Characterisation of the chemical environment and electronic structure of organic materials and metal-organic interfaces can be carried out with x-ray photoelectron spectroscopy (XPS) and near-edge x-ray absorption fine structure (NEXAFS) spectroscopy. The adsorption of molecules onto surfaces has been shown to change various spectral features which have previously been connected to changes in chemical bonding and charge distribution. However, these can be difficult to interpret due to overlapping features of multiple species and widely broadened spectra. Through the use of density functional theory (DFT) calculations we study two molecular isomers, azulene and naphthalene, adsorbed onto three metal (111) surfaces of silver, copper, and platinum. Categorised into three regimes of molecule-metal chemical bonding, we connect the changes seen in the spectra to the chemical bonding behaviour and decompose the signatures into initial core-state and final valence-state contributions. We analyse the effect of charge transfer, electronic hybridisation and dispersion effects, and aim to provide guidance for experimental spectral analysis.

The sensitivity of NMR chemical shifts to organic/inorganic interfaces – •VIVIANA PICCINNI¹, EMMANOUIL VEROUTIS², KARSTEN REUTER¹, JOSEF GRANWEHR², and CHRISTOPH SCHEURER¹ – ¹Fritz Haber Institute of the Max Planck Society, Berlin – ²Forschungzentrum Jülich, IEK-9, Jülich

Composite polymer/ceramic solid electrolytes are promising materials for Liion batteries due to their high stability and safety. Yet, their organic/inorganic interface is believed to hinder the ionic conduction. NMR experiments on a poly(ethylene oxide)/Li_{1.5}Al_{0.5}Ti_{1.5}(PO₄)₃ electrolyte have shown that Li ions cross the interface on a timescale of seconds. To remedy the problem, mechanistic insights are required, but even the polymer/ceramic interface structure is unknown.

We therefore investigate representative potential binding situations between the two materials by computing the NMR shielding tensors, in order to verify whether there is a significant change in the chemical shifts depending on the interface structure. Due to the high computational cost, a simplified model exhibiting the same local chemical interactions is constructed, composed by an AlPO₄ slab and ethane-1,2-diol. NMR measurements on an AlPO₄/methanol system have also been carried out.

While the computed NMR properties are sensitive to changes in the interface structure, experiments reveal no chemical shifts variations in the ¹H NMR methanol/AlPO₄ spectra relative to neat methanol. This can be ascribed to the presence of surface water in AlPO₄, which would leave no available binding sites for methanol/AlPO₄ interactions.

O 28.6 Tue 11:45 S051

Classifying Chiral Structure by a Convolutional Neural Network — •PEER KASTEN¹, MANDY STRITZKE², JOHANNES TIM SEIFERT¹, BJÖRN MÖLLER³, TIMO DE WOLFF², TIM FINGSCHEIDT³, and UTA SCHLICKUM¹ — ¹Institut für Angewandte Physik, Technische Universität Braunschweig — ²Institut für Analysis und Algebra, Technische Universität Braunschweig — ³Institut für Nachrichtentechnik, Technische Universität Braunschweig

Scanning tunneling microscopy (STM) is an important tool to image surfaces at atomic scale. To examine structures of molecules in STM images can be a difficult and time-consuming task. We present a method to recognize chirality within experimentally observed self-assembled molecular structures using the convolutional neural network (CNN) based object detection framework Faster R-CNN. Thereby we can classify unit cells in the image towards one of both chiral structures.

To train the neural network, a sufficient amount of correctly labeled images is necessary. To obtain such data and labels, we utilize a method to create realisticlooking, synthetic STM images in varying zoom-sizes containing lifelike properties such as noise and step edges along with corresponding labels.

Using this synthetic data, we trained a model capable of classifying synthetic images at sizes ranging from 8 nm to 100 nm with high performance. Evaluations of the CNN's predictions for real images show that this network trained on synthetic data can generalize towards inference on real images.

O 28.7 Tue 12:00 S051 Energy landscaping with external electric fields: Selective stabilization of interface polymorphs — JOHANNES CARTUS, ANDREAS JEINDL, •ANNA WERKOVITS, and OLIVER HOFMANN — Graz University of Technology, Graz, Austria The polymorphs that inorganic/organic interfaces assume can have drastic consequences for the interface properties (such as, e.g., the work function). It is, therefore, of great relevance for applications in organic electronics to achieve precise control of the interface polymorphism. The stability of the respective polymorphs is determined by deposition conditions (e.g., temperature and pressure). In this contribution we investigate electric fields as an additional handle for better control over the polymorphism, thus selectively stabilizing polymorphs at conditions where they were previously inaccessible.

Using density functional theory calculations augmented by a smart-data machine learning approach (SAMPLE) we demonstrate how electric fields can be used to foster desired or even previously unseen polymorphs. Tetracyanoethylene (TCNE) on Cu(111) is an ideal test system because its work function can change by more than 3 eV for different polymorphs.

#### O 28.8 Tue 12:15 S051

Interlayer orbital overlap governing thin-film geometry: the role of interfacial charge transfer — •FABIO CALCINELLI, ANDREAS JEINDL, LUKAS HÖR-MANN, and OLIVER HOFMANN — Institute of Solid State Physics, NAWI Graz, Graz University of Technology, Petersgasse 16, 8010 Graz, Austria

Organic thin films exhibit a large structural variability, and the substrate on which they grow has a relevant influence on their polymorphism. Predicting which structure a thin film will assume on a substrate is impossible through traditional first-principle modeling alone, because of the combinatorial explosion in the number of possible polymorphs. However, recent developments in machinelearning assisted structure search have made structure-to-property investigations accessible. Employing smart-data machine learning, we demonstrate the impact that different substrates can have on the geometry of the first two layers of a thin film. We identify the energetically most favourable geometries for benzoquinone on silver and on graphene, and compare their electronic properties. While the polymorphs formed in the first layer of benzoquinone are very similar, for the second layer we find two significantly different structures. We explain this difference as an effect of the interplay between different charge transfer on the two substrates, and different interlayer orbital overlap for the two structures. Furthermore, we investigate the systematic impact of interlayer orbital overlap in defining the most stable polymorphs for different charge transfers.

#### O 28.9 Tue 12:30 S051

Polymorph trapping by optimized deposition conditions: A first-principles prediction for TCNE/Cu(111) — •ANNA WERKOVITS, ANDREAS JEINDL, LUKAS HÖRMANN, JOHANNES J. CARTUS, and OLIVER T. HOFMANN — Institute of Solid State Physics, NAWI Graz, Graz University of Technology, Petersgasse 16, 8010 Graz, Austria

Physical properties of small-molecule organic semiconductors are strongly determined by their polymorphs. Depending on the orientation in which molecules adsorb on the substrate, properties can significantly vary, as is the case, e.g. for tetracyanoethylene (TCNE) on Cu(111).

We propose conditions under which TCNE remains in the energetically less favorable lying position also for higher coverages. This requires fulfilling two prerequisites: To enable ordered growth, the temperature must be high enough to allow for sufficient diffusion of lying molecules, whereas the temperature must be low enough to inhibit the reorientation to the upright-standing position.

In this work, we utilize the nudged elastic band method and density functional theory to compute energy barriers. By means of the harmonic transition state theory temperature-dependent diffusion and reorientation rates are obtained for predicting a temperature range where the kinetic stabilization is attained.

**Controlling the translation of a single molecule** – •GRANT J. SIMPSON¹, MATS PERSSON², and LEONHARD GRILL¹ – ¹University of Graz, Graz, Austria – ²University of Liverpool, Liverpool, UK

Controlling both of the orientation and the direction of translation of a single molecule is crucial to the understanding of molecular machines [1,2]. In addition, overcoming microscopic reversibility and realising unidirectional motion is a major criterion if a molecular machine is to do any meaningful work. Here, we report how single molecules can be translated in a directional manner over a metallic surface using voltage pulses from the tip of a scanning tunnelling microscope. Directionality of motion is possible due to translations occurring via an asymmetrically accessible intermediate state. The reaction pathway is discussed as well as how this molecular motion can be coupled to the motion of surface adsorbates.

The incorporation of C=C bonds into conjugated nanostructures with additional functional groups (e.g. nitrogen substitution) has attracted extensive attention in recent years due to their intriguing electronic properties. However, the activation modes inside the toolbox of on-surface synthesis are still limited. We present the novel on-surface formation of CN-substituted phenylene vinylene chains on the Au(111) surface, thermally induced by annealing the substrate stepwise at temperatures between 220°C and 240°C. The reaction is investigated by scanning tunneling microscopy (STM) and density functional theory (DFT). Supported by the calculated reaction pathway, we assign the observed chain formation to a Knoevenagel condensation between an aldehyde and a methylene nitrile substituent.

#### O 29.3 Tue 11:00 S052

Self-assembly and on-surface Ullmann-type polymerisation of a DPP-based molecular wire on Au(111). — •MICHAEL CLARKE¹, ABIGAIL BELLAMY-CARTER², FERDINANDO MALAGRECA³, DAVID B. AMABILINO⁴, and ALEXANDER SAYWELL¹ — ¹School of Physics & Astronomy, University of Nottingham, NG7

Diketopyrrolopyrrole (DPP) is a chemical moiety which may act as an electron acceptor within organic electronic-devices and exhibits a high charge carrier mobility. [1] Charge transport within such systems is affected by the local arrangement, and orientation, of molecules/domains; hence controlled formation of ordered structures is of interest. Self-assembly of functionalised DPP species is a route towards ordered structures [2], and on-surface protocols allow monomer units to be covalently coupled under appropriate reaction conditions (e.g. Ullmann-type reactions [3]). Here we study an alkyl chain functionalised DPP unit possessing aryl-hide groups to facilitate on-surface covalent coupling. The self-assembled structure of the monomer units is characterised and ordered polymers, formed via thermal treatment, are investigated using Scanning Tunnelling Microscopy (STM). [1] Y. #### O 29.4 Tue 11:15 S052

Quantifying the diffusion of porphyrins on Au(111): A temperaturedependant STM study — •MATTHEW EDMONDSON and ALEX SAYWELL — School of Physics & Astronomy, University of Nottingham, Nottingham, UK The diffusion of surface-confined molecules is a fundamental step within the formation of self-assembled structures and on-surface reactions. Scanning probe microscopies provide a route to characterising the diffusion pathways of these molecules, and allow a quantitative analysis of energetic barriers via Arrheniustype rate analysis.(1) In particular, SPM allows the relationship between atomicscale surface structures and molecular diffusion to be explored; a potential method for influencing on-surface reactivity.(2)

The Au(111) surface, frequently used as a substrate for on-surface coupling reactions (3), exhibits the well-known 'herringbone' reconstruction which may influence the diffusion of molecule species. In this work, we report on the diffusion of individual 2H-TPP on the Au(111) surface; characterising the diffusion rate via variable-temperature scanning tunnelling microscopy within specific regions of the reconstructed surface. The energy barrier to diffusion (obtained via Arrhenius analysis) was found to differ between the FCC and HCP regions of the herringbone reconstruction, indicating that local geometric/electronic surface features play a role in on-surface diffusion.

#### O 29.5 Tue 11:30 S052

LT-STM induced reversible chiral switching of thiophene-based molecule on Au(111) — •SUCHETANA SARKAR^{1,2}, KWAN HO AU-YEUNG^{1,2}, TIM KUEHNE^{1,2}, DMITRY A. RYNDYK^{2,3}, Albrecht Waentig^{1,4}, Xinliang Feng^{1,4}, and Francesca Moresco^{1,2} – ¹Center for Advancing Electronics Dresden, TU Dresden, 01062 Dresden, Germany -²Institute for Materials Science, TU Dresden, 01062 Dresden, Germany -³Theoretical Chemistry, TU Dresden, 01062 Dresden, Germany —  $^4\mathrm{Chair}$  of Molecular Functional Materials and Faculty of Chemistry & Food Chemistry, TU Dresden, 01062 Dresden, Germany

In the ongoing quest for miniaturization of machines, single molecule machinery holds a plethora of possibilities. Advancements in nanoscale imaging techniques, such as Scanning Tunneling Microscopy and Spectroscopy(STM, STS), allows not only the addressing of single molecules individually but through tunneling electrons/electric field stimulation with an STM tip, one can experimentally study fundamental properties of molecules such as pi-conjugation and charge transfer to a surface, and the effect it has on the switching behavior. We present the design and synthesis of a nanoswitch which exhibits a reversible switching from achiral to chiral mode on Au(111). The electronic states of both conformations have been measured with a high degree of spatial resolution, thereby showing the pathways of the electron-induced isomerization. Furthermore, we demonstrate this effect being suppressed on Ag(111).

O 29.6 Tue 11:45 S052

Enravelling effects of dispersion interactions in enantioselective adsorption - •RAYMOND AMADOR^{1,2}, SAMUEL STOLZ³, NESTOR MERINO-DIEZ¹, OLIVER GROENING¹, ROLAND WIDMER¹, and DANIELE PASSERONE^{1,2} — ¹Empa - Dübendorf, Dübendorf, Switzerland — ²ETH Zürich, Zürich, Switzerland — ³Department of Physics, UC Berkeley, United States

van der Waals (vdW) interactions play a central role in a wide variety of systems. They are responsible for many natural processes, and thus, an accurate description of vdW forces is essential for improving our understanding phys-

ical phenomena. In this talk, we present our findings on the role of nonlocal vdW interactions in the enantioselective adsorption and debromination of the 10,10² dibromo-9,9² bianthracene (DBBA) and 9-Phenanthracenylboronic acid (9PBA) molecules, as catalyzed by chiral surfaces of the palladium-gallium (PdGa) intermetallic compound. After a brief recapitulation on the framework of density-functional theory (DFT), we discuss its principle shortcomings within the context of many-body perturbation theory, and how our current calculations address and rectify these faults via higher-order treatments of the exchange integrals. We then present several figures of interest: adsorption configurations before and after geometry optimizations and charge localization plots of adsorption, and explore effects of both vdW interactions and the nonlocal exchange term via inclusion of hybrid functionals. In doing so, we provide the foundations for further study of non-local electronic correlation in chirality.

O 29.7 Tue 12:00 S052

The role of Adatoms for the Adsorption of F4TCNQ on Au(111) - •RICHARD Berger, Andreas Jeindl, Lukas Hörmann, and Oliver Hofmann — TU Graz Institut für Festkörperphysik, Graz, Österreich

Molecular adsorption on inorganic substrates often includes the incorporation of native adatoms within the adsorbate layer. The presence of the adatom in the adlayer causes significant changes in the electronic structure of the interface affecting properties such as the adsorption geometry, the bonding type, and the work function. Here we investigate the adsorption of F4TCNQ on Au (111), which is a prototypical system for the adsorption of an acceptor type molecule on a metallic substrate. Using density functional theory, we show that incorporating adatoms significantly changes the interface charge transfer and modifies the Fermi-level pinning mechanism for the adsorbed species. Furthermore, we find that the 5d orbitals of the Au adatom hybridize with the F4TCNQ molecular orbitals, introducing covalent coupling within the adlayer. The combination of this effect explains why the incorporation of adatoms, despite the high cost of extracting them from the bulk, is energetically favorable.

#### O 30.1 Tue 10:30 S053 Surface Phase Transitions in Atomistic Detail and with Femtosecond Resolution — • WOLF GERO SCHMIDT — Universität Paderborn

Ab initio molecular dynamics on ground and excited-state potential energy surfaces may be used to gain deep insight in the driving forces and mechanisms of surface phase transitions and can greatly assist the interpretation of experimental data. This is illustrated in my talk using two prominent examples: (i) Photoholes localized at the Brillouin zone boundary of the In/Si(111)(8x2) surface are shown to drive an ultrafast (8x2)  $\longrightarrow$  (4x1) phase change that is accompanied by an insulator-metal transition [1,2]. (ii) Thermal excitation of the Au/Si(553)(1x6) surface leads to soft Au chain vibrations that reduce transiently the Au electron affinity, which lowers the barrier for a  $sp^2 + p \rightarrow sp^3$  hybridization change of Si step edge atoms. This leads eventually to an order-disorder phase transition and the formation of a two-dimensional spin liquid [3].

Dimer coupling energies of the Si(001) surface examined by SPA-LEED -•Christian Brand, Giriraj Jnawali, Jonas Fortmann, Mohammad Tajik, Alfred Hucht, Peter Kratzer, Hamid Mehdipour, Björn Sothmann, and MICHAEL HORN-VON HOEGEN - Department of Physics and Center for Nanointegration CENIDE, University of Duisburg-Essen, Lotharstraße 1, 47057 Duisburg

Though the surface of Si(001) belongs to the most famous in the world still some of its properties and phenomena are unrevealed. Si(001) exhibits buckled dimers in the topmost layer, arranged in dimer rows, and thus forming a  $(2 \times 1)$  reconstruction at room temperature. Upon cooling the structure undergoes an disorder-order transition to the  $c(4 \times 2)$  reconstructed ground state. High-resolution SPA-LEED (Spot Profile Analyzing - Low Energy Electron Diffraction) was used to quantify the structural change along the transition upon heating from low to high temperatures. Rapid cooling in the regime of critical slowing down formed a so-called domain structure with typical size of ~ 14 nm. The data is analyzed in the framework of the anisotropic 2D Ising model and complemented by density functional theory calculations. We determined a phase transition temperature of  $T_c = 190.6$  K, critical exponents  $\beta$ ,  $\gamma$ , and v of the Ising model and the coupling constants  $J_{\parallel} = (-24.9 \pm 1.3)$  meV and  $J_{\perp} = (-0.8 \pm 0.1)$  meV of the Si dimers by solving Onsager's equation and evaluating the correlation length ratio of the two directions.

Reduced contact resistance to gallium nitride by plasma-assisted atomic layer  $\textbf{deposition} - \bullet \textbf{MAXIMILIAN CHRISTIS} - \textbf{Walter Schottky Institut, Technische}$ Universität München

Gallium nitride is an industrially relevant III-V semiconductor that draws significant attention for a range of both established and emerging applications, including for light emitting diodes, power electronics, photocatalysis, and sensing. Established contacting schemes for GaN rely on wet-chemical surface preparations and post-metallization high-temperature ( $\geq 600^\circ \mathrm{C})$  annealing processes, which complicate fabrication and may adversely affect device performance. Here, we present a low-temperature gas-phase process ( 200 °C) that reduces the Schottky barrier height and the contact resistivity at the GaN/metal interface. In particular, we employ H2 plasma-enhanced atomic layer deposition (ALD) that creates an ultimately thin, homogeneous AlOx monolayer using oxygen from the native gallium oxide as oxidant. This AlOx coating reduces the surface band bending and results in Ohmic current-voltage characteristics for n-doped GaN contacted by Ti metal. In ongoing work, we are also exploring how the monolayer AlOx ALD approach can be applied to improve contacts to p-doped GaN in combination with high work function metals. Among the various applications that could benefit from this low thermal budget contact fabrication strategy, we are investigating how such metal/semiconductor structures impact the electrocatalytic performance of n-GaN/Pt cathodes for water splitting.

