zero charge. This implies an easier reorganization of the interfacial water molecules facilitating charge transfer trough the double layer. The tendency of Cu(111) to restructure is found to dominate its electrochemical properties. The structural changes of the electrode surface are intimately related to the electric field at the solid/liquid interface and to its electrocatalytic activity, in general.

# O 8.2 Mon 11:00 S054

**Cu(111) reconstruction and oxidation imaged in oxygen free alkaline media with electrochemical scanning tunneling microscopy** — •TONI MOSER, AN-DREA AUER, and JULIA KUNZE-LIEBHÄUSER — Department of Physical Chemistry, University of Innsbruck, Innrain 52c, Innsbruck, Austria

Cu has recently gained attention due to its capability to efficiently oxidize CO at low overpotentials^[1]. However, the structural evolution of the surface at anodic potentials causing initiation of oxide formation under complete exclusion of oxygen has yet to be fully understood. While Cu(111) oxidation has previously been studied with electrochemical scanning tunneling microscopy (EC-STM), investigations without atmospheric oxygen and without contamination from dissolved glassware in alkaline media are sparse. Recent results indicate a significant delay in the anodic formation of Cu₂O in completely deaerated alkaline electrolyte, which indicates a significant impact of dissolved O2 on the oxidation of copper surfaces. In this work, we focus on the in-situ investigation of hydroxide adsorption on and oxidation of Cu(111) via EC-STM, eliminating atmospheric oxygen by conducting the experiments inside an Ar-filled glove box. The delayed formation of an amorphous oxide layer at anodic potentials and subsequent reduction processes at cathodic potentials, where a smoothening of the surface can be observed, as well as new insights into the hydroxide adsorption structure are presented.

Enhanced Field Effects at Protruding Defect Sites in Electrochemistry? – A Theoretical Evaluation — •SIMEON D. BEINLICH^{1,2}, NICOLAS G. HÖRMANN¹, and KARSTEN REUTER¹ — ¹Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany — ²Technical University of Munich, Munich, Germany Does electrochemistry at protruding surfaces sites differ significantly from that at ideal low-index surfaces? Intuitively, classical electrostatics suggest a local field enhancement at protruding sites. In this case, a dipole-field-like picture would

suggest a pronounced potential-dependence of adsorption energies at such sites. Here, we evaluate these dependencies for various adsorbates on vicinal Pt(111) surfaces using first-principles calculations in combination with a fully grand canonical approach [1]. Our results show an enhancement of the local electric field at pristine surfaces. However, it is lifted upon adsorption and hence does not cause the anticipated stronger field-effects. Nevertheless, we observe dramatic variations in the potential-dependence which can be rationalized from the differences in surface dipoles that form upon adsorption. These correlate with site coordination showing a consistent trend across adsorbates and adsorption sites.

We rationalize these findings and discuss how the adsorption behavior changes on defect-rich, undercoordinated surfaces in an electrochemical environment.

**Vapor adsorption on carbon nanomembranes (CNMs)** — •EN-NEITA KHAYYA, PETR DEMENTYEV, and ARMIN GÖLZHÄUSER — Faculty of Physics, Bielefeld University, 33615 Bielefeld, Germany

Intrinsically porous carbon nanomembranes (CNMs) demonstrate promising mass transfer properties with respect to separation of liquids and gases. To complement the permeation studies with CNMs, we introduce a spectroscopic experiment for probing adsorption of vaporous substances on their surface under ambient conditions. Polarization-modulation infrared reflection absorption spectroscopy (PM IRAS) is used to quantify the number of adsorbed species with the help of innovative calibration approaches, including azeotropic mixtures and immobilization in a polymer matrix. Water and alcohols are found to readily condense on supported CNMs yielding liquid-like interfaces. The results are consistent with the vapor permeation rates measured in free-standing CNMs.

## O 8.5 Mon 11:45 S054

Investigating Zirconium Nitride Cathodes for the Electrochemical Nitrogen Reduction Reaction — •TEODOR APETREI, SASWATI SANTRA, VERENA STREIBEL, and IAN D. SHARP — Walter Schottky Institut, Technische Universität München, Garching, Germany

The electrochemical nitrogen reduction reaction (NRR) can convert nitrogen to ammonia at ambient conditions. The most critical factor to activate N2 is to cleave the N-N triple bond. Transition metal nitrides have been proposed as electrocatalysts for the NRR, with computational studies predicting that N-N bond cleavage can be facilitated via a Mars-van-Krevelen mechanism. Herein, we experimentally test this prediction by investigating sputter-deposited ZrN thin films for the NRR. Our investigations indicate that small amounts of ammonia are indeed produced when pristine ZrN thin films are used as NRR cathodes. However, we also observe nitrogen loss and electrochemical instabilities, which could indicate a sacrificial rather than catalytic role of ZrN. Hence, to accelerate the rate-limiting N-N bond splitting step and facilitate nitrogen replenishment, we anchor Fe SACs onto ZrN. Our preliminary results indicate that high-temperature attachment of Fe SACs leads to overall smaller current densities. However, electrochemical measurements and comparative XPS and XRD studies of the pre- and post-NRR samples suggest an increased nitrogen stability within the Fe-modified ZrN films and improved electrochemical stability. Whether this Fe-modification also facilitates N-N bond dissociation and boosts the NRR activity is currently investigated.

Towards Understanding Platinum Degradation: Modelling the Growth of Nanoislands — •FRANCESC VALLS MASCARO¹, MARC T.M. KOPER¹, and MARCEL J. ROST² — ¹Leiden Institute of Chemistry, Leiden University — ²Huygens-Kamerlingh Onnes Laboratory, Leiden Institute of Physics, Leiden University Platinum is the catalyst of choice in many electrochemical energy conversion systems like fuel cells due to its superior activity. However, the stability of platinum catalysts is limited under fuel cell operation conditions. This degradation process has been extensively studied by cyclic voltammetry and inductively coupled plasma mass spectrometry (ICP-MS) [1, 2]. The origin of this degradation is most likely linked to the roughening of the surface due to the nucleation and growth of platinum nanoislands [3, 4, 5, 6]. In this work, we model, fully analytically and with the support from electrochemical data, the growth of these nanoislands on Pt(111) in perchloric acid. The model here presented successfully describes the surface growth taking place during the oxidation-reduction cycling. Different parameters such as the flux of adatoms and vacancies were obtained from the fittings between the model and the experimental data.

Neural network surrogates for kinetic Monte Carlo models of electrocatalytic surfaces — •Younes HASSANI ABDOLLAHI^{1,2}, JÜRGEN FUHRMANN³, and SEBASTIAN MATERA^{1,2} — ¹Institut f. Mathematik, Freie Universität Berlin, Arnimallee 6, 14195 Berlin, Germany — ²Fritz-Haber-Institut der Max-Planck-Gesellschaft, Faradayweg 4-6, 14195 Berlin, Germany — ³Weierstraß-Institut f. Angewandte Analysis u. Stochastik, Mohrenstr. 39 10117 Berlin, Germany

The kinetic Monte Carlo method (kMC) is the physically most sound approach for addressing the kinetic interplay of elementary processes at electrocatalytic surfaces but also comes at high computational costs. Therefore, computationally efficient surrogate models are highly desirable which allow the utilization of kMC simulation results in coarser scale simulations.

Using the oxygen reduction reaction on Pt(111) as a prototypical example, we investigate regression neural networks as surrogates to reproduce the stationary TOF as a function of all reaction conditions, i.e. electrostatic potential, concentrations, and temperature. We found that a relatively shallow perceptron with 2 layers of 32 and 32 neurons, respectively, and SiLU activation functions serve as an appropriate choice. We demonstrate the performance of this model with a varying number of kMC data points. Finally, we discuss how this model can be incorporated into a multiscale modeling approach, which addresses the interaction of transport and kinetics.

Two distinct 4f states in mixed-valent  $\text{TmSe}_{1-x}\text{Te}_x - \text{•}$ CHUL HEE MIN¹, MICHAEL HEBER², SIMON MÜLLER³, LUKAS WENTHAUS², MARKUS SCHOZ², DMYTRO KUTNYAKHOV², LENART DUDY⁴, HENDRIK BENTMANN³, FEDERICO PRESSACCO², MATTHIAS KALLÄNE¹, WOOJAE CHOI⁵, YONG SEUNG KWON⁵, FRIEDRICH REINERT³, and KAI ROSSNAGEL¹ - ¹IEAP, CAU Kiel, Germany -²DESY, Hamburg, Germany - ³EP7 and ct.qmat, University of Würzburg, Germany - ⁴Synchrotron SOLEIL, Saint-Aubin, France - ⁵Dep. of EMS, DGIST, South Korea

From the strong electron correlation effects in rare earth compounds, rich phase diagrams emerge with tunable ground states, which underlie a series of unique physical phenomena and quantum states, including quantum criticality, topological Kondo insulators, and diverse charge-neutral quasiparticle formations. However, despite their importance, the nature of such composite quasiparticles is difficult to characterize because all coherent spectral features develop in a similar way. Using angle-resolved photoemission spectroscopy (ARPES) together with time-resolved PES, we have addressed distinct coherent 4*f* features in unique mixed-valence TmSe_{1-x}Te_x. Our findings open the path for future investigations of small energy-scale excitations and may provide a framework for understanding the dynamics and entangled nature of correlated electrons.

Time- and angle-resolved photoemission study of magnetic topological insulators  $MnBi_2Te_4$  and  $MnBi_4Te_7 - \cdot PAULINA MAJCHRZAK^1$ , KLARA VOLCKAERT¹, DEEPNARAYAN BISWAS¹, DENNY PUNTEL², WIBKE BRONSCH², FEDERICO CILENTO², XING-CHEN PAN³, YONG CHEN^{1,3}, and SØREN ULSTRUP¹ - ¹Dept. of Physics and Astronomy, Aarhus University, DK - ²Elettra - Sincrotrone Trieste, IT - ³Advanced Institute for Materials Research, Tohoku University, JP

Van der Waals heterostructures comprising layers of intrinsically antiferromagnetic topological insulator (TI) MnBi₂Te₄ and non-magnetic TI Bi₂Te₃ offer a rich toolbox for engineering exotic quantum phenomena. Magnetic and transport properties of these materials are strongly affected by the interplay between bulk and surface states with divergent topologies resulting from hybridisation between the top layers.

Here, we disentangle those complex interactions in the time domain with TR-ARPES. We discuss the interband dynamics in bulk and surface states as a function of stacking and surface terminations for  $MnBi_2Te_4$  and  $MnBi_4Te_7$ . Our results fill a knowledge gap in understanding of interlayer coupling in  $MnBi_2Te_4$ -based heterostructures.

### O 9.3 Mon 15:30 H3

Electronic and phonon dynamics in 1T-TiSe₂ with ultrafast core-level transient absorption spectroscopy in the extreme ultraviolet — •TOBIAS HEINRICH¹, HUNG-TZU CHANG¹, SERGEY ZAYKO¹, MURAT SIVIS^{1,2}, and CLAUS ROPERS^{1,2} — ¹Max Plank Institute for Multidisciplinary Sciences, Göttingen, Germany — ²4th Physical Institute - Solids and Nanostructures, University of Göttingen, Germany

Extreme ultraviolet (XUV) transient absorption spectroscopy with high harmonic sources is ideally suited to investigate the complex interplay between lattice and electronic degrees of freedom on ultrafast timescale [1]. Here, we compare the experimental result of highly sensitive XUV transient absorption spectroscopy on the charge density wave (CDW) compound 1T-TiSe2 with density functional theory (DFT) simulations to disentangle electronic and phonon contributions to the transient absorption spectra. In addition to photo excited carriers we observe two coherently excited phonon modes that can be assigned to the  $A_{1g}$  optical mode (6 THz) and the  $A_{1g}^*$  (3.3 THz) amplitude mode associated with the CDW formation [2]. The modes show distinct spectral fingerprints which are reproduced by DFT calculations such that their dynamics can be individually analyzed. It is found that only the amplitude mode vanishes at higher fluences, corroborating the proposed mechanism of non-thermal CDW melting [3]. [1] A. R. Attar *et al.*, ACS Nano **14**, 11, 15829-15840 (2020)

Coherent phonon-driven transient modulation of a Dresselhaus-type spin splitting in *Td*-WTe₂ — PETRA HEIN¹, STEPHAN JAUERNIK¹, HERMANN ERK¹, LEXIAN YANG^{2,3}, YANGPEN QI^{4,5}, YAN SUN⁵, CLAUDIA FELSER⁵, and •MICHAEL BAUER¹ — ¹Institute of Experimental and Applied Physics, University of Kiel, Germany — ²State Key Laboratory of Low Dimensional Quantum Physics, Department of Physics, Tsinghua University, Beijing, China — ³Frontier Science Center for Quantum Information, Beijing, China — ⁴School of Physical Science and Technology, ShanghaiTech University, China — ⁵Max Planck Institute for Chemical Physics of Solids, Dresden, Germany

Time- and angle-resolved photoemission spectroscopy is used to study transient changes of the electronic structure in the Weyl-semimetal Td-WTe₂ in response to the excitation of coherent phonons. A Fourier-transform of the three-dimensional experimental data yields phonon-mode resolved insights into such coupling processes. Results of our analysis reveal a transient modulation of a Dresselhaus-type spin splitting of electronic bands that is selectively driven by the excitation of an interlayer shear mode of the layered compound [1]. The results provide real-time insights into electron-phonon coupled processes that are of vital importance for a light-driven topological phase transition in Td-WTe₂.

In materials with multiple competing orders, ultrashort light pulses can induce metastable states that are not accessible at thermodynamic equilibrium. One of such, the metallic hidden (H) phase of 1T-TaS₂, is of particular interest as it features an order-of-magnitude change in resistivity, promising for novel energy-efficient high-speed memory devices. We use time- and angle-resolved photoe-mission spectroscopy (trARPES) to investigate the electronic band structure and

formation dynamics of the metastable H-state in 1T-TaS₂. The band structure mapping of H-state reveals suppression of correlation effects and metallization, suggesting a critical role of interlayer stacking order of the TaS₂ sheets in the phase transition. The fluence-dependent dynamics provides strong evidence that the charge density wave amplitude mode governs a collective, ultrafast switching pathway to the H-state. This is further corroborated by demonstrating coherent control of the switching efficiency into the H-phase using a multi-pump-pulse excitation scheme.

Influence of carbon buffer layer on non-equilibrium carrier dynamics of epitaxial graphene and WS2/graphene heterostructures - •LUKAS BRUCKMEIER¹, NIKLAS HOFMANN¹, LEONARD WEIGL¹, JOHANNES GRADL¹, NEERAJ MISHRA^{2,3}, STIVEN FORTI², CAMILLA COLETTI^{2,3}, and Isabella GIERZ¹ — ¹Faculty for Physics, University of Regensburg, Regensburg, Germany – ²Center for Nanotechnology Innovation@NEST, Istituto Italiano di Tecnologia, Pisa, Italy — ³Graphene Labs, Istituto Italiano di Tecnologia, Genova, Italy The non-equilibrium photocarrier dynamics of epitaxial graphene on SiC(0001) have been studied in detail in the past. The fact that the graphene layer rests on a second two-dimensional carbon buffer layer (BL) - the well-known ( $6\sqrt{3} \times$  $6\sqrt{3}$ )R30° reconstruction - was believed to be of minor importance for the interpretation of the time-resolved data. We use time- and angle-resolved photoemission spectroscopy to show that photoexcitation of the graphene/BL heterostructure is followed by a short-lived transient decrease in binding energy of the Dirac cone indicating a transient charging of the graphene layer with excess electrons. We attribute the transient n-doping of the graphene layer to the resonant excitation of a direct electronic transition between the non-dispersive states of the BL located 0.5eV below the Fermi level and the Dirac cone. We further show that this direct electronic transition affects the charge transfer dynamics in epitaxial WS2/graphene/BL heterostructures.

# O 9.7 Mon 16:30 H3 Ultrafast phonon thermalization in a monolayer crystal — •Hyein Jung — Fritz-Haber-Institut der MPG

Understanding energy flow in semiconductors following a perturbation is key for future applications. Observing dynamic processes on their fundamental time scales enables studying energy transfer processes between intrinsic subsystems, and subsequently understanding the coupling between them. Here we study ultrafast lattice dynamics in monolayer WSe2, carried out using femtosecond (high-energy) electron diffraction (FED).

We studied the lattice response to laser excitation by probing laser-induced variations in Bragg peak intensities, which reflect changes in incoherent lattice vibrations (quantified by atomic mean squared displacements, MSD). We implement a novel approach to analyze such diffraction data, by which we disentangle element-specific vibrational responses in the sub-picosecond time domain.

Through this analysis, we observe a series of steps in the evolution of the lattice response through varying trends of the two elements (W, Se). These observations suggest a cascade of electron-phonon and phonon-phonon scattering processes occurring on short picosecond time scales. We interpret these by means of energy transfer between phonon groups using on ab-initio calculations of the partial phonon density of states phonon. These results demonstrate that our element-specific approach enables a deeper understanding of the cascade of e-ph and ph-ph energy transfer processes following excitation.

O 9.8 Mon 16:45 H3 k-dependent band gap renormalization in monolayer WS2 revealed by tr-

**ARPES** — •Niklas Hofmann¹, Alexander Steinhoff², Leonard Weigl¹, Johannes Gradl¹, Tim Wehling^{2,3}, Sivan Refaely-Abramson⁴, Neeraj MISHRA^{5,6}, STIVEN FORTI⁵, CAMILLA COLETTI^{5,6}, and Isabella Gierz¹ -¹University of Regensburg, 93040 Regensburg, Germany — ²University of Bremen, 28359 Bremen, Germany — ³University of Hamburg, 22607 Hamburg, Germany — ⁴Weizmann Institute of Science, 7610001 Rehovot, Israel — ⁵Center for Nanotechnology Innovation @NEST, Istituto Italiano di Tecnologia, 56127 Pisa, Italy – ⁶Graphene Labs, Istituto Italiano di Tecnologia, 16163 Genova, Italy Monolayer transition-metal dichalcogenides show strong enhancement of Coulomb interactions due to their reduced dimensionality with immediate effects on both the optical as well as the single-particle band gap. Photogenerated electron-hole pairs have been shown to result in a giant band gap renormalization that has been attributed to efficient screening of the Coulomb interaction. The corresponding band structure changes are predicted to show a pronounced momentum dependence that we resolve using time- and angle-resolved photoemission spectroscopy on monolayer WS2 supported by a graphene substrate. Excellent agreement with ab initio calculations allows us to disentangle the intricate interplay of different many-body contributions to the observed transient band structure renormalization with important implications for the optoelectronic properties of 2D semiconductors.

O 9.9 Mon 17:00 H3

Pump helicity-dependent anisotropic population dynamics in the topological insulator Sb2Te3 — •JAN BÖHNKE¹, HAYDAR ALTUG YILDIRIM^{1,3}, STEPHAN SCHMUTZLER¹, JAIME SÁNCHEZ-BARRIGA², OLIVER RADER², COR-NELIUS GAHL¹, and MARTIN WEINELT¹ — ¹Fachbereich Physik, Freie Universität Berlin, Berlin, Germany — ²Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Berlin, Germany — ³Leibniz-Institut für Astrophysik, Potsdam, Germany

The specific spin texture of Dirac cone like topologically protected surface states (TSS) and the long electron mean free path allow for spin-polarized currents at the surface of topological insulators. Optical control of such currents has been discussed controversially.

We investigated the role of direct and indirect population channels for the unoccupied TSS on Sb2Te3 in 2D momentum space by time and angle-resolved two-photon photoemission spectroscopy. Excitation with 1.55 eV photons leads to an initially anisotropic population of the Dirac cone, dependent on the helicity of the excitation pulse and the azimuthal orientation of the sample. The strongest anisotropy is found in the energy range of the warped Dirac cone. It exhibits predominantly a 3-fold symmetry originating from the symmetry group of the bulk material. This contribution accordingly does not correspond to a macroscopic current in the TSS. On a time scale of 100 fs the population anisotropy is masked by electrons scattering from the bulk conduction band into the TSS.

### O 9.10 Mon 17:15 H3

Spatio-temporal imaging of bright and dark excitonic quasiparticles in twisted TMD heterostructures — •Jan Philipp Bange¹, David Schmitt¹, Wiebke Bennecke¹, AbdulAziz AlMutairi², Guiseppe Meneghini³, Daniel Steil¹, R. Thomas Weitz¹, Sabine Steil¹, G. S. Matthijs Jansen¹, Samuel Brem³, Ermin Malic³, Stephan Hofmann², Marcel Reutzel¹, and Stefan Mathias¹ — ¹I. Physikalisches Institut, Georg-August-Universität Göttingen, Germany — ²Department of Engineering, University of Cambridge, U.K. — ³Fachbereich Physik, Philipps-Universität Marburg, Germany

In two-dimensional van-der-Waals semiconductors, the weak Coulomb screening of charge carriers leads to exciting new material properties, such as bright and dark excitons with large binding energies. Consequently, when creating a heterostructure from two transition-metal dichalcogenide (TMD) monolayers with a type II band alignment, interlayer excitons can be formed [1]. Because dark excitons are not directly accessible with optical techniques, the spatial and lateral dynamics on the fundamental nanometer length scale remain largely unexplored. How do dark and interlayer quasiparticles form, relax and diffuse in the presence of a heterojunction, stress fields and inhomogeneities? Here, we address this question using time-resolved momentum and dark-field photoemission microscopy which enables us to study the ultrafast formation dynamics of different excitonic species in twisted WSe₂/MoS₂ heterostructures. [1] Schmitt *et al.*, arXiv2112.05011 (2021).

# O 9.11 Mon 17:30 H3

SHG imaging microscopy of ultrafast charge-transfer dynamics in twisted TMDC heterostructures — •MARLEEN AXT, JONAS E. ZIMMERMANN, GERSON METTE, and ULRICH HÖFER — Fachbereich Physik, Philipps Universität Marburg, Germany

Two-dimensional heterostructures of transition metal dichalcogenides (TMDC) represent very well-defined model systems of van-der-Waals interfaces. Many material combinations feature a type-II band alignment, which can separate photoexcited electrons and holes into different layers through ultrafast charge transfer leading to the formation of so-called interlayer excitons or interface excitons.

We investigate the ultrafast charge-transfer dynamics in TMDC heterostructures as a function of the stacking angle using time-resolved second-harmonic generation (SHG) imaging microscopy. This experimental technique combines the advantages of SHG with high temporal and spatial resolution. For differently twisted  $MoS_2/WSe_2$  heterostructures the electron transfer from  $WSe_2$  to  $MoS_2$ after resonant excitation (1.70 eV) was found to depend considerably on the twist angle. The transfer time is reduced from 85 fs down to 12 fs when going from a larger rotational mismatch (16°) towards 2H-stacking (52°).

# O 9.12 Mon 17:45 H3

Spin and charge carrier dynamics at a CuPc/WSe₂ heterostructure – •SEBASTIAN HEDWIG¹, GREGOR ZINKE¹, BENITO ARNOLDI¹, MARTIN AESCHLIMANN¹, and BENJAMIN STADTMÜLLER^{1,2} – ¹Department of Physics and Research Center OPTIMAS, TU Kaiserslautern, Erwin-Schroedinger-Str. 46, 67663 Kaiserslautern, Germany – ²Institute of Physics, Johannes Gutenberg University Mainz, Staudingerweg 7, 55128 Mainz, Germany

2D-Van-der-Waals systems are a highly intriguing class of low dimensional materials with promising spin functionalities for future nanoscale spintronic applications. Here, we show our approach to control the spin and charge carrier dynamics of the Van-der-Waals material WSe₂ by the adsorption of CuPc molecules. We conduct time-, angle- and spin-resolved photoemission experiments to investigate the optically excited carrier dynamics at the K- and  $\Sigma$ - points of WSe2. After an initial spin-selective excitation at the K-point, depending on the pump light polarization [1], we observe that the subsequent intraband scattering from the K- to the  $\Sigma$ -point of the bare WSe₂ conduction band coincides with a change of the carriers spin polarization. Both, the optical excitation and the subsequent relaxation process can be actively modified by appropriate adsorption of CuPc. In particular, the dominant optical excitation at the K-point of WSe₂ is replaced by a direct interlayer excitation from the CuPc into the WSe₂ layer. We will show that the strength of the interlayer excitation can be tuned and controlled by the polarization of the exciting light field.

A Customized IRAS System for Investigations of Adsorbates on Metal-Oxide Single Crystals — •DAVID RATH, JIRI PAVELEC, ULRIKE DIEBOLD, MICHAEL SCHMID, and GARETH S. PARKINSON — Institute of Applied Physics, TU Wien, Austria

The IRAS system GRISU (GRazing incident Infrared absorption Spectroscopy Unit) was developed to investigate adsorbates on metal oxide single crystals in the research field of single-atom catalysis [1]. It combines the commercially available FTIR spectrometer Bruker Vertex 80v with an UHV chamber [2]. The compact design requires only one CF150 port for the main optical components, features five mirrors for beam guidance placed in HV and UHV environment and optimises the system's performance, flexibility, and usability. The result is a small controllable focal-spot diameter (max. 3 mm) on the sample, motorised optical

Angle-resolved photoemission spectroscopy (ARPES) combined with THz excitation enables the investigation of lightwave-driven Dirac currents in the surface state of topological insulators with sub-cycle time resolution [1]. At low THz frequencies and moderate effective field strengths of a few kV/cm at the surface, we have shown that the current dynamics is dominated by intraband acceleration of the electrons within the surface band of Bi₂Te₃.

Here, we will show how such experiments can be extended to the strong-field regime at driving frequencies of 25-40 THz. This is challenged by strong energy and momentum streaking of the photoelectrons after photoemission as well as the requirement of ultrashort pulses for photoemission which also introduce considerable energy broadening of the ARPES spectra. We will discuss how these challenges can be successfully overcome in order to enable lightwave-ARPES at field strength of ~1 MV/cm despite surface screening. This paves the way for visualizing strong-field phenomena such as high-harmonic generation (HHG) [2] and the emergence of Floquet-Bloch states directly in the band structure on a sub-optical-cycle time scale.

O 10.4 Mon 16:00 H4 Design of Model Single-Atom Catalysts: Metal Adatoms, Monomeric Oxide Units, and Mixed Surface Layers on Oxide Surfaces — •ZDENEK DOHNALEK - Physical and Computational Sciences Directorate and Institute for Interfacial Catalysis, Pacific Northwest National Laboratory, Richland, WA 99354, USA

Single-atom catalysts have attracted significant attention due to their ultimate metal efficiency and the promise of novel properties. The sublimation of oxides and metals is employed to design monodispersed model systems with supported metal adatoms, monomeric oxide units, and ordered mixed oxide surfaces. Scanning tunneling microscopy, ensemble-averaged electron spectroscopies, and density functional theory are employed to achieve an atomic-level understanding. Specifically, the deposition of (MgO)1 monomers and (MoO3)n oligomers is studied on anatase TiO2(101) via direct evaporation of MgO and MoO3 powders. While gas phase (MgO)1 is readily immobilized at room temperature, (MoO3)n transiently diffuse, agglomerate, and spontaneously decompose into the (MoO3)1 monomers. The transient mobility of the oligomers is the key to the self-assembly of the ordered overlayers of (MoO3)1. Metal adatoms and mixed oxide surfaces are synthesized by the sublimation of Rh onto Fe3O4(001). Higher substrate temperatures facilitate Rh incorporation into the surface, leading to ordered mixed Rh-Fe3O4(001). Cryogenic deposition temperatures stabilize Rh on the surface and allow for the preparation of the pure Rh adatom phase. The effect of temperature and adsorbates on the stability of such model catalysts is explored.

### O 10.5 Mon 16:30 H4

**Rh** and Ir single atoms on Fe₃O₄(001): local structure affecting cat-alytic properties — •MATTHIAS MEIER^{1,2}, ZDENEK JAKUB¹, JIRI PAVELEC¹, MICHAEL SCHMID¹, ULRIKE DIEBOLD¹, CESARE FRANCHINI^{2,3}, and GARETH S.  $PARKINSON^1 - {}^1$ Institute of Applied Physics, Technische Universität Wien, Vienna, Austria – ²Faculty of Physics and Center for Computational Materials Science, University of Vienna, Vienna, Austria – ³Department of Physics and Astronomy, Alma Mater Studiorum, Università di Bologna, Bologna, Italy

Single-atom catalysts are often supported by cheap oxides, such as iron oxides. As a model system [1], magnetite (Fe₃O₄), specifically its (001) facet has been used because it offers stable sites for single-atom adsorption up to high temperatures. Here, I will demonstrate how important the support is for the stability of single-atoms, as well as their catalytic properties. Rh and Ir [2] single atoms utilize Fe vacancies in the subsurface of the reconstructed Fe₃O₄(001) unit cell to incorporate into the surface layer. Changing the positions of Fe atoms in the support as part of the incorporation process enables the single atoms to be accommodated in a more favorable configuration than if they were adsorbing on top of the surface. Their catalytic properties are drastically affected by changes

in the atomic environment. Incorporation temperatures vary depending on both coverage and the presence or absence of adsorbates, such as CO.