#### O 30.4 Tue 11:30 S053

Distance dependance and lateral change of electrostatic forces between Pb-islands and wetting layer on Pb/Si(111)-(7x7) — BEN LOTTENBURGER, •PAUL PHILIP SCHMIDT, DANIEL ROTHHARDT, MANUEL SCHULZE, and REGINA HOFFMANN-VOGEL — Universität Potsdam, Institut für Physik und Astronomie, Experimentelle Physik kondensierter Materie

Pb islands on silicon show a wide range of interesting properties, such as explosive island growth [1,2]. Previous work has already been able to explain some features, such as the unusual height distribution of the islands[3,4]. To understand this system in more detail, we have investigated the differences in the electrostatic interaction between the tip and the Pb islands on one side and the Pb-containing wetting layer on the other side. We have used scanning force microscopy in the non-contact frequency modulation mode and bias distance measurements in ultrahigh vacuum at ~120K. The Si has been cleaned by direct current heating. Subsequently, Pb has been vapor deposited. The Frequency shift as a function of tip-sample distance has been measured on both Pb islands and the wetting layer. The differences in force and work function between have been investigated both.

Growth of well-ordered K3C60 thin films on Bi2Se3 - •MICHAEL HERB and ISABELLA GIERZ — Department of Physics, University of Regensburg, 93040 Regensburg, Germany

The molecular solid K3C60 is a BCS-type superconductor with a critical temperature of 20K [1]. More intriguingly, K3C60 powder exposed to strong midinfrared driving fields exhibits the optical properties of a transient superconductor [2] possibly up to room temperature [3] and with nanosecond lifetimes [4]. The microscopic mechanism behind these observations remains poorly understood. We want to shed light onto this issue by measuring the transient band structure of driven K3C60 using time- and angle-resolved photoemission spectroscopy (tr-ARPES). These experiments cannot be performed on the originally used K3C60 powder as they require large, well-ordered K3C60 single crystals. Therefore, we investigate the growth of K3C60 thin films on different substrates using low-energy electron diffraction (LEED) and ultraviolet photoemission spectroscopy (UPS). We provide evidence for well-ordered growth on Bi2Se3, enabling future tr-ARPES studies on the material.

#### O 30.6 Tue 12:00 S053

Structure and origin of antiphase domains and related defects in thin GaP epilayers on As-modified Si(100) — •FRANZ NIKLAS KNOOP¹, AGNIESZKA PASZUK², BENJAMIN BORKENHAGEN^{1,3}, OLIVER SUPPLIE^{2,4}, MANALI NANDY², GERHARD LILIENKAMP¹, PETER KLEINSCHMIDT², THOMAS HANNAPPEL², and WINFRIED DAUM¹ — ¹IEPT, TU Clausthal — ²Institute of Physics, TU Ilmenau - ³Fallstein Gymnasium Osterwieck - ⁴Physics Department, HU Berlin The deposition of low-defect III-V-layers on Si(100) is impaired by the forma-

tion of antiphase domains (APDs) in the epilayer. We study the origin and formation of APDs and related defects in thin GaP buffer layers on nearly-singledomain, As-modified Si(100) substrates. By comparing results obtained by low energy electron microscopy (LEEM), AFM, STM and scanning Auger electron microscopy, we identify two different types of APD-related defects in the GaP layer and trace these defects back to residual minority (2x1) domains of the Si substrate. GaP growth on minority domain terraces with widths in the range 40-100 nm gives rise to APDs of comparable lateral dimensions. The observation of trench-like defects in the epilayer extending down to the surface of the substrate indicates that homogeneous layer-by-layer growth of GaP is impeded on narrow terraces (<20 nm) of the (2x1)-reconstructed minority domain of the substrate. We propose that insufficient nucleation of GaP on these terraces leads to the formation of trenches, while on wider minority terraces APDs are formed by 3D-like growth.

#### O 30.7 Tue 12:15 S053

Adsorption of CO and CO₂ on the Y-stabilized ZrO₂(100) surface — •SHUANG CHEN, XIAOJUAN YU, ERIC SAUTER, ALEXEI NEFEDOV, STEFAN HEISSLER, CHRISTOF WÖLL, and YUEMIN WANG — Institute of Functional Interfaces (IFG), Karlsruhe Institute of Technology (KIT), 76344 Eggenstein-Leopoldshafen, Germany

Understanding the stabilization mechanism of the Y- stabilized zirconia (YSZ) (100) surface has triggered a great debate over the past 30 years. In this work, we focused on a fundamental study on the surface structure of YSZ(100) by polarization-resolved infrared reflection absorption spectroscopy (IRRAS), in combination with grazing-emission X-ray photoelectron spectroscopy (XPS). The combined IR and XPS results allowed to gain detailed insight into the adsorption of carbon monoxide and carbon dioxide on YSZ(100) over a large coverage range from submonolayer to multilayers. The experimental data were further analyzed based on the density functional theory (DFT) calculations.

#### O 30.8 Tue 12:30 S053

Starting from a Fixed Geometry: Real-Time XPS Investigation of a Surface Reaction with Controlled Molecular Configurations - •TIMO GLASER¹, Christian Länger¹, Julian Heep¹, Jannick Meinecke², Mathieu Silly³, Ulrich Koert², and Michael Dürr¹ – ¹Institut für Angewandte Physik und Zentrum für Materialforschung, Justus-Liebig-Universität Giessen, Germany — ²Fachbereich Chemie, Philipps-Universität Marburg, Germany — ³Synchrotron SOLEIL, 91192 Gif sur Yvette, France

The relative orientation between two reactants can have a major influence on the reactivity and on the products of a chemical reaction. In gas-surface chemistry with well-defined single-crystal surfaces, the orientation and configuration of one reactant is fixed by the surface, but still the reacting gas molecules can impact on the surface in all possible orientations. Here we show how to constrain the relative orientation of both reactants by attaching a reactive group (ether) via a linker (cyclooctyne) on a single crystal surface. This keeps the reacting group in a highly-constrained configuration close to the surface. We demonstrate this concept for ether cleavage on silicon (001), the surface analogue of an S_N2 reaction. The kinetics of the further reaction of the ether group with the silicon surface is studied by means of real-time XPS using synchrotron radiation. We find both a low-energy barrier and a low prefactor, which we discuss in terms of the constrained starting configuration of the ether group. As this configuration represents the starting point of a low-energy pathway, it gives direct experimental access to the underlying reaction mechanism.

## O 31: Solid-Liquid Interfaces 3: Reactions and Electrochemistry

Time: Tuesday 10:30-12:30

O 31.1 Tue 10:30 S054 Towards a realistic description of electrified solid-liquid interfaces -•NICOLAS G. HÖRMANN — Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany

Atomistic modelling of electrified solid-liquid interfaces in the context of electrocatalytic and electrochemical transformations is a challenging task. This is in particular so as the description of many relevant processes involves the consideration of charge transfer, solvent reorganization and the long-range screening of the electrolyte. Many of these processes have been studied in the past using effective model hamiltonians and from a physical chemistry perspective, e.g. based on mean-field kinetic models. However, recent advances in the first-principlesbased description have opened up pathways to study the involved phenomena with atomistic resolution and to gain new, fundamental insights.

In this talk, I will give a brief overview of such recent developments, concentrating mainly on the use of and results from DFT calculations in continuum solvation environments[1]. Without doubt, such calculations have had a tremendous impact on the community, as they paved the way to describe the interfacial energetics in a grand-canonical framework, aka at applied potential conditions[2]. In addition to discussing a range of results obtained on model systems, I will as well clarify the evident limitations and inaccuracies of such an approach and discuss briefly possible future pathways to improve upon those.

O 31.2 Tue 11:00 S054 Electrostatic potentials in molecular dynamics — •Ludwig Ahrens-Iwers¹, GREGOR VONBUN-FELDBAUER¹, and ROBERT MEISSNER² - ¹Institute of Advanced Ceramics, Hamburg University of Technology, Hamburg, Germany — ²Institute of Polymers and Composites, Hamburg University of Technology, Hamburg, Germany

Location: S054

Molecular dynamics (MD) simulations in a constant potential ensemble are an increasingly important tool to investigate charging mechanisms in nextgeneration energy storage devices. The constant potential method (CPM) can be used in classical MD to model metallic electrodes at an electrostatic potential. In this method, charges of individual electrode atoms are set to meet the applied potential. Unfortunately, existing implementations are either highly specialized or not very performant.

As a new implementation of the CPM, the ELECTRODE package for the MD code LAMMPS is presented. This package integrates a particle-mesh solver to greatly reduce computation times of the long-range Coulomb interactions. Further, a dipole correction that is required for systems with a slab geometry is included. In addition to the CPM, the code features a constant charge method which distributes the charges within each electrode as well as a thermopotentiostat that utilizes the CPM algorithm. Moreover, the integration in LAMMPS allows the use of many tools from the base code and other packages.

O 31.3 Tue 11:15 S054

First-principles molecular dynamics simulations of electrified Pt(111)/H2O interfaces — •Lang Li, Nicolas G. Hörmann, and Karsten Reuter — Fritz-Haber-Institut der Max-Planck- Gesellschaft, Berlin, Germany

Metal-water interfaces play a fundamental role in electrochemistry. An accurate understanding of their properties is required in any attempt to describe electrochemical phenomena such as electrocatalytic reactions or charge transfer processes.

In this work, we benchmark the description of electrified Pt(111)/water interfaces based on first-principles molecular dynamics simulations at applied potential conditions using density functional theory. We apply the potential by introducing excess electrons that are counterbalanced by partially charged hydrogen atoms. This method is tested with a variety of slab setups and cell sizes. Additionally, we investigate different methods to determine the reference potential.

We analyze in detail the structure of the interface as well as the obtained capacitance vs. potential curves and compare these with published theoretical and experimental results [1]. Our results highlight the response of interfacial water to an applied potential and its importance for understanding the hump in the capacitance, observed at high electrolyte concentrations [2].

O 31.4 Tue 11:30 S054

First step of the oxygen reduction reaction on Au(111): An ab initio molecular dynamics study of the electrified metal/water interface — •ALEXANDRA M. DUDZINSKI, ELIAS DIESEN, HENDRIK H. HEENEN, VANESSA J. BUKAS, and KARSTEN REUTER — Fritz-Haber-Institut der MPG, Berlin, Germany

The oxygen reduction reaction (ORR) is a key electrocatalytic process for developing sustainable energy technologies. And yet, many aspects of the underlying reaction mechanism are still poorly understood at the molecular level. Especially at weak-binding electrode surfaces such as Au, even the ability to bind aqueous O2 species as a first mechanistic step remain unclear. Resolving these questions requires going beyond the simplified thermodynamic models of charge-neutral reaction intermediates that have been commonly used in computational electrocatalysis so far. Here, we perform molecular dynamics simulations based on periodic density-functional theory (DFT) to investigate O2 adsorption at an electrified Au(111)/water interface. We elucidate structural interfacial properties as a function of surface charge, and show that the latter can significantly alter the O2 binding energy. Adsorption is specifically enhanced under electric fields that are realistic for ORR operation, suggesting this as a very possible first electrochemical, rather than purely chemical step of the mechanism and showing that field effects in corresponding DFT models cannot be neglected. The resulting dependence on (absolute) electrostatic potential may further explain the superior activity measured experimentally for this catalyst in alkaline vs. acidic media.

O 31.5 Tue 11:45 S054

Modeling varying potential conditions in electrochemical simulations: The case of  $O_2/Au(111) - \bullet$ ELIAS DIESEN, ALEXANDRA M. DUDZINSKI, HENDRIK H. HEENEN, VANESSA J. BUKAS, and KARSTEN REUTER — Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin

While significant insight has been gained in recent years by DFT-based simulations of electrochemical processes, crucial methodological challenges remain, especially for accurate determination of reaction energies under operando conditions. One open question is how to represent the constant electrode potential in simulations of an electrified water/metal interface, where the simulation setup requires a constant charge in the simulation cell throughout the reaction. Here we compare different levels of treatment of the electrochemical interface: explicit ab initio molecular dynamics, an implicit solvent model, and a sawtooth-potential electric field in vacuum, for the case of  $O_2$  adsorption on Au(111). We characterize the dynamics near the surface and identify ways an applied electrode potential influences the adsorption. We find, in all methods, significantly

enhanced  $O_2$  adsorption at more reducing conditions. However, we also show that certain aspects of the process can only be captured using a fully explicit treatment of the solvent.

O 31.6 Tue 12:00 S054 Understanding the Interfacial Capacitance of 2D Materials in an Implicit Water Environment — •HEDDA OSCHINSKI^{1,2}, NICOLAS G. HÖRMANN¹, and KARSTEN REUTER¹ — ¹Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany — ²Technical University of Munich, Germany

The interfacial capacitance (C) is a central quantity in electrochemistry. For metal electrodes, C is dominated by the double layer capacitance that derives from the potential drop in the solvent. However, the finite density of states (DOS) in semiconducting 2D electrodes alters the picture and leads to a vanishing C around the point of zero charge. This entails a challenge in describing the energy-potential relation and the connected field effects when considering adsorbates.

To explore this challenge, we study the interfacial capacitance for 2D metal halides  $MX_2$ , using density-functional theory in a continuum solvent environment. We break down *C* into a DOS-filling-related quantum capacitance and the double layer capacitance. Our analysis demonstrates that such a separation into individual components is not straightforward. Nevertheless, the qualitative behavior of *C* can be rationalized, making this study a first step towards better understanding of 2D, in particular semiconducting, electrodes.

O 31.7 Tue 12:15 S054

**Two-Dimensional 2D Materials interfacing liquid water : the new frontier from ab initio simulations** — BENOIT GROSJEAN¹, FELIX MOUHAT¹, RODOLPHE VUILLEUMIER¹, FRANCOIS-XAVIER COUDERT², and •MARIE-LAURE BOCQUET¹ — ¹Ecole Normale Supérieure, PSL university and CNRS, Paris, France — ²Chimie Paris Tech, PSL university and CNRS, Paris, France

In spite of their computational cost, quantum dynamic insights open unprecedented avenues for the use of 2D materials for nanofluidics. In this talk, I will report on our recent theoretical findings on 2D materials like G (graphene), BN (boron nitride) and GO (graphene oxide) by means of Ab Initio Molecular Dynamics (AIMD) and their implications to rationalize their peculiar fluid transport and filtration properties. We demonstrate that the charging of pristine ideal 2D materials in aqueous conditions originate from the hydroxide anion and is crucially dependent of the electronic structure of the 2D layers ranging from chemisorption to physisorption. [1] We could pioneer the concept of static versus mobile extrinsic charges on prototypical 2D materials that have a huge impact on electro-kinetic transport.[2] We also predict that the water reactivity is further enhanced on hydrid sheets like planar G-BN heterostructure [3]. Finally, we explore the properties of various GO models in neutral water and we unveil several chemical processes [4].

## O 32: Poster Tuesday: Adsorption and Catalysis 1

Time: Tuesday 11:00–13:00

#### O 32.1 Tue 11:00 P3

Analysis of Electron-Transfer in Water-Based Dye-Sensitized Solar Cells -•DANIEL HOLZHACKER¹, ANDREAS RINGLEB¹, RAFFAEL RUESS², and DERCK SCHLETTWEIN¹ — ¹Justus-Liebig-Universität Gießen, Institut für Angewandte Physik — ²Justus-Liebig-Universität Gießen, Physikalisch-Chemisches Institut Dye-sensitized solar cells (DSSCs) present a possible low-cost technology for the conversion of sunlight into electrical energy. Most DSSCs are based on electrolytes with organic solvents. Due to environmental reasons it is attractive to replace organic solvents by water. In view of the damage typically caused to DSSCs by water contaminations, the use of water as contact solution represents a big challenge. Complete aqueous DSSCs were assembled with a combination of different organic dyes (D51, D35 and Y123) and organic redox mediators (TEMPO, AZADO and TEMPOL). The combination of Y123 and TEMPO yielded remarkable efficiencies of up to 4.4%. Although heavily limited in the fill factor, TEM-POL proved to be an interesting alternative, as its solubility in water is dramatically increased in comparison to TEMPO. Similar open circuit voltages and short circuit currents were reached but large overpotentials of electron transfer at the electrodes still limited TEMPOL-based cells. Subsequently, the electrolyte and electrode surfaces were modified in order to reduce the respective overpotentials.

#### O 32.2 Tue 11:00 P3

Novel corrugated geometric moiré pattern of a semi-periodically buckled, zebra-like topography of Xe on Ag(110) — •INGA CHRISTINA LANGGUTH and KARINA MORGENSTERN — Chair of Physical Chemistry I, Ruhr-Universität Bochum, Bochum, Germany Location: P3

Solid rare gas films on metal single crystals are currently gaining interest due to their beneficial properties. As non-ionic, low interacting insulator surfaces they offer a potential application for unperturbed surface science studies. STM investigations of a thin xenon (Xe) film of several monolayers on Ag(110) reveal a novel corrugated structure of a semi-periodically buckled, zebra-like topography. The outstanding feature of this surface is a non-uniform distribution of buckled row orientations and distances. Instead of domain boundaries separating different phases, a gradual transition of row orientations is observed. The corrugated row pattern can be attributed to a geometric moiré pattern at the interface of the incommensurable Ag(110) and Xe(111) crystal lattices. A gradual change of the row orientation can further be explained by a gradually changing Xe-lattice orientation with respect to Ag(110) within a narrow angle regime. The stability of this semi-periodic structure against annealing reveals a remarkably flat potential energy surface for the turning of the Xe layer relative to the Ag(110) surface. The corrugated surface may serve as an interesting substrate for further studies of geometric confinement effects in an anisotropic environment.

O 32.3 Tue 11:00 P3

**On-surface Synthesis of Naphthalocyanines with Extended**  $\pi$ **-Systems** — •Lukas J. Heuplick¹, Qitang Fan¹, Dmitriy A. Astvatsaturov², Dennis Körmer¹, Tatiana V. Dubinina², and J. Michael Gottfried¹ — ¹Fachbereich Chemie, Philipps-Universität Marburg, Marburg, Germany — ²Moscow

The distinct optical and electronic properties of phthalocyanines (Pc) make them interesting in a wide field of applications. Here we report the on-surface synthesis

of new naphthalocyanines with differently extended  $\pi$ -systems. This reaction in form of a cyclization is studied for different dicarbonitriles on the Ag(111) and Au(111) surfaces by scanning tunneling microscopy (STM) and X-ray photoelectron spectroscopy (XPS). 6,7-Diphenyl-2,3-naphthalenedicarbonitrile (DP-NDN) forms naphthalocyanines only with co-adsorbed Fe atoms on Ag(111) and Au(111). The larger 6,7-di(2-naphthyl)-2,3-naphthalenedicarbonitrile (DNNDN) can undergo this reaction directly on Ag(111) without co-adsorbed metal, resulting in the corresponding Ag-NPc.

O 32.4 Tue 11:00 P3 Adaptive training of a machine-learned model for nonadiabatic hydrogen chemistry on multiple facets of Copper. — •WOJCIECH G. STARK, JULIA WEST-ERMAYR, OSCAR A. DOUGLAS-GALLARDO, JAMES GARDNER, and REINHARD J. MAURER — University of Warwick, Coventry, United Kingdom

Traditionally, molecular dynamics methods utilise the Born-Oppenheimer approximation and dynamics are governed by a single potential energy surface. However, on metallic surfaces often the energy exchange between adsorbate and electronic excitations in the metal is significant and causes the breakdown of the Born-Oppenheimer approximation. There are multiple methods to include such nonadiabatic effects, with one of the most efficient being molecular dynamics with electronic friction (MDEF). MDEF introduces nonadiabatic effects via additional electronic friction forces, which can be calculated with time-dependent perturbation theory based on Density Functional Theory. However, a meaningful comparison between computational simulations and experiments demands the capability to run tens of thousands of MDEF trajectories. We present highdimensional machine-learning based interatomic potential and electronic friction models that enable the simulation of nonadiabatic molecular dynamics of hydrogen scattering and associative desorption at different copper surfaces. We construct deep neural network representations via iterative adaptive sampling based on the target dynamical observables, namely the scattering and reaction probabilities.

O 32.5 Tue 11:00 P3 Adsorption and Diffusion of NH3 on Rutile TiO2(110): An STM Study — •HANNA BÜHLMEYER¹, KRAEN CHRISTOFFER ADAMSEN², TAO XU¹, LUTZ LAMMICH², JÖRG LIBUDA¹, STEFAN WENDT², and JEPPE VANG LAURITSEN² — ¹Interface Research and Catalysis, ECRC, Friedrich-Alexander-Universität Erlangen-Nürnberg, Egerlandstraße 3, 91058 Erlangen, Germany — ²Interdisciplinary Nanoscience Center, Aarhus University, Gustav Wieds Vej 14, 8000 Aarhus, Denmark

The adsorption of NH3 on TiO2 is an important step for many reactions in environmental catalysis such as the selective catalytic reduction (SCR) of NOX over V2O5/TiO2 and the removal of NH3 from air and water over TiO2. To obtain a detailed understanding of the surface chemistry of NH3 on TiO2, we investigated the adsorption of sub-monolayers of NH3 on clean, hydroxylated, and O-precovered rutile TiO2(110) surfaces by means of scanning tunneling microscopy (STM) under ultrahigh vacuum (UHV) conditions. We found that on the clean TiO2(110) surface at 120 K, NH3 adsorbs exclusively as monomers. On the hydroxylated TiO2(110) surface at 160 K, we observe 2(NH3) pairs and (NH3)2 dimers in addition to the majority of monomeric NH3. At 270 K, monomeric NH3 and surface hydroxyls diffuse together along the [001] direction. Additionally, NH3 can also diffuse along the surface hydroxyl bridge in the [1-10] direction. On the surface precovered by O adatoms (Oot) at 160 K, we observe the formation of NH2OH and 2(NH2OH) species formed by the interaction of NH3 monomers with Oot and Oot pairs.

#### O 32.6 Tue 11:00 P3

**Real-space study of carbenes using a diazofluorene precursor adsorbed on a Cu(111) surface** – •HUSSAIN MAZHAR¹, JULIEN ROWEN², WOLFRAM SANDER², and KARINA MORGENSTERN¹ – ¹Lehrstuhl für Physikalische Chemie I, Ruhr-Universität Bochum, 44801 Bochum, Germany – ²Lehrstuhl für Organische Chemie II, Ruhr-Universität Bochum, 44780 Bochum, Germany

Carbene is a reactive intermediate playing a vital role for many synthesis in the pharmaceutical industry [1]. Here, we study their properties on a metal substrate in real space using scanning tunnelling microscopy (STM) at 5 K. As carbenes are highly reactive species, they cannot be deposited directly on metal surfaces. The arrangement of their precursors on the surface is crucial for the carbene reactivity upon carbene formation. Diazofluorene molecules, already studied on the Ag(111) surface [2], are used as a precursor of the carbene to compare the influence of the surface on carbene reactivity. The STM study reveals dimer and cluster formation of the carbene precursor molecules on Cu(111) when de-

posited at 50 K and 100 K. While at 50 K more dimer formation occurs, at 100 K cluster formation is noticeable. An electrostatic surface potential map is used to determine charge distribution of the dimers. For carbene formation, a particular energy is required to cleave the diazo part from the molecule. In this study, we used STM manipulation to estimate the energy for the dissociation of the molecule. [1] Patil, Siddappa A, Future Med. Chem. 7. (2015) 1305-1333 [2] Mieres-Perez, Joel, J. Am. Chem. Soc. 143. (2021) 4653-4660

O 32.7 Tue 11:00 P3

Thickness-dependent energy level alignment of terrylene molecules on WS2 monolayer — •QIANG WANG¹, SIFAN YOU³, BJÖRN KOBIN², PATRICK AMSALEM¹, LIFENG CHI³, STEFAN HECHT², and NORBERT KOCH¹ — ¹Institut für Physik & IRIS Adlershof Humboldt-Universität zu Berlin, Berlin, Germany — ²Department of Chemistry & IRIS Adlershof Humboldt-Universität zu Berlin, Berlin, Germany — ³Institute of Functional Nano and Soft Materials (FUNSOM) , Soochow University, Suzhou, China

The exceptional large surface ratio makes 2D TMDC notably sensitive to extrinsic modification. In particular, we study the Van der Waals structure of WS2 monolayers modified by the conjugated terrylene molecules. We show the terrylene/WS2 heterostructures exist in different stacking configurations dependent on the layered coverage, revealed by photoemission spectroscopy and scanning tunnelling microscopy (STM). Electronically, the hybrid heterostructures exhibit type-II energy level alignment. It is further determined that the ionization potentials of terrylene, are reduced by 0.54 eV as the molecule switching from flatlying to standing orientation. The adsorption behaviour is spatially resolved by STM, indicating two different atomic assembles. As determined by photophysical characterization, low energy electron-hole pairs are also populated upon molecule deposition. Meanwhile the external dielectric screening lowers the Rydberg states of WS2. Our findings reveal the vertical 2D heterostructures enable effective tailoring of both electronic and photophysical properties, which can be applied for various optoelectronic devices.

O 32.8 Tue 11:00 P3

Nanocar Race II: How fast and how long can we drive nano-vehicles? — •TIM KÜHNE¹, KWAN HO AU YEUNG¹, SUCHETANA SARKAR¹, OUMAIMA AIBOUDI², SOYOUNG PARK², FRANZISKA LISSEL², and FRANCESCA MORESCO¹ — ¹Center for Advancing Electronics Dresden, TU Dresden, 01062 Dresden, Germany — ²Leibniz Institute of Polymer Research, 01062 Dresden, Germany

Scanning tunneling microscopy has progressed far beyond just being a probing technique. We can now address and manipulate single molecules and atoms with a great degree of precision and repeatability. The 2nd Nanocar Race saw surface science groups from across the globe design and synthesize molecules of at least 70 atoms with the intent of driving it on Au(111). The conversion of electric impulse from the tip to controllable translation of the nanocar along the FCC sites of Au(111) was demonstrated by each team, although the design philosophy and mediating physics theories varied across the board. Here, we present the TU Dresden nanocar. It was successfully manipulated via inelastic tunneling electrons for 290nm during the 24-hour race.

O 32.9 Tue 11:00 P3

First-Principles Study of Methanol and Benzene Adsorption on  $In_2O_3(111)$ — •ANDREAS ZIEGLER¹, MARGARETA WAGNER², ULRIKE DIEBOLD², and BERND MEYER¹ — ¹Interdisciplinary Center for Molecular Materials and Computer Chemistry Center, FAU Erlangen-Nürnberg, Germany — ²Institute of Applied Physics, TU Wien, Austria

Indium oxide is widely used as transparent conductive oxide for electrodes in semiconductor devices, but it is also a promising new catalyst for hydrogenation and dehydrogenation reactions, e.g. methanol synthesis. To probe the reactivity of the most stable (111) termination of  $In_2O_3$ , we studied the adsorption of methanol and benzene, two prototypical polar and nonpolar molecules, by DFT geometry optimizations and Car-Parrinello molecular dynamics (CPMD) simulations. We find that the unit cell of the In₂O₃(111) surface is chemically quite heterogeneous: by searching for the most favorable configurations of methanol with increasing coverage from one to nine molecules per unit cell we find that the first three methanol molecules dissociate in one specific region of the unit cell, followed by molecular adsorption on neighboring sites, confirmed by TPD, XPS and ncAFM experiments. Also benzene prefers to adsorb at one specific site in the unit cell. Due to the large size of the unit cell, the benzene molecules are well separated. CPMD simulations show that the molecules can freely rotate and are well trapped at their adsorption site. However, rotation is suppressed for benzene derivatives with additional side groups.

Anisotropic carrier dynamics in single crystalline graphite — •HAUKE BEYER, PETRA HEIN, KAI ROSSNAGEL, and MICHAEL BAUER — Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, Germany

Time- and angle-resolved photoelectron spectroscopy at 35 fs time-resolution is employed to study the carrier dynamics in the Dirac cone of graphite upon excitation with linearly polarized light. Due to the pseudo spin degree of freedom, the nascent photogenerated carrier distribution exhibits a strong anisotropy in momentum space. We observe the formation of a quasi-thermalized distribution on ultrafast timescales (~10 fs) through e-e interactions exhibiting a clear azimuthal anisotropy similar to findings for graphene [1]. For the azimuthal thermalization our data reveal a characteristic time scale of  $40 \pm 10$  fs. The residual non thermal part of the electron distribution shows a time-dependent shift in energy by ~150 meV, which we assign to the formation of a steplike distribution due to e-ph interactions. The results are in good qualitative agreement with calculations based on a model introduced in Ref. [2].

High-harmonic generation from the surface state of Bi₂Se₃ with THz driving fields — •TIM BERGMEIER, SUGURU ITO, JENS GÜDDE, and ULRICH HÖFER — Fachbereich Physik, Philipps-Universität Marburg, Germany

The acceleration of charge carriers through the Dirac-point in the topologically protected surface state (TSS) of topological insulators (TIs) by strong electric fields with frequencies in the THz range gives rise to a nontrivial type of unusually efficient high-harmonic generation (HHG) as demonstrated for Bi₂Te₃ [1]. The long scattering times in the TSS resulting from spin-momentum locking are imprinted in the observation that the high-harmonic orders can be continuously shifted in frequency by varying the carrier-envelope phase of the driving field. This makes it possible to investigate the unusual transport properties in the TSS by this all optical method even at buried interfaces.

Here, we present first results for  $Bi_2Se_3$  by using a newly developed setup that enables THz-HHG with a stable carrier-envelope phase at a repetition rate of 200 kHz reaching field strengths of up to 10 MV/cm in the frequency range of 12-90 THz. We show how the contribution of electrons in the TSS to the HHG spectra can be determined by measurements with varying field strengths and THz-frequencies above and below the bulk band gap, while analyzing the polarization of the high harmonic signal for different directions of the excitation in momentum space.

## O 33.3 Tue 11:00 P3

Towards time-resolved photoemission orbital tomography on van-der-Waals heterostructures — •WIEBKE BENNECKE, DAVID SCHMITT, JAN PHILLIP BANGE, MATTIS LANGENDORF, KATHARINA D. FEESER, DANIEL STEIL, SABINE STEIL, MARCEL REUTZEL, G. S. MATTHIJS JANSEN, and STEFAN MATHIAS — I. Physikalisches Institut, Georg-August-Universität Göttingen

Heterostructures of two-dimensional van-der-Waals materials with molecular thin films provide an exceptional platform to tailor electronic energy level alignments that govern the optoelectronic response of such materials. In addition to the energy-level alignment, a detailed knowledge of the electronic wavefunctions in these systems would help to fundamentally understand optical excitations, exciton generation, charge-transfer and relaxation processes. Here, time-resolved orbital tomography is a promising method that potentially provides such information. On this poster, we show first results of femtosecond orbital tomography of PTCDA monolayers adsorbed on bulk as well as monolayer WSe₂.

#### O 33.4 Tue 11:00 P3

**Transient optical properties in non-equilibrium laser excited noble metals** — •MARIUS WENK¹, PASCAL D. NDIONE¹, SEBASTIAN T. WEBER¹, DIRK O. GERICKE², and BAERBEL RETHFELD¹ — ¹Department of Physics and OPTIMAS Research Center, Technische Universität Kaiserslautern — ²CFSA, Department of Physics, University of Warwick

Ultrashort laser pulses can induce strong modifications of material properties of solids such as creating highly transient optical parameters. After excitation with lasers of high power, the conduction electrons thermalize quickly to a hot Fermi distribution. Yet, the band occupation numbers can still be far from equilibrium.

We study excitation of noble metals such as copper and gold with visible photons. We use a two-temperature model and construct electron density-resolved rate equations to simulate the non-equilibrium band occupation [1]. Applying the results of the simulation, particularly the occupation and temperature data, we compute the time-resolved dielectric function based on the Drude-Lorentz formalism. In order to compare the results with experimental data, we calculate the transient optical properties such as probe reflectivity and transmissivity. Our predictions are compared with time-resolved measurements of optically excited metals, thus providing insights to electron dynamics on femto- and picosecond timescales.

LabVIEW based software solution for tr-ARPES experiments - •JOHANNES GRADL¹, NIKLAS HOFMANN¹, LEONARD WEIGL¹, YU ZHANG², CEPHISE CACHO³, NEERAJ MISHRA^{4,5}, STIVEN FORTI⁴, CAMILLA COLETTI^{4,5}, and Is-ABELLA GIERZ¹ - ¹Department of Physics, University of Regensburg, 93040 Regensburg, Germany – ²Central Laser Facility, STFC Rutherford Appleton Laboratory, Harwell Campus, Didcot OX11 0DE, United Kingdom — ³Diamond Light Source, Harwell Campus, Didcot OX11 0DE, United Kingdom — ⁴Center for Nanotechnology Innovation @NEST, Istituto Italiano di Tecnologia, 56127 Pisa, Italy — ⁵Graphene Labs, Istituto Italiano di Tecnologia, 16163 Genova, Italy Time- and angle-resolved photoemission spectroscopy (tr-ARPES) is an experimental technique used for visualizing non-equilibrium carrier dynamics as well as transient band structures of photoexcited samples as a function of energy, momentum, and time. A tr-ARPES setup ideally includes femtosecond pump pulses with tunable photon energy, femtosecond extreme ultraviolet probe pulses an ultrahigh vacuum chamber equipped with a cryo-cooled sample manipulator and a photoelectron analyzer as well as additional features for in situ sample preparation and characterization. In addition to this hardware, the execution of tr-ARPES experiments requires a user-friendly software for hardware control, data acquisition, and real time data visualization. We will present our LabVIEW based software solution and demonstrate its successful implementation with a series of data sets from a WS2/graphene van der Waals heterostructure.

O 33.6 Tue 11:00 P3

Ultrabroadband THz-STM and its application to study hot electron dynamics in metals — NATALIA MARTÍN SABANÉS^{1,2}, FARUK KRECINIC¹, •VIVIEN SLEZIONA¹, TAKASHI KUMAGAI^{1,3}, FABIAN SCHULZ^{1,4}, LUIS ENRIQUE PARRA LOPEZ¹, ALKISTI VAITSI¹, MARTIN WOLF¹, and MELANIE MÜLLER¹ — ¹Fritz-Haber Institute of the Max-Planck Society, Berlin, Germany — ²IMDEA Nanoscience, Madrid, Spain — ³Institute of Molecular Science, 444-8585 Okazaki, Japan — ⁴CIC NanoGUNE BRTA, San Sebastian, Spain

Localized ultrafast currents across the junction of a scanning tunneling microscope (STM) can be generated by photo-assisted hot electron tunneling or *cold* lightwave-induced tunneling. In addition, but so far not considered, fs laser excitation can induce a transient thermalized electron distribution that can give rise to an ultrafast current component. Here we investigate the role of ultrafast thermionic tunneling for photoinduced hot electron tunneling from a photoexcited STM tip [1]. We access the dynamics of hot electron tunneling by phaseresolved sampling of ultrabroadband Terahertz (THz) waveforms inside the STM junction. Our results reveal the strong nonthermal character of photoinduced hot electron tunneling, and provide a new route to probe hot electron dynamics in metals using THz-STM. Furthermore, we report on the development of an ultrabroadband THz-STM with tunable optical excitation for the spatiotemporal investigation of photocarrier dynamics at metal-semiconducting interfaces. [1] N. Martín Sabanés et al., 10.48550/arXiv.2205.08248

#### O 33.7 Tue 11:00 P3

Dark Exciton Formation Dynamics in TMDC Monolayers — •SARAH ZAJUSCH¹, LASSE MÜNSTER¹, RAUL PEREA-CAUSIN¹, SAMUEL BREM¹, KATSUMI TANIMURA¹, JENS GÜDDE¹, YAROSLAV GERASIMENKO², RUPERT HUBER², ERMIN MALIC¹, ULRICH HÖFER¹, and ROBERT WALLAUER¹ — ¹Fachbereich Physik, Philipps-Universität Marburg, Germany — ²Fachbereich Physik, Universität Regensburg, Germany

Charge transfer processes in two-dimensional TMDCs are governed by the formation of excitons. The excitonic landscape comprises optically accessible bright excitons as well as momentum- and spin-forbidden dark states. Our experimental setup combines time-resolved momentum microscopy with probe energies in the XUV regime which provides direct access to k-resolved exciton dynamics within the whole Brillouin zone on an ultrafast time scale.