O 10.6 Mon 16:45 H4

Atomic-Level Studies of  $C_2H_4$  on Clean and  $Rh_1$  Single-Atom Decorated  $Fe_3O_4(001) - \bullet$ PANUKORN SOMBUT¹, LENA PUNTSCHER¹, CHUNLEI WANG¹, MANUEL ULREICH¹, JIRI PAVELEC¹, ALI RAFSANJANI-ABASSI¹, MATTHIAS MEIER², ULRIKE DIEBOLD¹, CESARE FRANCHINI^{2,3}, MICHAEL SCHMID¹, and GARETH S. PARKINSON¹ - ¹Institute of Applied Physics, TU Wien, Austria - ²Faculty of Physics, Center for Computational Materials Science, University of Vienna, Austria - ³Alma Mater Studiorum, Università di Bologna, Bologna, Italy

The local binding environment of metal-oxide supported single-atom catalysts (SACs) determines how reactants adsorb and therefore plays a decisive role in catalysis. Here, we study how Fe₃O₄(001)-supported Rh₁ adatoms interact with ethylene (C₂H₄) using DFT, combined with experimental surface science techniques (TPD, XPS, and STM). We show that C₂H₄ physisorbs on the clean Fe₃O₄(001). We also identify and model different molecule orderings at different coverages that agree nicely with STM images and TPD data. Then, we study C₂H₄ adsorption at 2- and 5-fold coordinated Rh sites at the Fe₃O₄(001) surface, and show that the local environment has a strong effect on the adsorption properties: 2-fold Rh can adsorb two C₂H₄ molecules, while 5-fold Rh can only host a single C₂H₄ molecule. Finally, we investigate coadsorption of C₂H₄ with

CO, a vital step towards enabling the hydroformylation reaction, and show that this is feasible only at 2-fold coordinated Rh sites.

**Model catalysis of single atoms on ultrathin solid films** – •KAI Wu – College of Chemistry and Molecular Engineering, Peking University, Beijing 100871, China

Metal atoms at surfaces play a key role in catalysis and related disciplines. A new strategy is introduced to prepare ultrathin films like oxides on surfaces which are further utilized to prepare stablized metal atoms. Since the surface free energy of a bulk oxide is much lower than the chemical potential or free energy of the metal atoms, one can play the game by reducing the thickness of the oxide film, even down to one atomic monolayer, which is grown on a bulk metal substrate. In such a way, the chemical potential of the oxide thin film can be tweaked by the underlying bulk metal substrate. Once the chemical potential or free energy of the ultrthin oxide support is tuned to such an extent that it becomes comparable with those of the metal atoms, can one then stablize these metal atoms without additional measures. Such an approach may be termed as surface free energy strategy to prepare uncoordinated metal atoms at surfaces. Scince the metal atoms are truly unprotected and therefore their physicochemical properties could be intrinsic, in sharp contract to those of coordinated metal atoms prepared by surface coordination and crystal engineering strategies. In this presentation, several systems of the unprotected metal atoms including alkali and transition metal atoms on ultrathin films such as metallic oxides and carbides grown on bulk metal substrates are employed to explore surface catalysis.

Quantum Nuclear Effects in Thermal Transport of Semiconductors and Insulators — •HAGEN-HENRIK KOWALSKI¹, MATTHIAS SCHEFFLER¹, MARIANA ROSSI², and CHRISTIAN CARBOGNO¹ — ¹The NOMAD Laboratory at the FHI-MPG and HU, Berlin, Germany — ²MPI for Structure and Dynamics of Matter, Hamburg, Germany

Accounting for the nuclear motion is essential for the prediction of various material properties, from thermal conductivity to the relative stability of different polymorphs. Often, it is assumed that quantum nuclear effects (QNEs) are decisive at low temperatures, but that anharmonic effects can be neglected in this limit. Conversely, it is often presumed that anharmonicity is influential at elevated temperatures, but that QNEs are not active in this limit. In this work, we investigate the interplay of QNEs and anharmonicity by extending a recently proposed anharmonicity metric [1] to path integral molecular dynamics (PIMD). Our *ab initio* MD and PIMD calculations for solid Argon, Silicon, Lithium Hydrid, and Pentacene further substantiate that QNEs can have a massive impact even at room temperature and beyond, especially in weakly bonded systems [2]. Furthermore, we show that QNEs can induce strong anharmonic effects –beyond the applicability realm of perturbation theory– even at 0K. We discuss the underlying microscopic mechanisms and hence elucidate why QNEs and strong anharmonicity often go hand in hand in real materials.

Volume Dependence of Excitation Energies of Sodium Clusters in GW — •ŠTĚPÁN MAREK and RICHARD KORYTÁR — Department of Condensed Matter Physics, Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic

Prediction of molecular junction transport properties is a challenging task. One particularly complicated aspect of the problem is accurate description of binding between the molecule and the electrodes. Effect of image charges and nonground state properties of the molecule-electrode system are expected to induce significant error when using DFT to evaluate the junction properties. GW is a post-DFT method that is assumed to fix some of the problems of bare DFT approach. In this contribution, we explore the (size) convergence properties of spectrum of sodium clusters using GW, and compare it to predictions by DFT and HF. We discuss the strategies to remove quasi-degeneracies induced by symmetries of the clusters, and their impact on critical properties of the spectrum, namely gap and average level spacing. Our analysis serves as a guide towards convergence studies of molecular junctions using GW.

*Ab initio* phonon self-energies: To screen, or not to screen — •JAN BERGES¹, NINA GIROTTO², TIM WEHLING³, NICOLA MARZARI^{4,1}, and SAMUEL PONCÉ⁵ — ¹University of Bremen, Germany — ²Institute of Physics, Zagreb, Croatia — ³University of Hamburg, Germany — ⁴EPFL, Switzerland — ⁵UCLouvain, Belgium Location: H6

First-principles calculations of phonons are often based on the adiabatic approximation and a Brillouin-zone sampling that is not sufficient to capture Kohn anomalies. These shortcomings can be remedied through corrections to the phonon self-energy arising from the low-energy electrons. A well-founded correction method exists [Calandra, Profeta, and Mauri, Phys. Rev. B **82**, 165111 (2010)], which only relies on readily available (adiabatically) *screened* quantities. However, many-body theory suggests to use one *bare* electron–phonon vertex in the phonon self-energy [Giustino, Rev. Mod. Phys. **89**, 015003 (2017)] to avoid double counting. This can be seen as a limiting case of downfolding to *partially screened* phonons and interactions [Nomura and Arita, Phys. Rev. B **92**, 245108 (2015)]. We compare these approaches using the examples of TaS₂, MgB₂, ndoped MoS₂, and p-doped diamond. We confirm the robustness of the former method, while the latter allows for systematic improvements to describe correlations or metal–insulator transitions.

O 11.4 Mon 15:45 H6 Implementation of DFT+U+J and the minimum-tracking linear response method for polaron formation modeling — •ZIWEI CHAI^{1,3}, KARSTEN REUTER³, HARALD OBERHOFER^{1,2}, and LIMIN LIU⁴ — ¹Chair for Theoretical Chemistry, Technische Universität München — ²Chair for Theoretical Physics VII, Universität Bayreuth, Germany — ³Fritz-Haber-Institut der Max-Planck-Gesellschaft — ⁴School of Physics, Beihang University

In many oxides charge carriers localize as small polarons. However, treating them with semi-local first-principles density-functional theory (DFT) tends to be a challenge usually addressed by hybrid DFT or Hubbard-corrected DFT+U. We present our implementation of DFT+U+J based on a "tensorial" representation of the subspace and the "minimum-tracking linear response method" which can determine U and J parameters from first-principles in the CP2K package. We performed systematic tests to prove the validity of the implementation.

Finally, the formation of polarons can be modeled by either breaking the symmetry of the initial structure or imposing an implicit or explicit constraining potential on the local orbital occupation. On top of our DFT+U+J implementation, we thus present the subspace occupancy-constraining potential (SOCP) approach to simulate the formation of polarons by constraining the occupancy number of the relevant local orbitals. Any polaronic configuration can thus straightforwardly be accessed without the need to explicitly break the system's symmetry.

Signatures of molecular conformation in the evolution of DFT-based single molecule conductance — •HECTOR VAZQUEZ — Inst. of Physics, Czech Academy of Sciences

Single molecules placed between two nanoelectrodes represent the ultimate limit in downscaling of electronic components. Electron transport simulations based on DFT-NEGF have enabled the understanding of conducting junctions and the interpretation of experiments [1]. However, these computationally costly calculations are often carried out for a small number of representative junction structures. In contrast, in room temperature experiments, the geometry of the molecule is expected to change significantly.

Here we describe and apply an approximate method to calculate molecular conductance within DFT for thousands of geometries. By combining it with room-temperature molecular dynamics (MD) simulations of the junction [2], we obtain the evolution of conductance for thousands of structure-conductance points. We analyze several geometric parameters and their effect on conductance, including quantum interference. This analysis on large datasets of DFTbased calculations reveals the signatures of molecular structure on junction conductance.

Quantifying Interactions in Organic Monolayers — •PIERRE-MARTIN DOM-BROWSKI, STEFAN RENATO KACHEL, LEONARD NEUHAUS, TOBIAS BREUER, J. MICHAEL GOTTFRIED, and GREGOR WITTE — Philipps-Universität Marburg, Germany

The formation of molecular nanostructures is determined by the interplay of intermolecular and molecule-substrate interactions, whose experimental determination is challenging. Temperature-programmed desorption (TPD) is a wellestablished technique capable of quantifying these interactions, but its analysis is by no means trivial and therefore rarely done quantitatively for large adsorbates. In the present study, we analyse the desorption kinetics of the two organic semiconductors pentacene and perfluoropentacene from Au(111) and MoS2 surfaces to show the potential of TPD and highlight challenges for larger adsorbates. [1,2] Combining TPD with scanning tunnelling microscopy, work function measurements and theoretical modelling, we show that intermolecular interactions are dominated by the intramolecular charge distribution. We are further able to determine the coverage-dependent prefactor of desorption with unprecedented precision, which enables a correlation of the desorption signal with the activation of specific degrees of freedom of motion of adsorbed molecules. Lastly, we compare the differences in molecule-substrate interactions for the two substrates at hand, which reveals that entropy can stabilize organic monolayer films on MoS2 despite a weak molecule-substrate bond.

O 12.2 Mon 15:15 S051

Toward Understanding Thermal and Electric Properties of Single Molecular Junctions and Self-Assembled Monolayers — •MOHAMED IBRAHIM¹, PHILIPP WIESENER¹, LUKE O'DRISCOLL², MARTIN BRYCE², and ACHIM KITTEL¹ — ¹Oldenburg University, Oldenburg, Germany — ²Durham University, Durham, England

Over the last years, implanting organic molecules in devices is continuously attracting large attention because of their small size (nm scale), tunable electronic and thermal properties by manipulating individual atoms. Therefore, it is obvious to extend the field of thermoelectrics using molecules to cool devices and sensors very locally. A single layer of well organized molecules is formed and realized by the self assembly mechanism, which allows molecular moieties to be adsorbed spontaneously on a surface producing large domains. This motivated us to report here about the characterisation of selfassembled oligo phenylene ethynylene dithiol molecules (OPE3), and some specifically modified forms by mainly adding side groups to it on gold surfaces by means of X-ray photoelectron spectroscopy (XPS), reflected electron energy loss (REELS), and ultraviolet photoelectron spectroscopy (UPS). The results show that the unsubstituted OPE3 has a high densely packed SAM with a thickness 1.7 nm, while the presence of substituents, attached to the middle ring, led to variation of the SAM film thickness. This indicates changes in the geometric configuration of the  $\pi$  stacking of OPE3 especially, tilt angle and packing densities. Parent OPE3 REELS spectrum shows a band gap value of 2.01 eV which is totally different than the reported value in the literature.

of Novel Materials (MARVEL), École Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland —  2 Centro S3, CNR–Istituto Nanoscienze, 41125 Modena, Italy

Dynamical potentials are needed to predict accurate spectral, transport, and in general embedding properties of materials. The non-linearity introduced by the frequency changes at a fundamental level the problem to address, moving from the diagonalization of an operator, e.g., the Kohn and Sham Hamiltonian in density-functional theory, to the Dyson inversion of a self-energy. Here, we propose a novel treatment of frequency-dependence able to solve Dyson-like equations via an exact mapping to an effective non-interacting problem, extending to the non-homogeneous case the algorithmic inversion method (Chiarotti et al., PRR, 2022). A sum-over-poles representation for the self-energy, together with the static one-particle Hamiltonian, are used to build a (larger) effective Hamiltonian having the excitation energies of the system as eigenvalues and the Dyson orbitals as projections of the eigenvectors. As a case study, we consider the paradigmatic system of  $\rm S_r VO_3$  to compute accurate spectra and energetics of the material.

O 12.3 Mon 15:30 S051 **Molecular orientation and phase transitions of DHTAP** – •CLAUDIA LÓPEZ-POSADAS¹, MICHAEL GYÖRÖK¹, ANTONY THOMAS², THOMAS LEONI², OLIVIER SUN² CONTAD RECKTR² and RETER ZERRENDED D¹ ¹Institute of Experimental

POSADAS¹, MICHAEL GYÖRÖR¹, ANTONY THOMAS², THOMAS LEONI², OLIVIER SIRI², CONRAD BECKER², and PETER ZEPPENFELD¹ — ¹Institute of Experimental Physics, Johannes Kepler University Linz, Altenberger Str. 69, 4040 Linz, Austria — ²Aix-Marseille University, CNRS, CINaM, UMR 7325, F-13288 Marseille, France

The structure and orientation of 5,14-dihydro-5,7,12,14-tetraazapentacene (DHTAP) layers deposited on Cu(110), Cu(110)-(2x1)O and the Cu(110)/Cu(110)-(2x1)O stripe phase was studied using reflectance difference spectroscopy (RDS), Scanning Tunneling Microscopy (STM) and Low Energy Electron Diffraction (LEED). The evolution of the RDS signal allows to identify the sequential formation of up to three monolayers as well as a phase transition upon completion of the first one. On Cu(110), DHTAP molecules in the first monolayer are always lying flat with their long molecular axis aligned parallel to the [-110]-direction of the Cu(110) surface. However, for subsequent layers the orientation critically depends on the deposition temperature T. At T=240K the DHTAP molecules are mostly aligned parallel to the ones in the first layer, whereas at room temperature and above their preferential orientation is orthogonal to the molecules in the first layer, the coexistence of the two orientations can be observed at a critical temperature of T=270K. Finally, the main optical transitions and the orientation of the transition dipole moments of the DHTAP layers were extracted from the RDS spectra.

Nickel(II) Porphyrins on Metal Surfaces: Oxidation-State Tuning and Formation of a Supramolecular Mixed-Valence Adsorbate Structure — •JAN HER-RITSCH, QITANG FAN, MARIE-IRÈNE ALBUS, LUKAS RUPPENTHAL, LUKAS J. HEUPLICK, LEONARD NEUHAUS, TOBIAS WASSERMANN, and J. MICHAEL GOT-TFRIED — Philipps-Universität Marburg

Nickel tetrapyrrole complexes are structurally related to biologically relevant molecules (e.g., F430 cofactor, tunichlorin, nibalamine) and are promising precursors for novel functional interfaces. Here, we report on the influence of the interaction at the metal/organic interface on the electronic structure of a nickel octaethyl porphyrin (Ni(OEP)) monolayer on different coinage metal surfaces studied by XPS, UPS, STM, NEXAFS and LEED. On Ag(111), Ni(OEP) forms a mixed-valent adsorbate phase in which the Ni centers occur in two different oxidation states. The two separate peaks in the Ni 2p XP spectrum indicate that about 40% of the Ni centers are reduced. STM and LEED show an incommensurate superstructure with an ordered arrangement of the metal centers in different oxidation states. Further insights into the valence electronic structure were obtained by UPS and NEXAFS. On the more reactive Cu(111) surface, Ni(OEP) forms a long-range ordered structure in which nickel centers are uniformly reduced; whereas on the most inert Au(111) surface, the oxidation state of the Ni centers remains unaffected by adsorbate interactions.

O 12.5 Mon 16:00 S051

Electronic and structural properties at the NiTPP/O-Cu(100) interface — •JONAH ELIAS NITSCHKE¹, HENNING STURMEIT¹, IULIA COJOCARIU², VITALIY FEYER², ALESSANDRO SALA², ANDREAS WINDISCHBACHER³, PETER PUSCHNIG³, STEFANO PONZONI¹, GIOVANNI ZAMBORLINI¹, and MIRKO CINCHETTI¹ — ¹Department of Physics, TU Dortmund University, Germany — ²Peter Grünberg Institut (PGI-6), Forschungszentrum Jülich, Germany — ³Institute of Physics, University of Graz, Austria Depending on the strength of the molecule-substrate interaction, charge transfer, chemical reactions or a redistribution of the electronic cloud may occur at organic-metal interfaces. Here, we investigate the structural and electronic properties of Nickel tetraphenylporphyrin molecules (NiTPP) deposited on oxygenpassivated Cu (100) surface. By using a multi-technique approach, which combines LEED and STM, we reveal a coverage dependent superstructure with multiple domains that ultimately reduces into a single unit cell.

In the latter configuration, STM measurements show that the NiTPP molecules adsorb either with the macrocycle planar to the surface on in a saddle-shape configuration, with the pairs of opposite pyrrole rings tilted upwards. STS and photoemission orbital tomo-graphy measurements show that, contrary to the NiTPP adsorbed on the bare Cu(100) surface, where a significant charge transfer is observed, the oxygen overlayer quenches the charge transfer at the interface, thus offering a simple approach to physically decouple of the molecular film from the underlying substrate.

O 12.6 Mon 16:15 S051

Surface Chemical Bond and Molecular Topology of Polycyclic Aromatic Systems — •LUKAS RUPPENTHAL¹, FLORIAN MÜNSTER¹, BENEDIKT P. KLEIN¹, JAN HERRITSCH¹, LEONARD NEUHAUS¹, STEFAN R. KACHEL¹, PENGCAI LIU², XING-YU CHEN², JIAWEN CAO², LARS E. SATTLER³, SEBASTIAN M. WEBER³, QI-TANG FAN¹, GERHARD HILT³, XIAO-YE WANG², and J. MICHAEL GOTTFRIED¹ — ¹Department of Chemistry, Philipps-University Marburg, Germany — ²College of Chemistry, Nankai University Tianjin, China — ³Institute of Chemistry, Carl von Ossietzky University Oldenburg, Germany

Metal/organic interfaces have a large impact on the performance of organic (opto-)electronic devices. Therefore, the detailed understanding of their chemical, electronic and geometric structure is important for the further technological development. Many common organic semiconductors contain  $\pi$ -electron systems with alternant topologies, whereas non-alternant alternatives have only recently found increasing attention due to their unusual electronic properties. Here, we compare the alternant polycyclic aromatic molecule pyrene with its non-alternant isomers acepleiadylene and azupyrene regarding their interaction with Cu(111) surface, using PES, NEXAFS, TPD and STM. The non-alternant isomers are also interesting as molecular models of graphene defects, e.g. azupyrene for the Stone-Wales defects. In all cases, the non-alternant isomers show increased metal/molecule-interaction due to their reduced HOMO-LUMO gap, which brings the LUMO energetically closer to the Fermi energy of the metal, causing stronger hybridization with electronic states of the metal surfaces.

# O 12.7 Mon 16:30 S051

Tailoring the organic-semiconductor/metallic interface: From self-assembly to heteromolecular phases of carboxylic acids on Ag surfaces — • MATTHIAS Blatnik, Veronika Stará, Anton Makoveev, Jakub Planer, Thomáš Krajňak, Pavel Procházka, and Jan Čechal — CEITEC BUT, Brno, CZ Atomic-level understanding of the metal/organic-semiconductor interface has become paramount in the strife for the development and fabrication of more efficient organic electronic devices in recent years. Interfacial properties are crucially linked to molecule-molecule and molecule-substrate interactions, molecular functionalization (e.g., deprotonation), a precise energy level alignment, substrate termination or the formation of multi- or heterolayers with a different organic compound. All these have to be well understood through the study of model systems in ultra-clean conditions before technological advances can be achieved. Here, we present a model system of self-assembled aromatic carboxylic acids (e.g., 4,4' Biphenyl Dicarboxylic Acid, 1,3,5-Benzenetribenzoic Acid) on Ag surfaces (orientations (100) and (111)). We explore the effects of the metal substrate's orientation on formation and growth of single molecular phases, introduce a monolayer thick layer as a charge injection layer and study the formation of a heteromolecular compound with an additional organic material (e.g., pentacene). We employ low energy electron microscopy (LEEM) and diffraction (µLEED), as well as STM and XPS to give a real-time view and detailed information on nucleation and growth of the molecular phases and transformations and the chemical composition.

# O 12.8 Mon 16:45 S051

Highly ordered commensurate structures of merocyanines on Ag(100) — •ANNA JULIANA KNY¹, MAX REIMER², NOAH AL-SHAMERY¹, RITU TOMAR¹, THOMAS BREDOW¹, SELINA OLTHOF², and MORITZ SOKOLOWSKI¹ — ¹Institut für Physikalische und Theoretische Chemie der Universität Bonn, Germany — ²Department für Chemie der Universität zu Köln, Germany

Vacuum deposited films of the merocyanine molecule 2-[5-(5-dibutylaminothiophen-2-yl-methylene)-4-*tert*-butyl-5*H*-thiazol-2-ylidene]-malononitrile (HB238) and its derivatives have been investigated in the context of organic solar cells [1].

Although the specific structural order in these films is important for the optical properties, only very little is known about the adsorption and ordering of merocyanines on surfaces. Therefore, we investigated monolayers of HB238 on a Ag(100) surface by SPA-LEED, STM, XPS, UPS, and DFT calculations.

Upon deposition onto the Ag(100) surface at room temperature the formation of a commensurate superstructure is observed. It is composed of homochiral HB238 aggregates of four molecules. We discuss the surface bonding and structure formation in dependence of the specific functional groups and, furthermore, the sterically demanding donor substituents. For the role of the latter one, we also investigated derivatives of HB238 on Ag(100). The merocyanines were synthesized and kindly provided by the group of Prof. K. Meerholz (Cologne).

Supported by the DFG through the research training group 2591. [1] JACS 137 (2015) 13524.

Van der Waals Heteroepitaxy: Intrinsic Epitaxial Alignment of Perfluoropentacene Films on Transition Metal Dichalcogenides — •MAXIMILIAN DREHER, DARIUS GÜNDER, and GREGOR WITTE — Philipps-University Marburg, Germany

In this work, we have studied the formation and azimuthal alignment of crystalline adlayers of the organic semiconductor (OSC) perfluoropentacene (PFP) on the basal plane of several transition metal dichalcogenides (TMDC) single crystals, which are further compared to graphite and hBN. The quite inert basal planes of TMDCs enable an unrestricted growth of OSCs without the requirement of relaxation in terms of commensurability at the interface, since molecules exhibit a stronger interaction among each other than with the substrate. Nevertheless, the crystalline PFP multilayers exhibit distinct azimuthal twist angles relative to the substrate surface, which we could rationalize by so called 'on-line coincidences' introduced by Forker et al. recently. [1] Here, the molecules do not favor a specific adsorption site at the interface as it is often described by commensurate superstructures. Instead the bulk crystal structure remains unperturbed down to the interface, but a specific twist angle is adopted, where molecules avoid unfavored adsorption sites. The extreme sensitivity of the resulting twist angles by small deviations in the crystal structure enabled us further to use the large thermal expansion of the OSC to control the twist angles by changing the substrate temperature during deposition. [1] Forker et al., Soft Matter 13, 1748-1758 (2017) [2] Dreher et al., Chem. Mater. 32, 20, 9034-9043 (2020)

# O 12.10 Mon 17:15 S051

Steering Self-Assembly of Three-Dimensional Iptycenes on Au(111) by Tuning Molecule-Surface Interactions — LUKAS GROSSMANN^{1,2}, •EVA RINGEL^{1,2}, WOLFGANG HECKL^{1,2}, and MARKUS LACKINGER^{1,2} — ¹Deutsches Museum, Museumsinsel 1, 80538 München — ²Technische Universität München, Physics Department, James-Franck-Strasse 1, 85748 Garching

Three-dimensional organic molecules have been neglected in studies on surfaces, even though their self-assemblies exhibit a far greater variability than their planar counterparts. While planar molecules adsorb mostly flat on surfaces, three-dimensional molecules can adopt vastly different adsorption geometries. This additional degree of freedom can result in self-assembly of entirely different supramolecular structures. Moreover, adsorption geometries can be steered by tuning molecule-surface interactions, thereby providing a new means for 2D crystal engineering. In this respect, iptycenes are highly stable, but currently underexplored model compounds. Here, we study self-assembly of three-fold symmetric triptycene derivates with extended anthracene blades on Au(111) surfaces. Additionally, the influence of intrinsic dipole moments was investigated by comparing analogs with peripheral fluorine substitution. All structures were resolved by Scanning-Tunneling-Microscopy under ultra-high vacuum conditions. On pristine Au(111), the molecules maximize the area of contact, whereas iodine-passivation affords hexagonal porous structures that feature optimized molecule-molecule interactions through face-to-face stacking of all anthracene blades.

Adsorption of Submonolayer Coverages of Phenylphosphonic Acid on Rutile TiO2(110) — •ALEXANDER WOLFRAM¹, MAXIMILIAN MUTH¹, JULIA KÖBL¹, NATALIYA TSUD², SASCHA MEHL³, HANS-PETER STEINRÜCK¹, and OLE LYTKEN¹ — ¹Friedrich-Alexander Universität Erlangen-Nürnberg, Lehrstuhl für Physikalische Chemie 2, Egerlandstr. 3, 91058 Erlangen, GER — ²Charles University, Faculty, of Mathematics and Physics, Department of Surface and Plasma Science, Holešovičkách 2, Prague, 18000, Czech Republic — ³Elettra-Sincrotrone Trieste SCpA, Strada Statale 14, km 163.5, Trieste, Basovizza, 34149, Italy

The interfaces of oxide surfaces with organic molecules are crucial for the performance of devices, such as dye-sensitized solar cells, sensors and organic electronics. All these devices contain interfaces where organic molecules are bound to surfaces, often using covalent anchoring groups. These anchoring groups strongly influence the interface and thus the device performance. An interesting anchoring group is the phosphonic acid group, which is well known to bind strongly to oxide surfaces. At ELETTRA sinchrotrone in Trieste we investigated submonolayer coverages of phenylphosphonic acid on a rutile  $TiO_2$  (110) surface with high-resolution X-ray photoelectron spectroscopy (XPS) and near-edge Xray absorption fine structure (NEXAFS) spectroscopy. Based on the changes in the O 1s and P 2p core levels, we are able to identify the different binding motifs present on the surface at different temperatures, while the NEXAFS intensities gives us information about the orientation of the phenyl moiety.

O 12.12 Mon 17:45 S051 Accurate determination of adsorption-energy differences of metalloporphyrins on TiO2(110) 1x1 — • MAXIMILIAN MUTH, ALEXANDER WOLFRAM, EL-MAR KATAEV, JULIA KÖBL, HANS-PETER STEINRÜCK, and OLE LYTKEN — Univ. Erlangen-Nürnberg

A deeper knowledge of the behavior between porphyrin molecules and the rutile TiO2(110) surface and is of crucial importance for the development of new applications. Especially the usage of such systems in photocatalysis or solar cells are promising possibilities. Therefore, we investigated the adsorption energy of three different metallo-tetraphenylporphyrins (MTPP M = Mg, Co, Zn). Un-

A new setup for dimensional nanometrology using soft X-rays — •LEONHARD LOHR¹, RICHARD CIESIELSKI¹, ANALÍA FERNÁNDEZ HERRERO², ANDREAS FISCHER¹, ALEXANDER GROTHE¹, FRANK SCHOLZE¹, and VICTOR SOLTWISCH¹ — ¹Physikalisch-Technische Bundesanstalt (PTB), Abbestraße 2-12, 10587 Berlin, Germany — ²Helmholtz-Zentrum Berlin für Materialien und Energie, Albert-Einstein-Straße 15, 12489 Berlin, Germany

Measuring nanostructured surfaces on small test patterns on dies from semiconductor fabs is an important metrology challenge. The geometrical dimensions of metrology test structures, such as linear gratings, must be determined with uncertainties in the sub-nm range. By using methods such as small angle X-ray scattering or X-ray fluorescence under grazing incidence, the photon beam spot size becomes too large for sufficient accurate measurements.

We present a new setup, mounted on the soft X-ray beamline in PTB's laboratory at the electron storage ring BESSY II. This setup works with synchrotron radiation in an ultra-high vacuum and with lubricant-free mechanics. Its small and compact design enables to detect scattered monochromatic soft X-rays under angles of incidence up to 30 degrees. The setup reduces photon beam spot size and covers diffraction patterns like them from scattered hard X-rays under grazing incidence. Depending on the incident photon energy, fluorescence from small excited regions of the sample can be measured simultaneously.

We present first measurement results from small test patterns which are located by imaging the surface using a large photon beam.

### O 13.2 Mon 15:15 S052

Synthesis of metal sulfide nanoribbons on graphene by self-assembly — •XUEJIAO ZHANG, KELVIN ANGGARA, VESNA SROT, XU WU, PETER A. VAN AKEN, and KLAUS KERN — Max Planck Institute for Solid State Research, 70569 Stuttgart, Germany

Bottom-up synthesis of nanostructures on surface have relied on the selfassembly of nanoscale building blocks. The diversity of accessible nanostructures however have been constrained by the limited choice of atomic and molecular building blocks that can be evaporated on surface. Here we bypass this limitation by using complex inorganic ions generated from electrospray ionization as building blocks to synthesize nanostructures on surfaces. We deposited HMonS3n+1** (n = 4-6) ions onto a freestanding single-layer graphene by Electrospray Ion-Beam Deposition (ESIBD), and imaged the resulting nanostructures by aberration-corrected Scanning Transmission Electron Microscopy (STEM). The molecules were observed to form anisotropic, single-layered, crystalline MoS2 nanoflakes (< 100 nm2), which in turn self-assembled into MoS2 nanoribbons extending as far as 1  $\mu$ m. The first observation of such nanostructures evidences the potential of this approach to prepare previously inaccessible nanomaterials on surfaces.

**Ni kagome lattice on Pb(111)** — •GUSTAV BIHLMAYER¹, YEN-HUI LIN², STE-FAN BLÜGEL¹, and PIN-JUI HSU² — ¹Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich, D-52425 Jülich, Germany — ²Department of Physics, National Tsing Hua University, Hsinchu, 30013, Taiwan Deposition of atomically thin films on well-ordered surfaces sometimes allows realizing new structural motives that have no correspondence in the bulk phases. Here we observe that, at low temperatures, submonolayer growth of Ni on a Pb(111) substrate leads to well-ordered, hexagonal islands. In scanning tunneling microscopy (STM) two types of edges with very different apparent height and scattering properties are observed. From density functional theory (DFT) calculations and STM images with atomic resolution we conclude that the Ni atoms form a kagome lattice and the islands show saw-tooth edges. Comparison of STM and DFT data suggests that some Ni atoms are incorporated in the subsurface layer and give rise to the low observed height of the islands and the strong fortunately, temperature programmed desorption, a typical method for the determination of adsorption energies is not applicable for this particular system because of the irreversible adsorption of the monolayer in direct contact to the TiO2-surface. For this reason, instead, we compared the adsorption-energy of the three MTPPs relatively to each other by using a layer exchange experiment. We adsorb mixtures of always two different MTPPs on top of each other and allow the molecules to diffuse during a heating ramp. Eventually, an equilibrium state forms in which the MTPP with the higher adsorption-energy will enrich in the monolayer in direct contact with surface while the weaker adsorbing MTPP will be enriched in the multilayer. After further heating for multilayer desorption we determine the concentrations of the MTPPs found in the remaining monolayer by using XPS and use them to calculate the difference in adsorption-energy of MTPPs via the equilibrium constant.

Location: S052

difference observed at their edges. From the DFT calculations we conclude that the Ni island is non-magnetic and the electronic structure shows some characteristics of the kagome lattice, i.e. flat bands also visible in scanning tunneling spectra.

How covalent chemistry affects the surface dipole of metallic nanostructures — RUSTEM BOLAT^{1,2}, •JOSE M. GUEVARA¹, MARVIN KNOL^{1,2}, PHILIPP LEINEN¹, RUSLAN TEMIROV^{1,2,3}, OLIVER T. HOFMANN⁴, REINHARD J. MAURER⁵, F. STEFAN TAUTZ^{1,2}, and CHRISTIAN WAGNER^{1,2} — ¹Forschungszentrum Jülich, Germany — ²RWTH Aachen University, Germany — ³Universität zu Köln, Germany — ⁴Graz University of Technology, Austria — ⁵University of Warwick, UK

Scanning probe experiments often encounter nanostructures of undercoordinated metal atoms, either as the investigated system or at the tip apex. While the electrostatic properties of extended planar surfaces are textbook material, the interaction of metal adatoms with the surface and with each other opens an interesting playground in which our intuition for the covalent chemistry of such metal structures is limited.

Here we investigate Ag and Au adatoms, monoatomic chains and small clusters, on the Ag (111) surface using quantum dot microscopy. We image the electrostatic potential above these nanostructures and quantify the respective surface dipoles. The two species of adatoms behave antagonistic, as the surface dipoles are positive for Ag and negative for Au structures. The measured dipoles are in excellent agreement with density functional theory calculations. We disentangle the influence of individual adatom-surface and adatom-adatom bonds down to individual atomic orbitals.

Gold nanostructures with varying physicochemical surrounding examined with surface second harmonic generation circular dichroism spectroscopy — •NATALIE FEHN¹, EHSAN VAHIDZADEH², KARTHIK SHANKAR², UELI HEIZ¹, and ARAS KARTOUZIAN¹ — ¹Physical Chemistry, Department of Chemistry and Catalysis Research Center, Technical University of Munich — ²Electrical and Computer Engineering Deptartment, Faculty of Engineering, University of Alberta

The sophisticated second-order spectroscopic methods of surface second harmonic generation (s-SHG) and s-SHG circular dichroism spectroscopies (s-SHG-CD) provide additional and complementary structural information in regards to their linear counterparts, absorbance and CD spectroscopy. Because of their surface sensitivity, s-SHG and s-SHG-CD represent an excellent choice for the investigation of molecular thin films and supported plasmonic structures, such as nanoparticles and clusters. We are especially interested in the interaction of such nanostructures with their surroundings, e.g. chiral molecule adsorbates or oxide layers, with the goal of observing a chiral response from the originally achiral particles. Those particles may then serve as catalysts in asymmetric heterogeneous catalysis. This contribution will focus on our research with emphasis on supported gold nanostructures.

O 13.7 Mon 16:30 S052

Elucidating the chirality of polycrystalline films with fundamental and SHG-CD — •KEVIN LIANG¹, FLORIAN RISTOW², JAKOB SCHEFFEL², NATALIE FEHN¹, REINHARD KIENBERGER², UELI HEIZ¹, ARAS KARTOUZIAN¹, and HRISTO IGLEV² — ¹Physical Chemistry, Department of Chemistry and Catalysis Research Center, Technical University of Munich — ²Physics Department E11, Technical University of Munich

Preferential desorption of enantiomers of 1,1'-Bi-2-naphthol (BINOL) has been observed, depending on the handedness of circularly polarised light, which is of interest for enantioenrichment processes. Therefore, characterisation of the enantiomeric excess of the sample and the understanding of its chirality is key. However, that requires further studies and greater clarification to be carried out and obtained, respectively. This contribution discusses the optical properties of BINOL thin films with fundamental and second harmonic generation (SHG) circular dichroism spectroscopy (CD) with different sample preparation methods, enantiomeric compositions and under varying experimental conditions. Depending on the previous conditions mentioned, the observed CD and anisotropy (g) value can be even of opposite sign for the same thin film.

O 13.8 Mon 16:45 S052

**AFM studies of ion-exchange treated glass surfaces** — •FABIAN HÖHN^{1,3}, FABIAN ULLMANN^{1,3}, NORBERT ARNDT-STAUFENBIEL², and STEFAN KRISCHOK^{1,3} — ¹Institute of Physics, TU Ilmenau, Weimarerstraße 25, Ilmenau, Germany — ²Fraunhofer Institute for Reliability and Microintegration, Gustav-Meyer-Allee 25, Berlin, Germany — ³Center of Micro-and Nanotechnologies, TU Ilmenau, Gustav-Kirchhof-Straße 7, Ilmenau, Germany

There is a big difference between the bond strength of glass and its respective tensile strength. The reason for this discrepancy is assumed to be so-called "microcracks", this surface damage is considered to massively reduces the tensile strength. We assume that these damages widen by stretching the surface and become thus more visible. Another point that will be investigated, regarding this matter, is micro waveguides in glass. These are created by silver ion exchange in glass. It is assumed that the mentioned surface damages are a cause for reduced quality of these waveguides. For this purpose, we examine the difference in topography between untreated Gorilla V1 glass from Corning, a sample stretched using the three-point method and a sample in which a silver ion exchange was carried out on the surface. The difference in topography is first described qualitatively and then determined quantitatively with roughness parameters. Finally, a comparison of the three samples should provide an insight into the topography of glasses under stress and a contribution to the optimization of the mentioned waveguides.

O 13.9 Mon 17:00 S052

**Processing copper surfaces with ultrashort laser pulses to reduce secondary electron yield** – •ELENA BE2^{1,2}, MARCEL HIMMERLICH¹, ANA KAREN REASCOS PORTILLA¹, PIERRE LORENZ³, KLAUS ZIMMER³, MAURO TABORELLI¹, and ANDRÉ ANDERS^{2,3} – ¹CERN, European Organization for Nuclear Research, 1211 Geneva 23, Switzerland – ²University of Leipzig, Linnéstr. 5, 04103 Leipzig, Germany – ³Leibniz Institute of Surface Engineering (IOM), Per-moserstr. 15, 04318 Leipzig, Germany

Ultrashort-pulse laser processing in air is employed to engrave micro- and nanostructures on copper surfaces aiming to reduce secondary electron emission. Parameters such as the laser power and scanning speed are varied to investigate their influence on the resulting structures. The morphology, as well as the chemical composition of the laser-treated surfaces, are analyzed by scanning electron microscopy (SEM) and X-ray photoelectron spectroscopy (XPS), respectively. At low power and high scanning speed, only slight changes to the surface topography occur, whereas compact, cauliflower-like nanostructures and micrometer deep trenches are generated at high power and low scanning speed. The higher the accumulated laser fluence, the more material is ablated and the more oxidized particles are redeposited. A clear correlation exists between the accumulated fluence for processing with 355, 532 and 1064 nm photons, and the resulting secondary electron yield of the surface. Its maximum can be reduced from 2.2 to 0.7. Mastering these dependencies helps to develop a system that enables laser processing of beam pipes of selected magnets in the Large Hadron Collider.

Highly ordered three-dimensional Ni-TiO2 nanopore arrays as sodium-ion battery anodes — •MO SHA, HUAPING ZHAO, and YONG LEI — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Sodium-ion batteries (SIBs) represent an effective energy storage technology with potentially lower material costs than lithium-ion batteries. Here, we show the electrochemical performance of SIBs with electrode design at the nanoscale. Highly ordered three-dimensional (3D) selfsupported Ni-TiO2 nanopore arrays (NiNPA@TiO2) with highly oriented nanoporous structures are fabricated using nanoimprited AAO templating technique and applied as nanostructured anodes for SIBs applications. Their large specific surface area can ensure a high capacity, and their highly oriented and stable nanoporous structure can facilitate ion transport. The NiNPA@TiO2 nanoarrays delivered a reversible capacity of 240 mAh g-1 after 100 cycles at the current density of 50 mAh g-1 and were able to retain a capacity of 105 mAh g-1 at the current density as high as 5 A g-1. Their large active sites, high ion accessibility, fast electron transport, and excellent electrode integrity were shown as great merits to obtain the presented electrochemical performance. Not limited to the SIBs electrodes, the highly ordered 3D heterostructured nanoarrays as a promising electrode design for other electrochemical energy conversion and storage devices.

The importance of the dipole at the metal tip apex when approaching closer with a CO tip — •SHINJAE NAM, OLIVER GRETZ, THOMAS HOLZMANN, ALFRED JOHN WEYMOUTH, and FRANZ J. GIESSIBLE — University of Regensburg, Regensburg, Germany

By functionalizing the tip with a single CO molecule, the resolution of atomic force microscope (AFM) can be drastically increased. The contrast enhancement produced by a CO tip has been explained in terms of strong Pauli repulsion and the associated tilting of the probe molecule. Although these two interactions play a dominant role at very close distances, recent experiments show that other interactions, especially electrostatic forces, are also important to understand the observed contrast. Here, we used Lateral Force Microscope, a variant of frequency modulation atomic force microscopy, to quantify the interaction between a CO tip and a CO on the Cu (111) surface. Interestingly, one more feature appeared in the measurement when we measured closer to the surface at the side of the surface CO. Following the results of other investigations, we include the electrostatic force in our simulations. We modeled our tip as a quadrupole, including a dipole at both the metal tip and on the CO molecules. We found that the dipole of the metal apex of the tip becomes a much greater influence as we approach closer to the surface.

Chemical bond imaging using torsional and flexural higher eigenmodes of **qPlus sensors** — •DANIEL MARTIN-JIMENEZ¹, MICHAEL G. RUPPERT², ALEXANDER IHLE¹, SEBASTIAN AHLES³, HERMANN A. WEGNER³, ANDRÉ SCHIRMEISEN¹, and DANIEL EBELING¹ — ¹Institute of Applied Physics, Justus Liebig University Giessen, Heinrich-Buff-Ring 16, 35392 Giessen (Germany). — ²University of Newcastle, Callaghan, NSW, 2308 (Australia). — ³Institute of Organic Chemistry, Justus Liebig University Giessen, Heinrich-Buff-Ring 17, 35392 Giessen (Germany).

Non-contact atomic force microscopy (AFM) with CO-functionalized tips allows to visualize the chemical structure of adsorbed molecules and identify individual inter- and intramolecular bonds. Herein, we analyze the suitability of qPlus sensors, which are commonly used for bond imaging, for the application of modern multifrequency AFM techniques. Two different qPlus sensors were tested for submolecular resolution imaging via actuating torsional and flexural higher eigenmodes and via bimodal AFM. The torsional eigenmode of the first sensor is perfectly suited for performing lateral force microscopy (LFM) with single bond resolution. The advantage of using a torsional eigenmode is that the same molecule can be imaged either with a vertically or laterally oscillating tip without replacing the sensor simply by actuating a different eigenmode. Submolecular resolution is also achieved by actuating the 2nd flexural eigenmode of our second sensor. With laser Doppler vibrometry measurements and AFM simulations we can rationalize the image contrast mechanism of the 2nd eigenmode.

3D Force mapping of single organic molecules at room temperature -•TIMOTHY BROWN, PHILIP BLOWEY, JACK HENRY, and ADAM SWEETMAN -University of Leeds, Leeds, UK

Scanning probe microscopy has established itself as a highly effective technique in the study of surfaces and molecules. In particular, non-contact atomic force microscopy has yielded enormous progress in our ability to characterise materials at the atomic scale, including the ability to resolve the chemical structure of individual molecules, and to acquire 3D force-maps with intramolecular resolution.

Intramolecular imaging is almost exclusively performed using qPlus sensors at cryogenic temperatures, as the functionalisation of the tip via a CO molecule (required for intra-molecular imaging) is only stable at near liquid helium temperatures. Although it has been shown that intramolecular imaging may be performed at higher temperatures, via use of semi-conducting, rather than metallic substrates, acquisition of high density 3D data sets generally requires long acquisition times. Hence the lack of thermal equilibrium between the tip and sample at room temperature makes acquisition of these datasets at elevated temperatures extremely challenging.

In this talk we present the first demonstration of high resolution 3D force mapping of a single organic molecule at room temperature using conventional silicon cantilevers. We show how the challenges of operating in a room temperature experimental environment can be overcome to acquire reproducible 3D force maps of a resolution and quality previously only demonstrated at low temperature.

Monitoring of molecular configurations during manipulation with a scanning probe microscope – •Joshua Scheidt^{1,2}, Alexander Diener^{1,2} MICHAEL MAIWORM³, ROLF FINDEISEN³, KURT DRIESSENS², F. STEFAN TAUTZ¹, and Christian Wagner¹ — ¹Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, Jülich, Germany — ²Maastricht University, Data Science and Knowledge Engineering, Maastricht, Netherlands - ³Control and Cyber-Physical Systems Laboratory, Technische Universität Darmstadt, Darmstadt, Germany

A bold vision of nanofabrication is the assembly of functional molecular structures with a scanning probe microscope (SPM). Such an approach allows the

quick variation of conformation and composition of (supra)molecular systems and an assessment of these parameters on the envisioned functionality. However, monitoring the molecular conformations during manipulations remain elusive due to the dual role of the SPM tip as an actuator and an imaging probe. We present an approach which enables monitoring based on continuously gathered force gradient data using a particle filter approach, which solves the inverse problem of conformation monitoring by comparing current force gradient data to a structured set of simulations stored in the form of a finite state automaton. This allows using molecular simulations with wall-times for completion much longer than the time scale of the experiments. Our proof-of-principle investigations are based on the vertical SPM manipulation of a PTCDA (3,4,9,10-perylenetetracarboxylic dianhydride) molecule on the Au(111) surface.

### O 14.5 Mon 16:00 S053

Real-space imaging of  $\sigma$ -hole by means of Kelvin probe force microscopy. — •Aurelio Gallardo¹, Benjamín Mallada², Bruno de la Torre², and Pavel JELÍNEK $^1 - {}^1$ FZU of the CAS, Prague, Czech Republic -  2 RCPTM-CATRIN, Palacký University, Olomouc Czech Republic

Anisotropic charge distributions on individual atoms, such as  $\sigma$ -holes, are crucial for the structural properties of certain systems. Nevertheless, the existence of  $\sigma$ -holes has only been demonstrated indirectly, either observing the interaction between halogenated molecules or by theoretical calculations. However, there was no experimental technique that would allow the spatail resolution of anisotropic atomic charges.

To tackle this problem, we employed Kelvin probe force microscopy (KPFM) which imaging mechanism relays on the electrostatic tip-sample interaction. To achieve the requested resolution, we developed a theoretical description of the KPFM imaging mechanism on atomic scale, which enables optimize the experimental setup. Namely we demonstrated both theoretically and experimentally that probe tip functionalization by a single Xe atom enhances the spatial resolution to directly visualize the anisotropic charge of the  $\sigma$ -hole, as well as the quadrupolar character of the carbon monoxide molecule. [1]

We believe that this work large already outstanding imaging capabilities of scanning probe techniques. In particular, this KPFM technique will enable better description of charge distribution in molecular complexes as well as on surfaces. References: [1] Mallada et al., Science 374, 863-867 (2021)

O 15.1 Mon 15:00 S054 Hydration Layer Mapping at Solid-Liquid Interfaces — • ANGELIKA KÜHNLE - Physical Chemistry I, Department of Chemistry, University Bielefeld, Universitätsstraße 25, 33615 Bielefeld, Germany

Solid-liquid interfaces are omnipresent in nature and technology. Under ambient conditions, the properties of many materials are governed by a thin layer of water at the interface. Understanding processes occurring at the solid-liquid interface thus almost always requires a detailed knowledge of the hydration structure at the interface. Recent improvements in atomic force microscopy (AFM) instrumentation now enable molecular-level insights into the three-dimensional (3D) solvation structure at the interface.

In this talk, the capability of 3D AFM will be presented by discussing the hydration structure at the gypsum-water interface. Gypsum, the dihydrate of calcium sulfate, is an abundant rock-forming mineral in the Earth's crust. It is composed of alternating bilayers of calcium sulfate and water. Upon cleavage, the crystal water is exposed. What is the fate of this crystal water at the aqueous interface? Comparing 3D AFM data with water density maps derived from molecular dynamics simulations allows for elucidating molecular-level details of the gypsum-water interface. Our findings indicate that the crystal water at the interface remains tightly bound, even when in contact with bulk water. Thus, the interfacial chemistry of gypsum is governed by the crystal water rather than the calcium or sulfate ions.

Self-assembly and thin film growth dynamics of an ionic liquid on Au(111) investigated in real space — MANUEL MEUSEL¹, MATTHIAS LEXOW¹, AFRA GEZMIS¹, SIMON SCHÖTZ¹, MARGARETA WAGNER², •SIMON JAEKEL¹, ANDREAS Bayer¹, Florian Maier¹, and Hans-Peter Steinrück¹ — ¹Chair of Physical Chemistry II, University of Erlangen-Nürnberg (FAU), Germany — ²Institute of Applied Physics, Technical University of Vienna, Austria

Ionic liquids (IL) are organic salts with low melting points, often at or even below room temperature. They have shown promise as solvents and electrolytes, but have also become part of novel catalytical concepts involving solid metal catalysts.

In this context, our group studied the self-assembly and growth dynamics of thin films of 1,3-dimethylimidazolium bis[(trifluoromethyl)sulfonyl]imide ([C₁C₁Im][Tf₂N]) on the model surface of Au(111) using scanning probe microscopy[1,2,3]. Our experiments show that the film undergoes distinct phases between the growth of the wetting layer and subsequent multilayers. Further, 2D film growth is shown to be in competition with the growth of a metastable 3D droplet phase, with the dominant growth mode determined by a combination of temperature and nucleus formation.

Hydration layers at the graphite-water interface: Attraction or confinement? – Hagen Söngen¹, Ygor Morais Jaques², Lidija Zivanovic², Sebastian Seibert¹, •Ralf Bechstein¹, Peter Spijker², Hiroshi Onishi³, Adam S. Foster^{2,4}, and Angelika Kühnle¹ – ¹Physical Chemistry I, Bielefeld University, Germany —  2 COMP Centre of Excellence, Department of Applied Physics, Aalto University, Helsinki, Finland – ³Department of Chemistry, Kobe University, Japan - ⁴Division of Electrical Engineering and Computer Science, Kanazawa University, Japan

Water molecules at solid surfaces typically arrange in layers. The physical origin of the hydration layers is usually explained by (1) the attraction between the surface and the water and/or (2) the confinement of water due to the presence of the surface. While attraction is specific for the particular solid-solvent combination, confinement is a general effect at surfaces. A differentiation between the two effects is critical for interpreting hydration structures. At the graphitewater interface, the solid-solvent attraction is often considered to be negligible. Nevertheless, we observe hydration layers using three-dimensional atomic force microscopy at the graphite-water interface. We use Monte Carlo simulations to explain why confinement alone could cause the formation of hydration layers. With molecular dynamics simulations, we show that at ambient conditions, there is a significant graphite-water attraction which is pivotal for the formation of layers at the graphite-water interface.

# O 15.4 Mon 16:00 S054

Investigation of the wetting layer of [C1C1Im][Tf2N] on Pt(111) by variable temperature scanning tunneling microscopy — •AFRA GEZMIS, SIMON JAEKEL, MANUEL MEUSEL, ANDREAS BAYER, FLORIAN MAIER, and HANS-PETER STEINRÜCK — Lehrstuhl für Physikalische Chemie II, Universität Erlangen-Nürnberg, Egerlandstr. 3, 91058 Erlangen, Germany

With the introduction of Ionic liquids (IL) novel catalytic concepts like the Solid Catalyst with Ionic Liquid Layer (SCILL) approach have emerged. In a SCILL system, a high surface area solid substrate is covered with a thin IL film, and this film modifies catalytically active surface sites at the support. In order to gain better insights in the underlying effects, it is crucial to obtain a detailed understanding of the IL/solid interface. Due to the low vapor pressure of ILs, these interfaces can be investigated in ultra-high vacuum by surface science methods. Herein, we present our first study on the adsorption behavior of 1,3-dimethylimidazolium bis[(trifluoromethyl)sulfonyl]imide ([C1C11m][Tf2N]) on the reactive Pt(111) surface by variable-temperature for coverages up to a closed wetting layer, in particular the formation of 2D islands and their temperature-dependent size. Interestingly, we were even able to detect mobile, single ion pairs on the surface, while for the 2D structures only limited mobility was seen.

bias-dependent switching of molecular nanostructures at the liquid-HOPG interface: the influence of concentration — •BAOXIN JIA¹, MIHAELA ENACHE¹, SANDRA MIGUEZ-LAGO², MILAN KIVALA², and MEIKE STÖHR¹ — ¹Zernike Institute for Advanced Materials, University of Groningen, Netherlands — ²Institute of Organic Chemistry, University of Heidelberg, Germany

Here we discuss the influence of concentration on the bias-dependent switching of a carboxy-functionalized triarylamine derivative at the nonanoic acid-HOPG interface studied by STM. For a fully saturated solution, a porous phase (chickenwire) was observed for negative sample bias and a close-packed phase for positive sample bias. For a 50% saturated solution, a second porous phase (flower) coexisted with the chickenwire phase at negative sample bias, while the closepacked phase was observed at positive sample bias. For a 20% saturated solution, the two porous phases and the close-packed phase coexisted at positive sample bias, while the two porous phases were observed at negative bias. For all concentrations investigated, a reversible phase transformation between the porous phases and the close-packed phase was accomplished by changing the bias polarity. Additionally, the switching behaviour for a 10:1 mixture of the triarylamine derivatives and 1,3,5-tris(4-carboxyphenyl) benzene molecules at the interface was studied. No intermixed structures were observed. Instead, both molecules formed networks separately but still showed a bias-induced phase transformation. However, the switching occurred for each molecule separately and no effect of cooperativity was detected.

O 15.6 Mon 16:30 S054 In-situ investigation of surface band-bending in the ZnO(0001)-OH/electrolyte interface via the excitonic response. — •LUIS ROSILLO-OROZCO, CHRISTOPH COBET, and KURT HINGERL — Johannes Kepler University, Linz, Austria

In recent years, the effects of adsorbates on the surface band-bending in ZnO have been studied in UHV and characterized by Valence-Band XPS [1],[2]; showing an alteration of the space-charge region due to the electron transfer that occurs in the absorption processes. In this work we aim to understand the surface optical properties of a hydroxide stabilized ZnO(0001)-OH surface, previously obtained by chemical etching by Valtiner et al. [3], in contact with 0.1M Na-ClO4 as an electrolyte at a certain applied potential. By changing the cell applied potential, we can, in principle, produce any form of band bending at the semiconductor surface [4] including the flat-band condition. We use in-situ spectroscopic ellipsometry while varying the cell applied potential in order to study the response of the discrete excitons due to the inner electrical fields created by the band bending. We can identify the flat-band potential (Vfb) as the one where the imaginary part of the pseudo-dielectric function shows no change at the energy corresponding to the discrete exciton transition. By modulating the potential barrier at the interface we are able to investigate the response of the excitons at any given applied potential. Furthermore, given the significant sensibility of the band-bending to a surface dipole change, it is possible to use this technique to look into the effects of a modification of the surface such as adsorbates.

# O 15.7 Mon 16:45 S054

**Dynamic Polymorph Formation of a Trimesic Acid Derivative at Solid-Liquid Interface** – •RICHA ARJARIYA¹, VIPIN MISHRA¹, GAGANDEEP KAUR¹, SANDEEP VERMA¹, MARKUS LACKINGER², and THIRUVANCHERIL G GOPAKUMAR¹ – ¹Department of Chemistry, Indian Institute of Technology Kanpur, Kanpur, UP-208016, India – ²Department of Physics, Technical University of Munich, James-Franck-Strasse 1, Garching 85748 and Deutsches Museum, Museumsinsel 1, Munich 80538, Germany

In this work we show the self-assembly of a tricarboxylic acid derivative of trimesic acid (BTA) at heptanoic acid-, nonanoic acid-graphite interface. At both

interfaces BTA forms a trimer based-self-assembly, super-flower (SF) pattern. The spontaneously formed SF pattern is observed to be dynamically converting to a dimer-based assembly, chicken-wire pattern (CW), at heptanoic acidgraphite interface while scanning. Interestingly, at nonanoic acid-graphite interface, SF pattern remains stable and not converted to CW pattern. We attribute that the formation energy of both SF and CW patterns is comparable. The difference in the stability of different patterns in heptanoic acid and nonanoic acid is most likely related to the solubility of BTA in these solvents.[1,2]

O 15.8 Mon 17:00 S054

in-situ optical probe of chloride-induced surface states in Cu(110)/liquid interfaces — •SAUL VAZQUEZ-MIRANDA¹, KURT HINGERL¹, and CHRISTOPH COBET^{1,2} — ¹Johannes Kepler Universität Linz Altenberger Straße 69 4040 Linz, Austria — ²Johannes Kepler Universität, Linz School of Education, A-4040 Linz, Austria

While surface states (SSs) appearance and role in metal-electrolyte interfaces are still a controversial debate. The existence of SSs, permits control and tunability of electronic properties of metal-electrolyte interfaces. Resonant excitations among them could enhance, e.g. photocatalytic reactions. SSs and other properties are readily adjustable via an applied electrical potential that is, by promoting changes in the adsorption of ionic species. The electrolyte induces additional scattering and screening effects, so that the electron charge distributions can differ considerably in the presence of high electric fields. We report, by means of electrochemical impedance spectroscopy (EIS) jointly with in-situ reflectance anisotropy spectroscopy (RAS), which aimed to assess the evolution of surface properties and SSs occurring at Cu (110) in contact with an HCl solution. Thereafter, by modeling the RAS response and in comparison with EC-STM measurements, specific surface structures have been identified and ascribed to the optical response. In a specific potential range, three additional resonances are detected in RAS that can be explained by two-dimensional confined SSs.

### O 15.9 Mon 17:15 S054

In-situ electrochemical X-ray photoelectron spectroscopy as laboratory technique to study the electrified interface — •CHRISTOPH GRIESSER, DANIEL WIN-KLER, TONI MOSER, and JULIA KUNZE-LIEBHÄUSER — Department of Physical Chemistry, University of Innsbruck, Innrain 52c, Innsbruck, Austria

The interface between a charged metal and an aqueous electrolyte is the most commonly studied in electrochemical surface science, as its properties determine the reactivity of many systems relevant for technological applications. More specifically, in the electrocatalytic conversion of energy, the activity, selectivity and efficiency are determined by the charge transfer between electrolyte and electrode, which is governed by the interfacial properties of the system. Therefore, a fundamental understanding of the interplay between applied potential and surface/interface chemistry is pivotal to further advance energy conversion and storage technologies. While there are several in-situ methods, to characterize the surface structure under reaction conditions, the surface chemistry (i.e. the elemental composition of the surface and the oxidation state of the components) itself is still most often investigated via ex-situ X-ray photoelectron spectroscopy (XPS). This work presents first in situ electrochemical XPS results obtained with a laboratory near ambient pressure (NAP-) XPS system. We show, that it is possible to track the oxidation state of a bulk gold (Au) electrode under reaction conditions, i.e. during anodic oxidation.