Although structural features are very similar for different semiconductor TMDC materials, slight variations in both electronic band ordering and excitonic binding energy can drastically modify the excited population dynamics. We present a comparison of exciton formation in the two extreme cases of WS₂ and MoSe₂ monolayers after valley-sensitive excitation with circular polarized light. On the one hand, in MoSe₂ the bright KK-exciton is the energetically most favorable state. On the contrary, in WS₂, we additionally observe the ultrafast formation of energetically lower dark KK'- and K $\Sigma$ -excitons. The microscopic understanding of these processes is crucial with regard to interlayer exciton formation in TMDC heterostructures.

## O 33.8 Tue 11:00 P3

Time- and Angle-Resolved Photoelectron Spectroscopy with Nano-Focused Surface Plasmon Polaritons — •ALEXANDER NEUHAUS, PASCAL DREHER, DAVID JANOSCHKA, MICHAEL HORN-VON HOEGEN, and FRANK-J. MEYER ZU HERINGDORF — Faculty of Physics and Center for Nanointegration, Duisburg-Essen (CENIDE), University of Duisburg-Essen, 47048 Duisburg, Germany. Non-perturbative interactions of intense light fields with the electronic band structure in a solid can result in transient electronic properties. The experimental conditions required to realize the necessary field strength can be realized in nano-optical systems, as these can be designed to provide tremendous enhancements of the local field amplitude. Ultimately, observing the non-equilibrium

electron dynamics in such systems requires a combination of precise control over the local driving field, state resolution, and spatial selectivity. Here, we explore electron emission from nano-focused femtosecond surface

plasmon polariton (SPP) pulses, providing us with deep-subwavelength spatial selectivity. Time- and angle-resolved photoelectron spectroscopy with attosecond precision provides us access to the coherent and incoherent dynamics of the electron emission process. The technique is applied to the system Cs/Au(111), where we find a resonant enhancement of the electron emission by an image potential state.

#### O 33.9 Tue 11:00 P3

Ultra Fast Dynamics in Modified Thiophene based Conjugated Donor-Acaptor Organcic Polymers — •TOBIAS REIKER^{1,2}, CARSTEN WINTER¹, DEB KUMAR BHOWMICK^{1,2}, NILS FABIAN KLEIMEIER^{1,2}, ZITONG LIU³, DEQING ZHANG³, and HELMUT ZACHARIAS^{1,2} — ¹Center for Soft Nanoscience, University of Münster, Germany — ²Physikalisches Institut, University of Münster, Germany — ³Institute of Chemistry, Chinese Academy of Science, Beijing, China

Thiophene-based polymers are promising candidates for solar cell, OLED or transistor applications. An internal donor - acceptor system is formed by coupling thiophene polymers with pyrrole chains. The charge transport behavior can be tuned by different alkyl side chains since they influence the electronic structure. A direct assessment of the intramolecular and intermolecular dynamics may guide synthesis routes. With pDPP4T, pDPP4T and pDPTTT we investigated the electronic dynamics of verified high hole-mobility organic semiconductors. Either the backbone or the side chains were modified. In contrast, another polymer pF8T2 with bi-thiophene in the backbone was used, but with fluorene instead of pyrrole as acceptor. These different molecular configurations are intended to provide insights into the change in electron configuration due to both backbone modification and intermolecular packing. We report results of temporally resolved photoemission studies on thiophene polymers on silicon substrates.

#### O 33.10 Tue 11:00 P3

**Density-dependent electron-phonon coupling in multiband systems.** — •TOBIAS HELD, SEBASTIAN T. WEBER, and BAERBEL RETHFELD — Department of Physics and Research Center OPTIMAS, TU Kaiserslautern, Germany

If a solid is irradiated with a short-pulsed laser in the visible spectrum, the energy is almost entirely absorbed by the electrons while the lattice remains cold. The subsequent energy flow between electrons and phonons is usually described by the electron-phonon coupling parameter, which plays a central role in the Two-Temperature Model and most other temperature-based models. This coupling parameter depends on a multitude of observables. Most frequently a dependence on the electron temperature is considered.

In this work, we aim to investigate how a varying density distribution between different electron subsystems affects the coupling parameter. In gold, we distinguish between sp- and d-electrons and in magnetic nickel between majority and minority spins. Our results show that for gold, the total coupling strongly depends on the density distribution, while for nickel it is largely independent on the spin densities. In the latter case, the individual coupling contributions of the bands change significantly with density but mostly compensate each other in terms of the total coupling.

Electron Dynamics of an intercalated Graphene Layer on Nickel — •KATHARINA HILGERT¹, CHRISTINA SCHOTT¹, EVA WALTHER¹, KAMAN YU¹, MARTIN AESCHLIMANN¹, and BENJAMIN STADTMÜLLER^{1,2} — ¹Department of Physics and Research Center OPTIMAS, University of Kaiserslautern, 67663 Kaiserslautern Germany — ²Institute of Physics, Johannes Gutenberg University Mainz, 55128 Mainz, Germany

One of the great challenges in information technology is to develop novel concepts for the realization of active functional units on eversmaller length scales. The simplest approach to reduce the size of any device structure is to employ atomically thin materials as graphene with their unique electronic and optical properties. However, these are often altered on surfaces due to strong chemical interaction with the substrate material. On this poster we present our approach to restore and design the electronic properties of graphene on a Ni(111) surface by intercalation of lead atoms. The changes in the electronic band structure of graphene on Ni(111) are monitored by angle resolved photoelectron spectroscopy with extreme ultra violet radiation. On the highly reactive Ni(111) surface, the linear dispersion of the Dirac cone of the free-standing graphene sheet is completely suppressed by the strong graphene surface interaction. This changes significantly after the intercalation of Pb. The band structure of the graphene/Pb/Ni(111) system reveals again the linear dispersion resembling the behavior in free-standing graphene. This has clear consequences on the carrier dynamics near the K-point as we will discuss in this contribution.

## O 34: Poster Tuesday: Scanning Probe Techniques 2

Implementation of a Scanning Tunneling Microscope for Measurements in Electrochemical Environment — •FABIAN SCHRÖFEL, MATTHIAS GREVE, KARSTEN TARHOUNI, and OLAF MAGNUSSEN — Institute of Experimental and Applied Physics, Kiel University, Kiel, Germany

The atomic-scale understanding of processes at the interface between solid electrodes and liquid electrolytes is of high importance for electrochemical energy storage and conversion. Electrochemical scanning tunneling microscopy (EC-STM) is a key technique for the investigation of such interfaces. Operating an STM in an electrochemical environment requires special measures, as the potentials of both STM tip and sample need to be controlled and electrochemical currents at the tip need to be kept way below the tunneling current.

Here, we report details on a new ECSTM built in our group. It consists of a newly developed STM head that is optimized for studies in electrochemical environment, high scanning frequencies, and low thermal drift. The instrument is based on a commercial SPECS Nanonis STM controller that we equipped with a custom-build bipotentiostat and coarse-approach. A suitable control software for electrochemical studies, which we integrated into the Nanonis software, allows to perform cyclic voltammetry parallel and separate from the STM measurements. Characterization of the mechanical stability of the STM and first STM images and electrochemical data will be presented.

## O 34.2 Tue 11:00 P3

## Determining the phase transfer function of an STM for coherent spin operations — $\cdot$ EVERT STOLTE — TU Delft

Coherent control of single spin transitions in atoms on a surface has been achieved with electron spin resonance scanning tunnelling microscopy (ESR-STM).[1] Extending that control to a series of sequential gates on different transitions and developing more complex gates requires radio frequency (RF) pulses at different frequencies with controlled relative amplitudes and phases, which are both affected by the transfer function of the power line to the tunnel junction. While the amplitude transfer function can be determined through a welldescribed rectification procedure [2], characterizing the phase transfer function remains challenging. Straightforward transmission or reflection measurements are excluded as it is not possible to separate phase rotations incurred on the way into the STM from those happening on the outward journey.

Here we report on the development of an in-situ method to determine the phase transfer function at radio frequencies that can be readily implemented to standard ESR-STM setups. The method is based on the envelope detection of the beat signal that is generated by adding two continuous wave RF signals separated by an audio frequency. The effectivity of the procedure is tested through pumpprobe autocorrelation measurements with square pulses, which should show a reduced minimum width if the phase correction is successful.

Performance of an electrically driven q-plus sensor in a commercial Joule Thomson STM — •HESTER VENNEMA, LAËTITIA FARINACCI, and SANDER OTTE — Delft University of Technology, Delft, The Netherlands

The q-plus sensor is a wide-spread tool for performing combined STM-AFM measurements in ultra-high vacuum at cryogenic temperatures. Here, we implement the use of q-plus sensors in a JT-STM. Contrary to other set-ups in which q-plus sensors are used, we do not drive our sensor mechanically, via an excitation of the Z-piezo, but electrically, with the excitation signal directly sent to the tuning fork.

In order to characterize the performance of our homemade q-plus sensors we develop a set-up to test their response to an electrical drive in ambient con-

Location: P3

ditions. Following M. Lee et al. [1], we can disentangle the mechanical and electrical response of the sensors to the driving signal. After transfer into the JT-STM, we demonstrate the possibility to use electrically driven q-plus sensors for combined STM-AFM measurements: with a Q factor around 20000 we can control the amplitude of the oscillation to be as low as 70 pm. Our first principle measurements are performed on a CuCl2/Cu(100) surface [2]. We investigate with local contact potential difference measurements the local change of work function that leads to the confinement of field emission resonances above such vacancy patches.

#### O 34.4 Tue 11:00 P3

**Development of a compact millikelvin STM for single spin resonance** – •DARIA SOSTINA¹, DAVID COLLOME², WANTONG HUANG², MATE STARK², CHRISTOPH SÜRGERS², PHILIP WILLKE², and WOLFGANG WERNSDORFER² – ¹Institute for Quantum Materials and Technologies (IQMT), Karlsruhe Institute of Technology, Karlsruhe, Germany – ²Physikalisches Institut (PHI), Karlsruhe Institute of Technology, Karlsruhe, Germany

In the last decade detection and manipulation of spins at the atomic scale has been achieved by combining techniques like electron spin resonance (ESR) with scanning tunneling microscopy (STM) [S. Baumann et al., Science 350 (6259), 417-420 (2015) ]. However crucial properties of potential quantum spins such as the spin relaxation time T1 and the phase coherence time T2 remain short. Both T1 and T2 are affected by the proximity to the tip and substrate, which provide thermally excited electrons [P. Willke et al., Science Advances 4(2), 1543 (2018)]. A potential solution lies in lowering the temperatures utilizing dilution refrigerators (DR). Here, we present the design and implementation of a unique DR-STM optimized for ESR reaching millikelvin temperatures. Since the ground state population scales with the resonance frequency, better RF transmission at high frequencies is also desired for ESR-STM. In the compact dilution fridge, the RF line is optimized by a short total length of cables as well as using high-frequency cabling up until the tip. As a result, we believe that our compact DR-STM will help to improve ESR-STM paving the way for quantum information processing using single spin centers on surfaces.

#### O 34.5 Tue 11:00 P3

**Design of a high-stability miniaturized scanning tunneling microscope for small-bore cryostats** — •FELIX HUBER, STEPHAN SPIEKER, and SEBASTIAN LOTH — University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany

Low-temperature scanning tunneling microscopy (STM) setups are typically housed in large cryostats and require proportionally large vacuum chambers, as well as extensively shielded custom-built laboratories to reach the signal-tonoise ratios (SNR) desired for cutting-edge reasearch. Yet, by miniaturizing the STM-head, the SNR can be significantly improved, due to the favorable scaling of resonance frequencies [1], thermal characteristics and the cryostat hold time. The STM design presented here, is optimized to work in noisy environments, provides optical access to the tunnel junction, and can be used in a standardbore cryogenic dewar due to its small volume and dimensions [2]. This design could be used for experiments requiring long averaging times, and may serve as an easy upgrade to existing room-temperature setups.

**Functionalized Tips in low-temperature AFM/STM - Fabrication and Application** — •LORENZ BRILL, MARCO GRÜNEWALD, ROMAN FORKER und TORSTEN FRITZ — Friedrich-Schiller-Universität, Jena, Germany

AFM with functionalized tips has been an emergent and fast growing field in the last couple of years. The chemical passivation of the metal tip achieved via functionalization allows for images with atomic or intramolecular resolution to be recorded.

In our contribution, we detail the fabrication of CO-functionalized tips with a commercial low-temperature STM/AFM by Specs Surface Nano Analysis GmbH and demonstrate atomic resolution on a Cu(111)-surface. Furthermore, we show structure elucidation of organic molecular islands on the Cu(111)-substrate via atomic resolution images.

This technique shows great promise for further investigations, especially in areas not accessible via conventional STM, e.g. detailed structure analysis of 1,4-benzoquinone on metal substrates.

Setup for laser-based time-resolved momentum microscopy — •Felix PASSLACK, STEFANO PONZONI, GIOVANNI ZAMBORLINI, and MIRKO CINCHETTI — Department of Physics, TU Dortmund University, Otto-Hahn-Straße 4, Dortmund, Germany

In this work, we characterize the performance of a recently installed timeresolved angular-resolved photoemission spectroscopy (tr-ARPES) system. trARPES is performed by coupling an optical beamline for pump-probe spectroscopy[1] to a state-of-the-art momentum-microscopy photoemission spectrometer (KREIOS MM, SPECS GmbH). This allows for an almost continuous tunability of the pump photon energy between 0.5eV and 3.8eV while capturing the full photoemission horizon of the 6eV probe. The performance of the system is characterized through a set of measurements on the topological insulator Bi₂Se₃, for which both the static electronic structure and the out of equilibrium electron dynamics are already extensively studied in literature following the evolution of the electronic structure with an energy resolution in the order of 50meV, a momentum resolution of  $0.005A^{-1}$  and a time resolution below 500 fsthroughout the whole photoemission horizon. In particular, thanks to the ultimate angular acceptance of the photoemission microscope, we are able to track the dispersion of the photoexcited states in  ${\rm Bi}_2{\rm Se}_3$  up to  $\pm 0.48A^{-1}$  and 1eV above the Dirac point, beyond the practical limitations of conventional high-resolution ARPES spectroscopy with 6eV photons. O 34.9 Tue 11:00 P3

Development and characterization of a Herriott-type multipass cell compression-setup for fs-pulses and variable repetition rates — •LASSE STERNEMANN¹, KARL SCHILLER¹, ALAN OMAR², MATIJA STUPAR¹, MIRKO CINCHETTI¹, and CLARA SARACENO² — ¹Department of Physics, TU Dortmund University, Otto-Hahn-Straße 4, 44227 Dortmund, Germany — ²Ruhr-Universitaet Bochum, Germany

We present developement and characterization of a Herriott-style multipass cell aimed at achieving ultrashort pulses with high peak power. The setup is used as a driving laser for a high repetition rate HHG (High Harmonic Generation) source for time-resolved momentum microscopy.

The setup compresses the pulses generated by a commercial Ytterbium-based laser (Carbide, Light Conversion) with an average power of 50 W and a variable repetition rate between 100 kHz and 1 MHz. The pulses are first spectrally broadened by self-phase-modulation by passing through a non-linear  $\chi^{(3)}$  medium multiple times. Then, a pair of negative group-dispersion-delay coated mirrors compress the pulse by dispersion correction. By moving the non-linear medium within the multipass cell we were able to compress the pulses from 242 fs to around 45 fs for different high repetition rates while keeping a transmission of over 90 % and peak powers between 1 GW and 2 GW [1].

**Positioning of DNA origami based nanostructures on surfaces by lithographic patterning** — ZHE LIU¹, ZUNHAO WANG², BIRKA LALKENS³, DAESUNG PARK², JANNIK GUCKEL², JULIANE BREITFELDER³, and •MARKUS ETZKORN¹ — ¹Institute of Applied Physics, Technische Universität Braunschweig, 38106 Braunschweig, Germany — ²Physikalisch Technische Bundesanstalt, 38116 Braunschweig, Germany — ³Institute of Semiconductor Technology, Technische Universität Braunschweig, 38106 Braunschweig, Germany

Self-assembly protocols of functionalized DNA-origami structures can be used to create large amounts of identical hybrid nanostructures. We use this approach to create structures with tunable plasmonic properties. In our study, dimers of 15 nm gold nanoparticles with an average gap of 7 nm were self-assembled in solution. In order to control the positioning of such DNA-origami structures on surfaces, we created surface areas with hydrophobic/hydrophilic contrast by electron beam lithography and dry oxidative etching. This protocol offers positional control on the sub 10 nm scale. Here we will present results for hexamethyld-isilazane (HDMS) covered silicon, but the approach can be utilized for various substrates and nanostructures. Our origami/dimer structures. We achieve an efficiency in positioning, that is the ratio of origami in wanted to those in un-wanted positions, of above 95%. Important parameters controlling the efficiency are discussed.

 $O~35.2~Tue~11:00~P3\\ \textbf{Investigation of the plasmonic Phase-Change Materials AgSnTe_2 and}\\ \textbf{In_3SbTe_2 for tuning nanoantenna resonances} — •KILIAN WILDEN, LUKAS CONRADS, ANDREAS HESSLER, MATTHIAS WUTTIG, and THOMAS TAUBNER — I. Institute of Physics (IA), RWTH Aachen University$ 

Providing a high optical contrast between their amorphous and crystalline phases, phase-change materials (PCMs) can serve for many applications in nanophotonics. [1] Optical pulses can be used for switching between those two states. This enables the tunability of antenna resonances by changing the surrounding medium. Currently, a novel material class of switchable infrared plasmonic PCMs is rising, which is characterized by a negative permittivity and therefore a Drude-like behaviour in the crystalline. This plasmonic PCM In₃SbTe₂ (IST) offers resonance tuning by reconfiguring the antenna shapes of rod antennas and even more complex ones with magnetic resonances.[2] AgSnTe2 (AST) is another plasmonic PCM with a smaller plasma frequency and higher plasmonic losses than IST. Here, we investigate directly optically written antenna structures of crystalline AST. The quality of the plasmonic resonances is compared to IST antennas. Furthermore, the well-established concepts of reconfiguring antenna geometries are applied to inverse antenna structures, in which amorphous holes are created in a crystalline plasmonic surrounding. Their resonance behavior can be described by Babinet's principle. [1] M. Wuttig, H. Bhaskaran and T. Taubner, Nature Photonics 11, 465-476 (2017). [2] A. Heßler et al., Nature Communications 12, 924 (2021).

Large area writing of reconfigurable metasurfaces with the plasmonic PCM  $In_3SbTe_2 - \bullet$ NATALIE HONNÉ¹, LUKAS CONRADS¹, ANDREAS ULM², ANDREAS HESSLER¹, MATTHIAS WUTTIG¹, ROBERT SCHMITT², and THOMAS TAUBNER¹ - ¹I. Institute of Physics (IA), RWTH Aachen University - ²Fraunhoferinstitut für Produktionstechnologie

Phase-change materials (PCMs) are optimal candidates for optical components being non-volatile and reversibly switchable. Their amorphous and crystalline phases differ tremendously in their properties. Conventional PCMs exhibit a large contrast in their refractive index and can be used to tune antenna resonances by influencing their surrounding.[1] Recently, plasmonic PCMs, like In₃SbTe₂, has been introduced. They switch between a dielectric (amorphous) and a metallic (crystalline) phase in the complete IR and enable optical writing of metallic nanoantennas directly in a dielectric surrounding.[2] Large area writing of reconfigurable metasurfaces is a key feature for tuneable nanophotonic devices. Here, the Nanoscribe Photonic Pofessional GT is used, a femtosecond laser writer with an infrared wavelength. Large area direct laser crystallization is investigated to fabricate antenna arrays of several hundred micrometers. Finally, a beam steering device is designed and fabricated. This work paves the way towards large area fabrication of functional metasurfaces in the IR with the ability of rapid prototyping for IR nanophotonic devices.

The miniaturization of electrical and optical components allowed many technological and economic advancements over the last decades. Devices that permit control over the polarization of light are crucial in telecommunication and quantum optics but are usually realized as bulky optical systems and thus require further miniaturization. Here we aim at designing a uniquely compact converter and detector based on nanostructures. The device consists of a vertically oriented gold double helix coupled to a planar two-wire transmission line. The helix acts as a sensitive antenna for circularly polarized light, while the plasmonic transmission line guides plasmons on-chip. With numeric analysis we show that antisymmetric modes can be excited in both double helix and two-wire waveguide allowing spatial matching. Furthermore, one can match impedances of both components to maximize power transfer by adjusting their sizes. Finally, we developed fabrication protocols: while the helix can be directly written with an electron-induced deposition, the plasmonic waveguide can be cut from singlecrystalline gold flake utilizing focused gallium-ion beam milling. We achieved high structuring resolution with both methods, allowing for efficient coupling to transform linear to circular polarization while retaining a device size of just a few microns.

We use plasmonic gratings to achieve transverse magnetic routing of the light emission of a nearby quantum well exciton via an external magnetic field. In a hybrid plasmonic-semiconductor (Cd,Mn)Te/(Cd,Mg)Te quantum well (QW) structure the effect of the plasmonic grating period on the directional emission spectra is measured using a Fourier imaging setup to obtain angular and energy resolved photoluminescence spectra for opposite transverse magnetic fields. We achieve a strong directionality of the QW emission of up to 15% at low temperature of about 5 K and magnetic fields of 500 mT with a grating period of 240 nm and demonstrate the effect of the changing SPP dispersion on the directional emission characteristics.

#### O 35.6 Tue 11:00 P3

Mapping Lamb, Stark and Purcell effects at a chromophore-picocavity junction with hyper-resolved fluorescence microscopy — •ANNA ROSŁAWSKA¹, TOMÁŠ NEUMAN^{1,2,3}, BENJAMIN DOPPAGRE¹, ANDREI G. BORISOV³, MICHELAN-GELO ROMEO¹, FABRICE SCHEURER¹, JAVIER AIZPURUA², and GUILLAUME SCHULL¹ — ¹Université de Strasbourg, CNRS, IPCMS, UMR 7504, F-67000 Strasbourg, France — ²Center for Materials Physics (CSIC-UPV/EHU) and DIPC, Paseo Manuel de Lardizabal 5, Donostia - San Sebastián 20018, Spain — ³Institut des Sciences Moléculaires d'Orsay (ISMO), UMR 8214, CNRS, Université Paris-Saclay, 91405 Orsay Cedex, France

Light-matter interaction plays a crucial role in the properties of light emission from single molecules. Here, we show that it can be probed with sub-molecular precision thanks to the atomically-confined electromagnetic field at the scanning tunneling microscope tip apex, which acts as a picocavity for localized plasmons. Such strong fields interact with the molecular exciton via Purcell, Lamb and Stark effects, which enable tuning the emission energy and line width. Hyper-resolved fluorescence maps of these two parameters can be understood as images of the static charge redistribution upon electronic excitation of the molecule, and the distribution of the dynamical charge oscillation associated with the molecular exciton, respectively [1].

Steps towards fluorescence detected two-dimensional electronic spectroscopy of a single molecule — •SANCHAYEETA JANA and MARKUS LIPPITZ — Chair for Experimental Physics III, University of Bayreuth, Bayreuth, Germany

Two-dimensional electronic spectroscopy (2DES) is an ultrafast spectroscopic technique which gives information about the coupling between molecular energy levels. As spectroscopy of a single molecule by fluorescence detection is

a well established technique, we want to explore whether fluorescence-detected 2DES is possible at very low concentrations, ideally even on a single molecule. We use a sequence of four phase-modulated pulses to excite the molecules and collect the fluorescence by a high NA objective. The signal amplitude is demodulated at several mixing frequencies to extract the rephasing and nonrephasing contributions.

In this work, we study the 2D spectra measured from an ensemble of molecules in solution and discuss the challenges to experimentally measure 2D spectra from a single molecule.

Near-field spectroscopic predictions of low-temperature, gate-tunable plasmon-phonon coupling in the LaAlO₃/SrTiO₃ two-dimensional electron gas — •JULIAN BARNETT¹, YIGONG LUAN¹, FELIX GUNKEL², and THOMAS TAUBNER¹ — ¹I. Institute of Physics (IA), RWTH Aachen University — ²Peter Grünberg Institute, Forschungszentrum Jülich

Heterointerfaces of SrTiO₃ and LaAlO₃ give rise to a buried two-dimensional electron gas (2DEG) between polar insulators, that is very sensitive to local defects but difficult to characterize on the nanoscale. It was recently shown that scanning near-field optical microscopy (SNOM) enables the extraction of local 2DEG properties with nanoscale lateral resolution by using phonon-enhanced near-field spectroscopy. Interestingly, the 2DEG mobility increases strongly at low temperatures and the charge carrier concentration can be tuned via gating, allowing control over the electronic properties.

Here, we predict that the plasmon-phonon-coupled near-field response will undergo a transition from a phonon-dominated regime to a plasmon-dominated regime with rising 2DEG mobility, which translates to a fundamentally different near-field spectrum. Additionally, we show that the plasmon-dominated regime could allow for the extraction of the 2DEG depth distribution with nanoscale lateral resolution, potentially enabling its mapping around defects. These inIntegrated plasmonic nanocircuits are highly promising building blocks for future quantum optical applications. In combination with self-assembled epitaxially grown GaAs quantum dots as stable, bright and narrow-band single-photon sources, ultra-compact nanocircuits operating below the diffraction limit can be designed [1]. A crucial aspect is the coupling of the quantum dot emission into plasmonic waveguide modes. In this work, we demonstrate the coupling of a single near-surface GaAs quantum dot to a silver nanowire by introducing a 100nm thick dielectric spacer layer. We characterize the nanostructure by comparing different imaging methods involving low-temperature cathodoluminescence and photoluminescence as well as confocal laser reflection mapping. Supported by 3D numerical simulations, we find that resonant plasmonic wires can enhance the waveguide coupling efficiency.

Generation of Rotating Fields via Archimedean Spirals — •ESRA ILKE ALBAR, HEIKO APPEL, and FRANCO BONAFE - Max Planck Institute for the Structure and Dynamics of Matter, Center for Free Electron Laser Science, 22761 Hamburg, Germany

Twisted light (optical vortex), has the distinctive feature that it carries orbital angular momentum. This special type of electromagnetic field promises exciting opportunities for the interaction with matter, and it is expected to enhance spectroscopic techniques. Twisted light already has a vast potential of applications ranging from astronomy and optical tweezers to spintronics. Given this broad spectrum of applications and exciting prospects, it becomes worthwhile to investigate new and efficient methods to generate optical vortices. In this sense, metallic Archimedean spirals in the micro- and nanoscale are good candidates to produce such vortices. We design Archimedean spirals and test their performance in terms of generating field vortices. We perform numerical simulations with the Octopus code which employs the Riemann-Silberstein representation to propagate Maxwell's equations in real-time. Circularly-polarized light is passed through the designed structure, which is modeled both as a non-dispersive linear medium, and as Drude medium. We found that the out-coming field's angular momentum is altered by the structure. By using two different material models the effect of the materials' optical properties and the sole geometrical factors on the angular momentum outcome could be distinguished.

#### O 37.4 Wed 11:30 H3

Theory of radial oscillations in metal nanoparticles driven by optically induced electron density gradients — • ROBERT SALZWEDEL¹, ANDREAS KNORR¹, Dominik Höing^{2,3}, Holger Lange^{2,3}, and Malte Selig¹ - ¹Institut für Theoretische Physik, Nichtlineare Optik und Quantenelektronik, Technische Universität Berlin, 10623 Berlin, Germany $-{}^2 {\rm Institut}$  für Physikalische Chemie, Universität Hamburg, 20146 Hamburg, Germany — ³The Hamburg Centre for Ultrafast Imaging, 22761 Hamburg, Germany

Upon optical excitation, metal nanoparticles oscillate in radial breathing modes. These oscillations are assumed to be driven mainly by the thermalization of hot electrons impulsively heating the lattice, which can be described classically [1,2]. Based on a combined approach of quantum hydrodynamics and Heisenberg equations of motion for the optical excitation of electron gas in metal nanoparticles and the associated electron-phonon interaction, we discuss the contribution of additional coherent sources to the radial breathing oscillations.

Our results reveal a more direct coupling mechanism between the field and phonons compared to the established interpretation of experiments: the optical pulse induces spatial gradients in the electron density that drive phonon oscillations coherently and directly on the time scale of the optical excitation. Therefore, thermal and coherent contributions must be considered in the early times of the oscillation.

Near-field imaging of hyperbolic shear polaritons in gallium oxide — •SÖREN WASSERROTH¹, JOSEPH R. MATSON², XIANG NI³, GIULIA CARINI¹, KATJA DIAZ-GRANADOS², MAXIMILAN OBST⁴, ENRICO MARIA RENZI³, EMANUELLE GALIFI³, Susanne Kehr⁴, Lukas M. Eng⁴, Martin Wolf¹, Thomas G. Folland⁵, Andrea Alu³, Joshua D. Caldwell², and Alexander Paarmann¹ – ¹Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany – ²Vanderbilt University, Nashville, USA – ³City University of New York, New York, USA –  4 Technische Universität Dresden, Dresden, Germany —  5 University of Iowa, Iowa, USA

Controlling the propagation direction and other properties of light in a material and at an interface is a very active field in current research. Strong anisotropy in crystals can lead to a hyperbolic dispersion featuring coupled light-matter interactions known as polaritons with highly directional propagation. Recently [1], it was shown that the additional anisotropy in monoclinic crystals, such as beta phase gallium oxide (bGO), gives rise to tilted wave fronts and asymmetric responses, called hyperbolic shear polaritons (HShPs).

Here, we will show mid-infrared free electron laser based near-field imaging of HShPs in bGO. Gold discs are used as local emitters on the bGO substrate. By changing the IR wavelength we observe the rotation and asymmetry of the HShPs. We compare the obtained images to simulated near-field contributions. [1] Passler et al., Nature 602, 595 (2022)

## O 37.6 Wed 12:00 H3 Long-wave infrared super-resolution wide-field microscopy using sum**frequency generation** – •RICHARDA NIEMANN¹, SÖREN WASSERROTH¹, GUANYU LU², CHRISTOPHER R. GUBBIN³, SIMONE DE LIBERATO³, JOSHUA D. CALDWELL², MARTIN WOLF¹, and ALEXANDER PAARMANN¹ – ¹Fritz Haber Institute of the Max Planck Society, Berlin, Germany - ²Vanderbilt University, Nashville, USA — ³University of Southampton, UK

We present our approach in infrared-visible (IR-VIS) sum-frequency generation (SFG) microscopy as a new tool for super-resolution imaging in the IR range.[1] Here, the imaging contrast in the microscope emerges from the IR resonances while the spatial resolution is provided by the SFG wavelength, i.e., well below the IR diffraction limit. As a proof of concept, we study localized phonon polaritons in sub-diffractional nanostructures made of Silicon Carbide.[2,3] A free electron laser as IR light source offers high-power laser pulses with tunable wavelengths.[4] We are able to resolve phonon polariton modes in individual subdiffractional nanostructures and achieve a spatial resolution of ~1.4  $\mu$ m corresponding to  $\lambda_{IR}/9.[1]$  Full spectral mapping over the whole SiC Reststrahlenband allows the spectroscopic identification of the polariton resonances, while the high spatial resolution reveals the microscopic origin of the SFG emission.

Observation of Hyperbolic Shear Polaritons in Monoclinic Crystals -•Giulia Carini¹, Nikolai C. Passler¹, Xiang Ni², Guangwei Hu^{2,3} , Joseph R. Matson⁴, Martin Wolf¹, Mathias Schubert⁵, Andrea Alù², Joshua D. Caldwell⁴, Thomas G. Folland⁶, and Alexander Paarmann¹ – ¹FHI, Berlin, Germany —  2 CUNY, NY, USA —  3 NUS, Singapore, Singapore —  4 Vanderbilt University, Nashville, TN,USA —  5 University of Nebraska, Lincoln, NE, USA — ⁶University of Iowa, Iowa City, IA, USA

Surface phonon polaritons, light-matter coupled waves, have recently attracted much attention due to their versatility in nanophotonic applications in the infrared. In particular, highly anisotropic materials have been shown to support hyperbolic polaritons, which enable a deep sub-wavelength confinement of light [1,2].

In our contribution, we investigate the emergence of a new class of hyperbolic surface waves, that we call hyperbolic shear polaritons (HShPs), in the monoclinic crystal  $\beta$ -gallium oxide (bGO) [3]. The symmetry breaking in the in-plane hyperbolic propagation is directly linked to the frequency dependence of the optical axis directions within the monoclinic plane, resulting in shear phenomena in the non-diagonalizable dielectric permittivity tensor. We experimentally demonstrate the hyperbolic in-plane dispersion of these new polariton modes by means of Otto-type prism coupling.

Transverse magnetic routing of light emission in hybrid plasmonicsemiconductor nanostructures: Towards operation at room temperature -•Lars Klompmaker¹, Alexander N. Poddubny², Eyüp Yalcın¹, Leonid V. Litvin³, Ralf Jede³, Grzegorz Karczewski⁴, Sergij Chusnutdinow⁴, TOMASZ WOJTOWICZ⁵, DMITRI R. YAKOVLEV^{1,2}, MANFRED BAYER^{1,2}, and ILYA А. Акімоv $^{1,2} - {}^{1}$ Experimentelle Physik 2, Technische Universität Dortmund, 44221 Dortmund, Germany —  2 St. Petersburg —  3 Raith GmbH, Konrad-Adenauer-Allee 8, 44263 Dortmund, Germany —  4 Institute of Physics, Polish Academy of Sciences, PL-02668 Warsaw, Poland — ⁵International Research Centre MagTop, PL-02668 Warsaw, Poland

We studied the transverse magnetic routing of light emission from a hybrid plasmonic-semiconductor quantum well (QW) structure where the exciton emission from the QW is routed into surface plasmon polaritons propagating along a nearby semiconductor-metal interface. In our diluted magnetic semiconductor (Cd,Mn)Te/(Cd,Mg)Te QW structure the magnitude of routing is governed by the circular polarization of the exciton optical transitions, induced by the magnetic field. A strong directionality of emission of 15 % was measured at low temperatures of 20 K, but for increasing temperatures it decreases to 4 % at about 65 K due to the decreasing magnetic susceptibility. To avoid this strong temperature dependence we also suggest an alternative design based on a nonmagnetic (In,Ga)As/(In,Al)As QW structure.

Location: H4

Time: Wednesday 10:30-12:30

#### **Topical Talk**

O 38.1 Wed 10:30 H4 Electrochemical Microcalorimetry — • ROLF SCHUSTER and MARCO SCHÖNIG - Institute of Physical Chemistry, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany

We investigate electrochemical reactions at single electrodes by measuring the accompanying heat changes. The heat reversibly exchanged during an electrode process is directly correlated to the reaction entropy of the half-cell reaction including all side reactions, e.g., ordering processes of the solvent or coadsorption processes of anions. Thus, measuring the heat exchange during an electrochemical process provides independent information on the ongoing reaction, which is complementary, e.g., to the potential-current relation, usually measured by cyclic voltammetry or impedance spectroscopy.

In this contribution we will briefly discuss some theoretical aspects of electrochemical microcalorimetry of single electrodes and present our strategy to measure the heat evolution upon surface electrochemical processes. With our setup we are sensitive to heat effects originating from minute conversions of a few percent of a monolayer of an electroactive species.

We will present examples for entropy changes upon anion adsorption and double layer charging on Au(111) and discuss the effect of configurational entropy of the adlayer. The hydrogen adsorption on Pt-films deals as an example of a prototypical surface electrochemical reaction. Time-resolved studies of the heat evolution during Cu bulk deposition will demonstrate the implications from heat measurements on the subsequent reaction steps of this complex reaction.

O 38.2 Wed 11:00 H4

Direct Assessment of the Proton Affinity of Individual Surface Hydroxyls with AFM and DFT — •Bernd Meyer¹, Margareta Wagner², Martin SETVIN², MICHAEL SCHMID², and ULRIKE DIEBOLD² - ¹Interdisciplinary Center for Molecular Materials and Computer Chemistry Center, FAU Erlangen-Nürnberg, Germany — ²Institute of Applied Physics, TU Wien, Austria

The state of protonation/deprotonation of individual surface sites has far-ranging implications in all areas of chemistry. However, common experimental measurements of surface acidity are integral techniques which give only average quantities integrated over the whole surface. Here we show that an OH-functionalized tip of an atomic force microscope (AFM) can be used for quantitative insights into the acidity of individual surface OH groups [1]. The chosen model oxide, In2O3(111), offers four types of surface O atoms with distinct properties, each giving rise to a characteristic force-distance curve after protonation. Densityfunctional theory (DFT) calculations demonstrate a linear correlation between the force minimum and the proton affinity of the surface hydroxyls. By benchmarking the calculations to known proton affinities and  $pK_a$  values of gas-phase molecules, the force minima provide a direct measure of proton affinity distributions and  $pK_a$  differences at the atomic scale.