Structure dependent product selectivity of the CO electroreduction on Au(111) electrodes modified with Cu adatoms - •DANIEL WINKLER, TONI MOSER, CHRISTOPH GRIESSER, MATTHIAS LEITNER, and JULIA KUNZE-LIEBHÄUSER — University of Innsbruck, Innrain 52c, 6020 Innsbruck, Austria The efficient conversion of carbon dioxide (CO₂) into valuable hydrocarbons could be a promising solution for storage of excess energy and carbon neutral transportation. The electrochemical reduction of CO₂ has been extensively studied on different monometallic surfaces, where Cu remains the only metal providing a sufficient formation activity to value-added products, such as methane or ethylene. Despite this beneficial behavior, further strategies to increase the product selectivity must be found. This can be accomplished by understanding the exact CO₂ reduction reaction (CO₂RR) mechanism, which remains one of the most challenging problems. Here we focus on the carbon monoxide (CO) reduction on Au(111) electrodes modified with different coverages of Cu adatoms to address this issue. Differential electrochemical mass spectrometry (DEMS) shows an increase in selectivity for the formation of ethylene at low Cu coverages. In situ electrochemical scanning tunneling microscopy (EC-STM) and X-ray photoelectron spectroscopy results suggest that two different neighboring CO adsorption sites present at the interface between the metallic Cu islands and the Au(111) surface, which is maximized at low coverages, provide ideal conditions for a facilitated CO-CO coupling reaction resulting in an enhanced formation of ethylene.

Tailoring the carrier dynamics of WSe₂ by the adsorption of CuPc - •GREGOR ZINKE¹, SEBASTIAN HEDWIG¹, BENITO ARNOLDI¹, MARTIN AESCHLIMANN¹, and BENJAMIN STADTMUELLER^{1,2} - ¹Department of Physics and Research Center OPTIMAS, TU Kaiserslautern, Erwin-Schroedinger-Str. 46, 67663 Kaiserslautern, Germany — ²Institute of Physics, Johannes Gutenberg University Mainz, Staudingerweg 7, 55128 Mainz, Germany

Tailoring the electronic properties and carrier dynamics of 2D-Van-der-Waals materials is a highly promising way to design spin functionalities in low dimensions. This is often achieved by the formation of heterostructures with other Van-der-Waals materials.

Here, we functionalize the carrier dynamics of the prototypical Van-der-Waals material WSe₂ by the adsorption of the aromatic molecule CuPc. Using timeand angle-resolved photoemission with XUV-radiation, we investigate the temporal evolution of the excited states at the K- and  $\Sigma$ -points of WSe₂ after an optical excitation. For the bare WSe2, we find a spin selective excitation at the K-point depending on the pump light polarization [1], which is followed by a spin-flip scattering from the K- to the  $\Sigma$ -point. After the adsorption of CuPc, the excitation scheme is completely altered. In particular, we uncovered a direct interlayer excitation from the CuPc into the WSe2 layer that dominates the carrier dynamics of the CuPc/WSe₂ heterostructure.

Numerous Improvements on Ultrafast Pump-Probe RHEED Experiment — •Jonas Fortmann¹, Christian Brand¹, Thorben Groven¹, Mohammad Tajik¹, Michael Horn-von Hoegen¹, and Thomas Duden² — ¹Department of Physics and Center for Nanointegration CENIDE, University of Duisburg-Essen, Lotharstraße 1, 47057 Duisburg —  2 Construction office, Mustangweg 17, D-33649, Bielefeld

During the last year, major improvements have been made to our ultrafast timeresolved reflection high energy electron diffraction (tr-RHEED) experiment. In particular, the previous detection unit consisting of a multichannel plate and a cooled CCD camera has been replaced by a single electron sensitive CMOS based camera (TVIPS TemCam XF-416), which allows spot profile analysis with its superior resolution and signal-to-noise ratio and no blooming. Flatfielding of the detector is achieved with a home-built electron source at 20 keV accompanied by an external EM-deflection unit. In addition, the 80 fs-laser pump pulse  $(\lambda = 800 \text{ nm})$  has been upgraded with an optical parametric amplifier (Topas

resolution is challenging and limits the understanding of this complex interface. Electrochemical reflection anisotropy spectroscopy (RAS) is a powerful emerging tool in spectroelectrochemistry [1], which we apply to a number of systems relevant for energy and matter conversion. Here, we present initial results on InP and Au in aqueous systems as well as select post-Li battery systems. For InP, we can directly observe stability windows with respect to applied potentials and electrolyte composition. We highlight the potential and challenges of electrochemical RAS from a perspective of both computational and experimental spectroscopy.

Ultrafast optical spectroscopy of few-layer TMDCs under ultrahigh-vacuum conditions — •MAXIMILIAN FRANZ, KILIAN KUHLBRODT, JAN GERRIT  ${\it Horstmann, and \ Claus \ Ropers - Max-Plank-Institut \ für \ Multidisziplinäre}$ Naturwissenschaften, Göttingen, Germany

Optical pump-probe spectroscopy (OPP) has enabled detailed investigations of the nonequilibrium optical properties of atomically thin materials, with prominent examples in graphene or transition metal dichalcogenide (TMDCs) heterostructures [1]. However, these materials are often susceptible to oxidation and contamination under atmospheric conditions, resulting in strongly altered physical and chemical properties [2]. Here, we present the development of an OPP setup for the investigation of dynamics in few-layer TMDCs and heterostructures under ultrahigh vacuum (UHV) conditions. We present first results on the ultrafast phase transition in 1T-TaS₂ samples using time-resolved reflectance and transmittance measurements with fs temporal and  $\mu$ m spatial resolutions. Furthermore, we discuss possible applications, e.g., layer-selective optical excitation of TMDC heterostructures, and the combination of OPP with structuresensitive techniques like ultrafast low-energy electron diffraction [3].

Description for the electronic non-equilibrium after ultrashort laser excitation of metals - •MARKUS UEHLEIN, SEBASTIAN T. WEBER, and BAER-BEL RETHFELD — Department of Physics and Research Center OPTIMAS, TU Kaiserslautern, Germany

When a metal is excited by a femtosecond laser pulse in the visible range, electrons absorb the energy, resulting in a non-equilibrium energy distribution. This absorption behavior and the following thermalization to a hot Fermi distribution can be simulated using complex and numerically expensive Boltzmann collision integrals [1]. After the thermalization, the two-temperature model (TTM) can describe the relaxation of the heated electrons and the phonons in a simple way. It is, however, unable to trace non-thermal electrons.

We present an intermediate model, called extended TTM (eTTM). It was developed in Refs. [2, 3] and adds a system of non-equilibrium electrons to the TTM. Besides some improvements to the published versions, we compare the eTTM to the Boltzmann model as well as to the TTM [4]. In particular, we compare the spectral particle dynamics to a time-resolved two-photon photoemission measurement [5].

### O 16.6 Mon 18:00 P4

A setup for interferometrically time-resolved multi-photon photoemission benchmarked on Ag(111) — •HANNAH STRAUCH, MARCO MERBOLDT, JAN PHILIPP BANGE, DANIEL STEIL, G. S. MATTHIJS JANSEN, SABINE STEIL, MAR-CEL REUTZEL, and STEFAN MATHIAS — I. Physikalisches Institut, Georg-August-Universität Göttingen, Göttingen, Germany

Time- and angle-resolved photoemission is the method of choice to directly study the electron dynamics of condensed matter systems with energy and momentum resolution. After the system is excited by a pump pulse, a delayed second pulse induces photoemission and thus probes the materials response. To complement the obtained insight with information on the coherence of the response, single-color phase-locked pulse pairs can be employed. Here, we present a setup for interferometric time-resolved multi-photon photoemission based on a passively stabilized Mach-Zehnder interferometer which produces phaselocked pulse pairs and provides an optical delay precision below 60 as. We show interferometric time- and angle-resolved multi-photon photoemission data from the Shockley surface state and the first image potential state of the Ag(111) surface as a benchmark for our setup. Supported by an optical Bloch equation model we explore possibilities to interpret such a data set.

A promising application of the interferometer is in combination a high harmonic generation EUV beamline. This enables double-pump-probe experiments with access to the full Brillouin zone, and allows a comprehensive investigation of optical excitations.

Time-resolved ARPES probing *Rabi* Oscillations and *Landau-Zener-Stückelberg* Interferences in Graphene - a Proposal — • EDUARD MOOS, HAUKE BEYER, and MICHAEL BAUER — Institute of Experimental and Applied Physics, Kiel University, Germany

At sufficiently high intensities, the interaction of few-cycle laser fields with solids gives rise to strong-field effects envisioning novel and exciting strategies for controlling optical and electronic properties via the electric field waveform on subfemtosecond timescales. A striking example is the CEP-control of light-fielddriven currents in graphene due to Landau-Zener-Stückelberg (LZS) interferences [1] resulting from the complex interplay of field-driven adiabatic intraband and diabatic interband transitions. Simulations show that the LZS-interferences give rise to characteristic asymmetries in the momentum-distribution of the residual conduction band population in the Dirac cone on top of a symmetric quasi-periodic pattern indicative for Rabi oscillations. TRARPES using few cycle femtosecond pump laser pulses seems to be in ideal tool for the investigation of these processes and there dependence on parameters such as pulse peak electric field strength E0, laser polarization, and CEP phase. Based on preliminary results on graphite using 7 fs few-cycle NIR pump-pulses we will discuss in this presentation the prospects, but also the challenges that arise in such type of TRARPES experiment.

Laser-based low energy photoelectron diffraction of SnPc/graphite — •HERMANN ERK, STEPHAN JAUERNIK, PETRA HEIN, and MICHAEL BAUER — IEAP, CAU Kiel, Germany

Tin-phthalocyanine (SnPc) adsorbed on graphite has been studied using laserbased angle resolved photoemission spectroscopy (ARPES) at 5.9 eV photon energy and low energy electron diffraction (LEED). An ordered SnPc monolayer was prepared by thermal evaporation onto single crystalline graphite (SCG) flakes and subsequent annealing at 370 K. LEED data reveal an incommensurate ordered phase of the SnPc overlayer at room temperature. In the ARPES spectra the SnPc long-range order can be seen due to an adsorbate-induced backfolding of the band structure of graphite from the  $\overline{K}$  point to the center of the Brillouin zone. A comparison of ARPES spectra with simulations of the backfolded band structure under consideration of the LEED data will be discussed. First timeresolved ARPES measurements with the aim to address ultrafast changes in the SnPc long range order will be presented.

#### O 16.9 Mon 18:00 P4

Type II aligned TMD heterostructures: Probing moiré interlayer excitons with energy-, momentum-, and femtosecond time-resolution — •MARCEL REUTZEL¹, DAVID SCHMITT¹, JAN PHILIPP BANGE¹, WIEBKE BENNECKE¹, AB-DULAZIZ ALMUTAIRI², GIUSEPPE MENEGHINI³, DANIEL STEIL¹, R. THOMAS WEITZ¹, SABINE STEIL¹, G. S. MATTHIJS JANSEN¹, SAMUEL BREM³, ERMIN MALIC³, STEPHAN HOFMANN², and STEFAN MATHIAS¹ — ¹I. Physikalisches Institut, Georg-August-Universität Göttingen, Göttingen, Germany — ²Department of Engineering, University of Cambridge, Cambridge CB3 0FA, U.K. — ³Fachbereich Physik, Philipps-Universität, 35032 Marburg, Germany Transition metal dichalcogenides (TMDs) can be stacked into atomically thin

p-n junctions, where an optically excited intralayer exciton can decay into interlayer excitons. Here, the electron and the hole contribution to the quasiparticle reside in the neighbouring TMD layers.

On this poster, we show our recent progress towards the identification and characterization of the ultrafast charge transfer process across a type II interface. Using femtosecond momentum microscopy, we identify the distinct momentum fingerprints of various excitonic states in this system, notably the bright and dark intralayer excitons as well as the interlayer exciton. Most intriguingly, the momentum-resolved measurement provides quantitative access to the interlayer exciton wavefunction that is modulated within the moiré potential. O 16.10 Mon 18:00 P4

Influence of the static dielectric permittivity on ultrafast quasiparticles dynamics in WS₂ monolayers — •SUBHADRA MOHAPATRA^{1,2}, STE-FANO CALATI^{1,2}, QUIYANG LI³, XIAOYANG ZHU³, and JULIA STÄHLER^{1,2} — ¹Humboldt-Universität zu Berlin, Institut für Chemie,Berlin,Germany — ²Fritz-Haber-Institut der Max-Planck-Gesellschaft, Abt. Physikalische Chemie, Berlin, Germany — ³Columbia University, New York City, New York

In our recent fluence-and photon energy-dependent studies [1,2] of quasiparticle dynamics in WS₂ monolayers on fused silica (FS) and Si-SiO₂ substrates, we observed that excitonic screening solely reduces the binding energy of the excitons, leading to a transient blue-shift of the exciton resonance while quasi free carrier screening effectively shows a red shift, as the carrier-induced screening leads to a larger band gap renormalization than binding energy reduction. Further investigation of such fluence-dependent quasiparticle dynamics studies using a higher dielectric permittivity of a sapphire substrate, we found that scattering rates, relaxation time constants, and band gap renormalization are not influenced by the dielectric permittivity. On the contrary, the ratio of dynamic screening parameter of the excitons and their Bohr radius is approximately 4 times higher in sapphire than for FS, which must be a direct consequence of the increased dielectric permittivity likely leading to more localized excitons.

O 16.11 Mon 18:00 P4 Ultrafast Transport and Energy Relaxation of Hot Electrons in Au/Fe/MgO(001) Investigated by Linear Time-resolved Photoelectron Spec**troscopy** — •Florian Kühne¹, Yasin Beyazit¹, Detlef Diesing², Ping Zhou¹, Jesumony Jayabalan¹, and Uwe Bovensiepen¹ — ¹University of Duisburg-Essen, Physics — ²University of Duisburg-Essen, Chemistry Optically excited electrons and holes are of particular interest in solid-state physics because analysis of their dynamics allows a microscopic understanding of the interactions in non-equilibrium states. Here we want to discern the relaxation by such local inelastic processes and non-local transport effects. To analyze the ultrafast dynamics of charge carriers in the vicinity of the Fermi energy  $E_{\rm F}$ , femtosecond time-resolved linear photoelectron spectroscopy was applied. We report on first experimental results obtained by using 1.55 eV pump and 6 eV probe photons on an Au/Fe/MgO(001) epitaxial heterosystem, complementary to previous work in Beyazit et al., PRL 125, 076803 (2020). By pumping the Fe side, hot electrons are excited in the Fe layer, and subsequently injected into the Au layer and propagate to the surface, where they are probed by photoelectron emission spectroscopy. In the Fe side pumped data, we observe thickness dependent differences in relaxation compared to the Au side pumped data. In Au side pumping we observe efficient transport into the Fe layer. We will present an energy *E* dependent analysis of the propagation and energy density  $U(E, d_{Au})$  of electrons above  $E_{\rm F},$  which together with a two-temperature model shows a super diffusive transport limit.

O 16.12 Mon 18:00 P4

Investigations of polarons in hematite  $\alpha$ -Fe₂O₃(1-102) by means of nc-AFM and KMC — •JESÚS REDONDO^{1,2}, VÍT GABRIEL¹, GIADA FRANCESCHI³, IGOR SOKOLOVIĆ³, DOMINIK WRANA¹, FLORIAN KRAUSHOFER³, ERIK RHEINFRANK³, MICHELE RIVA³, GARETH S. PARKINSON³, MICHAEL SCHMID³, ULRIKE DIEBOLD³, PAVEL KOCÁN¹, and MARTIN SETVIN^{1,3} — ¹Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic — ²Faculty of Chemistry, University of the Basque Country, San Sebastián, Spain — ³Institute of Applied Physics, Vienna University of Technology, Vienna, Austria

Polarons are known to strongly influence the catalytic activity and the electronic, magnetic, and structural properties of transition metal oxides and halide perovskites. The study of polaron formation and dynamics is fundamental to understanding the actual mechanisms and yields of catalytic reactions in these materials. A new method for the investigation of electron and hole polarons is demonstrated. Charge carriers are injected with the AFM/STM tip into the surface of natural, Ti- and Ni-doped  $\alpha$ -Fe2O3(1-102). The injected charges form a cloud of electrons or holes trapped in the lattice. This cloud expands due to electrostatic interactions and thermally activated polaron hopping. Controlled annealing of the sample and characterization by Kelvin probe force microscopy (KPFM) provides information on polaron dynamics; these results are compared to kinetic Monte Carlo (KMC) simulations and the dependence of the polaron hopping activation energy on the doping is shown.

Influence of a BlueP interlayer on the properties of P2O on Au(111) — •FLORENTINE FRIEDRICH, MAXIMILIAN SCHAAL, FELIX OTTO, PHILIP GRIMM, MARCO GRUENEWALD, ROMAN FORKER, and TORSTEN FRITZ — Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany

Two-dimensional (2D) materials have attracted much attention in solid state physics in recent years due to their unique properties. Amongst others, one novel representative is the phosphorus allotrope blue phosphorene (BlueP) with its high charge carrier mobility and suitable band gap, that is used here as an interlayer to obtain a decoupling of the functional organic molecule 6,13pentacenequinone (P2O) from Au(111) surfaces. P2O is deposited in various film thicknesses (1 monolayer equivalent (MLE) up to 4-5 MLE) either on BlueP on Au(111) or directly on the metal substrate to investigate the influence of BlueP as an interlayer on the optical and structural properties of the P2O molecules. The film growth of P2O is monitored by in-situ differential reflectance spectroscopy (DRS), while the BlueP-Au substrate is kept at different temperatures. Further complementary experimental methods were low-electron energy diffraction (LEED), X-ray photoelectron spectroscopy (XPS), and lowtemperature scanning tunneling microscopy (LT-STM). It turns out that the BlueP interlayer influences the monolayer structure as well as the growth mode. In contrast to previous studies on  $C_{60}$ , the BlueP interlayer stays intact.

O 17.2 Mon 18:00 P4

Navigating the Polymorph-Jungle with Optimal Control techniques — •SIMON HOLLWEGER, ANNA WERKOVITS, RICHARD K. BERGER, and OLIVER T. HOFMANN — Institute of Solid State Physics, NAWI Graz, Graz University of Technology, Petersgasse 16, 8010 Graz, Austria

Properties of organic-inorganic interfaces are strongly dependent on the arrangement of the molecules on the surface. However, achieving a controlled growth of a polymorph with preferable physical properties is not straightforward at all - especially for metastable polymorphs.

In principle, starting from a thermodynamically easily accessible polymorph, kinetics can be utilized to stabilize a metastable polymorph. This can be done by promoting certain structural transitions by a-priori unknown sequentially changing growth conditions. Depending on the complexity of the transition network, often only a limited yield of the target polymorph can be reached during growth.

To computationally maximize the yield of the desired structure we use Optimal Control techniques. Therein, process parameters like temperature and pressure are varied to optimize parameter protocols. The transition network of our model system TCNE/Cu(111) is obtained via a combination of Transition State Theory and Density Functional Theory.

#### O 17.3 Mon 18:00 P4

Adsorption structure of mixed PTCDA derivatives on  $Ag(111) - \bullet$ AMIN KARIMI¹, JOSE M. GUEVARA¹, VERONIKA SCHMALZ², ULRICH KOERT², F. STE-FAN TAUTZ¹, and CHRISTIAN WAGNER¹ - ¹Peter Grünberg Institut (PGI 3), Forschungszentrum Jülich , Jülich, Germany - ²Chemistry Department, Philipps Universität Marburg, Marburg, Germany

For molecular manipulation and SPM tip functionalization, the mode of anchoring molecules to the tip is decisive. We recently found that PTCDA binds to a Ag tip with two oxygen-metal bonds after it is retracted from the surface. While this is crucial for its stabilization in a vertical state, the two bonds reduce the degrees of freedom during manipulation in the tip-molecule-surface junction. To overcome this problem, we synthesized a PTCDA derivative (reduced PTCDA), in which one carboxylic oxygen is replaced by two H atoms. For molecular manipulation, this allows choosing between one or two tip-oxygen bonds. Here we present a study on the absorption structures formed by a mixture of PTCDA and reduced PTCDA on the Ag(111) surface with the help of low-temperature NC-AFM/STM. We observe that despite the minimal modification of reduced PTCDA compare to PTCDA, the mixture of both molecules exhibits a strongly different behaviour compared to the regular island growth of pure PTCDA. Particularly striking is the coexistence of zero-, one-, and two-dimensional structures. A likely explanation for such diverse structures is the influence of longrange electrostatic interactions related to the in-plane dipole moment of reduced PTCDA.

O 17.4 Mon 18:00 P4 Single-domain molecular layers on Ag (110) — •RAVI PRIYA, WEISHAN WU, and PETER JAKOB — Department of Physics, Philipps-Universität Marburg, Germany

Single domain molecular layers have been explored on the non-hexagonal Ag(110) substrate. The absence of rotational domains for fcc (110) metal substrates allows for growing layers with uniform azimuthal orientation of

deposited molecules. In our study we have investigated various molecules and configurations that may form single domain molecular layers (including mirror domains). Specifically, PTCDA, NTCDA, phthalocyanines (CuPc, SnPc, TiOPc) and regio-selectively substituted pentacene species (pentacene, pentacene-quinone, pentacene-tetrone, quinacridone) were deposited and examined in terms of their structure using SPA-LEED, and their vibrational signature using IR - spectroscopy. Among them, PTCDA, NTCDA and pentacene have been found to form single domain structures. In the case of PTCDA two prominent phases, the brick-wall (BW) and the herringbone (HB) phases exist, and they are readily distinguished not only by their LEED patterns but also from their vibrational signatures. Another finding refers to the increased molecule - metal interaction on Ag (110) vs. Ag (111) that leads to an extra energy (down)shift of the LUMO, thereby having a significant impact on interfacial dynamic charge transfer (IDCT) of vibrational modes [1].

Generation of synthetic chiral structured images for computer vision applications — •JOHANNES TIM SEIFERT¹, PEER KASTEN¹, MANDY STRITZKE², BJÖRN MÖLLER³, TIMO DE WOLFF², TIM FINGSCHEIDT³, and UTA SCHLICKUM¹ — ¹Institut für Angewandte Physik, Technische Universität Braunschweig — ²Institut für Analysis und Algebra, Technische Universität Braunschweig — ³Institut für Nachrichtentechnik, Technische Universität Braunschweig

Scanning tunneling microscopy (STM) is a well-established tool to measure surface topographs with atomic precision. Since data generation is slow using STM, we present a tool to create synthetic images with realistic noise and defects, which provides labeled training data for neural networks. We compare two methods evaluating chiral structures in STM images using Deep Learning.

As one approach to classify structures, we are using semantic segmentation based on the U-Net architecture to create maps showing the distribution of both chiralities. Additionally, we use a faster R-CNN architecture for object detection to locate and classify each chiral structure individually.

Since the approaches serve different use cases, they also have separate label requirements. We show that models trained using only our synthetic images perform successfully for real STM Images.

#### O 17.6 Mon 18:00 P4

Ultrafast dynamics of quantum confined surface electrons in a T4PT-based metal-organic network on noble metals — •NILS BELLENBAUM¹, LU LYU¹, EVA WALTHER¹, TOBIAS EUL¹, BENITO ARNOLDI¹, MARTIN AESCHLIMANN¹, and BENJAMIN STADTMÜLLER^{1,2} — ¹Technische Universität Kaiserslautern and Research Center OPTIMAS, Erwin-Schrödinger Straße 46, 67663 Kaiserslautern, Germany — ²Institute of Physics, Johannes Gutenberg University Mainz, Staudingerweg 7, 55128 Mainz, Germany

Two-dimensional metal-organic networks have emerged as intriguing architectures to design and control quantum confinment of electrons at surfaces. In our work, we focus on the metal-organic network T4PT/Cu(111) comprised of triangular 2,4,6-tris(4-pyridine)1,3,5-triazine (T4PT) molecules adsorbed on a copper substrate. Using momentum-resolved photoemission, we demonstrate a spatial confinement of the free electron-like surface state of Cu(111) in the pores of the network structure. Similarly, the dispersion of the unoccupied image potential state (IPS) of Cu(111) is modulated by the network's periodic potential, leading to a severe increase of the effective band mass of the IPS. Finally, we discuss the influence of periodic modulation of the IPS on its energy and momentum-dependent population time using timeresolved two photon momentum microscopy. Our findings provide a first glimpse onto tunability of the electron dynamics at surfaces by spatial confinement in nanoporous metalorganic network structures.

#### O 17.7 Mon 18:00 P4

**Organic Molecules on the Cu(110)-(2x1)O Striped Phase** — •ILIAS GAZ-IZULLIN, CHRISTOPHE NACCI, and LEONHARD GRILL — Physical Chemistry Department, University of Graz, Heinrichstrasse 28, 8010 Graz, Austria

The deposition of molecules onto single-crystal surfaces allows their investigation at the single-molecule level by scanning tunneling microscopy (STM) and gives access to the controllable on-surface synthesis of 2D materials. Here, we have studied dibromo-p-terphenyl molecules on the Cu(110)-(2x1)O striped phase under ultra-high vacuum conditions with low-temperature STM. The Cu(110)-(2x1)O striped phase is of particular interest since it offers alternating stripes of (metallic) copper areas and of oxygen-covered areas where the adsorbed organic molecules are slightly decoupled from the metal substrate and hence have higher mobility.

Previously, the Cu(110)-(2x1)O striped phase was used as a template for the synthesis of organometallic structures having different sizes and shapes depend-

Location: P4

ing on the width of copper stripes [1]. The focus of our study is how annealing affects the molecular adsorption on the surface. It turns out that the molecules form organometallic chains on the copper areas, oriented in three surface directions. Increasing the sample temperature from 300 K to 450 K changes the orientation of the organometallic chains and the shape of the Cu-O areas. Possible interactions leading to such behaviour are discussed.

Adsorption of phthalocyanine monolayers on Ag(110) - •GAANA КАINIККАRA, RAVI PRIYA, and PETER JAKOB — Phillips University of Marburg Vibrational properties and long range ordering of TiOPc, CuPc and SnPc molecular layers on the non-hexagonal Ag(110) surface have been investigated using IR-spectroscopy and SPA-LEED. Special emphasis is put on a comparison with the related Ag(111) substrate surface that is characterized by a somewhat weaker molecule - metal interaction strength. This hypothesis is supported by distinct differences in the vibrational line shapes of modes associated with interfacial dynamical charge transfer [1], the primary cause being an extra shift in the energetic position of the former LUMO with respect to the Fermi energy for the Ag(110) substrate. Another objective in our study was to identify structural changes in the (layered) structural arrangement, both during the growth process, as well as annealing of the layers. Due to their only slightly different footprint, the molecules display similar long range ordered phases. Our primary focus thus concerned the identification of possibly inclined arrangements in the coverage range of 1-2 monolayers [1] P. Jakob, Peter and S. Thussing. "Vibrational Frequency Used as Internal Clock Reference to Access Molecule-Metal Charge-Transfer Times." Phys. Rev. Lett. 126, 116801 (2021).

Visualizing self-assemblies of electrosprayed complex molecules on surface: a non-contact force microscopy study — •GEMA NAVARRO¹, ANTOINE HINAUT¹, SEBASTIAN SCHERB¹, SHUYU HUANG¹, YIMING SONG¹, KLAUS MÜLLEN¹, THILO GLATZEL¹, AKIMITSU NARITA², and ERNST MEYER¹ — ¹Department of Physics, University of Basel, Klingelbergstrasse 82, 4056 Basel, Switzerland. — ²Max Planck Institute for Polymer Research, Ackermannweg 10, D-55128 Mainz, Germany.

Building up functional 2D supramolecular assemblies requires the unit blocks involved in their bottom up formation to be already complex. In the construction of the tailored nanostructures, different approaches can be adopted in order to circumvent the limitations of the traditional wet chemical methods [1,2]. Among them, specifically the Electrospray Deposition (EDS) technique emerges as suitable pathway to explore the adsorption of organic compounds with higher structural complexity [3].

In the present work, we report the adsorption of complex molecules on a noble metal surface. Our study focus on the influence of intermolecular and surface-molecule interactions in the observed assemblies. The deposition of the molecules is carried out by HV-EDS. Furthermore, visualization of the molecules is achieved by means a home-made Atomic Force Microscopy (AFM) set-up, in non-contact operation mode.

С₆₀ - PEN Diels - Alder Cycloaddition Reaction on Ag(110) — •Монаммер Suhall Ansari, Ravi Priya, and Peter Jakob — Department of Physics, Philipps - Universität Marburg, Germany

Ultrathin films of  $C_{60}$  and pentacene (PEN) have been prepared on Ag(110) and their vibrational properties, as well as thermal evolution investigated by IR spectroscopy. Monolayer species are found to display distinctly different vibrational signatures as compared to higher layers, so the characterization of the grown hetero layers is straightforward. Moreover, the excellent spectral resolution and chemical selectivity allowed us to unambiguously identify the  $C_{60}$  - PEN Diels-Alder adduct [1]. In our thermal evolution study, the formation and decomposition of the  $C_{60}$  - PEN reaction product as well as the abundances of the  $C_{60}$  and PEN compounds have been examined. Production of the adduct species requires a weak thermal activation (annealing to 350 K) and proceeds largely independent of the  $C_{60}$  / PEN stacking sequence. We find that this reaction occurs exclusively at the (abrupt) interface of  $C_{60}$  and PEN for layered arrangements and is fully reversible, meaning that further annealing to 450 K (and higher) produces again  $C_{60}$  and PEN, with the latter desorbing thermally and thus depleting the initial concentration of reactants.

First Steps Towards Carbon-Based Heisenberg Chains on Au(111) — •NILS KRANE¹, ELIA TURCO¹, ANNIKA BERNHARDT², MICHAL JURÍČEK², PASCAL RUFFIEUX¹, and ROMAN FASEL¹ — ¹nanotech@surfaces Laboratory, Empa - Swiss Federal Laboratories for Materials Science and Technology, Dübendorf, Switzerland — ²Department of Chemistry, University of Zurich, Zurich, Switzerland

Carbon based  $\pi$ -magnetism has been a growing field of interest in the recent years. By tailoring nanographenes with atomically price shape and size it is possible to tune their electronic properties and create magnetically non-trivial groundstates. A recent study has demonstrated the formation of triangulene-based Haldene chains, consisting of spin-1 building blocks and featuring gapped spin excitation in the bulk [1]. On the other hand, a Heisenberg chain consisting of coupled spin-1/2 units is predicted to be gapless, due to a continuum of spin excitations above the ground state.

Here we present the first steps towards synthesizing all-carbon spin-1/2 chains. Phenalenyl-based precursers are used for a bottom-up approach to form oligomers of different lengths and spin-excitation gaps. The low activation barrier of hydrogen-passivated phenalenyl was found to be a potential inhibitor of the radical formation, which is required for the covalent coupling of the building blocks.

**The effect of morphology of an intercalated Au layer on electronic properties of Graphene** — •AMIRHOSSEIN BAYANI and KARIN LARSSON — Department of Chemistry-Ångström laboratory, Uppsala University, Uppsala, Sweden

Thermal Intercalation processes have recently made it possible to produce large quasi free-standing graphene layers on different substrates. One method, which is based on thermal annealing, uses a 4H-SiC (0001) substrate with an attached carbon buffer layer onto the Si-face of the substrate. Various types of metals have then been used with the purpose to intercalate these metal atoms between SiC and the buffer layers, thereby creating a monolayer (ML) of graphene with an intact Dirac point. Moreover, when positioning heavy metal atoms under graphene, the spin-orbit coupling will increase and thereby enhances the Rashba band splitting. This phenomenon comes from the breakage of a mirror symmetry due to interaction with the substrate. To the knowledge of the authors, the role of the morphology of the intercalated layer on the electronic properties of graphene has not yet been considered and it is worth considering this effect when electronic properties of graphene is wanted to be studied after intercalation. Here we show how the morphology of the intercalated Au layer will affect the electronic properties of a ML of graphene. The possibility to induce a band gap at the Dirac point of graphene by manipulating the staggered potential of a 4H-SiC/Au substrate, is thereby looked for. The calculations are based on density functional theory (DFT) + SOC.

Intercalation of epitaxial graphene on SiC(0001) with sulfur — •SUSANNE WOLFF, NICLAS TILGNER, TASSILO RAUSCHENDORFER, FLORIAN SPECK, and THOMAS SEYLLER — Chemnitz University of Technology, 09126 Chemnitz, Germany

Epitaxial growth of graphene on SiC in argon atmosphere is a well-established method to produce high quality films. There, the first grown carbon layer is partially covalently bound to the substrate and lacks the graphene-like electronically properties. This so-called buffer layer can be decoupled from the substrate by intercalation. Furthermore, the choice of intercalant manipulates the electronic properties of the decoupled graphene.

We investigated the intercalation of a buffer layer with sulfur by X-ray photoelectron spectroscopy (XPS) and angle-resolved photoelectron spectroscopy (ARPES). The intercalation process was performed in a two-zone furnace where the FeS₂ precursor and the buffer layer can be heated separately. An argon gas flow transports the sublimated sulfur to the sample. Partial intercalated samples show two sulfur peaks at different binding energies in XPS. They can be attributed to intercalated sulfur and sulfur on top of the not intercalated buffer layer. ARPES measurement in the vicinity of the Dirac point showed that sulfur intercalation results in p-type doped decoupled graphene layers.

twisted graphene on Ir(111) and SiC(0001) studied by SPA- LEED — •MOHAMMAD TAJIK¹, CHRISTIAN BRAND¹, BIRK FINKE¹, KARIM OMAMBAC¹, LAURENZ KREMEYER¹, FRANK MEYER ZU HERINGDORF^{1,2}, and MICHAEL HORN-VON HOEGEN^{1,2} — ¹Universität Duisburg-Essen — ²center for nanointegration duisburg-essen

when graphene is placed on a crystalline surface, the periodic structures within the layers superimpose and a moiré superlattices form. Small lattice rotations between the 2D-layer and the substrate strongly modify the moiré superlattice, upon which many electronic, vibrational, and chemical properties depend. Here we report on such structural modification of epitaxial graphene grown on metallic Ir(111) and semiconducting SiC(0001) surfaces. The spontaneous reorientation in the degree- and sub-degree-range of graphene on Ir(111) depends on the substrate temperature during growth. This effect is described by a 2D coincidence network favored by strain reduction together with the dissimilar thermal expansion of the substrate and graphene. For graphene on SiC(0001) only the oriented R0* phase is found due to the higher bonding strength to the substrate. Upon H and Sn intercalation this interaction can be reduced such that the graphene layer is lifted from the substrate. Finally, we present a detailed analysis of an unusually broad diffraction background found for graphene and hex-BN on both substrates.

#### O 18.5 Mon 18:00 P4

On the Way to Twisted Bilayer Graphene: Formation and Decoupling of 0°-Rotated Epitaxial Graphene — •HAO YIN^{1,2}, MIRIAM RATHS^{1,2}, MARK HUTTER^{1,2}, FRANÇOIS C. BOCQUET¹, and CHRISTIAN KUMPF^{1,2} — ¹Peter Grünberg Institute (PGI-3), Forschungszentrum Jülich and Jülich-Aachen Research Alliance (JARA), Fundamentals of Future Information Technology, Jülich, Germany — ²Experimentalphysik IV A, RWTH Aachen University, Aachen, Germany

On the way to twisted bilayer graphene with a twisting angle of  $30^{\circ}$ , we investigated the graphene growth on 6H-SiC(0001) using an unconventional epitaxial growth method named 'surfactant-mediated growth', which is based on annealing the SiC surface in borazine atmosphere. Here, we report a LEEM-based study on two different samples, on which we observed different surface morphologies with varying numbers of stacked graphene layers. A large-scale uniform graphene  $R0^{\circ}$  monolayer is found on the first sample that was annealed to 1330°C. This sample is a promising candidate for producing 30° TBG. Interestingly, some regions of the graphene  $R0^{\circ}$  layer exhibit different brightness contrasts at specific start voltages, without showing significant differences in their LEEM-IV curves. The second sample was annealed 50°C higher, causing the formation of graphene multilayer domains. We utilized LEEM and LEEM-IV in order to determine the number of layers as well as the distribution of multilayer graphene domains. Furthermore, we discuss the influence of the annealing temperatures in terms of the formation and decoupling of the epitaxial graphene layers.

#### O 18.6 Mon 18:00 P4

Vertical structure of Sb-intercalated quasi-freestanding graphene on SiC(0001) — YOU-RON LIN^{1,2,3}, SUSANNE WOLFF^{4,5}, •MARK HUTTER^{1,2,3}, SER-GUEI SOUBATCH^{1,2}, TIEN-LIN LEE⁶, F. STEFAN TAUTZ^{1,2,3}, THOMAS SEYLLER^{4,5}, CHRISTIAN KUMPF^{1,2,3}, and FRANÇOIS C. BOCQUET^{1,2} — ¹Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, Germany — ²Jülich Aachen Research Alliance (JARA) — ³Experimentalphysik IV A, RWTH Aachen University, Germany — ⁴Institute of Physics, Faculty of Natural Sciences, TU Chemnitz, Germany — ⁵Center for Materials, Architectures and Integration of Nanomembranes (MAIN), TU Chemnitz, Germany — ⁶Diamond Light Source Ltd., Didcot, Oxfordshire, UK

Using the normal incidence x-ray standing wave (NIXSW) technique, we have investigated the vertical structure of quasi-freestanding monolayer graphene (QFMLG) obtained by intercalation of antimony under the  $(6\sqrt{3} \times 6\sqrt{3})$  R30° reconstructed graphitized 6H-SiC(0001) surface, also known as zeroth-layer graphene. We found that Sb intercalation decouples the QFMLG very well from the substrate. The distance from the QFMLG to the Sb layer almost equals the expected van der Waals bonding distance of C and Sb. The Sb-intercalation layer itself is mono-atomic, very flat, and located much closer to the substrate, at almost the distance of a covalent Sb-Si bond length. All data is consistent with Sb located on-top of the uppermost Si atoms of the SiC bulk.

O 18.7 Mon 18:00 P4

**Bi(110) islands on epitaxial graphene** — •SERGII SOLOGUB^{1,2}, JULIAN KOCH¹, CHITRAN GHOSAL¹, and CHRISTOPH TEGENKAMP¹ — ¹Institut für Physik, TU Chemnitz, Reichenhainerstr. 70, 09126 Chemnitz — ²Institute of Physics, NAS of Ukraine, Nauki avenue 46, 03028 Kyiv

The atomic structure and morphology of ultrathin epitaxial Bi islands grown on the graphene/SiC surface was examined by SPA LEED and STM. Bi films with an average height of a few bilayers were deposited at RT and annealed at 410 K for 30 min afterwards. A Volmer-Weber growth mode with a predominance of the Bi(110) orientation was found. LEED patterns show that the Bi(110) structure has three domains rotated by 60°, with each domain having two subdomains rotated by  $\pm 2^{\circ}$  with the zig-zag direction of Bi parallel to the armchair direction of graphene and four (minority-)subdomains with the zig-zag direction of Bi parallel to the zig-zag direction of graphene. Moreover, STM investigations revealed an elongation of the islands in the zig-zag direction of Bi as well as preferential ("magic") thicknesses (even numbers of Bi monolayers).

Additionally, magneto transport measurements using a 4 T magnet were performed in order to investigate the influence of the Bi islands on the weak localization effekt in graphene.

#### O 18.8 Mon 18:00 P4

Quantum well states in Bi(110) islands grown on epitaxial graphene — •CHITRAN GHOSAL and CHRISTOPH TEGENKAMP — Institut für Physik, TU Chemnitz

The semimetal Bi attracts a lot of interest because of its unique electronic properties such as a low carrier concentrations and large carrier mobilities coming along with mesoscopic Fermi wavelength giving rise to robust quantum confinement effects and spin polarized states in thin films [1]. In this work we studied the growth of Bi on n-type doped monolayer graphene (MLG) on SiC(0001) by means of STS and STM. While for low coverages Bi(110) islands are formed Bi(111) structures were found for higher coverages. This allotropic transition occurs at 10 monolayers (3.3nm) and is significantly larger than the critical coverage reported for Bi on Si(111) [2]. In contrast to Bi/MLG, the deposition of Bi on HOPG results in the formation of islands with an odd number of layers. These differences were attributed to different substrate screening effects. Irrespective of the interface, Bi seems to grow rather in a relaxed bilayers fashion, i.e. supporting the formation of black phosphorous structures [2]. Spectroscopy performed on islands of different heights revealed a large gap opening (750 meV) at the center of 4 ML islands. In addition, we found signatures of edge states, which might refer to a non-trivial topology within these QWS-stabilized nanostructures.

Identification of electronic structures and atomic configuration of Nitrogen defects on graphene/Pt(111) — •JEONG AH SEO^{1,2}, HYUNMIN KANG^{3,4}, YOUNG JAE SONG^{3,4}, JUNGSEOK CHAE¹, and ANDREAS J. HEINRICH^{1,2} — ¹Center for Quantum Nanoscience, Institute for Basic Science, Seoul, Korea — ²Department of Physics, Ewha Womans University, Seoul, Korea — ³Department of Nano Engineering, Sungkyunkwan University (SKKU), Suwon, Korea — ⁴SKKU Advanced Institute of Nano Technology (SAINT), Sungkyunkwan University (SKKU), Suwon, Korea

Nitrogen doped graphene is considered as an effective method for modulating the electronic states and properties of graphene. We have prepared nitrogen doped graphene on Pt(111) surface, grown by deposition of pyridine precursor molecules. We figured out there exist several types of defects including graphitic nitrogen and pyridinic nitrogen structure. The imaging of the defects is performed using low temperature scanning tunneling microscope (STM) and atomic force microscope (AFM). The defects preferred to have strong triangular shape features above certain bias voltage. To figure out the features of nitrogen dopant atom, we measured bias dependent STM images, scanning tunneling spectroscopy and AFM imaging. We have observed prominent difference in spectroscopic feature near the fermi energy between defects and pristine graphene. In addition, we also have observed atomic configuration of defect site using AFM. With the aid of STM simulation based on calculated results from the density functional theory, possible candidates of defect types will be provided.

#### O 18.10 Mon 18:00 P4

**Bell-shaped Electron Diffraction Component in 2D Materials** — •HANNAH KOHLER, FRANK MEYER ZU HERINGDORF, and MICHAEL HORN-VON HOEGEN — Faculty of Physics and Center for Nanointegration, Duisburg-Essen (CENIDE), University of Duisburg-Essen, 47048 Duisburg, Germany

In low energy electron diffraction a bell shaped component (BSC) is observed for graphene on SiC and Ir(111) and for hBN on Ir(111) [APL118 (2021) 241902]. The distinctiveness of this broad diffuse intensity appears to be indicative of a highly ordered 2D layer. Several attempts were made to explain the origin of the BSC, but the mechanism remains at large still unclear. In particular, a classification in which 2D systems a BSC exists is missing. Low energy electron microscopy (LEEM) combines the possibility to investigate the BSC with micro-diffraction ( $\mu$ -LEED) and *in-situ* imaging. It was found that the BSC can in fact be detected not only on graphene and hBN, but also on *ex-situ* chemical-vapor-deposition-grown MoS₂. In graphene on Ir(111) the full width at half maximum (FWHM) of the BSC decreases with an increase in rotational angle of the graphene. Measurements after Cs intercalation of the graphene show a smaller FWHM compared to the non-intercalated graphene layer.

#### O 18.11 Mon 18:00 P4

**Buffer Layer Characterization of Epitaxial Graphene on Silicon Carbide with** Scanning Tunneling Microscopy — •BENNO HARLING¹, ANNA SINTERHAUF¹, PETER RICHTER², PHILIP SCHÄDLICH², THOMAS SEYLLER², and MARTIN WENDEROTH¹ — ¹IV. Physikalisches Institut, Georg-August-Universität Göttingen, Germany — ²Institut für Physik, Technische Universität Chemnitz, Germany

In this contribution, we present a scanning tunneling microscopy study on the buffer layer of epitaxial graphene on 6H-silicon carbide (SiC) at 8 K and room temperature in UHV. The local configurations and properties of the buffer layer still leave many open questions concerning the interactions between graphene and substrate. Our goal is to disentangle the contributions of the graphene and the underlying buffer layer to the tunneling current on a local scale and to establish an understanding of the responsible mechanisms. We employ multibias imaging to investigate buffer layer contributions to the tunneling current. This measurement mode takes quasi-simultaneous STM images line per line at given bias voltages resulting in a connected stack of topography maps. This allows to observe the changes of the topography in dependency of the applied bias voltage, with much lower dependency on tip modifications while scanning. We connect local corrugation changes to relative heights and the overall corrugation tendency within the stack. Financial support of the Deutsche Forschungsgemein schaft (DFG) is given by project We 1889/13-1 and We 1889/14-1.

#### O 18.12 Mon 18:00 P4

**Intercalation of Fe under graphene on Ir(110)** – •JASON BERGELT, AF-FAN SAFEER, STEFAN KRAUS, JEISON FISCHER, and THOMAS MICHELY – II. Physikalisches Institut, Universität zu Köln, Zülpicher Str. 77, 50937 Köln, Germany

Graphene on Ir(110) is a single-crystal, where graphene is nearly strain free and the resulting moiré pattern consists of waves with crests and troughs along the [001]-Ir direction. Also it has been shown that the growth of graphene prevents the formation of nano-facets that are present in bare Ir(110) at room temperature. In this work, we intercalated several layers of Fe between Gr and unreconstructed Ir(110). By using scanning tunneling microscopy (STM) and low energy electron diffraction (LEED), we confirm that Fe grows pseudomorphic with respect to unreconstructed Ir(110). Due to strong adhesion of graphene to Ir(110), deposition of Fe on a closed graphene layer results in the formation of clusters on the surface and negligible intercalation at temperatures where alloying of Fe with Ir(110) is absent. Therefore, we implemented a procedure to etch with molecular oxygen small holes of controlled size into graphene. Moreover, we investigated the temperature and evaporation flux dependence of intercalation. Furthermore, we discuss the limit of pseudomorphic growth in view of the formation of a reconstruction at thicker intercalated Fe films.

#### O 18.13 Mon 18:00 P4

Strongly correlated boundary states in topologically insulating chiral graphene nanoribbons tuned by contact potential — •LEONARD EDENS¹, FRANCISCO ROMERO¹, SOFIA SANZ², AMELIA DOMÍNGUEZ-CELORRIO⁵, MANUEL VILAS-VARELA³, JINGCHENG LI⁴, DAVID SERRATE⁵, DIEGO PEÑA³, and NACHO PASCUAL^{1,2} — ¹CIC nanoGUNE BRTA, San Sebastián, Spain — ²DIPC, San Sebastián, Spain — ³CIQUS and Departamento de Química Orgánica, Univ. de Santiago de Compostela, Spain — ⁴School of Physics, Sun Yat-sen University, Guangzhou, China — ⁵INMA, and Univ. de Zaragoza, 50009 Spain

Chiral graphene nanoribbons present a special class of nanographenes in that their distinct edge symmetry causes a topologically nontrivial band dispersion. Truncating such a ribbon results in a pair of symmetry-protected topological end states predicted to be spin-polarized. Metal substrates interact with the molecular orbitals, transferring charge and screening electron-electron correlations. We decouple the nanoribbons by dragging them onto an ultrathin large bandgap insulator using an STM, and also synthesize them on a low-work function surface. Scanning tunneling spectroscopy on the surface intermetallic GdAu2 reveals a near-neutral ribbon, showing its end state spin-split. On MgO/Ag(001), the ribbons are highly decoupled, leading a greatly enhanced tunneling lifetime, vibronic sidebands, a negative charge and an enhanced correlation gap of opening far in the quantized conduction band.

#### O 18.14 Mon 18:00 P4

**Structural investigation of Pb intercalated graphene on SiC** – •SHAISTA AN-DLEEB, JULIAN KOCH, CHITRAN GHOSAL, and CHRISTOPH TEGENKAMP – Institut für Physik, TU Chemnitz, Reichenhainerstr. 70, 09126 Chemnitz

In order to modify the electronic properties of graphene, intercalation experiments have received a lot of attention recently. In this research, we examined the intercalation of Pb on carbon buffer layer on SiC(0001) using SPA-LEED and STM. The samples were prepared in UHV by several cycles of Pb deposition using MBE at RT followed by annealing at temperatures ranging from 500 to 900°.

In LEED the intercalated phase shows six characteristic spots around the (00)spots, which we correlated with a striped phase in STM. The local structure on the stripes shows two honeycomb Pb layers with approximately twice the lattice constant of graphene and turned by  $\pm 7.5^{\circ}$  with respect to graphene. The corresponding spots in LEED coincide with two buffer layer spots. Their energy dependent behavior was analyzed.

#### O 18.15 Mon 18:00 P4

Spectroscopic evidence of BCS-BEC crossover in FeSe monolayer — •WANTONG HUANG^{1,6}, HAICHENG LIN¹, GAUTAM RAI², YUGUO YIN¹, LIANYI HE¹, QI-KUN XUE^{1,5}, STEPHAN WOLFGANG HAAS^{2,3}, STEFAN KETTEMANN^{3,4}, XI CHEN^{1,5}, and SHUAI-HUA JI^{1,5} — ¹State Key Laboratory of Low-Dimensional Quantum Physics, Department of Physics, Tsinghua University, Beijing 100084, China — ²Department of Physics and Astronomy, University of Southern California, Los Angeles, CA 90089-0484, USA — ³Jacobs University, Campus Ring 1, 28759 Bremen, Germany — ⁴Division of Advanced Materials Science, POSTECH, San 31, Hyoja-dong, Nam-gu, Pohang 790-784, South Korea — ⁵Frontier Science Center for Quantum Information, Beijing 100084, China — ⁶Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany

It has been difficult to realize the crossover from Bardeen-Cooper-Schrieffer (BCS) to Bose-Einstein condensates (BEC) in solids. Here we report direct evidence of BEC in a FeSe monolayer. The Fermi energy of the FeSe film can be tuned by graphene/SiC substrate to realize a BCS-BEC crossover. As the Fermi energy drops, the local density of states measured by STM evolves continuously from a BCS gap to a step-like asymmetric spectrum of BEC state. The theoretical calculation based on a two-band model reproduces well the measured spectra and, in particular, identifies features in the quasi-particle density of states that indicate a transition from the BCS to the BEC regime. In addition, the Zeeman splitting of the quasi-particle states is found to be consistent with the characteristics of a condensate.

#### O 18.16 Mon 18:00 P4

Investigating the correlated ground state of metallic monolayer MoS₂ with scanning tunneling spectroscopy — •CAMIEL VAN EFFEREN, JEISON FISCHER, THOMAS MICHELY, and WOUTER JOLIE — II. Physikalisches Institut, Universität zu Köln, Germany

Using contactless chemical doping [1], we grow metallic monolayer  $2H-MoS_2$  on a graphene on Ir(111) substrate. Since this method leaves the surface accessible, we perform real space investigations of correlated behavior in metallic monolayer  $MoS_2$  via scanning tunneling microscopy (STM) and spectroscopy (STS). In STS, we find a broad depression in the density of states around the Fermi level, of about 100 meV. Upon closer inspection, the depression is revealed to consist of a series of small gaps and peaks, spaced by 26-28 meV. This interval corresponds to a flat band in the phonon dispersion of  $MoS_2$ . The appearance of the peaks can be explained by strong coupling between the  $MoS_2$  electrons and phonons at the high-symmetry K-point of the Brillouin zone, and may point to the formation of Holstein polarons. The behavior of the polarons is studied near grain boundaries, edges and defects, where the polaron bands are suprisingly seen to bend under the influence of charge.

Artificial electronic lattices on InAs(111)A — •RIAN LIGTHART and INGMAR SWART — Condensed Matter and Interfaces, Debye Institute for Nanomaterials Science, Utrecht, The Netherlands

Artificial electronic lattices are a promising tool to elucidate novel effects in the quantum world. The Scanning Tunnelling Microscope (STM) allows to build the lattices by manipulating atoms with nanoscale precision and to probe the electronic properties. The electronic lattices consist of artificial atoms on a metal-lic/semiconducting crystal with a surface state which acts as a 2D electron gas (2DEG). The 2DEG is patterned by scatterers on the surface creating artificial atoms. The versatile artificial atoms are used in lattices to study the effect of structure on electronic characteristics.

An already well-known system is CO on Cu(111), however, this system has a low energy resolution of 80 mV due to coupling of the surface state with bulk states. Here, the promising InAs(111)A surface with native In adatoms is studied since it has a higher energy resolution of around 5 meV. Vertical manipulation allows to place multiple In-adatoms in vicinity of each other. The In adatoms create a potential well that confines the surface state electrons of InAs. The artificial atom created can be coupled into dimers with different bond strengths by varying the distance or by introducing bridge sites. The artificial electronic lattices created on InAs(111)A can help to probe new characteristics in the lattices due to the vastly improved energy resolution.

O 18.18 Mon 18:00 P4 **Resonant photoemission studies at the Fe 3***p* **threshold on thin FeTe/Bi**₂**Te**₃ **and FeSe/Bi**₂**Se**₃ — •MARTIN VONDRÁČEK¹, TOMÁŠ SKÁLA², KAREL CARVA², GUNTHER SPRINGHOLZ³, and JAN HONOLKA¹ — ¹Institute of Physics of the Czech Academy of Sciences, Prague, CZ — ²Charles University, Faculty of Mathematics and Physics, Prague, CZ — ³Johannes Kepler University, Institute of Semiconductor and Solid State Physics, Linz, AT

Monolayers (MLs) of tetragonal FeTe and FeSe grow on hexagonal Bi₂Se₃(111) and Bi₂Te₃(111) substrates as three 60°-rotated domains. In scanning tunnelling spectroscopy, a gap appears at the Fermi level of FeTe/Bi₂Te₃ suggesting interface-induced superconductivity below Tc  $\approx 6$  K [1]. FeSe/Bi₂Se₃ remains in a gapless state [2]. Unconventional superconductivity in Fe-chalcogenides (FeChs) is believed to be correlated to the texture of the Fermi strate at  $\Gamma$ - and M-points. However, ARPES data of FeCh MLs on Bi₂Ch₃ is complex due to the superposition of contributions from all three domains. Here we show photon energy dependent UPS data probing  $k_z$  dispersions along the  $\Gamma$ -*Z* direction. Fano-like modulations of valence band intensities are observed in the energy range 30-80 eV, indicative of a resonant photoemission effect at the Fe 3*p* edge around 55 eV. Our ML data is compared to previous bulk studies [3].

Electronic and structural properties of Fe-doped SnS van der Waals crystals — •DAMLA YESILPINAR^{1,5}, MARTIN VONDRÁČEK¹, ČESTMIR DRAŠAR², PATRIK ČERMAK², ONDŘEJ CAHA³, KAREL CARVA⁴, VÁCLAV HOLÝ⁴, JAN PROKLEŠKA⁴, HARRY MÖNIG⁵, and JAN HONOLKA¹ — ¹Institute of Physics, AV ČR, Na Slovance 1999/2 182 21 Praha 8, CZ — ²Faculty of Chemical Technology, University of Pardubice, Studentská 573, 532 10 Pardubice, CZ — ³Department of Condensed Matter Physics, Masaryk University, Žerotínovo nám. 617/9, 601 77 Brno, CZ — ⁴Department of Condensed Matter Physics, Charles University, Ke Karlovu 5, 121 16 Prague, CZ — ⁵Physikalisches Institute, Wilhelm-Klemm Str. 10, 48149 Münster, DE

We investigate the effect of low concentrations of iron on the physical properties of SnS van der Waals crystals grown from the melt. By means of scanning tunneling microscopy (STM) and photoemission spectroscopy we study Fe-induced defects and observe an electron doping effect in the band structure of the native p-type SnS semiconductor. Atomically resolved and bias dependent STM data of characteristic defects are compared to *ab initio* DFT simulations of vacancy (V_S and V_{Sn}), Fe substitutional (Fe_{Sn}) and Fe interstitial (Fe_{int}) defects. In line with our EXAFS data, we propose the importance of Fe_{int} and discuss possible pairing defects, e.g. with V_S.

O 18.21 Mon 18:00 P4

In Operando Soft X-Ray Photoemission Spectroscopy of TaS₂ and HfS₂ based memristive devices — •TAMMO ZIMMERMANN¹, ALENA NIERHAUVE^{1,2}, MATTHIAS KALLÄNE^{1,2}, JENS BUCK^{1,2}, ZHANSONG GENG³, CHAO ZHANG³, FRANK SCHWIERZ³, MARTIN ZIEGLER³, and KAI ROSSNAGEL^{1,2,4} — ¹Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität Kiel, 24098 Kiel, Germany — ²Ruprecht-Haensel-Labor, DESY and CAU Kiel, 22607 Hamburg and 24098 Kiel, Germany — ³Department of Electrical Engineering and Information Technology , TU Ilmenau, 98684 Ilmenau, Germany — ⁴Deutsches Elektronen-Synchroton DESY, 22607 Hamburg, Germany

In neuromorphic engineering interface-based memristive devices (IMDs) are promising candidates to mimic synaptic behavior. A refined understanding of bias-induced changes in the band structure and the underlying transport mechanisms of layered transition-metal dichalcogenide-based IMDs will improve the development toward future applications, e.g., in artificial neural networks. Here, we show first *in operando* position- and momentum-resolved soft x-ray photoemission spectroscopy measurements obtained from transistor-like  $TaS_2$ - and HfS₂-based IMDs.

#### O 18.22 Mon 18:00 P4

Comparison of spin-crossover properties between thin film and bulk sample of a binuclear Fe(II) complex — •MARCEL WALTER¹, SANGEETA THAKUR¹, CLARA TROMMER², FELIX TUCZEK², SEBASTIEN ELIE HADJADJ¹, JORGE TORRES¹, and WOLFGANG KUCH¹ — ¹Institut für Experimentalphysik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin — ²Institut für Anorganische Chemie, Christian-Albrechts-Universität zu Kiel, Max-Eyth-Straße 2, 24118 Kiel

Spin-crossover molecules (SCMs) are a promising material in the field of spintronics, due to the reversibility of switching between a high-spin and a low-spin state, which can be triggered by light and temperature [1]. The focus of our research is to deposit large SCMs to explore cooperativity in spin switching on surfaces. A pulsed-valve vapor deposition method is used for thin films. This has the advantage of depositing (sub-) monolayers of SCMs in an UHV environment without applying large amounts of thermal energy, which can decompose the large SCMs. We compare the spin-switching behavior of the dinuclear SCM [{Fe(H₂B(pz)₂)₂( $\mu$ -bipy-ac-bipy)] as thin film on highly oriented pyrolytic graphite and as bulk sample using X-ray absorption spectroscopy. The spin-crossover properties were examined for thermal-induced spin state switching as well as for light-induced excited spin-state trapping. The results show that the thin films are locked in a mixed spin state while the bulk sample switches completely, although the equilibrium temperature of the spin states is comparable.