**Revisiting the OH adsorption on Pt(111) in static water environments** — •ALEXANDRA C. DÁVILA LÓPEZ, NICOLAS G. HÖRMANN, THORBEN EGGERT, and KARSTEN REUTER — Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany

The partial solvation of adsorbates typically leads to altered adsorption energies at solid-liquid interfaces as compared to vacuum. While such solvation effects can be treated most accurately based on *ab initio* molecular dynamics simulations, an according description is hardly feasible for a large number of systems e.g. across different substrates, adsorbates and adsorbate coverages due to prohibitive computational costs. As a result, many studies rely on an approximate treatment based on static water environments. In this work, we study solvation effects based on our previously introduced method [1] to generate a wide range of different static water adlayers. In particular, we analyze the adsorption energy of solvated OH on Pt(111) for a variety of explicit solvation environments and OH configurations. The results are benchmarked against available theoretical and experimental literature data [2, 3], and they highlight prevailing uncertainties in the description of solvation effects.

Measuring the reaction volume of an electrochemical surface process: Cu underpotential deposition on Au(111) — •LISA HIRSCH, BIANCA KRUMM, TAMARA MEYER, and ROLF SCHUSTER — Karlsruhe Institute of Technology

Information about the reaction volume of electrochemical surface reactions is rather scarce [1-3] albeit this thermodynamic quantity would allow conclusions on solvent contribution and possible side processes. With a specifically designed electrochemical cell, we determined the variation of the cell potential of a (111)-textured Au-film in CuSO₄ / H₂SO₄ vs a Cu reference electrode, while applying pressure pulses of moderate amplitude (< 10 bar) and durations of several seconds, starting at different rest potentials. According to the pressure dependend potential variation, we calculated the reaction volume  $\Delta_R V$  of the processes at the working electrode. For rest potentials in the Cu UPD region,  $\Delta_R V$  varies only slightly ( $\pm$  8cm³/mol) around  $\Delta_R V = 18 \text{cm}^3/\text{mol}$ , its value for Cu bulk deposition, moderately peaking upon formation of the ( $\sqrt{3} \times \sqrt{3}$ ) Cu UPD structure. Positive of the Cu UPD, in the sulfate adsorption region,  $\Delta_R V$  drops to smaller values. We check the integrity of the measured potential variations by their dependence on the pressure amplitude as well as by measuring the symmetrical Cu|Cu²⁺,SO²⁺₄|Cu cells.

**Enter the Void: Cavity Formation at Metal-Water Interfaces** — •THORBEN EGGERT^{1,2}, NICOLAS G. HÖRMANN¹, and KARSTEN REUTER¹ — ¹Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany — ²Technical University of Munich, Munich, Germany

Cavity formation is an important concept when rationalizing the solvation of ions. However, most studies analyze cavities only in bulk liquids, omitting that their properties may change dramatically at solid-liquid interfaces.

Here, we study cavities at interfaces, particularly their free energy of formation based on molecular dynamics simulations. Specifically, we use a particle insertion approach, as well as the Multistate Bennett Acceptance Ratio method. We demonstrate that cavity formation at interfaces is dependent on the substrate material, which can be partially rationalized by the substrate-specific interfacial water structure. Furthermore, we observe stabilized cavities behind the first solvation layer of water.

These results might on the one hand rationalize recent theoretical suggestions of a non-electrostatic, attractive force on ions near interfaces, and on the other hand enable the improvement of implicit solvation models, which typically neglect substrate-specificity in their description.

#### O 38.6 Wed 12:00 H4

Impact of confined water on solvation and adsorption/desorption energetics of charged ions at the electrified interface — •ZHENYU WANG, MIRA TODOR-OVA, and JÖRG NEUGEBAUER — Department of Computational Materials Design, Max-Planck-Institut für Eisenforschung, Max-Planck-Str.-1, D-40237, Düsseldorf, Germany

Understanding processes at electrified solid/liquid interfaces is crucial for many systems and a wide range of applications in electrochemical industry, catalytic sciences and biological engineering. Using a prototypical model system of a single ion in water confined between two charged electrodes, we perform nanosecond-scale atomistic molecular dynamics simulations to study the dielectric behavior of chemically pure water as well as the solvation of ions in the presence of an electric field. For weak electric fields we find that the screening charge density of water is proportional to the external electric intensity, in agreement with classical polarization theory. Probing the interface structure by the single Na+/Cl- ion we investigate the formation and evolution of the ion's solvation shell as function of the electrode-ion distance. Comparing potential profiles from Na+/Cl- calculations for different charge states and positions, we elucidate the role of screening and solvation shell size on reorganization energies and transmission barrier of the ions close to the interface.

#### O 38.7 Wed 12:15 H4

Are organic solvents key to enable CO₂ electro-reduction on Mo₂C as promised in theory? — •THOMAS MAIREGGER¹, CHRISTOPH GRIESSER¹, HAOBO LI², NICOLAS HÖRMANN³, KARSTEN REUTER³, and JULIA KUNZE-LIEBHÄUSER¹ — ¹Department of Physical Chemistry, Innsbruck, Austria — ²University of Adelaide, Adelaide, Australia — ³Fritz Haber Institute, Berlin, Germany

It has been proposed in active-site computational screening studies that  $Mo_2C$  is an effective electrocatalyst for the electrochemical  $CO_2$  reduction reaction  $(CO_2RR)$  to valuable fuels, such as hydrocarbons and alcohols. However, the competing hydrogen evolution reaction (HER) has been found to exclusively take place.[1] Reason for this is the formation of a surface oxide film upon air exposure or immersion of  $Mo_2C$  into aqueous electrolytes that impedes the formation of the desired higher reduction products.[1]

Here we investigate the CO₂RR activity of polycrystalline hexagonal Mo₂C in non-aqueous electrolyte to avoid passivation of the electrode and circumvent the high HER activity. We show that Mo₂C is capable of reducing CO₂ in reasonable amounts in an acetonitrile electrolyte, with an onset at -1.08 V_{SHE}.[1] The nature of the products, among them gaseous CO, depends on the concentration of water in the electrolyte. Furthermore, we show that the acetonitrile has a stronger impact on the CO₂ electro-reduction than previously believed.

Automated calculation of surface energies of arbitrary crystals — •FIRAT YAL-CIN and MICHAEL WOLLOCH — Computational Materials Physics, Faculty of Physics, University of Vienna, Kolingasse 14-16, 1090 Vienna

The surface energy is one of the most fundamental properties of the surface facets of a crystal, determining the stability, equilibrium shape, catalytic activity, and other phenomena like surface segregation and roughening. In this work, we present a high-throughput workflow to calculate the surface energies of arbitrary crystals, accounting for all possible Miller indices and different terminations, using density functional theory (DFT). By employing available open-source libraries and custom-made tools, every step from querying bulk structures from various databases to the generation of slabs with precise geometries and subsequent DFT calculations is performed automatically and with minimal user input. Surface energies, Wulff shapes, as well as all in- and outputs, are automatically Location: H6

saved into an easily accessible, OPTIMADE compliant database. Example results are presented for some non-trivial surfaces with complex geometries to showcase the capabilities and validate our approach.

#### O 39.2 Wed 10:45 H6

High-throughput calculations of heterogeneous interfaces for tribology — •Michael Wolloch^{1,2}, Gabriele Losi³, Omar Chehaimi³, Firat Yalcin¹, Mauro Ferrario⁴, and M. Clelia Righi³ — ¹CMP, University of Vienna, Vienna, Austria — ²VASP software GmbH, Vienna, Austria — ³DIFA, University of Bologna, Bologna, Italy — ⁴FIM, UNIMORE, Modena, Italy

We have shown in the past that fundamental properties of sliding interfaces like adhesion, friction, and ultimate strength, are closely connected to one another and the re-arrangement of charge at the interface [1-3]. We extended the previously presented approach for homogeneous interfaces to nearly arbitrary interfaces of crystalline surfaces, allowing us to treat heterogeneous interfaces of multi component systems [4].

In this talk we will present the fault tolerant and fully automatic workflow we developed, as well as initial results of the ongoing high-throughput studies we are conducting.

Part of this work was supported by ERC grant 865633 (SLIDE); [1] Wolloch et al. Sci. Rep. 9, 17062 (2019), [2] Restuccia et al. Comput. Mater. Sci., 154:517-529 (2018), [3] Wolloch et al. PRL 121, 026804 (2018) [4] Wolloch et al. Comput. Mater. Sci., 207:111302 (2022)

#### O 39.3 Wed 11:00 H6

The Influence of Temperature and Wear on Nanoscale Friction Anisotropy - •JENNIFER KONRAD, DIRK DIETZEL, and ANDRE SCHIRMEISEN - Institute of Applied Physics, Justus-Liebig University Giessen, 35392 Giessen, Germany On atomically flat surfaces, the nanoscale friction force measured by atomic force microscopy shows a distinct variations dependent on the sliding direction of the AFM-tip. This anisotropy occurs as a consequence of the surface structure and is related to different energy barrier heights along different directions of the sample surface. In this work, this anisotropy of friction force is now analyzed as a function of temperature under UHV conditions on hexagonal latices like HOPG or MoS2 and also on ionic crystals with 90 degree symmetry like NaCl. At low sample temperatures, the friction force as deduced from the thermally activated Prandtl Tomlinson Model increases, and thermally activated random jumps become more unlikely, which direct influences the stability of the different sliding directions. This can be confirmed for HOPG and MoS2, while, our results for the ionic crystals additionally show that the both the absolute friction and the anisotropy are not only influenced by temperature, but also reflect temperature dependent wear effects.

#### O 39.4 Wed 11:15 H6

Dissipative frictional mechanism over Moiré superstructure — •YIMING SONG¹, XIANG GAO², ANTOINE HINAUT¹, SEBASTIAN SCHERB¹, SHUYU HUANG¹, ODED HOD², MICHAEL URBAKH², and ERNST MEYER¹ — ¹Department of Physics, University of Basel, Basel, Switzerland — ²Department of Physical Chemistry, School of Chemistry, The Raymond and Beverly Sackler Faculty of Exact Sciences and The Sackler Center for Computational Molecular and Materials Science, Tel Aviv University, Tel Aviv, Israel.

Friction force microscopy experiments performed on graphene-coated platinum surfaces that exhibit a variety of moiré superstructures demonstrate that, in addition to the well-known atomic stick-slip dynamics, a new dominant energy dissipation mechanism emerges. The observed velocity dependence of friction displays two distinct regimes: (i) at low velocities, the friction force is small and nearly constant; whereas (ii) above some threshold, friction increases log-arithmically with velocity. The threshold velocity, separating the two frictional regimes, decreases with increasing normal load and moiré superstructure period. Atomistic molecular dynamics simulations demonstrate that the main contribution to frictional energy dissipation results from the elastic deformation and subsequent relaxation of moiré ridges caused by the pushing action of the tip as it slides over the superstructure. Based on the simulation results we develop a semi-phenomological model, which makes it possible to calculate friction under measurement conditions and provides excellent agreement with the experimental observations.

O 39.5 Wed 11:30 H6 Investigating thermal and directional motion in molecular friction processes by photonic force microscopy — •SUBHROKOLI GHOSH and ALEXAN-DER ROHRBACH — Lab for Bio- and Nano-Photonics, Department of Microsystems Engineering (IMTEK), University of Freiburg, Georges-Koehler-Allee 102, 79110 Freiburg, Germany

Friction of a moving particle is a complex process of energy dissipation to the environment, which is important on most length scales, time scales and across disciplines. Several theories approach the molecular origin of friction, but a com-

prehensive understanding is still missing. Usually, the relation between dynamic friction and velocity is quantified by a coefficient, which depends on various parameters. Two main routes to determine the friction coefficient can be addressed by either from a directed particle motion or from its thermal motion. In both cases, Photonic Force Microscopy (PFM) has proven to be one of the most elegant techniques that can be utilized to better understand friction on mesoscopic length scales, specially at soft (-bio) interfaces. Towards this aim, we employ PFM with high-frequency axial tracking for directed and frequency dependent measurements of different bead-surface model systems, starting from simple poly-styrene (PS) bead- glass surface. From Brownian dynamics simulations, in combination with experiments, we obtain better insights on the friction coefficient and its dependency on different system parameters. From this, we developed a theoretical model describing the microscopic origin of friction through molecular on- and off-binding processes.

#### O 39.6 Wed 11:45 H6

Single Asperity Sliding Friction across the Superconducting Phase Transition — WEN WANG, • DIRK DIETZEL, and ANDRÈ SCHIRMEISEN — Institute of Applied Physics, Justus Liebig University Giessen, Giessen, Germany

When analyzing sliding friction, it is usually an intriguing question to identify the different dissipation mechanisms contributing to friction. Usually, a number of different channels for dissipation are considered including phonon and electron systems, plastic deformation, and crack formation. Among these, especially the role of the electron system for energy dissipation often remains elusive. In this contribution, we now present experiments single asperity sliding friction monitored during AFM-measurements on a high-T_c BSCCO-superconductor. These measurements reveal a distinct temperature dependence of friction in a temperature range between 40 K and 300 K [1]. While the overall friction decreases with temperature as predicted by models about thermally activated friction, we find a distinct friction peak at about 95K. This peak can be explained by a superposition of different energy dissipation channels, where the influence of electronic contributions vanishes when cooling below the superconducting phase transition  $T_c$ . Our experiments thereby unambiguously link electronic friction effects to the number of normal state electrons in the superconducting phase below  $T_c$ . In addition, we analyze single asperity friction of BSCCO in the proximity of step-edges, where layer-defects reveal the potential influence of the topmost-layer on electronic friction contributions. **Fingerprint of a structural phase transition during superlubric sliding** — •EBRU CIHAN^{1,2}, DIRK DIETZEL¹, and ANDRE SCHIRMEISEN¹ — ¹Institute of Applied Physics, Justus-Liebig University Giessen, 35392 Giessen — ²Institute for Materials Science, TU Dresden, 01062 Dresden

Although the fundamental concept of structural superlubricity (i.e. ultra-low friction observed between clean and atomically flat, incommensurate surfaces) is very straightforward, the effective energy barrier for lateral motion still depends on the exact structural dynamics at the sliding interface. In fact, it can be computationally predicted that the superlubricity of amorphous structures is less effective than that of crystalline structures, however this is not always easy to demonstrate experimentally. But we have now overcome this challenge by measuring the friction of antimony nanoparticles on highly oriented pyrolythic graphite in the high temperature regime, i.e. between 300 K and 750 K, where the interface can be restructured. At about 450 K, we trigger a phase transition in antimony nanoparticles, which also allows us to establish a direct link between friction and the interface structure. More specifically, our experiments reveal that the friction level decreases in the more crystalline state where the collective force cancellations are more effective. Due to the irreversible character of the phase transition, a reduced friction level can then also be observed after cooling back to room temperature. The reduction of friction can be associated with a decrease of the characteristic scaling factor of about 16%, as theoretically anticipated from the 'scaling law' for superlubricity.

## O 40: Organic Molecules at Surfaces 4: Chemistry on Surfaces

Time: Wednesday 10:30-12:45

#### O 40.1 Wed 10:30 S051

On-surface synthesis of planar  $\pi$ -extended cycloparaphenylenes featuring an all-armchair edge topology — FEIFEI XIANG¹, SVEN MAISEL², SUMIT BENIWAL¹, VLADIMIR AKHMETOV^{2,3}, CORDULA RUPPENSTEIN³, MIRUNALINI DEVARAJULU¹, ANDREAS DÖRR¹, OLENA PAPAIANINA³, ANDREAS GÖRLING², KONSTANTIN AMSHAROV^{2,3}, and •SABINE MAIER¹ — ¹FAU Erlangen-Nürnberg, Dept. of Physik — ²FAU Erlangen-Nürnberg, Dept. of Chemistry and Pharmacy — ³Institute for Chemistry, University Halle-Wittenberg

[n]cycloparaphenylenes ([n]CPPs) have attracted significant attention due to their unique cyclic structure and highly effective para-conjugation leading to a myriad of fascinating (opto-)electronic properties. However, their strained topology prevents the  $\pi$ -extension of CPPs to convert them either into armchair nanobelts or planarized CPP macrocycles. We have successfully tackled this long-standing challenge and present the bottom-up synthesis and characterization of atomically precise in-plane  $\pi$ -extended [12]CPP on Au(111) by low-temperature scanning probe microscopy/spectroscopy combined with density functional theory.[1] The planar  $\pi$ -extended CPP represents the first nanographene with an all-armchair edge topology. The exclusive paraconjugation at the periphery yields delocalized electronic states and the planarization maximizes the overlap of p-orbitals, which both reduce the bandgap compared to conventional CPP. Calculations predict ring currents and global aromaticity in the doubly charged system.

#### O 40.2 Wed 10:45 S051

Electronic Properties of N-Heterotriangulene based Charge Transfer Complexes — •MOHSEN AJDARI¹, RONJA PAPPENBERGER¹, INA MICHALSKY², LEONIE PAP¹, CHRISTIAN HUCK¹, MARVIN HOFFMANN³, FRIEDRICH MAASS¹, MILAN KIVALA², ANDREAS DREUW³, and PETRA TEGEDER¹ — ¹Physikalisch-Chemisches Institut, Universität Heidelberg — ²Organisch-Chemisches Institut, Centre for Advanced Materials, Universität Heidelberg — ³Interdisziplinäres Zentrum für Wissenschaftliches Rechnen, Universität Heidelberg

N-heterotriangulenes (N-HTAs) are a class of organic electron-transporting semiconductors that belong to N-heteropolycyclic aromatic compounds, which are promising candidates for a variety of (opto) electronic applications. In this study, electronic high-resolution electron energy loss spectroscopy (HREELS) in combination with quantum-chemical theory are utilized to investigate the electronic properties of two N-HTA derivatives, N-HTA-550 and N-HTA-557 on Au(111). In addition, formation of charge transfer complexes (CTCs) with N-HTAs, acting as donor molecules in combination with two well-known cyanobased electron acceptor molecules, TCNQ and F4TCNQ is identified. Our findings indicate that formation of the 7-membered ring in N-HTA-557 by adding the -C=C- bridge leads to a narrowing of the optical gap size by 0.9 eV and a decrease in the first triplet state energy by 1.2 eV. Moreover, all donor/acceptor bilayer systems on Au(111) exhibit low-lying electronic transitions between 0.9 and 2.2 eV, which are attributed to the formation of CTCs.