O 18.23 Mon 18:00 P4

Neutral and charged excitations in two-dimensional MoTe₂ from first principles — •FRANZ FISCHER^{1,2}, ABDERREZAK BESTER¹, and GABRIEL BESTER¹ — ¹University of Hamburg, Institute of Physical Chemistry, 22761 Hamburg, Germany — ²Max Planck Institute for the Structure and Dynamics of Matter, 22761 Hamburg, Germany

Atomically thin layers of transition metal dichalcogenides attract remarkable interest due to their extraordinary electronic and optical properties. The lack of inversion symmetry in their crystal structure combined with strong spin-orbit interaction caused by heavy metal atoms gives rise to an extra valley degree of freedom as well as large spin splittings in the Brillouin zone.

We present an effective first-principle formalism that is extendable to study any order of neutral or charged excitation [1]. Our formalism relies on configuration interaction and the GW-approximation and reduces in the case of excitons to the standard form of the BSE. We will present results of the excited states in monolayer  $MoTe_2$  and their emergence from the particular single-particle configurations. In the future we want to extend our methodology to the temporal domain in order to study dynamics of excited states in 2D materials. [1] Phys. Rev. B. **100** 201403(R) (2019)

O 18.24 Mon 18:00 P4 Relaxation, the moiré potential and excited states for twisted TMDC bilayers — •CARL EMIL MØRCH NIELSEN, MIGUEL DA CRUZ, ABDERREZAK TORCHE, and GABRIEL BESTER — University of Hamburg, Institute of Physical Chemistry, 22761 Hamburg, Germany

In recent years, the research of transition metal dichalcogenides has amassed much attention due to interesting properties such as strong localisation of excited states. The field of twistronics emerged as twisting provides a new degree of freedom in engineering specific properties. However, the theoretical ab-initio approach shows an immediate challenge to overcome; large systems, where the moiré unit cell may hold thousands of atoms.

In this project, the aim is to theoretically study moiré confined optical excitations in twisted TMD vdW-homo and heterostructures. We have successfully integrated a force-field based method of relaxation using LAMMPS as suggested in a paper by Jain et. al. We have re-parameterized the SW and KC potentials seen in this paper and expanded the parameter set to include all possible bilayer TMD combinations. With these we can accurately model the associated local band gap variation, e.g. the moiré potential, taking into effect both lattice corrugation and atomic reconstruction. Our goal is now to investigate the excited state properties with our group-developed code from first-principles.

#### O 18.25 Mon 18:00 P4

**Tip-induced excitonic luminescence of an atomically-resolved van der Waals heterostructure** — •LUIS PARRA LOPEZ^{1,2}, ANNA ROSLAWSKA², FABRICE SCHEURER², STÉPHANE BERCIAUD², and GUILLAUME SCHULL² — ¹Department of Physical Chemistry,Fritz Haber Institute of the Max Planck Society, 14195 Berlin,Germany. — ²Université de Strasbourg,CNRS,IPCMS,UMR 7504,67000 Strasbourg,France.

Van der Waals heterostructures (vdWH) made from stacks of transition metal dichalcogenides and other 2D-materials are appealing systems to investigate light-matter interaction. Their optical response is dominated by tightly bound excitons that are sensitive to the presence of atomic-scale inhomogeneities. These inhomogeneities lie at length-scales below the spatial resolution accessible with standard optical spectroscopies.Here, we present an approach using a scanning tunneling microscope to induce the luminescence of an MoSe₂/FL-graphene vdWH [1].We correlate the atomic-scale landscape with the locally induced optical response and observe sizeable variations in the excitonic emission between different nm-sized areas. This study paves the way for novel investigations regarding the local properties of vdWH and highly localized excitons. To gain deeper insight into interlayer coupling mechanisms on the nanoscale, which occur on sub-ps timescales, requires additional high temporal resolution as well.I thus conclude with an outlook of an experimental setup capable of addressing ultrafast dynamics with fs-temporal and nm-spatial resolution[2].[1] Parra et al, arXiv:2204.14022(2022).[2] Müller et al, ACS photonics, 7(8),(2020).

#### O 18.26 Mon 18:00 P4

Changing structural and electronic properties of h-BN on Ir(111) by potassium intercalation — •PHILIP GRIMM, FRIEDRICH WANIERKE, FELIX OTTO, MAXIMILIAN SCHAAL, ROMAN FORKER, and TORSTEN FRITZ — Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany

2D hexagonal boron nitride (h-BN) is applied in electronics components, e.g., in gate dielectrics for transistors. However, its insulating behaviour is strongly influenced by the growth on metal substrates. One possibility to restore the in-

# sulating effect and to decouple h-BN is the intercalation of akali metals due to their low ionization energies.

In this study, we use h-BN grown by CVD on Ir(111) while potassium is deposited by thermal evaporation. The samples are investigated at various temperatures, the lateral structure by means of LEED as well as the electronic properties by means of XPS and (AR)PES. A ( $\sqrt{3} \times \sqrt{3}$ )R30° superstructure of K and a decrease of the moiré pattern originating from h-BN/Ir(111) is observed. In addition, the core levels and the band structure shifts to higher binding energies whereas the work function decreases by the similar value. Another observation is a disappearing band folding of the  $\sigma$ -bands. Due to the metastability of the superstructure at room temperature, we switched to low temperature at 35 K and observed even larger shifts of the core levels as well as of the band-structure ( $\approx$  3 eV). In conclusion, our results indicate an intercalation of K in the 2D-system and consequently h-BN is decoupled from Ir(111).

#### O 18.27 Mon 18:00 P4

Adsorption and Reaction of Bromine on h-BN/Rh(111) — •Eva Marie Freiberger, Natalie J. Waleska, Felix Hemauer, Valentin Schwaab, Hans-Peter Steinrück, and Christian Papp — Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany

Due to their unique chemical and electronic properties, rendering them promising for many applications, numerous two-dimensional materials (2DM) have been predicted, synthesized and characterized. To tailor the properties of 2DM towards possible applications, their chemical modification is of special interest. Hexagonal boron nitride (h-BN), a graphene analogue, exhibits a so-called nanomesh on Rh(111), which can be used as a template enabling spatially defined modification of the 2DM. Using this template, we aim for selective functionalization of h-BN/Rh(111) with halogens, which lead to strong electronic doping. Here, we present a synchrotron radiation-based high-resolution X-ray photoelectron spectroscopy (XPS) study on the adsorption and thermally induced reaction of bromine on h-BN/Rh(111). The adsorption of different amounts of bromine was followed in situ at 170 K, confirming the template effect of the nanomesh for low coverages. Based on temperature-programmed XPS (TPXPS) experiments, we propose covalent functionalization of the pores and a thermally induced on-surface reaction of bromine. Furthermore, the adsorption is observed to be reversible upon heating to 800 K. By shedding light on their controlled chemical modification on the molecular scale, our work paves the way for purposeful tailoring of the properties of 2DM.

#### O 18.28 Mon 18:00 P4

Structural investigation of antimony monolayers on Ag(111) — •STEFANIE HILGERS¹, JULIAN A. HOCHHAUS^{1,2}, MALTE G. H. SCHULTE^{1,2}, and CARSTEN WESTPHAL^{1,2} — ¹TU Dortmund University, Department of Physics, Otto-Hahn-Str. 4a, 44227 Dortmund, Germany — ²DELTA, TU Dortmund, Maria-Goeppert-Mayer-Str. 2, 44227, Dortmund, Germany

Similar to graphene and further elements of the 4th main group, Group-V elements such as antimony are also predicted to have extraordinary electronic properties. Because of the strong spin-orbit coupling and the resulting topological properties, antimony monolayers are of great interest for future electronic applications. Since the structural configuration of 2D-materials has major influence on the electronic properties of the material, structural investigations are highly relevant. In the here presented research we report on the synthesis and structural investigation of antimoy monolayers on Ag(111).

After several cleaning cycles in UHV, antimony is evaporated by a Kudsen cell to deposit monolayers on the Ag(111) surface. The well-known ( $\sqrt{3} \times \sqrt{3}$ )R30° superstructure can be identified by low-energy electron diffraction (LEED). In addition, a ( $2\sqrt{3} \times 2\sqrt{3}$ )R30° superstructure can be verified for higher coverages. Furthermore, the real space structure is investigated by scanning tunneling microscopy (STM).

# Live demodulation of pseudo-heterodyne SNOM at kHz repetition rates – •PHILIPP SCHWENDKE¹, SAMUEL PALATO¹, NICOLAI GROSSE², and JULIA STÄHLER¹ – ¹PC dept., FHI of the MPG and HU Berlin – ²ELAB, FHI of the MPG

Scanning near-field optical microscopy (SNOM) allows the spectroscopic investigation of functional surfaces with spatial resolution beyond the diffraction limit. For the observation of electron dynamics on a femtosecond and nanometre scale, common setups rely on high repetition rate laser systems in order to avoid the Nyquist limit, imposed by signal modulation through the tapping AFM tip. Phase-domain sampling schemes allow sample rates below the Nyquist frequency, permitting the use of kHz-class optical amplifiers for tunable wavelengths down to the UV and femtosecond time resolution. We introduce quadra-

ture demodulation for a robust and fast signal demodulation, while also simplifying the experimental setup.

Here, we illustrate and evaluate different methods for signal modulation and data analysis, with the aim of increasing the signal to noise ratio while maintaining high spatial resolution. The near-field contribution is identified through retraction curves, while noise and overall performance is evaluated on real-space images of a Si test sample, showing a significant signal contrast at high harmonic orders of tapping modulation. The presented methods are straightforward to combine with established optical methods, paving the way towards time-resolved SNOM and nano-spectroscopy.

#### O 19.3 Mon 18:00 P4

Designing a Scanning Probe Microscope to quantify electron correlations in novel 2D materials — •Nikhil Seeja Sivakumar, Henning von Allwörden, Daniel Wegner, Alexander Ako Khajetoorians, and Nadine Hauptmann — Institute for Molecules and Materials, Radboud University, Nijmegen, The Netherlands

Quantum phases in a single or few layers of van der Waal materials often exhibit novel types of charge and spin orders that are driven by electron correlations. To understand the role of electron-electron interactions, it is required to quantify the interplay between the geometric structure, charges and spins at the atomic scale. Scanning tunneling microscopy (STM) and its accompanying magnetic mode, spin polarized STM, are powerful techniques to study the geometric, electronic and magnetic structure, but their application is limited to metallic or semiconducting quantum phases. Here, we present the design and setup of a home-built scanning probe microscopy setup working at 1K based on a JT-stage with 4He, operating in a 3T out-of-plane magnetic field. The setup will combine STM with non-contact Atomic Force Microscopy, Kelvin Probe Force Microscopy, and Magnetic Exchange Force Microscopy to independently study the geometric, electronic and magnetic structure in insulating quantum phases of 2D materials, as well as at phase transitions to conducting phases. A gating stage will allow to study 2D materials in a device geometry.

**Nanoscale capacitance and dielectric permittivity measurements** — •PASCAL ROHRBECK¹, LUKAS DRAGO CAVAR^{1,2}, PETER REICHEL², and STEFAN A. L. WEBER^{1,2} — ¹Max Planck Institute for polymer research, Department physics at interfaces, Ackermannweg 10, 55128 Mainz, Germany — ²Johannes Gutenberg University, Department of Physics, Staudingerweg 10, 55128 Mainz, Germany The knowledge of capacitance and dielectric properties in the nanoscale is important to understand the basic physics of semiconductor materials, such as solar cells or battery materials.[1]

In this work, we demonstrate quantitative capacitance and dielectric constant measurements of individual nanostructures using an Atomic Force Microscope (AFM). The new Heterodyne Scanning Capacitance Microscopy (H-SCM) method is based on frequency mixing of two alternating current (AC)-voltages with frequencies in the MHz range. This new method enables quantitative measurements of tip-sample capacitance and local dielectric permittivity with the lateral resolution of the AFM. We can show that the H-SCM reduces the effect of stray capacitance and thereby yields superior lateral resolution.

Sphere Probes for Scanning Thermal Microscopy — •SOPHIE RODEHUTSKORS, FRIDOLIN GEESMANN, PHILIPP THURAU, and ACHIM KITTEL — Insitut für Physik, Carl-von-Ossietzky Universität Oldenburg

Scanning thermal microscopes based on STM and AFM have been used for years to observe near-field mediated heat transfer. Using custom-built coaxial thermo-couple tips in an STM setup, spatially highly resolved heat transfer measurements are possible [1]. The total heat transfer between a spherically approximated tip and a sample is expected to depend on the square of the tip's radius [2]. By attaching a 20  $\mu$ m borosilicate sphere to such a coaxial thermocouple sensor, heat flux sensitivity is further increased in distance-dependence measurements of the heat transfer between a cooled sample and a tip at room temperature for different materials. These sensors can be used for highly resolved radiative heat transfer measurements as well as for heat conduction measurements through self-assembled monolayers of organic molecules.

**A New Sensor Concept for Scanning Thermal Microscopy** — •MARVIN GLIT-TENBERG, PHILIPP WIESENER, and ACHIM KITTEL — Institut für Physik, Carl von Ossietzky Universität Oldenburg

Near-field mediated heat transfer (NFMHT) between two surfaces separated by a vacuum gap has become a widely investigated topic in the past decades. To measure this phenomenon, we are using a self-developed near-field scanning thermal microscope (NSThM) based on an STM. It is equipped with self-made thermocouple tips consisting of a platinum wire molten into a borosilicate glass capillary which is then coated with gold. Since the gold layer can also be used as a tunneling electrode, we were able to measure the thermoelectric voltage and the tunneling current between the tip and sample simultaneously. However, the voltage drop due to the tunneling current interfered with the thermo voltage, making break junction experiments investigating heat and electrical conduction uninterpretable. In a new design of the tips for the NSThM, the thermocouple is covered first by an insulating silicon dioxide film and finally by a second gold film, which then acts as a tunneling electrode separate from the hermocouple and eliminates crosstalk. These tips are called PASA-tips due to the sequence of materials (platinum-gold-silicon dioxide-gold). Some example measurements of radiative heat transfer and heat conduction with these tips are shown to illustrate their capabilities.

Implementation of a SPPX Setup and investigation of the delay-time modulation induced intensity modulation — •MARLO TEICHMANN, GEORG TRAEGER, and MARTIN WENDEROTH — V. Physical Institute, University of Göttingen, 37077, Göttingen, Germany

Shaken-pulse-pair-excited STM (SPPX-STM) successfully combines optical pump-probe techniques with STM to obtain high temporal and spatial resolution [1]. SPPX-STM achieves this by introducing a modulation of the delay time between pump- and probe pulses. The modulation of the delay time instead of the intensity leads to a constant thermal load and hence minimizes thermal effects. However, recent studies have shown that higher harmonics of this modulation causes additional undesirable signals in time resolved measurements [2].

In this study, we implemented a SPPX setup with two semiconductor lasers. These lasers can be triggered electronically which allows for delay times below Ins between pump- and probe pulse. We implemented two different pump probe schemes to suppress the additional signals, caused by the SPPX-Method. By choosing an improved modulation scheme, we show that it is possible to suppress the contribution of the higher harmonic signals by more than one order of magnitude.

Grating Coupled Illumination with Image Recognition for Scanning Tunneling Microcopy under Highly Stable and Truly Localized Optical Excitation — •GEORG A. TRAEGER¹, MARLO H. TEICHMANN¹, BENJAMIN SCHRÖDER^{1,2}, and MARTIN WENDEROTH¹ — ¹IV. Physikalisches Institut, Georg-August-Universität Göttingen, Germany — ²Max Planck Institute of Multidisciplinary Sciences, Göttingen, Germany

We present a versatile approach for a highly stable and localized optical excitation in a scanning tunneling microscopy (STM). Optical gratings on STM tips allow to excite a surface plasmon polariton (SPP), which travels to the tunneling junction and results in a highly confined optical excitation. Unfortunately, this technique comes with the drawback, that a much larger thermal load compared to the conventional direct illumination of the tunnel gap is introduced to the tip. This necessitates a high stability of the laser setup both in terms of longterm power stability and pointing[1]. The latter is limited by the mechanical decoupling of the STM from the environment, leading to independent movement of the microscope and the laser focus. We utilize an auto focus approach based on a CCD camera, which is aligned with the optical pathway of a fs-laser to achieve a active coupling between the laser and the STM. Studying ultrafast photo-currents in tunneling junctions we find that the new setup allows for STM operation under higly localized and background free illumination with a lateral resolution better than 2nm. Pd nanoparticles supported on ordered Co3O4(111): Particle size effects in electrochemical environment — •MAXIMILIAN KASTENMEIER¹, XIN DENG¹, TOMÁŠ SKÁLA², NATALIYA TSUD², LUKÁŠ FUSEK^{1,2}, VIKTOR JOHÁNEK², JOSEF MYSLIVEČEK², YAROSLAVA LYKHACH¹, OLAF BRUMMEL¹, and JÖRG LIBUDA¹ — ¹FAU Erlangen-Nürnberg, Erlangen, Germany — ²Charles University, Prague, Czech Republic

Pd nanoparticles (NPs) are efficient electrocatalysts for oxidation of ethanol in alkaline direct ethanol fuel cells. We investigated the morphology and the oxidation state of Pd NPs supported on well-ordered Co3O4(111) films as a function of the particle size after treatment in ultrahigh vacuum and in alkaline electrolyte under potential control. We combined synchrotron radiation photoelectron spectroscopy and scanning tunneling microscopy. Electronic metal support interaction associated with the charge transfer at the Pd/Co3O4(111) interface yield partially oxidized ultra-small  $Pd\delta$ + aggregates and Pd2+ species at Pd coverages below 0.1 ML followed by the growth of two-dimensional metallic Pd0 NPs at higher coverages. The stabilities of ultra-small and conventionallysized NPs supported on Co3O4(111) and HOPG were compared following an emersion from alkaline electrolyte at potentials between 0.5 and 1.5 VRHE. We observed different oxidation behavior related to two-dimensional and threedimensional morphologies of supported Pd NPs on Co3O4(111) and HOPG, respectively. In sharp contrast, the oxidation state of the ultra-small Pd deposits remains unchanged between 0.5 and 1.5 VRHE.

O 20.2 Mon 18:00 P4

Film growth and stabilty of the ionic liquid  $[C_1C_1Im][Tf_2N]$  on Cu(111) — •TIMO TALWAR, STEPHEN MASSICOT, FLORIAN MAIER, and HANS-PETER STEIN-RÜCK — Lehrstuhl für Physikalische Chemie 2, Friedrich-Alexander-Universität Erlangen-Nürnberg, Egerlandstr. 3, 91058 Erlangen

Ionic liquids (ILs) are salts with melting points below 100°C and extremly low vapor pressure. These properties made them promising candidates for various new catalytic concepts like solid catalysis with Ionic Liquid Layer (SCILL). In this context, the interplay of ILs with metal surfaces is highly important.

In this study, the growth and thermal behavior of ultrathin films of 1,3dimethylimidazolium bis[(trifluoromethyl)sulfonyl]imide  $[C_1C_1Im][Tf_2N]$  on Cu(111) are investigated under UHV conditions. The films are prepared in vacuum by physical vapor deposition and measured by angle-resolved and temperature-programmed X-ray photoelectron spectroscopy. Different film thicknesses are investigated to identify the underlying growth model, which is 2D growth up to 0.3 ML and 3D growth for higher coverages. Note that 1 ML corresponds to a bilayer of cations and anions irrespective of their arrangement. These films are stable up to 300 K. However above 300 K, the anion partly decomposes, and above 500 K, the remaining IL desorbs leaving a decomposed residual on the surface.

Supported through an ERC Advanced Investigator Grant (ILID 693398) to HPS and by the DFG (SFB 1452 CLINT).

#### O 20.3 Mon 18:00 P4

Influence of water in the electrolyte on the electrochromic characteristics of  $WO_3$  — •SOPHIE GÖBEL, THI HAI QUYEN NGUYEN, and DERCK SCHLETTWEIN — Justus-Liebig-Universität Gießen, Institut für Angewandte Physik

In view of global warming, the reduction of  $CO_2$  emissions in the energy sector, e.g. in private households is urgent. In this case, especially heat flow through windows has a main impact. With the help of so-called smart windows, the irradiation of sunlight can be controlled to decrease the energy consumption by air conditioning or heating systems. A possible approach to such switching is provided by electrochromic layers. One of the best observed materials for such smart windows is tungsten oxide  $WO_3$ . In this work, porous  $WO_3$  films were prepared via a sol-gel process and spin-coating on fluorine-doped tin oxide (*FTO*). In order to achieve the porous structure, polymers (*PEG*400 and *PIB*₅₀ – *b* – *PEO*₄₅) were added as additives in the precursor solution. To enhance the electrochromic characteristics of the  $WO_3$  films in contact to an electrolyte consisting of *LiClO*₄ in propylene carbonate, addition of water into the electrolyte was studied. The amount of added water was varied while the influence on the electrochemical system PTCDA/Ag(111) in a virtual environment (Unity) for improved intuitive understanding of the physical properties. Furthermore, we discuss the approach to interface this system with the scan controller for *online* experiments. The 3D Systems Touch X is used to provide tip control and haptic feedback. The physical observable (tunneling current, frequency shift, damping, force or others) at the tip position in the recorded data is translated into haptic feedback.

In situ surface X-ray diffraction studies of Pt(110) — •JAN OLE FEHRS¹, TIMO FUCHS¹, JAKUB DRNEC², MARTA MIROLO², SERHIY CHEREVKO³, VALENTIN BRIEGA³, DAVID HARRINGTON⁴, CHENTIAN YUAN⁴, and OLAF MAGNUSSEN¹ — ¹Christian-Albrechts Universität zu Kiel, Germany — ²European Synchrotron Radiation Facility, Grenoble, France — ³Helmholtz Institute Erlangen-Nürnberg for Renewable Energy, Germany — ⁴University of Victoria, Canada

The surface oxidation of platinum is an important process in the degradation of platinum electrocatalysts in PEM fuel cells. Previously, the oxidation of the (111) and (100) surfaces of platinum was investigated by Fuchs et al. to understand the underlying mechanisms and growth of the oxide structures. In this work the (110) surface was studied by similar in situ high energy surface X-ray diffraction (HESXRD) at the ID31 beamline of the European Synchrotron Radiation Facility. Unreconstructed as well as (1x2)-reconstructed Pt(110) surfaces were prepared and their restructuring upon oxidation was examined. Distinct differences in this restructuring of the unreconstructed and the (1x2)-reconstructed surface were found. The changes in occupancy of the topmost surface layers after one oxidation/reduction cycle are greater for the unreconstructed surface than for the reconstructed surface, suggesting that the latter is more stable upon oxidation. In accordance with this result, it was also found that the missing row reconstruction of the surface was only lifted during the reduction of the surface oxide.

O 20.5 Mon 18:00 P4 Increase of the Spectroelectrochemical Performance of WO₃ Films by Using Additives During Film Growth — •THI HAI QUYEN NGUYEN FLORIAN EBERHEIM¹, SOPHIE GÖBEL¹, PASCAL COP², MARIUS ECKERT¹, TIM P. SCHNEIDER¹, LUKAS GÜMBEL¹, BERND M. SMARSLY², and DERCK SCHLETTWEIN¹ — ¹Justus-Liebig-Universität Gießen, Institut für Angewandte  $\label{eq:Physik} Physik - {}^2 Justus-Liebig-Universität Gießen, Physikalisch-Chemisches Institut$ Tungsten oxide  $(WO_3)$  is commonly used as an electrochromic material in smart windows. The electrochromic performance of  $WO_3$  is highly influenced by the mixed electronic and ionic transport in the film and, thus, by the accessibility of the internal film volume. In this work, WO3 thin films were prepared by spin-coating from a precursor solution based on peroxotungstic acid and different polymer additives such as polyethylene glycol (PEG), a block copolymer  $(PIB_{50} - b - PEO_{45})$  and a combination thereof. The influence of the additives on the porosity and composition of WO3 was studied by, e.g., scanning electron microscopy, X-ray photoelectron spectroscopy and atomic emission spectroscopy. Electrochromic characteristics of the films were measured with  $LiClO_4$ in propylene carbonate as electrolyte. The intercalation of  $Li^+$  ions was analyzed by time-of-flight secondary ion mass spectrometry. The use of PEG provided microporous films leading to improved effective diffusion coefficients, transmittance modulations and response times compared to compact WO₃. Further improved characteristics were obtained for films with interconnected mesopores prepared with PEG and  $PIB_{50} - b - PEO_{45}$ .

Visualizing electrochemical interfaces with combined AFM/STM — •ANDREA AUER, BERNHARD EDER, and FRANZ GIESSIBL — Institute of Experimental and Applied Physics, University of Regensburg, Germany

Atomic force microscopy (AFM) that can be simultaneously performed with scanning tunneling microscopy (STM) modes using metallic tips attached to self-sensing quartz cantilevers (qPlus sensors) has advanced the field of surface science by allowing for unprecedented high spatial resolution under ultrahigh vacuum conditions. Applying a qPlus sensor-based AFM/STM setup to electrochemistry could offer new and groundbreaking possibilities to locally image both the 3D layering of the interfacial water and the lateral structure of the electrochemical double layer. In this work, a home-built AFM/STM instrument equipped with a qPlus sensor for operation under precise potential control in an electrochemical liquid cell is presented. Special care is taken in the preparation of etched Pt/Ir tips, which are attached to the qPlus sensor and subsequently

coated with insulating wax to allow for both AFM and STM measurements in the electrolyte with minimal leak currents. Ongoing work includes investigations of the potential-dependent structural interface organization of the electrochemical double layer on both highly oriented pyrolytic graphite (HOPG) and Au(111) electrodes in acidic media by means of (simultaneous) AFM/STM imaging and force spectroscopy.

O 20.7 Mon 18:00 P4 Phase-shifting electron holography in an environmental TEM - •ULRICH Ross¹, Jonas Lindner², Tobias Meyer², Michael Seibt¹, and Christian Jooss² – ¹IV. Physik Georg-August Universität Göttingen – ²IMP Georg-August Universität Göttingen

Off-axis electron holography is a phase reconstruction technique which enables access to the complex exit-wave of thin samples. Information on the phase and amplitude of the exit wave is useful in order to gain insight on nm-scale electromagnetic fields. In the field of catalyst research electrostatic surface fields are of particular interest, since the potential drop over the surface can be assumed to play a major role in the reaction mechanisms.

Conventional off-axis holography reconstruction operates via the Fourier domain. As a consequence, the accessible range of spatial frequencies is bandlimited by the carrier frequency of the hologram. A trade-off is always necessary in order to optimize fringe frequency, visibility, phase-contrast transfer and instrument stability for a certain range of spatial frequencies. In contrast, we demonstrate the implementation of phase-shifting holography at sub-nm resolution combined with an advanced drift correction scheme, and successfully match the results to multislice image simulations as well as conventional defocus series. The method is added to the in-situ capabilities of a third-order aberrationcorrected environmental TEM in order to investigate surface effects in catalytic platinum samples under low pressures of oxygen and water.

We investigated self-ordered structures of 3,4,9,10-perylene-tetracarboxylic acid (PTCA) on the Au(111) electrode interface. In recent electrochemical studies, the protonation/ deprotonation process of PTCA was studied, however no structural data information was reported, yet [1]. To investigate the structures of PTCA at the Au(111) electrode interface we used cyclic voltammetry (CV) and electrochemical STM (EC-STM). For negatively charged surfaces, we observed stripe like phases of PTCA with an edge-on orientation of the molecules that transform into a less dense phase at more positive potential with flat-lying molecules. We suppose that this transition is correlated with a partial deprotonation of the PTCA. Acknowledgement: This work was supported by the DFG through the research training group 2591, the DAAD (Deutscher Akademischer Austauschdienst) program Ostpartnerschaften and the NAWA (National Agency for Academic Exchange) program. The optical spectroscopy of InP(100) in contact with hydrochloric acid: A first-priciples study – •JONGMIN KIM^{1,2}, MARGOT GUIDAT^{1,2}, MARIO LÖW¹, and MATTHIAS M. MAY^{1,2} – ¹Institute of Physical and Theoretical Chemistry, Universität Tübingen, D-72076 Tübingen, Germany — ²Institute of Theoretical Chemistry, Universität Ulm, Ulm, Germany

The III-V semiconductors, such as indium phosphide (InP), show highest solar energy conversion efficiencies, and are commonly used for a variety of applications, particularly high-performance opto-electronic devices. However, these semiconductors face fundamental challenges since they tend to corrode in aqueous electrolytes [1]. A passivisation layer on their surface is the most efficient way to address this drawback. Studies have demonstrated that a system of the InP(100) in contact with hydrochloric acid exhibits high conversion efficiencies and reasonable stability. In this computational work, we investigate the interaction of InP(100) with hydrochloric acid by means of computational optical spectroscopy. Theoretically derived reflection anisotropy spectroscopy (RAS) is employed for the optical optical spectroscopy. According to our calculations, the RA spectra are significantly changed with probable surface geometries. A comparison of our results with experiment spectra reveals that the fully Cl-covered structure is the most reasonable surface. This verified structure can be used as a starting structure for further investigations of the InP(100)-electrolyte interface.

Imaging and Illumination of Self-Assembled Molecules at Solid and Liquid Interfaces — •BENSU GÜNAY, •SHILPA PANCHAMI RAJ, CHRISTOPHE NACCI, and LEONHARD GRILL — University of Graz

Nanotechnological approaches for photochemical on-surface synthesis of covalently-bonded nanostructures have received recent attention at solid/air and solid/liquid interfaces. At the solid/liquid interface, there is in principle always a dynamic equilibrium between the molecules adsorbed on the surface and those still dissolved in the supernatant solution. Additionally, on-surface photochemical activation of chemical reactions provides new reaction pathways and enables the formation of long-range ordered covalent structures. The scanning tunneling microscope (STM) is a powerful tool for observing such structures at surfaces. In this study we present STM measurements under ambient pressure and at room temperature at the solid/liquid interface. In a first step for investigating photoactivated polymerisation under such conditions, 2,5-didodecyl-1,4-di-1-propenyl benzene was introduced onto a highly oriented pyrolytic graphite (HOPG) surface. We report on the self-assembled structures as well as attempts for photochemical activation using various wavelengths at room temperature.

global symmetry is broken. Here, we report local signatures of the thickness dependent topology in intrinsic magnetic topological insulator MnBi₂Te₄ (MBT), using scanning tunneling microscopy and spectroscopy on molecular beam epitaxy grown MBT thin films. A thickness-dependent band gap with an oscillatory feature is revealed, which we reproduce with theoretical calculations. At step

The electronic structure of  $Bi_{12}Rh_3Ag_6I_9$ , a weak topological insulator (TI) candidate, is investigated by means of angle-resolved photoelectron spectroscopy (ARPES) and density functional theory calculations. The compound consists of alternating layers of a 2D TI in a Kagome configuration, separated by insulating spacer layers. The Kagome net is formed by rhodium centered bismuth cubes, while the spacer consists of silver and iodine. The results are compared to the mother material  $Bi_{14}Rh_3I_9$  [1], denoting the first experimentally observed weak TI. In particular, the influence of the silver substitution into the spacer layer and the potential modification of the coupling between the 2D TI layers is discussed.

O 21.3 Mon 18:00 P4 Characterisation of Fe adsorbates and their effect on the local density of states on topological insulators TlBiSe₂ and Bi₂Se₃ by means of combined STM/STS and AFM — •ADRIAN WEINDL, CHRISTOPH SETESCAK, ALEXANDER LIEBIG, and FRANZ J. GIESSIBL — University of Regensburg, Germany

Can one tailor the properties of the topological surface state (TSS) of topological insulators (TIs) by magnetic doping of the TI material? Here, we study the effect of magnetic adatoms on TI surfaces by means of combined scanning tunneling microscopy (STM) and atomic force microscopy (AFM). Two archetypical TIs,  $Bi_2Se_3$  and TlBiSe₂, are studied, which both have relatively large band gaps with their Dirac points well isolated and far from bulk states. While the surface of  $Bi_2Se_3$  is atomically flat, TlBiSe₂ exhibits a peculiar surface termination consisting of half a monolayer of thallium atoms sitting on top of a full selenium layer. Magnetic impurities, in this case single Fe adatoms, and their influence on the local density of states (LDOS) of the two TIs are investigated by means of scanning tunneling spectroscopy. We detect resonances in the LDOS for the Fe adatoms that arise due to the scattering of electrons in the TSS at these impurities. The position and shape of these resonances are a function of the exact adsorption position of the adatoms, which can be determined by means of atomically-resolved AFM measurements.

O 21.4 Mon 18:00 P4 Investigation of the V/TI interface by TEM and ARPES — •XIAO  $Hou^1$ , MAX VASSEN-CARL², MOHAMMED QAHOSH¹, XIANKUI WEI³, PETER SCHÜFFELGEN², CLAUS MICHAEL SCHNEIDER¹, and LUKASZ PLUCINSKI¹ — ¹PGI-6, Forschungszentrum Jülich, Germany — ²PGI-9, Forschungszentrum Jülich, Germany — ³ERC-2, Forschungszentrum Jülich, Germany Topological insulators (TIs) can host so-called Majorana zero modes (MZM) when proximitized with superconductors (SCs). Such a TI/SC system is a promising platform for realizing fault-tolerant quantum computers by employing braiding of the Majorana zero modes [1], in which a sharp interface between SC and TI is one of the prerequisites to realize the Majorana mode [2-3]. Here, vanadium(V) -  $(Bi_{0.08}Sb_{0.92})_2Te_3$  is chosen as the SC/TI system.

We use advanced transmission electron microscopy (TEM) and angleresolved photoemission spectroscopy (APRES) to study structural and electronic properties of the V/TI interfaces. High-resolution TEM and high-angle annular dark-field imaging provide details on crystallinity and atomic arrangements associated with various types of structural defects, while the energy-dispersive X-ray spectroscopy reveals the elemental distribution and also the interfacial interdiffusion. The band alignments between TI and V are studied using ARPES on ultrathin V films deposited on vacuum-transferred TI surfaces.

#### O 21.5 Mon 18:00 P4

Heterostructure engineering with the van der Waals topological insulator  $Bi_2Te_3$  — M. DITTMAR^{1,2}, •E. MANTEL^{1,2}, P. KAGERER^{1,2}, C. I. FORNARI^{1,2}, H. BENTMANN^{1,2}, and F. REINERT^{1,2} — ¹Exp. Physik VII, Uni Würzburg — ²Würzburg-Dresden Cluster of Excellence ct.qmat

Recently, combining magnetism and topology has emerged as a promising research field spanning from topological insulator (TI)-superconductor interfaces to intrinsic magnetic systems [1]. In these systems exciting new phenomena such as Majorana modes are predicted to emerge. Here we present two approaches to study these promising structures.

The first focuses on the intrinsically ferromagnetic monolayer of  $MnBi_2Te_4$ . In order to observe the predicted effects in this compound its Fermi level should be tuned inside the bulk band gap. Our approach to control the Fermi level position is to prepare a single layer of  $MnBi_2Te_4$  on top of a p-n-junction of  $Sb_2Te_3$  and  $Bi_2Te_3$  grown by molecular beam epitaxy (MBE). In the second approach we investigate the preparation of thin films of the TI  $Bi_2Te_3$  on superconductor substrates. In order to obtain more information about the crystalline structure and surface orientation, we use different characterization methods such as reflection high-energy electron diffraction, X-ray diffraction and low-energy electron diffraction. To investigate the impact on the electronic structures of these systems, angle resolved and X-ray photoemission specroscopy are employed. [1] M.M. Otrokov et al., Nature **576** (2019)

#### O 22: Poster Monday: Surface Structure, Epitaxy, Growth and Tribology

Ordering processes and phase transitions in amorphous carbon thin films induced by optical excitation — •CARL ARNE THOMANN¹, ADRIAN WITTROCK¹, ALEXANDRA WITTIG², FILIPE LOPES DIAS², DOMINIC STANGIER², WOLFGANG TILLMANN², and JÖRG DEBUS¹ — ¹Experimentelle Physik 2, TU Dortmund — ²Lehrstuhl für Werkstofftechnologie, TU Dortmund

Amorphous carbon is a metastable network of short-range ordered carbon atoms often used as protective coatings owing to their exceptional tribological properties. However, high temperatures in a tribological contact may cause considerable changes in the structural ordering, solid-to-solid phase transitions, and degradation of the film. In this work, we present an optical method to initiate and investigate the structural evolution including ordering processes of differently modified films. A pulsed pump laser with micrometer spot size introduces heat into the film, while a second laser probes the Raman scattering signatures. Increasing with laser power, five different stages of structural evolution are found: The first one is coined by thermally resistive amorphous carbon. It is followed by a continuous reduction in the number of lattice defects and non-sixfold aromatic rings. Further increasing pumping power induces a transition from a-C to defected graphite and eventually leads to graphite-dominant defect relaxation and an enhancement in hexagonal lattice areas. Our optical method provides a versatile tool to analyze temperature-induced structural surface changes in a controlled manner, which will improve the understanding about the conditions in tribological contacts.

#### O 22.2 Mon 18:00 P4

Interactions between bovine calf serum and metallic surface of hipimplant taper junctions — •ADRIAN WITTROCK¹, SASKIA HEERMANT¹, CHRISTIAN BECKMANN¹, MARKUS A. WIMMER², ALFONS FISCHER^{2,3}, and JÖRG DEBUS¹ — ¹Experimental Physics 2, TU Dortmund University, Dortmund, Germany — ²Department of Orthopedic Surgery, Rush University Medical Center, Chicago,

USA - ³Department Microstructure Physics and Alloy Design, Max-Planck-Institut für Eisenforschung GmbH, Düsseldorf, Germany

Within biomedical taper junctions metal surfaces interact with the human body fluid and sustain structural and chemical changes which are of particular interest from the medical and engineering point of view. To simulate the tribological contact of a hip implant taper junction, fretting tests of low-carbon CoCrMo alloys and high-nitrogen FeCrMnMoN steels are performed in bovine calf serum under different numbers of cycles. We investigate structural and chemical variations within the fretting contact by means of label-free and non-destructive Raman spectroscopy. A different absorption behavior of long-chained molecules is observed and the amide I band is shifted from  $1655 \text{ cm}^{-1}$  to about  $1665 \text{ cm}^{-1}$ , which indicates that once a protein is bound to the surface the conformation changes from  $\alpha$ -helix to a random or  $\beta$ -sheet structure. A general denaturation of proteins occurs during the fretting experiment. At the heavily worn sample positions lipids are not detected, but sp²-hybridized amorphous carbon is sometimes measured. Our results contribute to a deeper understanding about structural and chemical properties of biomedical tribological surfaces.

Distance dependence of local work function on Pb/Si(111) island — THOMAS SPÄTH¹, •DANIEL ROTHHARDT², MANUEL SCHULZE², and REGINA HOFFMANN-VOGLE² — ¹Karlsruhe Institut Technology, D76131 Karlsruhe, Germany — ²University of Potsdam, Institute of Physics and Astronomy, Experimentelle Physik kondensierter Materie, D14469 Potsdam, Germany

In order to gain a better understanding of diffusion of Lead (Pb) islands on Si(111)-(7x7), it is extremely important to provide a complete description of the electronic properties and the forces acting on the system. Using a Scanning Force Microscope in non-contact mode with Pt coated Si-cantilever allows us to perform point bias-approach measurements at 115 K on Pb islands. We have investigated how the local work function changes as a function of tip-sample distance

and how the electrostatic force changes as a function of the applied bias between tip and sample. The resulting force was calculated from the frequency shift distance curves using Baratoff's force inversion method. A significant change in the work function was found when the tip-sample distance was less than 1 nm, which could arise from the overlap of the tip wave functions and the sample wave functions.

#### O 22.4 Mon 18:00 P4

**Epitaxial growth of gold films on elemental superconductors** — •DONGFEI WANG¹, KATERINA VAXEVANI¹, JON ORTUZAR¹, STEFANO TRIVINI¹, DANILO LONGO¹, SAMUEL KERSCHBAUMER², MAXIM ILYN², CELIA ROGERO², and JOSÉ IGNACIO PASCUAL¹ — ¹CIC nanoGUNE-BRTA, 20018 Donostia-San Sebastian, Spain — ²Materials Physics Center (CSIC-UPV/EHU), San Sebastian 20018, Spain

In recent years, superconductivity proximity effect was employed in the designing of topological superconductors [1]. The basic principle in designing a topological superconductor is to introduce superconductivity, spin-orbital coupling and magnetism at the same time. Unfortunately, most of the available elemental superconductors shows less spin-orbital coupling. Gold (Au) is a material famous for its relatively large spin-orbital coupling strength. By placing Au on elemental superconductors, a superconducting system with strong spin-orbital coupling is expected [2]. In our research, Au films with different thickness were grown on elemental superconductors such as V(100) and Nb(110). The films quality were examined by STM as well as XPS technique. By placing magnetic molecules FeTPP on the surface Au/Nb(110), we demonstrate the tunability of magnetic exchange interaction between the molecule and the substrate with Yu-Shiba bound states. Moreover, great Kondo signal enhancements near the pyrrole sites are observed.

O 22.5 Mon 18:00 P4

**Preparation of highly pure Cu(110) surfaces** — •MANUEL SEITZ, ANDREAS CHRIST, MARKUS LEISEGANG, and MATTHIAS BODE — Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany

Ballistic transport of hot charge carriers on the nanoscale becomes more and more important for the development of microelectronic components [1]. The molecular nanoprobe (MONA) technique [2] is a novel method to investigate ballistic charge transport which has already been applied to detect anisotropic transport on the Pd(110) surface [3]. For a more detailed understanding, a survey of other anisotropic fcc(110) surfaces, e.g. Cu(110), is aspired. To detect characteristics intrinsic to the Cu(110) surface, a highly clean and defect-free area of the surface is needed. However, cleaning (110) surfaces with such high purity has proven to be challenging. In this presentation, we summarize our experiences with the preparation of Cu(110) which are compared to similar experiments on Cu(111). While optimizing the preparation parameters, i.e., sputter and anneal cycles, we found a high mobility of surface atoms at room temperature on the Cu(110) surface. Furthermore, upon sputtering the Cu(111) surface, island formation is observed besides the expected vacancy islands [4].

Nanotribological properties of Nitrogen doping-induced modification graphene in ultrahigh vacuum — •SHUYU HUANG^{1,2}, ANTOINE HINAUT¹, YIMING SONG¹, SEBASTIAN SCHERB¹, GEMA GNAVARRO¹, THILO GLATZEL¹, and ERNST MEYER¹ — ¹Department of Physics, University of Basel, 4056 Basel, Switzerland — ²Key Laboratory for Design and Manufacture of Micro-Nano Biomedical Instruments, School of Mechanical Engineering, Southeast University, Nanjing 211189, China

Graphene, as typical atomically-thin solid lubricant with potential applications in micro- and nano-electromechanical systems (MEMS/NEMS), has been extensively investigated on its nanotribological properties. In the present work, by using a novel experimental approach, for the first time we directly compare the frictional properties between pristine graphene and modified graphene on a single image, showing that atomic-scale friction can be significantly altered by Nitrogen doping-induced modification. Specifically, C60 nano-flakes are deposited as a mask on graphene/Ir (111) surface by thermal evaporation. The sample is then exposed to a nitrogen radical flux produced by a remote RF plasma source. After thermal annealing, to desorb C60 molecules, both nano-patterned modified graphene and pristine graphene, located below former C60 islands, surface is obtained simultaneously. By the means of high-resolution ultrahigh vacuum atomic force microscopy, the topography of surface with two different regions are characterized and discussed in non-contact mode and friction force variation is measured in contact mode.

#### O 22.7 Mon 18:00 P4

Investigation of indium fluctuation inside Al0.81In0.19N layers — •KEYAN JI¹, QIANQIAN LAN², YAN LU², MICHAEL SCHNEDLER¹, PHILIPP EBERT¹, and RAFAL E. DUNIN-BORKOWSKI² — ¹Peter Gruenberg Institut, Forschungszentrum Juelich, D-52425 Juelich, Germany — ²Ernst Ruska-Centre for Microscopy and Spectroscopy with Electrons, Forschungszentrum Juelich, D-52425 Juelich, Germany

We report on the characterization of Al0.81In0.19N/GaN heterostructures grown by Metalorganic Vapor Phase Epitaxy. The specimen was investigated by Electron Holography, High-angle annular dark-field (HAADF) imaging, Secondary-ion mass spectrometry, and Energy-dispersive X-ray spectroscopy. We reveal with different techniques that the Indium concentration gradually increases from 15% to the nominal value of 19% inside Al0.81In0.19N layers. We conduct quantitative analysis on experimental phase images from offaxis electron holography by comparing them with images calculated from the self-consistent electrostatic simulations. Our results illustrated that to accurately determine the electrostatic potential in semiconductor materials from electron holographic phase images, comprehensive knowledge of surface conditions, chemical compositions, and strains is required.

Measuring energy dissipation on Si(111) with Lateral Force Microscopy (LFM) — •THOMAS HOLZMANN, SHINJAE NAM, OLIVER GRETZ, ALFRED JOHN WEYMOUTH, and FRANZ JOSEF GIESSIBL — Universität Regensburg, Deutschland

In Lateral Force Microscopy (LFM), a cantilever is oscillated parallel to a sample surface at a set amplitude. The forces acting on such an oscillating cantilever are not necessarily conservative. The energy gain or energy loss can be position dependent, depending on the surface. We observed a strong lateral dependence of dissipation around adatoms of the 7x7-resconstruction of Si(111). We used LFM to measure this energy dissipation and applied different bias voltages between tip and sample, which changed the energy dissipation. Certain mechanisms, that contribute to energy dissipation, such as CO-bending (when using a CO-terminated tip) and chemical bonding should not be sensitive to changes in the bias voltage. Only the electrostatic part of the ineraction should be influenced by a change in the bias voltage. We developed a model to simulate the energy dissipation due to electrostatic forces similar to that proposed in Ondracek et al. Nanotechnology 27, 274005 (2016). In this model, electrons tunnel to a local quantum dot on the tip or sample before diffusing to the bulk. It can predict the area where the dissipation occurs. But surprisingly the dissipation signal changes its sign, depending on which side of the quantum dot the tip is located. Following this observation we looked at possible explanations for this behaviour.

O 23.1 Mon 18:00 P4

An Atomic Boltzmann Machine capable of Self-Adaption — BRIAN KIRALX¹, ELZE J. KNOL¹, •WERNER M.J. VAN WEERDENBURG¹, HILBERT J. KAPPEN², and ALEXANDER A. KHAJETOORIANS¹ — ¹Institute for Molecules and Materials, Radboud University Nijmegen, the Netherlands — ²Donders Institute for Neuroscience, Radboud University Nijmegen, the Netherlands

A grand challenge in creating materials with brain-like functionality is understanding multi-well systems. Such multi-well landscapes are linked to energybased machine learning models, often based on Ising spins. However, the typical short-ranged exchange coupling of Ising spins in real materials prohibit the connectivity required for multi-well landscapes. Therefore, understanding how to create multi-well systems and link these to attractor network models is vital [1].

We present an atomic Boltzmann machine capable of self-adaption using single Co atoms on Black Phosphorus (BP). Using the concept of orbital memory in Co atoms [2], we design a tunable multi-well energy landscape by patterning atoms with atomic manipulation in a scanning tunneling microscope (STM). By electrically gating the structure with the STM tip, we allow the dynamical exploration

of its configurations. Due to the anisotropic BP, we find two different timescales that emulate a fast "neural" and a slow "synaptic" timescale. We demonstrate the self-adaption of the synaptic weights to electrical stimuli and explore frequency-based input signals in new types of orbital memory.

**Pulling individual polar molecular wires off of a surface** — •CHRISTOPHE NACCI and LEONHARD GRILL — Department of Physical Chemistry, University of Graz, 8010 Graz, Austria

The frictional properties of individual nanostructures are strongly influenced by the reduced size and low dimensionality. Accordingly, challenging experiments are required to measure them. Probing the mechanical response of individual nanostructures on chemically different surfaces opens the possibility to explore how the static and dynamic friction depends on the interplay between structural commensurability and chemical composition. Here, we report the vertical pulling of DAD molecular wires [1] off metal surfaces by non-contact atomic force microscopy (AFM), performed under ultrahigh vacuum and at low temperatures. These are polar wires with alternating donor (D) and acceptor (A) groups incorporated in their chemical structure. The aim is to probe the mechanical response of individual molecular wires by force spectroscopy. To furthermore explore the role of structural commensurability between polymers and surface, the polar wires are grown on a variety of different surfaces, from stepped and corrugated surfaces to ultrathin insulating NaCl films on metal surfaces.

Efficient Sieving Performance with Carbon Nanomembranes (CNMs) — •YUBO QI, PETR DEMENTYEV, and ARMIN GÖLZHÄUSER — Bielefeld University, Bielefeld, Germany

Nanoporous membranes are promising candidates in ion transport and molecular separation; however, it is still a great challenge to achieve high permeability and selectivity. Carbon nanomembranes (CNMs) emerge as attractive materials for water purification, energy storage, and gas separation. In this work, we present facile CNMs fabrication from polycyclic aromatic hydrocarbons that are drop-cast onto arbitrary supports, including foils and metalized films. The electron-induced polymerization is shown to result in continuous sheets of various thickness, and the material is characterized by some spectroscopic and microscopic techniques. The permeation measurements with freestanding membranes reveal a high degree of porosity, and the water permeance ( $\sim 10^{-4}$  mol  $m^{-2} s^{-1} Pa^{-1}$ ) is four orders of magnitude higher than helium (~10⁻⁸ mol m⁻²  $\rm s^{-1}~Pa^{-1})$  with a membrane thickness of 3.0 nm. The ion transport properties were investigated via bias voltage applied across through CNMs. The nanomembrane showed the ability to sieve monovalent and divalent cations, selectivity of all cations follow the ordering  $K^+ > Na^+ > Li^+ > Ca^{2+} > Mg^{2+}$ . Functional CNMs fabricated from inexpensive precursors pave the way towards the rational design of 2D membranes for high efficient separation.

The properties of Niobium based devices are greatly influenced by the presence of surface oxygen. The highly stable NbO(111) overlayer on the Nb(110) surface is known to host a distinctive nanocrystal structure, as observed by scanning tunnelling microscopy. However the exact structure of this surface has remained a mystery. In order to understand this surface structure, we carry out density functional theory calculations, along with scanning tunnelling microscopy and X-ray/ultraviolet photoelectron spectroscopy experiments. We propose a new model, contrary to those previously proposed in the literature. The nanocrystal pattern is ascribed to a subtle reconstruction in the surface layer which locally breaks the hexagonal NbO(111) symmetry, giving rise to modulations in the local density of states. Excellent agreement is found between our model and the observed experimental data. We also investigate the underlying reasons that the surface adopts this unusual structure.

Helium Ion Microscopy of insulating Materials using Charge Compensation — •Michael Westphal¹, Natalie Frese¹, Yubo Qi¹, Hiroyuki Takei², Petr Dementyev¹, André Beyer¹, and Armin Gölzhäuser¹ — ¹Bielefeld University, Germany — ²Toyo University, Japan

Surface-sensitive imaging capabilities in nanotechnology have become increasingly important in recent years. While scanning electron microscopes (SEM) have become more powerful, they reach their limits when it comes to electrically insulating samples. The accumulation of charge carriers on the sample surface can lead to severe imaging artifacts which necessitates the application of conductive coatings. Helium ion microscopes (HIM) have the possibility to stabilize electric charges by using an electron flood gun to reveal nanoscopic sample features that would otherwise be covered by a conductive coating. In this contribution, we show the benefits of charge-compensated HIM imaging over conventional SEM imaging using the examples of SARS-CoV-2 virus particles [1], carbon nanomembranes from Aromatic Precursors without Headgroups, metal coated SiO₂- and carbon micro-spheres [2]. **2D** covalent organic frameworks from diboronic acids: the influence of the solvent — •WENBO LU, ETHAN MALONE, MIHAELA ENACHE, and MEIKE STÖHR — Zernike Institute for Advanced Materials, University of Groningen, Netherlands

Over the past years, two-dimensional (2D) covalent organic frameworks (COFs) have gained substantial interest for their use in nanopatterning, organic electronics, and as a basis for nanoreactors or molecular sieves. In particular, 2D COFs formed by polycondensation of boronic acids on surfaces have already yielded promising results [1, 2].

In this study, 2D COFs were synthesized by 1,4-benzenediboronic acid (BDBA) polycondensation on highly oriented pyrolytic graphite (HOPG) which resulted in the formation of a long-range ordered hexagonal molecular network. For the formation of the 2D COFs, a drop of BDBA solution was deposited onto HOPG, then placed in an autoclave and annealed at certain temperature. The structure and coverage of the 2D COFs was studied by scanning tunneling microscopy and atomic force microscopy under ambient conditions. In order to obtain both high quality as well as extended COFs, the influence of four solvents on the COF formation was studied. Our results provide guidance for obtaining high quality 2D COFs formed by boronic acid derivatives.

**On-surface synthesis of narrow porous graphene nanoribbons** — •CHRISTOPH DOBNER¹, MAMUN SARKER², ADRIAN EBERT¹, ALEXANDER SINITSKII², and AXEL ENDERS¹ — ¹Physikalisches Institut, Universität Bayreuth, Universitätsstraße 30, 95447 Bayreuth, Germany — ²Department of Chemistry, University of Nebraska-Lincoln, Lincoln, NE68588, USA

Fueled by the technological necessity to induce semiconducting properties in graphenic nanostructures, the search for strategies to manipulate their electronic properties has become an active field of research. Common control parameters that determine the band gap of graphene nanoribbons (GNR) are structural width, edge design and heteroatom doping. It has also been theoretically predicted that periodic vacancies can open up a band gap in to otherwise semimetallic 2D-graphene sheets. It is thus reasonable to expect that porosity could also contribute to the band structure of already semiconducting GNRs. In this work we present a strategy for the on-surface synthesis of porous GNRs using precursor. We will show that modified halogenation sites on the precursor molecules result in GNRs containing a periodic arrangement of vacancies along the ribbons backbones. Tunneling spectroscopy was used to determine the band edge locations and band gap width of such structures, revealing a increased band gap of 1.96 eV. Additional dI/dV mapping revealed that periodic electronic states are located at the edges and inside the backbone, induced by the porosity of the structures. Based on these findings a route towards considerably wider porous graphenic flakes will be discussed.

**Construction of a regular tessellation via bromine bond on a Ag(100) surface** — •WENCHAO ZHAO, NAN CAO, BIAO YANG, and JOHANNES V BARTH — Physics Department E20, Technical University of Munich, D-85748 Garching, (Germany)

Engineering 2D surface tessellations at the molecular level attracted major interest with the development of nanoscience and technology. To this end supramolecular self-assembly exploiting tailored molecular species and programmed intermolecular interaction are widely employed. Halogen bonds are promising for potential application due to the  $\sigma$ -hole anisotropic charge distribution of halogen atoms1,2,3. Herein, we address the behavior of ditopic bromine-terminated linear monomers on a Ag(100) surface at the molecular level, affording a tessellation guided by the surface symmetry. In the temperature range of 120 to 200 K, the building blocks form a porous nested grid structure stabilized by bromine bonds and molecule-substrate interactions. Two kinds of quad nodes are distinguished therein, involving a complex non-covalent bonding scheme. Interestingly, both nodes feature supramolecular chirality, entailing domains with both rectangular and trapezoid cavities. Our work introduces a new and complex surfaces. References 1. G. **Invited Talk** O 24.1 Tue 9:30 S054 Oxygen Evolution on Rutile Ruthenium and Iridium Dioxides - •YANG SHAO-HORN — MIT, Cambridge, MA, USA

Rutile oxides have been studied intensively for water oxidation in acidic solutions. Unfortunately, atomic details of processes occurring at the electrified interface and active sites are not well understood. In this work, we combine in situ surface sensitive techniques, electrochemical mass spectrometry and density functional theory calculations to elucidate oxygen evolution reaction (OER) on ruthenium and iridium dioxides. Using synchrotron-based ambient pressure X-ray photoelectron spectroscopy and in situ surface diffraction on single crystal surfaces coupled with density functional theory calculations, we show that with increasing potential from 0.5 VRHE, adsorbed water on the coordinalarge number of theoretical studies, there are few experiments where controlled N substitution has been achieved. We report the on-surface synthesis on Au of two different types of nanoribbons containing N atoms from specifically designed heteroaromatic precursors. The chemical structures of the resulting ribbons were characterized using scanning tunneling microscopy (STM) and noncontact atomic force microscopy (nc-AFM). We demonstrate the high quality ribbons growth, which involves a facile C-N bond formation at temperatures below typical C-C reactions. The electronic properties were further investigated by scanning tunneling spectroscopy (STS), which revealed unoccupied states localized on N atoms that are absent in the undoped sections. These results open new perspectives for growing and studying novel types of GNRs with the possibility to fine-tune electronic properties by controlled heteroatom substitution.

Location: H2

tively unsaturated sites (CUS) is successively deprotonated. Surface diffraction measurements and computation reveal what steps can be rate-limiting for OER. Such analyses are applied also to CUS sites on other surfaces as well as different IrO2 surfaces, from which fingerprints of surface oxygen atoms are correlated with OER activity. In order to connect learnings from single-crystals with practical catalysts, electrochemical activity measurements were combined with highly sensitive electrochemical mass spectrometry to quantify the amount of evolved oxygen and reveal three Tafel regimes at different overpotentials, which was rationalized by the coverage of the reaction intermediates. In summary, by employing different experimental and theoretical techniques to model surfaces and practical catalysts, we discuss the nature of the active sites catalyzing OER on ruthenium and iridium dioxides.

## 0 25: Focus Session: Atomic-Scale Characterization of Correlated Ground States in Epitaxial 2D Materials

The rapid expansion of the family of two-dimensional (2D) materials led to the observation of various quantum phases with correlated ground states in the 2D limit, such as unconventional superconductivity, charge density waves, and novel magnetic phases. On the fundamental level, there are various open questions regarding the mechanisms that underlie these correlated ground states, as well as the understanding of the role of the interface and dimensionality. The epitaxial growth of 2D materials on inert substrates under ultrahigh vacuum conditions and respective in situ investigation allows direct and unambiguous comparison between experimental findings and firstprinciples calculations. Experimentally, scanning tunneling microscopy methods are ideal to explore the electronic structure and magnetic properties of emerging 2D quantum phases with ultimate real-space and energy resolution at ultra-low temperatures. Theoretically, the use of density functional theory calculations requires atomically well-defined unit cells to precisely predict the electronic and magnetic properties. Combining these complementary approaches helps to elucidate the role of the substrate, defects, and the coupling between quasiparticles in stacked heterostructures.