#### O 40.3 Wed 11:00 S051

N-Heterotriangulenes Donors and Charge Transfer Complexes formed with strong Electron Acceptors investigated with Two-Photon Photoemission Spectroscopy – •JAKOB STEIDEL¹, INA MICHALSKY², MILAN KIVALA², and PETRA TEGEDER¹ – ¹Institute of Physical Chemistry, Heidelberg University, Im Neuenheimer Feld 253, 69120 Heidelberg – ²Institute of Organic Chemistry, Heidelberg University, Im Neuenheimer Feld 270, 69120 Heidelberg

Many opto-electronic devices such as organic photovoltaic cells or organic light emitting diodes utilize donor-acceptor-systems (D-A-systems). Triphenylamine derivatives are promising candidates for donors in D-A-systems.1 The introduction of an etheno-bridge in the planar triphenylamine derivative indolo[3,2,1jk]carbazole (N-HTA-550) creates a seven membered antiaromatic ring in the resulting N-Heterotriangulene-557 (N-HTA-557). While the molecular geometry is mostly preserved, the electronic structure is strongly modified by this additional -C=C-moiety.

In the present contribution we study the electronic properties of N-HTA-550 and N-HTA-557 on a Au(111) surface using two-photon photoemission (2PPE) spectroscopy and temperature programmed desorption (TPD). Furthermore the formation of charge transfer complexes with strong electron acceptors (TCNQ and F4TCNQ) is investigated utilizing both 2PPE and TPD.

#### O 40.4 Wed 11:15 S051

**Remarkably table metal-organic networks on an inert substrate: Ni-, Fe-,** and Mn-TCNQ on graphene — •ZDENĚK JAKUB¹, ANNA KUROWSKÁ¹, ON-DREJ HERICH¹, LENKA ČERNÁ¹, LUKÁŠ KORMOŠ¹, AZIN SHAHSAVAR¹, PAVEL PROCHÁZKA¹, and JAN ČECHAL^{1,2} — ¹CEITEC, Brno University of Technology, Czechia — ²Faculty of Mechanical Engineering, Brno University of Technology, Czechia

Potential applications of 2D metal-organic frameworks (MOF) require the frameworks to be monophase and well-defined at the atomic scale, to be decoupled from the supporting substrate, and to remain stable at the application conditions. Here, we present three systems meeting this elusive set of requirements: M-TCNQ (M = Ni, Fe, Mn) on epitaxial graphene/Ir(111). We study the systems experimentally by scanning tunneling microscopy, low energy electron microscopy and x-ray photoelectron spectroscopy. When synthesized on graphene, the 2D M-TCNQ MOFs are monophase with M1(TCNQ)1 stoichiometry, and we demonstrate their remarkable chemical and thermal stability: All the studied systems survive exposure to ambient conditions, with Ni-TCNQ doing so without any significant changes to its atomic-scale structure or chemical state. Thermally, the most stable system is Fe-TCNQ which remains stable above 500 °C, while all the tested MOFs survive heating to 250 °C. Overall, the modular M-TCNQ/graphene system combines the atomic-scale definition required for fundamental studies with the robustness needed for applications, thus it presents an ideal model for research in single atom catalysis or spintronics.

#### O 40.5 Wed 11:30 S051

Control of overlayer-substrate coupling via alkali doping in two-dimensional metal-organic networks — •BILLAL SOHAIL¹, PHIL J. BLOWEY², TIEN-LIN LEE³, PAUL T. P. RYAN³, DAVID A. DUNCAN³, GIOVANNI CONSTANTINI¹, D. PHIL WOODRUFF¹, and REINHARD J. MAURER¹ — ¹University of Warwick — ²University of Leeds — ³Diamond Light Source

We characterise a two-dimensional donor-acceptor network formed by coadsorption of alkali atoms and the prototypical acceptor molecule TCNQ (7,7,8,8tetracyanoquinodimethane) at different orientations of Ag surfaces. We characterise the adsorption structure with a combi- nation of normal incidence xray standing wave (NIXSW) measure- ments, Scanning Tunnelling Microscopy, and dispersion-inclusive Den- sity Functional Theory, which we find to be in excellent agreement with experiment. The adsorption structure sensitively depends on an inter- play of molecule-metal charge transfer and long-range dispersion forces, which are influenced by the co-adsorption ratio between alkali atoms and TCNQ. In general, alkali atom co-adsorption reduces the moleculesubstrate interaction strength, yet is energetically favoured compared to TCNQ co-adsorption with Ag adatoms. We show that the donor-acceptor ratio in the network is able to control the overlayer-substrate interaction, which strongly affects electronic properties such as the work function and the level alignment at the interface. Therefore, the concentration of alkali donor atoms can be used to tune electronic properties of the interface.

#### O 40.6 Wed 11:45 S051

Analysis of the 3-dimensional adsorption configuration of organic molecules by SPM manipulation and imaging — •ALEXANDER IHLE¹, DANIEL EBELING¹, DANIEL KOHRS², HERMANN A. WEGNER², and ANDRE SCHIRMEISEN¹ — ¹Institute of Applied Physics, Justus Liebig University Giessen — ²Institute of Organic Chemistry, Justus Liebig University Giessen

On-surface chemistry is a powerful tool for building covalent molecular structures such as chains, networks, or graphene nanoribbons (GNRs). In particular, the catalytic properties of the metal substrate as well as the 2D confinement facilitate the synthesis of new structures that are not accessible via solution chemistry. The Ullmann type coupling is one of the most frequently applied on-surface reaction for synthesizing C-C bonded structures. However, only limited information is available about the three dimensional adsorption conformation of the molecular educts and how this affects the reaction pathway. Here, we studied onsurface reactions of 9-X-10-(1,1':3',1"-terphenyl-5'-yl)anthracene (X= bromine, iodine) on Cu(111), Ag(111) and Au(111). Using low-temperature atomic force microscopy with CO-functionalized tips, we can identify the precise adsorption conformation of the pristine molecules as well as the intermediate and final products. In particular, the three dimensional conformation of the intermediates strongly inhibits the intermolecular coupling reaction between the educts on all surfaces. Instead, intramolecular bond formation is observed.

#### O 40.7 Wed 12:00 S051

STM growth studies of 5,14-ol-5,14-diborapentacyclo on low-index coinage metal surfaces — •WUN-CHANG PAN¹, JING QI¹, CARINA MÜTZEL², PAULA WEBER¹, FRANK WÜRTHNER², and MATTHIAS BODE¹ — ¹Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany — ²Institut für Organische Chemie & Center for Nanosystems Chemistry (CNC), Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany

In recent studies [1, 2], heteroatoms-doped precursors have frequently been used to polymerize graphene nanoribbons with a large variety of structures or dopant heteroatoms. Using cryogenic scanning tunneling microscopy, we investigated the structure of self-assembled 5,14-ol-5,14-diborapentacyclo (CM218) on low-index coinage metal surfaces. The main focus of our study is on CM218 on Ag(111), where we find that molecular clusters and chains coexist with molecular islands. At low annealing temperature  $T_{ann} < 100^{\circ}$ C, the islands exhibit a rail track-like structure with a rhomboid-shaped unit cell. Besides, we find irregular clusters and molecular chains. At higher  $T_{ann} \geq 180^{\circ}$ C, islands with a honeycomb (HC) structure are observed. Topographic images of these HCs display a pronounced bias dependence. Molecule-functionalized tips allow for high-resolution images of these structures for which we suggest structural models.

#### O 40.8 Wed 12:15 S051

Surface chemistry of dibromoindigo - effects of temperature and type of surface — •MANUELA HOCKE^{1,2}, MICHAEL SCHMITTEL³, WOLFGANG HECKL^{1,2}, and MARKUS LACKINGER^{1,2} — ¹Deutsches Museum, 80538 München — ²Technische Universität München, Physics Department, 85748 Garching — ³Center of Micro and Nanochemistry, Universität Siegen, 57068 Siegen, Germany

Mother Nature offers a great variety of suitable halogenated compounds, which can readily be used as precursor for on-surface Ullmann couplings. Here, we study the thermally activated surface chemistry of the famous dye Tyrian purple (6,6°-dibromoindigo) comparatively on Ag(111) and Au(111) by Scanning-Tunneling-Microscopy. On Au(111) we observed two distinct self-assembled structures comprised of fully intact molecules. Covalent structures were obtained either by deposition onto hot surfaces or subsequent heating, where the heating rate is crucial. On Ag(111) only one self-assembled structure was observed. The organometallic structure. Instead, we find remarkably diverse structures. The additional functionalization of 6,6'-dibromindigo with potent H-bond donor and acceptor groups renders the on-surface polymerization of this

compound particularly prone to additional influences of supramolecular bonds with a vivid contribution of the co-adsorbed dissociated bromine atoms. Moreover, the surprisingly large variation of the organometallic structures on Ag(111) and the profound dependence on preparation parameters indicate an unexpectedly large kinetic influence.

O 41.1 Wed 10:30 S052

Using polyaromatic hydrocarbons for graphene growth - •MATTHEW A. Stoodley^{1,2}, Benedikt P. Klein^{1,2}, Luke A. Rochford², Matthew EDMONDSON³, MARC WALKER², TIEN-LIN LEE¹, ALEXANDER SAYWELL³, REIN-HARD J. MAURER², and DAVID A. DUNCAN¹ — ¹Diamond Light Source, Did-cot, United Kingdom — ²University of Warwick, Coventry, United Kingdom — ³University of Nottingham, Nottingham, United Kingdom

Graphene, due to its widespread potential applications, has been one of the most studied materials this century. The most common approach to produce high quality graphene is through epitaxial growth utilising chemical vapour deposition (CVD) on copper surfaces. This method exploits the catalytic activity of copper to form highly crystalline, large area graphene. Traditionally, precursors used to grow graphene on Cu(111) require high pressures and elevated substrate temperatures, however, many cutting edge characterisation techniques cannot be used at such conditions. In this work, polyaromatic hydrocarbons (PAH) are used to grow high quality graphene on Cu(111) via CVD at relatively low surface temperatures. Furthermore, the low vapour pressure of the PAH permits us to synthesise graphene films in ultra-high vacuum conditions. We present a characterization of the grown graphene, by utilising a wide variety of techniques including Scanning Tunnelling Microscopy, X-ray photoelectron spectroscopy, normal incidence x-ray standing waves, and near edge X-ray adsorption fine structure.

O 41.2 Wed 10:45 S052

Stone-Wales defect: molecular model system reveals increased interaction with Cu(111) surface — •Benedikt P. Klein^{1,2,3}, Alexander Ihle⁴, Stefan R. Kachel¹, Lukas Ruppenthal¹, Samuel J. Hall², Daniel Ebeling⁴ RALF TONNER-ZECH¹, REINHARD J. MAURER², ANDRE SCHIRMEISEN⁴, and J. MICHAEL GOTTFRIED¹ — ¹Philipps-Universität Marburg, Germany — ²University of Warwick, Coventry, UK — ³Diamond Light Source, Didcot, UK ⁴Justus-Liebig-Universität Gießen, Germany

The properties of the graphene/metal interface are crucially influenced by the enhanced interaction of defects in the graphene layer with the metal substrate. However, due to experimental and computational constraints, it is difficult to investigate this interaction directly. We combine calculations with experimental analysis of large organic molecules adsorbed on metal surfaces as molecular model systems. We chose two model molecules, azupyrene and pyrene, which have the same aromatic topology as the prototypical Stone-Wales defect and the ideal graphene lattice, respectively. When adsorbed on the Cu(111) surface, we could show using TPD that the model defect binds much stronger to the surface. nc-AFM and NIXSW results furthermore prove a reduction in adsorption height while XPS, UPS, and NEXAFS show an increased electronic hybridisation between molecule and surface. DFT results agree with these findings and show a localized interaction with the metal surface, both for the molecular model systems and the defect embedded into the graphene layer.

#### O 41.3 Wed 11:00 S052

Determining the stability and catalytic formation of graphene on liquid Cu using machine-learning potentials — •HAO GAO¹, VALENTINA BELOVA², Maciej Jankowski², Hendrik H. Heenen¹, Gilles Renaud², and Karsten REUTER¹ — ¹Fritz-Haber-Institut der MPG, Berlin, Germany — ²ESRF, Grenoble, France

The recently discovered rapid, high-quality synthesis of graphene (Gr) on liquid Cu catalysts is microscopically still poorly understood. This is due to the difficult characterization of the Cu liquid surface. Especially in atomistic simulations, the large length and time scales necessary to reliably emulate the temporal evolution of the liquid are a major challenge. Corresponding molecular dynamics and future nanoelectronics applications. Here we investigate a hybrid heterostructure between pentacene molecules and 2D MoS2 nanocrystals deposited on Au(111) by means of Scanning Tunneling Microscopy and Density Functional Theory calculations.

In the MoS₂/Au interface, the lattice mismatch leads to the growth of extended monolayer films displaying a non-commensurate lattice with the metal substrate and typical features of point defects, identified as single sulfur vacancies.

The formation of atomically thin pentacene/MoS₂ lateral heterostructures is observed on the Au substrate. Interestingly, the inner regions of the  ${\rm MoS}_2$  layer are not covered by pentacene. The density of states changes sharply across the pentacene/MoS₂ interface indicating a weak interfacial coupling, which leaves unaltered the electronic signature of MoS₂ edge states. This work unveils the growth of abrupt lateral heterostructures toward hybrid devices based on organic/inorganic one-dimensional junctions.

Location: S052

simulations require large simulation cells and need to span well into the nanosecond regime - an endeavor presently intractable via first-principles methods. In this work we use computationally efficient machine-learning potentials (MLPs) trained to density-functional theory (DFT) data in order to extrapolate the firstprinciples predictive power to the required scales. Detailed benchmarking confirms that our MLP captures the involved physics well, accurately reproducing the experimentally determined Gr adsorption height. We apply the MLP to further study the catalytic mechanism of Gr synthesis in order to rationalize distinct reaction kinetics found experimentally. Our work draws a path for the use of reliably trained MLPs as a multiscale modeling technique to explore previously unchartered computational problems. In that we provide new insight into the domain of liquid metal catalysts which generally lack atomic-scale understanding.

#### O 41.4 Wed 11:15 S052

Properties of epitaxial graphene on various SiC terminations and polytypes investigated by low-energy electron microscopy — •Philip Schädlich^{1,} DAVOOD MOMENI PAKDEHI³, FLORIAN SPECK^{1,2}, KLAUS PIERZ³, and THOMAS Seyller 1,2  —  1 Technische Universität Chemnitz, Chemnitz, Germany — ²Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Chemnitz, Germany – ³Physikalisch-Technische Bundesanstalt, Braunschweig, Germany

The epitaxial growth of graphene on SiC has been improved from UHV growth to ambient pressure synthesis [1], and recently to the polymer-assisted sublimation growth (PASG) [2]. It results in an enhanced nucleation of the buffer layer and suppressed step bunching, which usually occurs upon the graphene formation by sublimation. Thus, PASG leads to homogeneous monolayer graphene with minimum step size equivalent to one or two SiC-bilayers. As a result of the latter, graphene on various surface terminations of the SiC substrate can now be systematically studied.

We utilize low-energy electron microscopy (LEEM) to identify the underlying substrate structure and to elucidate its delicate impact on the characteristic I(V) curves for different SiC polytypes. In addition, we investigate how the decoupling of the buffer layer from the substrate by hydrogen intercalation [3] influences the aforementioned effects.

#### O 41.5 Wed 11:30 S052

Quasiparticle Interference Effects Revealed in Potassium-Intercalated Epitaxial Monolayer Graphene — TOBIAS HUEMPFNER, •FELIX OTTO, ROMAN FORKER, and TORSTEN FRITZ — Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany

Epitaxial graphene is known for its fascinating physical properties, such as a linear dispersion at the K point, an anomalous quantum Hall effect and even superconductivity. These effects are based on the unique electronic structure of graphene, which can be tuned, e.g., by intercalation of metals. In this study, we scrutinize samples of epitaxial monolayer graphene (EMLG) on SiC(0001) intercalated with potassium by means of local and area-averaging experimental methods at low temperatures. For the highest accessible K concentration we find a highly ordered  $(2 \times 2)$  superstructure that the K atoms form below the uppermost graphene layer. Further, we observe that the K atoms also reside below the buffer layer of the EMLG on SiC(0001) sample that is located between the quasi-freestanding graphene sheet and the SiC substrate. This causes an effective decoupling of the buffer layer and a transformation to K-intercalated epitaxial bilayer graphene (EBLG). This configuration promotes strong n-doping of the graphene sheets, where besides a rigid shift of the Dirac bands to higher binding energies also filling of two parabolic interlayer bands is observed.

#### O 41.6 Wed 11:45 S052

Structural and electronic properties of a van der Waals heterostructure of two-dimensional Pb and epitaxial graphene — •BHARTI MATTA, PHILIPP ROSENZWEIG, OLAF BOLKENBAAS, KATHRIN KÜSTER, and ULRICH STARKE — Max-Planck-Institut für Festkörperforschung, Heisenbergstraße 1, 70569 Stuttgart, Germany

Intercalation is an established technique for manipulating the electronic properties of epitaxial graphene. Moreover, it is a way to confine otherwise unstable two-dimensional (2D) layers of elements, leading to unique physical properties compared to their bulk counterparts due to quantum confinement. In this work, we show uniformly Pb-intercalated quasi-freestanding monolayer graphene on SiC, which turns out to be essentially charge neutral. Additional bands - some crossing the Fermi level - can be clearly discerned, demonstrating the metallic character of 2D Pb sandwiched within the graphene/SiC heterointerface. The band velocity of the graphene Dirac cone changes at binding energies of around 0.6 eV and 1.1 eV, which points towards hybridization with these Pb bands. Low-energy electron diffraction reveals a 10×10 Moiré periodicity with respect to graphene. This is consistent with a triangular lattice of intercalated Pb that is strained by less than 2% relative to bulk-truncated Pb(111) and of which a  $(\sqrt{3} \times \sqrt{3})$ R30° supercell matches 2×2-SiC. However, finding direct signatures of the corresponding periodicities in the available band structure data is challenging. Our experimental results will provide a solid ground for further theoretical assessment of this system and better understanding of its properties.

#### O 41.7 Wed 12:00 S052

Surface Transport Properties of Pb- and Sn-intercalated Graphene — •M. GR-USCHWITZ, C. GHOSAL, Z. MAMIYEV, J. KOCH, S. WOLFF, T. SEYLLER, and C. TEGENKAMP — Institut für Physik, Technische Universität Chemnitz, Germany Intercalation experiments on epitaxial graphene are attracting a lot of attention at present as a tool to boost further the electronic properties of 2D graphene. In this work we studied the intercalation of Pb using buffer layers on 6H-SiC(0001). Recent DFT calculations suggest Pb atoms to act as electron donors thus allowing the doping level of the quasi-freestanding graphene layer to be tuned by the amount of intercalated material [1].