O 25.1 Tue 10:30 H2 Designer electronic states in van der Waals heterostructures - •PETER LIL-JEROTH — Department of Applied Physics, Aalto University, PO Box 15100, 00076 Aalto, Finland

Van der Waals (vdW) heterostructures provide unique opportunities for engineering exotic quantum states not found in naturally occurring materials. I will highlight this approach by describing our recent results on realizing topological superconductivity [1,2] and artificial heavy fermion systems in vdW heterostructures [3]. We use molecular-beam epitaxy (MBE) and low-temperature scanning tunneling microscopy (STM) for the sample growth and characterization. Topological superconductivity can be realized by combining ferromagnetic CrBr₃ on a superconducting NbSe₂ substrate [1,2], which brings together the necessary ingredients for topological superconductivity (out of plane ferromagnetism, Rashba-type spin-orbit interactions and s-wave superconductivity). On the other hand, the building blocks of heavy fermion systems - Kondo coupling between a lattice of localized magnetic moments and mobile conduction electrons - can be mimicked in a 1T-TaS2 / 1H-TaS2 heterostructure. These examples highlight the versatility of vdW heterostructures in realizing quantum states that are difficult to find and control in naturally occurring materials.

O 25.2 Tue 11:00 H2 **Topical Talk** Magnetic order in a coherent Kondo lattice in the 1T/1H TaSe2 heterostructure — Wen Wan¹, Rishav Harsh¹, Paul Dreher¹, Sandra Sajan¹, An-TONELLA MENINNO², ION ERREA², FERNANDO DE JUAN¹, and •MIGUEL UGEDA¹ - ¹Donostia International Physics Center (DIPC), Paseo Manuel de Lardizábal 4, 20018 San Sebastián, Spain — ²Centro de Física de Materiales (CSIC-UPV-EHU), Paseo Manuel de Lardizábal 5, 20018 San Sebastián, Spain

Kondo lattice systems are of fundamental importance for our understanding of quantum criticality and unconventional superconductivity. At the heart of their complexity lies the competition between the opposing forces of Kondo screening and magnetic interactions, which is revealed at very low temperatures as the moments start behaving coherently and eventually determines the fate of the ground state. While our understanding of Kondo lattices has traditionally relied on technically challenging strongly correlated bulk f-electron systems, new light is being shed on the problem thanks to heterostructures of 2D transition metal dichalcogenides, which realize a tunable Kondo lattice platform in a simple material. Here, we study the 1T/1H-TaSe2 heterostructure with high-resolution Scanning Tunneling Spectroscopy at 300 mK, and show a well resolved splitting of the Kondo peak, which increases monotonically in a non-linear fashion in the presence of an out-of-plane magnetic field. This behavior is unexpected for a fully screened Kondo lattice, and it originates instead from a ground state with residual magnetic order, consistent with a Kondo coupling much below the critical point in the Doniach phase diagram.

Protected and spin-polarized transport channels are the hallmark of topological insulators, coming along with an intrinsic strong spin-orbit coupling. Here we identified such corresponding chiral states in epitaxially grown zigzag graphene nanoribbons (zz-GNRs) on mesa-SiC(0001) templates, albeit with an extremely weak spin-orbit interaction. While the bulk of the monolayer zz-GNR is fully suspended across a SiC facet, the lower edge merges into the SiC(0001) substrate and reveals a surface state at the Fermi energy, which is extended along the edge and splits in energy toward the bulk. All of the spectroscopic details are precisely described within a tight binding model incorporating a Haldane term and strain effects. The concomitant breaking of time-reversal symmetry without the application of external magnetic fields is supported by ballistic transport revealing a conduction of  $G = e^2/h$  [1,2].

O 25.5 Tue 12:15 H2

Superconductivity of ultrathin crystalline Al films - •WERNER M.J. van Weerdenburg¹, Anand Kamlapure¹, Niels P.E. van Mullekom¹, XIAOCHUN HUANG¹, MANUEL STEINBRECHER¹, PETER KROGSTRUP², and ALEXANDER A. KHAJETOORIANS¹ — ¹Institute for Molecules and Materials, Radboud University Nijmegen, the Netherlands — ²Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, 2100 Copenhagen, Denmark

While bulk Al is one of the best known BCS superconductors (SC), it exhibits strange SC behavior in the thin film limit, e.g. a strong enhancement of the critical temperature  $T_c$  [1]. The transition from bulk to thin film can modulate the electronic structure and quasiparticle excitations, and the interface with the substrate becomes relevant [2]. Understanding the role of reduced dimensionality, screening and interface effects is important for SC quantum technology.

Here, we study epitaxially grown crystalline Al films on Si(111) as a function of film thickness. Using scanning tunneling microscopy / spectroscopy with temperatures down to 30 mK, we show a strong increase of both the SC gap size  $\Delta$ and  $T_c$  for coverages between 4 and 35 monolayers. Remarkably, we find that  $\Delta$ is threefold enhanced compared to the bulk value. We characterize the SC state of the thin films in (vector) magnetic field and find a new vortex structure. Realization of Pb honeycomb stuctures by intercalation of buffer layers on SiC(0001) — •Chitran Ghosal, Markus Gruschwitz, and Christoph Теденкамр — Institut für Physik, TU Chemnitz

The growth of 2D honeycomb lattices of group IV-elements has attracted a lot of interest during the last years. In contrast to graphene, the 2D analogues of Si and Ge can be stabilized on metals, while stanene and plumbene were recently prepared on compound crystals and magnetic substrates, respectively. Here we report on the intercalation of Pb using buffer layers (BL) on SiC(0001), resulting in the formation of freestanding and charge neutral graphene [1]. Depending on the bias voltage, scanning tunneling microscopy reveals complex Moiré structures, which are consistently explained in consideration of two plumbene lattices. These are rotated each by  $\pm 7.5^{\circ}$  with respect to graphene and, thus, are commensurate with the former  $6\sqrt{3} \times 6\sqrt{3}$  symmetry of the BL on SiC(0001). Locally, a  $(2 \times 2)$  pattern becomes visible in STM and is expected since the lattice constant of plumbene is twice as large as for graphene. Local spectroscopy (STS) done at 4 K reveals an electronic gap of 30 meV and is in qualitative agreement with the band structure of low-buckeled and charge-neutral plumbene.

Sn intercalation of the buffer layer/SiC(0001) interface studied by SPA-LEED and STM - •ZAMIN MAMIYEV, CHITRAN GHOSAL, and CHRISTOPH TEGENKAMP — Institut für Physik, Technische Universität Chemnitz, Chemnitz, Germany

Growth of graphene (Gr) with tailored properties and the simultaneous formation of an exotic 2D interface can be achieved by intercalation of different species below the buffer layer (BL) on SiC(0001). In this regard, Sn is interesting because of a potential Mott ground state imposed by the triangular lattice of Sn atoms at the interface and protected by the Gr layer. Therefore, we studied Snintercalation on BL/SiC(0001) by means of spot profile analysis low energy electron diffraction (SPA-LEED) and STM. Starting with a  $6\sqrt{3} \times 6\sqrt{3}$  BL surface, we deposited monolayers of Sn at RT and annealed subsequently to higher temperatures. The formation of quasi-free standing monolayer graphene (QFMLG) is confirmed by an apparent  $1 \times 1$  periodicity. Further insights for a successful decoupling of QFMLG were gained from inspecting the bell shape broadening of the diffraction spots, which is characteristic of weakly coupled 2D systems on surfaces. By further optimization of the post-intercalation treatment, a Sninduced  $\sqrt{3} \times \sqrt{3}$  reconstruction at the interface was achieved. Moreover, detailed studies showed a simultaneous transformation of  $6\sqrt{3} \times 6\sqrt{3}$  periodicity into a  $(\sqrt{39} \times \sqrt{39})$ R16.1° reconstruction with corresponding domains. Interestingly, the new periodicities formed by the intercalant atoms are triggered by the former symmetry of the BL structure.

## O 26: Surface Magnetism

Time: Tuesday 10:30-12:45

O 26.1 Tue 10:30 H4

Investigation of bubble domains in Fe₃GeTe₂ by spin-polarized scanning tunneling microscopy — •Namrata Bansal¹, Hung-Hsiang Yang¹, Philipp Ruessmann², Markus Hoffmann², Lichuan Zhang², Dongwook Go², Amir-Abbas Haghighirad³, Kaushik Sen³, Matthieu Le Tacon³, Yuriy Mokrousov², and Wulf Wulfhekel¹ — ¹Physikalisches Institut, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany — ²Peter Gruenberg Institut (PGI-1) and Institute for Advanced Simulation (IAS-1) Forschungszentrum Juelich GmbH, D-52425 Juelich — ³Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany

We investigated the magnetic structure of the van der Waal material, Fe₃GeTe₂ (FGT), using a home-built low temperature (0.7 K) spin-polarized scanning tunneling microscope (SP-STM). Out-of-plane magnetic imaging with chromiumcoated tungsten tip reveals bubble domains in FGT. When applying out-of-plane magnetic fields, the domain shape transitioned from elliptical to circular and collapsed at around 0.32 T. We observed an inverse relation between the size of the bubble domains and the magnetic fields. Benefiting from the spatial resolution of the SP-STM, the domain wall widths were determined, which contains infor-

O 26.2 Tue 10:45 H4 Magnetization switching on self-assembled structure of alpha-helixpolyalanine molecules observed by ambient STM  $- \cdot$ NGUYEN T. N. HA¹ L. RASABATHINA², O. HELWIG², A. mation about the exchange stiffness and the anisotropy constant of FGT.

Polyalanine (PA) with an alpha-helix conformation has gathered recently a lot of interest as the propagation of electrons along the helical backbone structure comes along with spin polarization of the transmitted electron. The magnetization switching on self-assembly of PA molecules on Au(111)/Co/Au/Pt/Al2O3 substrate by an external magnetic field resulting the preferentially transmitted electrons depending on molecule's specific handedness and the direction of magnetization. The transmission of the electrons through this structure comes along with an quite high efficient spin polarization. The tip-sample distance variation due to magnetization switching on PA films has shown the jumping states between up and down magnetic direction, while on the bare substrate without PA film the stable tip-sample distance was observed. This observation is further confirmed the spin filter behavior of PA film on a magnetic substrate due to CISS effect at nanoscale.[1]N.T.N.Ha et al, J. Phys. Chem. C,124,10,5734-5739,2020.

**Inelastic Electron Tunneling through Nanomagnetic Structures** — •DARIA MEDVEDEVA and JINDRICH KOLORENČ — Institute of Physics (FZU), Czech Academy of Sciences

Inelastic electron tunneling spectroscopy (IETS) is a well-established technique used for investigation of vibrational spectra and, more recently, also for characterization of spin excitations in nanosystems probed in scanning tunneling microscopes (STM). If a magnetic molecule is attached to the STM tip, the possibilities of the probe are expanded [1], for instance, one can observe how excitations in the molecule are modified by exchange interactions with the magnetic nanosystem adsorbed on a surface. We use an in-house implementation of cotunneling theory [2] to model IETS spectra of an STM tip decorated with nickelocene molecule (having spin 1) probing magnetic atoms with spins 3/2 and 2 subject to easy-axis anisotropy of varied direction. Experimentally, these situations were recently realized in an Fe adatom on Cu(100) [1] and in metal-organic chains, incorporating Co and Cr atoms, placed on Au(111) [3]. We discuss how accurate the theory is in reproducing the measured inelastic spectra, how the spectra depend on the direction of the magnetic anisotropy, and how important the appropriate alignment of the anisotropies of the probing molecule and the other spin is for efficient spin sensing.

#### O 26.4 Tue 11:15 H4

Magnetocrystalline anisotropy in two-dimensional EuAu₂ and GdAu₂: the role of band structure — •MARIA BLANCO-REY^{1,2}, RODRIGO CASTRILLO-BODERO³, KHADIZA ALI^{2,3}, POLINA SHEVERDYAEVA⁴, ENRIQUE ORTEGA^{1,3,2}, LAURA FERNANDEZ³, and FREDERIK SCHILLER^{3,2} — ¹Universidad del País Vasco UPV/EHU, Spain — ²Donostia International Physics Center, Spain — ³Centro de Física de Materiales CSIC-UPV/EHU-MPC, Donostia-San Sebastián, Spain — ⁴Instituto di Struttura della Materia ISM-CNR, Trieste, Italy

In rare earth (RE) intermetallic crystals, the magnetocrystalline anisotropy has a single-ion contribution from the f shell, often associated with a large orbital quantum number L, and an itinerant one, due to spin-orbit coupling effects in the band structure. As Eu and Gd are  $4f^7$  RE atoms, L in 2D atom-thick EuAu₂ and GdAu₂ is essentially quenched. Therefore, these systems allow us to isolate the itinerant electron contribution in this 2D compound family. X-ray magnetic circular dichroism shows out-of-plane anisotropy in EuAu₂, in contrast to in-plane in GdAu₂. By means of angle-resolved photoemission and density-functional theory, we explain these behaviours in terms of the occupation of the spin-orbit-split dispersive RE(d)-Au(s) hybrid bands, which is ultimately dictated by the RE valence state (Eu²⁺ and Gd³⁺). In terms of energy, the itinerant electron contribution is  $\approx$  1 meV per unit cell, which may eventually compete with the single-ion contribution.

## O 26.5 Tue 11:30 H4

Magnetic Domain Structures of Gd(0001)/W(110) Films — •PATRICK HAERTL, MARKUS LEISEGANG, and MATTHIAS BODE — Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany

Rare earth metal films are known to exhibit an extremely rich magnetic behavior. Depending on the sign of the RKKY coupling and details of the film preparation various domain structures have been observed, for example on Dy(0001)/W(110) films [1]. Here we report on experiments on Gadolinium (Gd) films epitaxially grown on W(110). Gd is a ferromagnetic metal with a Curie temperature of 293 K. Its half-filled 4f shell results in an almost spherical charge distribution which –in comparison to other rare earth metals– results in a very low magnetic anisotropy [2]. Our investigation on Gd(0001) films grown on W(110) indeed show a rather rich magnetic structure in spin-polarized STM studies. In agreement with earlier Kerr measurements [2], we find a thickness-dependent spin reorientation transition from in-plane at thin films to out-of-plane for films thicker than around 40 nm. The latter form up and down magnetized stripe domains which are tilted by  $\pm 30^{\circ}$  with respect to the W[001] direction. With increasing coverage their periodicity increases from (50  $\pm$  10) nm

up to (120  $\pm$  40) nm and domain branching is observed. We will discuss the energetics of transition of the magnetic structure.

Tuning the electron spin-polarization via tunneling through image states — MACIEJ BAZARNIK^{1,2} and •ANIKA SCHLENHOFF² — ¹Institute of Physics, Poznan University of Technology, Poland — ²Department of Physics, University of Hamburg, Germany

Image-potential states (IS) are unoccupied electronic states in front of polarizable surfaces. Towards step edges, IS energy bands bend [1], leading to laterally localized IS at the rim of nanoislands [2]. Our spin-resolved scanning tunneling microscopy (SP-STM) and spectroscopy experiments on nanomagnets reveal a spin-polarization of the IS rim state, causing a spatial modulation of the electron spin-polarization above uniformly magnetized nanoislands. An inversion of the electron spin-polarization is found at specific energies. When the electrons relax from the IS into the surface, a spin-transfer torque (STT) is excerted on the sample [3]. We show that according to the IS-induced inversion of the electron spin-polarization, the STT also changes its sign. Our findings indicate that the IS in front of the surface serves as a spin-filter that can tailor the spinpolarization of the resonant tunneling current. The existence of the rim state and its impact on the electron spin-polarization is expected at the step edge of any magnetic adlayer-substrate system. Hence, nanostructuring a magnetic surface enables tuning the local spin-polarization and thus tailoring the STT for currentinduced magnetization switching.

**Circular dichroic UV-PEEM measurements of magnetic surfaces: From Magnetic Domain Imaging to Magnetoplasmonics** – •MAXIMILIAN PALESCHKE and WOLF WIDDRA – Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Germany

Over the last decades, the rapid progress in the ultrafast optical manipulation of magnetic materials has opened the development of several new methods for the investigation and control of spin and magnetization dynamics. Here, we investigate magnetic thin films and nanostructures on nanometer-femtosecond scales with a newly-designed experimental setup. We combine state-of-the-art time-resolved photoemission electron microscopy (PEEM) with circular dichroism imaging and normal incidence excitation via a tunable femtosecond fiber laser system.

In this talk, we report on two dichroism imaging techniques, namely magnetic circular dichroism (MCD) and the recently discovered plasmonic dichroism. The first is used to image magnetic in-plane and out-of-plane domains of ferromagnetic surfaces. The second was successfully used to image propagating surface plasmon polaritons (SPPs) on a ferromagnetic material in threshold photoemission for the first time [1]. With this, we show clear edge-induced SPPs with sub-micrometer wavelength and propagation length of about 3.5  $\mu$ m on polycrystalline Ni $_{80}$ Fe $_{20}$  microstructures. This finding extends experimental investigation of SPPs to materials with high plasma frequency and large damping.

Chirality-induced electron spin polarization in chiral CuO and  $CoO_x$  catalyst surfaces — •PAUL VALERIAN MÖLLERS¹, JIMENG WEI², SUPRIYA GHOSH², SOMA SALAMON³, MANFRED BARTSCH¹, HEIKO WENDE³, DAVID WALDECK², and HELMUT ZACHARIAS¹ — ¹Center for Soft Nanoscience, WWU Münster, Germany — ²Department of Chemistry, University of Pittsburgh, Pittsburgh, USA — ³Faculty of Physics and Center for Nanointegration Duisburg-Essen, Universität Duisburg-Essen, Germany

Spin-polarized catalytic surfaces can greatly enhance the selectivity of chemical reactions, e.g., in a photoinduced water splitting process. Here, we confirm that spin-polarized (photo)currents can be obtained from chiral cupric oxide¹ (CuO) and cobalt oxide² (CoO_x), and explore the underlying mechanism. Chiral oxide thin films were deposited using a method pioneered by Switzer et al.³ Photoelectrons were excited with deep-UV laser pulses and their average spin polarization (SP) was measured. For CuO thin films, correlating the SP values with electron energy spectra reveals that the measured SP values can be rationalized assuming an intrinsic SP in the chiral oxide layer and a chirality-induced spin selectivity (CISS)-related spin filtering of the electrons. On chiral CoO_x layers, the SP was found to depend on the Co oxidation state, which allows for reversible switching of the preferred spin orientation. The results support efforts towards a rational design of further spin-selective catalytic oxide materials.

Surprisingly fast adsorbate excitation: CO/Ru(0001) probed with X-ray absorption spectroscopy — •ELIAS DIESEN¹, HSIN-YI WANG², JOHANNES VOSS¹, ALAN C. LUNTZ¹, and ANDERS NILSSON² — ¹SUNCAT Center for Interface Science and Catalysis, SLAC National Accelerator Laboratory, Menlo Park, California, USA — ²Stockholm University, Sweden

Energy transfer between substrate excitations and adsorbate motion plays an essential role in determining chemical reactivity and selectivity on surfaces. Femtosecond pump-probe experiments, using an X-ray probe pulse from a free electron laser, give unique insights into such processes due to the short pulse duration and species-selective probing. We measure the time evolution of the C K-edge X-ray absorption spectrum from CO/Ru(0001) after excitation by a femtosecond high-intensity optical laser pulse, and use detailed spectrum simulations to distinguish excitations of different modes [1]. We find high excitation of the CO internal stretch and frustrated rotation modes within 200 fs of laser excitation - one order of magnitude faster than theoretical predictions. Consequences for our understanding of ultrafast adsorbate excitation will be discussed.

Are vacancies in field ion microscopy artefacts? A DFT study — •SHYAM KAT-NAGALLU, JÖRG NUEGEBAUER, and CHRISTOPH FREYSOLDT — Department of computational materials design, Max Planck Institut für Eisenforschung GmbH, Max-Planck- Str. 1, 40237, Düsseldorf, Germany.

Resolving the atomic structure of engineering materials in 3D continues to be an extensive research field. Field ion microscopy under evaporating conditions (3D-FIM) is one of the few techniques capable of delivering such atomic-scale information, allowing to even image vacancies and their interactions with solute atoms in alloys. However, the quantification of the observed vacancies and their origins are still a matter of debate. It was suggested that high electric fields (1-10 V/Å) used in FIM could introduce artefact vacancies. To investigate the possibility of this mechanism, we used density functional theory (DFT) simulations. Stepped Ni surfaces with kinks were modelled in the repeated slab approach with a (971) surface orientation. A field of up to 4 V/Å was introduced on one side of the slab using the generalized dipole correction. Contrary to conventional wisdom, we show that the reaction barrier to form vacancies on the electrified metal surface increases compared to the field-free case. We also find that the electric field can introduce kinetic barriers to a potential "vacancy-killing" mechanism. We compare these findings with field evaporation models proposed in the literature.

Modeling electron beam damage in Gold nanoparticles and MoS2 — •CUAUHTEMOC NUÑEZ VALENCIA¹, MATTHEW HELMI LETH LARSEN¹, WILLIAM B. LOMHOLDT², PEI LIU², DANIEL KELLY², THOMAS W. HANSEN², and JAKOB SCHIØTZ¹ — ¹DTU Physics, Technical University of Denmark, Kgs. Lyngby, Denmark — ²DTU Nanolab, Technical University of Denmark, Kgs. Lyngby, Denmark

Beam damage in High-Resolution Transmission Electron Microscopy (HRTEM) is poorly understood theoretically, and not yet well described phenomenologically. The interaction between the specimen and the electron beam changes significantly depending on the material: semiconductors (like MoS2) and metals (like Gold) have different lifetime excitations and beam damage can be triggered in different mechanism.

pseudomorphic growth even prevails up to a Mn film thickness of 4 AL. Spinresolved data were acquired with W tips which had been magnetized on Mn layers by *in-situ* treatment on Mn/W(001). This allowed us to collect topographic and spin-resolved data on the same scanning area. Applying this method, we identify a magnetic zig-zag  $2\sqrt{2} \times \sqrt{2}$  structure on 3 AL Mn and a strongly biasdependent labyrinth overlay structure on 4 AL. Potential spin structures will be discussed.

In this study, we investigate the beam damage in MoS2 and Gold nanoparticles simulating the macroscopic timescale with a Kinetic Monte Carlo like algorithm, using different approaches: long Molecular Dynamics (MD) simulations for Gold and statistical model using different threshold energy (T_D) values for MoS2 considering the thermal vibrations.

The second approach for modeling the beam damage in MoS2 was through ab Initio Molecular dynamics the calculation of the threshold energies for the different scenarios. Where a Kinetic Monte Carlo simulation was implemented for study the dynamics of the defect production and the beam damage for MoS2.Also, we studied the effect in the T_D when we remove or add electrons to the MoS2.

Electron-driven mobility of the hydrogen-bonded ammonia clusters — •PRASHANT SRIVASTAVA¹, DANIEL MILLER², and KARINA MORGENSTERN³ — ¹Chair of physical chemsitry-I, Ruhr University Bochum, Germany — ²Department of Chemistry, Hofstra University, 106 Berliner Hall, Hempstead, New York 11549, United States — ³Chair of physical chemsitry-I, Ruhr University Bochum, Germany

Electron-driven processes in polar solvents are of great interest to study, e.g., electron solvation in ammonia plays a vital role in ozone layer depletion. We study the impact of electrons on the ammonia clusters adsorbed on a copper surface using a combination of low-temperature scanning tunneling microscopy, femtosecond laser pulses, and ab-initio calculations. Photo-injected electrons from the copper surface lead to diffusion or desorption of the second layer of the clusters. Upward mass transport (UMT) and downward mass transport (DMT) also play an important role in modifying the hydrogen-bonded network of these clusters. Theoretical calculations confirm electron solvation into the second layer. We present a molecular-scale insight into the interactions of photo-injected electrons with the ammonia clusters in the second layer. Our results show that this interaction can modify an ammonia cluster and enhance its mobility.

Distribution of Charge and Lattice Defects via Machine Learning. — VIKTOR BIRSCHITZKY¹, MICHAEL PREZZI¹, MARCO CORRIAS¹, LORENZO PAPA¹, IGOR SOKOLOVIC², ALEXANDER GORFER¹, MARTIN SETVIN^{2,3}, MICHAEL SCHMID², ULRIKE DIEBOLD², CESARE FRANCHINI^{1,4}, and •MICHELE RETICCIOLI¹ — ¹University of Vienna (Austria) — ²Institute of Applied Physics, TU Wien (Austria) — ³Charles University, Prague (Czech Republic) — ⁴University of Bologna (Italy)

Lattice defects and localized charge on oxide surfaces impact the properties of the material to a different degree depending on their spatial distribution. However, the high number of possible defect configurations poses practical challenges to first-principles studies. Here, we propose a machine-learning-accelerated approach to explore in the framework of density functional theory the spatial configurations of charge and lattice point defects. We apply this approach to analyze the distribution of surface oxygen vacancies on rutil TiO₂(110). The attractive interaction with small polarons (electrons localized on the Ti atoms) are revealed to weaken the repulsion between oxygen vacancies, favoring particular arrangements of the vacancies. The resulting distribution can be compared with the patterns identified by computer vision algorithms on scanning-probe microscopy images.

Switchable interfaces based on bistable molecules: tetrachloropyrazine on Pt(111) — •LUKAS HÖRMANN, ANDREAS JEINDL, and OLIVER T. HOFMANN — Institute of Solid State Physics, NAWI Graz, Graz University of Technology, Petersgasse 16, 8010 Graz, Austria

Organic/inorganic interfaces govern the properties of many organic electronic devices. To imbue devices with additional functionality, it would be useful to make these interface properties reversibly switchable by means of easily accessible external parameters, such as the temperature.

In this work, we realize such a switchable interface with tetrachloropyrazine (TCP) on Pt(111). TCP can either chemisorb or physisorb on the Pt(111) surface, forming a double-well potential with strongly differing adsorption geometries. These allow forming diverse interface structures with notably different work functions and coherent fractions (obtained by X-ray standing wave measurements).

We model this switchable interface using a machine learning algorithm, based on Gaussian process regression. This facilitates structure search for commensurate as well as higher-order commensurate adlayers. We find three different classes of interface structures with varying work functions and coherent fractions and demonstrate that external stimuli, such as temperature and pressure, allow to reversibly shift between these different classes. Based on our insights, we discuss how systems need to be constructed so that the switch between different states leads to an even larger change in their properties.

Substrate enhanced Jahn-Teller effect in single molecule junctions — •MORITZ FRANKERL¹, LAERTE PATERA^{2,3}, THOMAS FREDERIKSEN⁴, JASCHA REPP³, and ANDREA DONARINI¹ — ¹Institute for Theoretical Physics, University of Regensburg — ²Catalysis Research Center, Technical University of Munich — ³Institute of Experimental and Applied Physics, University of Regensburg — ⁴Donostia International Physics Center (DIPC), Spain

The stabilization of several charge states of single molecules deposited on nonconductive NaCl films [1] allows to map out the electronic transition between different charge states by means of single-electron alternate-charging scanning tunneling microscopy [2].Copper-phthalocyanine (CuPc) revealed a Jahn-Teller splitting (JTS) of its doubly degenerate LUMOs upon charging and, more surprisingly, the occupation of the same LUMO for both electrons upon double charging. We show by DFT calculations complemented by a group-theoretical analysis how the JTS for CuPc in gas phase is not sufficient to explain this behavior. We propose, instead, a cooperation between molecule and substrate deformation which enhances the strength of the JT coupling. The result is based on a microscopic model of the electron-phonon coupling between the molecule and the underlying thick layer of NaCl. The magnitude of the obtained substrateinduced JTS highlights the impact of the substrate on the electronic configuration of charged molecules, far beyond the mere charge stabilization. Impact of electron-phonon interaction on metal-organic interface states — •LUKAS ESCHMANN, JAN NEUENDORF, and MICHAEL ROHLFING — Institut für Festkörpertheorie, Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany

We discuss electron phonon interaction (EPI) in the context of metal-organic adsorbate systems and the occurring nearly-free electron-like interface states (IS) whose energy *E* is strongly coupled to the vertical binding distance *d* with a coupling strength of  $\lambda = \Delta E / \Delta d$  that is in the order of 1 eV/Å for several adsorbate systems.

We present an EPI model that is based on ab-initio data and uses the nearly-free electron-like character of the IS to obtain an analytic expression for the temperature induced renormalization of the latter^{1,2}. We find that the energy shift is dominated by the coupling to the out-of-plane phonon modes that change the average binding distance and scales quadratically with the coupling strength, i.e.,  $\sim \lambda^2$ . Applied to the system of a NTCDA layer adsorbed on Ag(111), our model predicts a renormalization of the IS onset energy through quantum mechanical coupling with the adsorbate phonons by -10 meV per 100 K. With this, we are able to explain the discrepancy between a classical lifting-effect and the experiment, thus revealing the important impact of EPI on spectroscopic states at metal-organic internal interfaces.