In this work we present results about the large-area intercalation of Pb and Sn, investigated by means of electron diffraction, scanning tunneling microscopy,

photoelectron spectroscopy and in-situ surface transport. The intercalation of Pb and Sn results in formation of almost charge neutral graphene. In case of Pb, the intercalated layer consists of 2 ML and shows a strong structural corrugation. The epitaxial heterostructure provides an extremely high conductivity of  $\sigma = 100 \text{ mS/}\square$ . However, below 70 K we found a metal-insulator transition which we assign to the formation of minigaps in epitaxial graphene, possibly induced by a static distortion of graphene following the corrugation of the interface layer [2]. Sn intercalation does not cause such a transition while yielding a conductivity of  $\sigma = 2.5 \text{ mS/}\square$ .

O 41.8 Wed 12:15 S052

Electron correlation effects in highly-doped single-layer graphene — •VIVIEN ENENKEL¹, PHILIPP ROSENZWEIG², HRAG KARAKACHIAN², FABIAN PASCHKE¹, ULRICH STARKE², and MIKHAIL FONIN¹ — ¹Fachbereich Physik, Universität Konstanz, 78457 Konstanz, Germany — ²Max-Planck-Institut für Festkörperforschung, Heisenbergstraße 1, 70569 Stuttgart, Germany

Electronic correlations in graphene are expected to be strongly enhanced when there is a very high density of states at the Fermi level, giving rise to many-body states such as superconductivity or charge density waves (CDW) [1]. While the latter have been reported for example in Ca-intercalated bilayer graphene [2,3], in case of epitaxial monolayer graphene no direct evidence of correlated electronic ground states has yet been reported. We investigate heavily n-doped monolayer graphene on SiC(0001), obtained by Yb intercalation underneath zero-layer graphene. Here, a van Hove singularity (VHS) is pushed to the Fermi level, giving rise to an extended VHS, effectively pinning an almost nondispersive flat band at EF [4]. Low-temperature STM reveals several distinct structures of Yb-intercalated graphene, which we attribute to differing arrangements of the Yb at the interface. dI/dU spectra show a pronounced gap feature centered at EF, whose response to field and temperature variations allows the interpretation of the feature as a CDW state.

## O 42: Metal substrates 2

Time: Wednesday 10:30-11:45

O 42.1 Wed 10:30 S053

Atomic structure determination of epitaxially grown tin perovskite CsSnBr₃ on gold surfaces — •MADAD ABBASLI¹, JENNY SCHRAGE¹, JIAQI CAI¹, JEREMY HIEULLE², ALEX REDINGER², CARSTEN BUSSE¹, and ROBIN OHMANN¹ — ¹University of Siegen, Department of Physics, Germany — ²University of Luxembourg, Department of Physics and Materials Science, Luxembourg

Tin perovskites can be efficient and environmentally friendly substitutions to lead perovskites, but they have a drawback due to oxidation from  $\text{Sn}^{2+}$  to  $\text{Sn}^{4+}$ . Here, we present an in-situ study of epitaxially grown CsSnBr₃ on Au(111) and Au(100) in ultrahigh vacuum (UHV) using scanning tunneling microscopy (STM), low energy electron diffraction (LEED) and x-ray photoelectron spectroscopy (XPS). By co-evaporation of the precursor molecules CsBr and SnBr₂ submonolayers up to a few monolayers are obtained. On Au(111), CsSnBr₃ grows in three differently oriented domains due to the hexagonal symmetry of the substrate. On Au(100), which has square symmetry, identical to CsSnBr₃, but with about half of the lattice constant of the perovskite, we observe a (2x2) superstructure. Chemical analysis shows no indication of tin oxidation, which demonstrates the importance of preparation of tin perovskites in vacuum using evaporation.

#### O 42.2 Wed 10:45 S053

**Peculiar growth of Mn on Ir (111) investigated by SP-STM** — •ARTURO RODRÍGUEZ SOTA, VISHESH SAXENA, ANDRÉ KUBETZKA, JONAS SPETHMANN, ROLAND WIESENDANGER, and KIRSTEN VON BERGMANN — Institut für Nanostruktur- und Festkörperphysik, Universität Hamburg

The growth of metallic layers has been studied for many years, from single atom coverages via clusters and islands to extended films. The experimental parameters used during the growth, such as deposition temperature or amount of material, determine the resulting phase. Usually, only one phase is present for a given preparation, but for europium on graphene the coexistence of clusters and islands of has been documented. This was attributed to several effects including charge transfer from the metal clusters to the substrate in a precise window of coverage and temperature [1].

Here we study the growth of Mn on Ir(111) using spin polarized scanning tunneling microscopy (SP-STM). In this metallic system we have found the co-existence of clusters and islands for any Mn sub-monolayer coverage. We have

Location: S053

characterized the clusters in detail at low temperature and found several different configurations made out of three atoms. The Mn islands exhibit a reconstruction that disappears when the layer is completely closed. The monolayer presents the Néel state as its magnetic ground state.

O 42.3 Wed 11:00 S053

Breaking down of Stoner band ferromagnetism induced by interface formation — •DAVID JANAS¹, ANDREA DROGHETTI², IULIA COJOCARIU³, VI-TALIY FEYER³, STEFANO PONZONI¹, MILOS RADONJIĆ⁴, IVAN RUNGGER⁵, LIVIU CHIONCEL⁶, GIOVANNI ZAMBORLINI¹, and MIRKO CINCHETTI¹ — ¹TU Dortmund University, Dortmund, Germany — ²Trinity College, Dublin, Ireland — ³Forschungszentrum Jülich, Jülich, Germany — ⁴University of Belgrade, Belgrade, Serbia — ⁵National Physics Laboratory, Teddington, United Kingdom — ⁶University of Augsburg, Augsburg, Germany

Interfaces between ferromagnetic transition metals and molecules or atoms display intriguing spin properties that have been invoked to explain the peculiar behavior of a variety of molecular spintronic and spin-optoelectronic devices [1]. Despite its relevance, a satisfying model for the hybridization occurring at such interfaces has not yet been presented. Experimentally, this is due to the lack of information on the interface band structure in the whole Brillouin zone, while, theoretically, the role of electron correlation has up to now mostly been neglected. Here, we overcome these limitations using state-of-the-art experimental and theoretical methods to explore the model interface between iron and an ordered oxygen layer. We use spin-resolved momentum microscopy to provide access to the complete spin-resolved interface band structure and explain our findings using DFT+ $\Sigma_2$  calculations that go beyond the one-electron approximation [2].

A μ-Photoreactor for Investigating Planar Hydrogen Evolution Catalysts at Ambient Condition — •CLARA ALETSEE, MARTIN TSCHURL, and UELI HEIZ — Physical Chemistry, Department of Chemistry & Catalysis Research Center, Technical University of Munich Photocatalytic water splitting and alcohol reforming offer promising alternatives for clean  $H_2$  production, in contrast to the industrially applied steam reforming of fossil fuels. However, the understanding of the reaction mechanisms ,which is indispensable for tailored performance improvement, is complicated by the structural complexity of powdered catalyst. In contrast, well-defined planar catalysts are already used for fundamental studies in ultra-high vacuum, but a simple extrapolation of the results to applied conditions is impractical due to a significant pressure difference.

Herein, we present a  $\mu$ -photoreactor for the evaluation of planar model catalysts like single crystals or epitaxially grown semiconductors at ambient conditions in a continuous gas flow. In this system, the catalyst serves as the bottom of the reactor, while a 200  $\mu$ m O-ring on top defines the reactor volume of 12  $\mu$ L. It is sealed by a UV-vis transparent lid with lithographically implemented channels for the gas flow toward the quadrupole mass spectrometer for product analysis. The functionality is demonstrated by ethanol photoreforming over a Pt loaded TiO₂ catalyst. This concept will not only enable the evaluation of planar photocatalysts, but also the investigation of the transferability of UHV results to applied systems.

Structure of Amorphous Phosphorus from Machine Learning-Driven Simulations — •YUXING ZHOU, WILLIAM KIRKPATRICK, and VOLKER L. DERINGER — Department of Chemistry, Inorganic Chemistry Laboratory, University of Oxford Oxford OX1 3QR, UK

Amorphous phosphorus (a-P) has long attracted interest because of its complex atomic structure, and more recently as an anode material for batteries. However, accurately describing and understanding a-P at the atomistic level remains a challenge. In this talk, we show that a general-purpose Gaussian approximation potential (GAP) model for phosphorus can be created by machine learning (ML) from a suitably chosen ensemble of quantum-mechanical results. Its accuracy in describing the amorphous phase is demonstrated via large-scale moleculardynamics simulations on the atomic structure of a-P: the calculated structure factors yield good agreement with earlier experimental evidence. Abundant fivemembered rings are found in the structural model, which are the building block of more complex clusters. We provide new insights into the cluster fragments under pressure: an analysis of cluster fragments, large rings, and voids suggests that moderate pressure (up to about 5 GPa) does not break the connectivity of clusters, but higher pressure does. Changes in the simulated first sharp diffraction peak during compression and decompression indicate a hysteresis in the recovery of medium-range order. Our work provides a starting point for further computational studies of a-P, and more generally it exemplifies how ML-driven modeling can accelerate the understanding of disordered functional materials.

**Realistic Structural Properties of Amorphous SiNx from Machine-Learning-Driven Molecular Dynamics** — •GANESH KUMAR NAYAK¹, PRASHANTH SRINIVASAN², JURAJ TODT³, ROSTISLAV DANIEL¹, and DAVID HOLEC¹ — ¹Department of Materials Science, Montanuniversität Leoben, Leoben, Austria — ²Franz-Josef-Strasse 18 — ³Erich Schmid Institute of Materials Science of the Austrian Academy of Sciences, Jahnstrasse 12, Leoben, Austria

Machine-learning(ML)-based interatomic potentials can enable simulations of extended systems with an accuracy that is largely comparable to DFT, but with a computational cost, that is orders of magnitude lower. Molecular dynamics simulations further exhibit favorable linear (order N) scaling behavior.

Amorphous silicon nitride (a-SiNx) is a widely studied noncrystalline material, and yet the subtle details of its atomistic structure and mechanical properties are still unclear. Due to the small sizes of representative models, DFT cannot reliably predict its structural properties and hence left an anisotropic order parameter. Here, we show that accurate structural models of a-SiNx can be obtained using an ML-based inter-atomic potential. Our predictions of structural properties are validated by experimental values of mass density by X-ray reflectivity measurements and by radial distribution function measured by synchrotron Xray diffraction.

Our study demonstrates the broader impact of ML potentials for elucidating structures and properties of technologically important amorphous materials.

#### O 43.3 Wed 11:00 S054

Combined experimental-computational directed sampling approach to modelling amorphous alumina — •ANGELA HARPER¹, STEFFEN EMGE², PIETER MAGUSIN^{2,3}, CLARE GREY², and ANDREW MORRIS⁴ — ¹Cavendish Laboratory, University of Cambridg — ²Department of Chemistry, University of Cambridge

-  3 Institute for Life Sciences & Chemistry, Hogeschool Utrecht-  4 School of Metallurgy and Materials, University of Birmingham

Understanding the electronic and atomic level structure of materials is imperative for discovering the next generation of solid state electronic devices. Yet for amorphous materials, it is non-trivial to determine the exact local ordering. In this talk, I outline a method for modelling disordered materials, using experimentally directed sampling of static configurations from *ab initio* molecular dynamics¹. We calculate experimentally relevant spectra and properties including X-ray absorption edges, nuclear magnetic resonance chemical shieldings, and the electronic density of states, with first principles accuracy. This model is validated on amorphous alumina, a widely used coating material in electronic devices, and identify two distinct five-fold coordinated geometries of AlO₅, as well as localised states at the conduction band minimum. By leveraging both experimental and computational data in our approach we highlight the need for experimentally informed calculations which lead to a more detailed understanding of complex materials, and develop an approach that is widely applicable to the modelling community.

Structural phases and thermodynamics of BaTiO₃ from an integrated machine learning model — •LORENZO GIGLI¹, MAX VEIT¹, MICHELE KOTIUGA², GIOVANNI PIZZI², NICOLA MARZARI², and MICHELE CERIOTTI¹ — ¹Laboratory of Computational Science and Modeling (COSMO), Institute of Materials, École Polytechnique Fédérale de Lausanne, CH-1015 Lausanne, Switzerland — ²Theory and Simulation of Materials (THEOS) and National Centre for Computational Design and Discovery of Novel Materials (MARVEL), École Polytechnique Fédérale de Lausanne, Switzerland

Modeling the ferroelectric transition of any given material requires three key ingredients: (1) a model of the potential energy surface, that describes the energetic response to a structural distortion; (2) the free energy surface sampled at the relevant, finite-temperature conditions; and; (3) the polarization of individual configurations that determines the observed polarization and the phase transitions. To this aim, we make use of an integrated machine-learning framework, based on a combination of an interatomic potential and a microscopic polarization model, which we use to run Molecular Dynamics simulations of ferroelectrics with the same accuracy of the underlying DFT method, on time and length scales that are not accessible to direct ab-initio modeling. This allows us to uncover the microscopic nature of the ferroelectric transition in barium titanate (BaTiO₃) and to identify the presence of an order-disorder transition as the main driver of ferroelectricity. The framework also allows us to reconstruct the temperature-dependent BaTiO₃ phase diagram, with first-of-its-kind accuracy.

O 43.5 Wed 11:30 S054 Dielectric properties of BaTiO₃ from an integrated machine-learning model — •Max Veit¹, LORENZO GIGLI¹, MICHELE KOTIUGA², GIOVANNI PIZZI², NICOLA MARZARI², and MICHELE CEIROTTI¹ — ¹Laboratory for Computational Science and Modeling (COSMO), Ecole Polytechnique Fédérale de Lausanne, Lausanne, CH — ²Laboratory for Theory and Simulation of Materials (THEOS), Ecole Polytechnique Fédérale de Lausanne, Lausanne, CH

#### O 43.8 Wed 12:15 S054

Modeling the finite-temperature behavior of ferroelectric materials from first principles has always been challenging due to the large supercells and long simulation times required for adequate sampling. Here we demonstrate the use of an integrated machine learning (ML) model of the potential energy and polarization surfaces of barium titanate ( $BaTiO_3$ ) to overcome these difficulties and run long MD simulations with DFT accuracy. We use these simulations to compute the frequency-dependent dielectric response function, finding a spectrum qualitatively similar that obtained with previous effective-Hamiltonian simulations as well as to experimentally measured profiles, with some remaining discrepancies that we trace back to the underlying DFT model. Finally, we discuss possible extensions of the model to explicitly include long-range interactions, previously included only in an implicit, emergent manner. We expect this integrated, generally applicable modeling technique to become a valuable tool for elucidating the ferroelectric behavior of a wide variety of materials.

#### O 43.6 Wed 11:45 S054

The first-principles phase diagram of monolayer nanoconfined water — •VENKAT KAPIL¹, CHRISTOPH SCHRAN¹, ANDREA ZEN², JI CHEN³, CHRIS PICKARD¹, and ANGELOS MICHAELIDES¹ — ¹University of Cambridge, UK — ²Universitá di Napoli Federico II, Italy — ³Peking University, Beijing, China

Water in nanoscale cavities is ubiquitous and of central importance to everyday phenomena in geology and biology, and at the heart of current and future technologies in nano-science. A molecular-level picture of the structure and dynamics of nano-confined water is a prerequisite to understanding and controlling the behavior of water under confinement. Here we explore a monolayer of water confined within a graphene-like channel using a framework that combines developments in high-level electronic structure theory, machine learning, and statistical sampling. This approach enables a treatment of nano-confined water at unprecedented accuracy. We find that monolayer water exhibits surprisingly rich and diverse phase behavior that is highly sensitive to temperature and the van der Waals pressure acting within the nano-channel. Monolayer water exhibits numerous molecular ice phases with melting temperatures that vary by over 400 degrees in a non-monotonic manner with pressure. In addition, we predict two unexpected phases: a *hexatic-like* phase, which is an intermediate between a solid and a liquid, and a superionic phase with a high electrical conductivity exceeding that of battery materials. Our work suggests that nanoconfinement could be a promising route towards superionic behaviour at easily accessible conditions.

#### O 43.7 Wed 12:00 S054

Exploring amorphous graphene with empirical and machinelearned potentials — •ZAKARIYA EL-MACHACH1¹, MARK WILSON², and VOLKER L. DERINGER¹ — ¹Department of Chemistry, Inorganic Chemistry Laboratory, University of Oxford, Oxford OX1 3QR, UK — ²Department of Chemistry, Physical and Theoretical Chemistry Laboratory, University of Oxford, Oxford OX1 3QZ, UK

The structure of amorphous graphene (aG) lacks long range order whilst having short and medium range order yielding a rich and complex configurational space, which is yet to be fully understood. Here we report on an atomistic modelling study of aG using a machine learning (ML) based force field. ML force fields are typically "trained" on data from highly accurate but computationally costly density functional theory (DFT) computations. Atomistic models created by such ML methods can achieve near DFT accuracy at a fraction of the computational cost. One key assumption is that the global energy can be separated into sums of local energies. The physical interpretation of ML local energies is an interesting research question. We find that local and nearest neighbour (NN) ML energies can inform the generation of aG models from crystalline graphene via a Monte-Carlo bond switching algorithm. Bond switches are introduced as Stone-Wales defects, with the local energies of the defect pair and its NNs used in the acceptance criterion. Established empirical force fields are used in the same way and the resulting structures are studied. Our results provide insight into the modelling of amorphous graphene and into the nature of ML potential-energy models.

Machine learning for estimation of spin models in undoped cuprates — •DENYS Y. KONONENKO¹, ULRICH K. RÖSSLER¹, JEROEN VAN DEN BRINK^{1,2}, and OLEG JANSON¹ — ¹Institute for Theoretical Solid State Physics, IFW Dresden, Dresden, Germany — ²Institute for Theoretical Physics, TU Dresden, Dresden, Germany

Undoped cuprates tailor a fascinating variety of low-dimensional and frustrated spin models, which can be indirectly characterized by the transfer integrals. The estimation of transfer integrals is related to a relatively complicated computational procedure which includes besides DFT calculation also a Wannierization. We propose a data-driven approach to replace this computationally demanding procedure.

We employ the Gaussian Process Regression model, trained on the results of high-throughput DFT calculations to estimate transfer integrals in undoped cuprates. The model learns from data the dependency between the local crystal environment of copper atoms pair and the corresponding value of transfer integral. The site position function of the local crystal environment is represented as a finite-dimensional vector composed of decomposition coefficients in the truncated basis of Zernike 3D functions [1]. The vector descriptor incorporates the spatial configuration and chemical composition of the local crystal environment. The proposed approach can be utilized for a rapid assessment of the spin models of new cuprates using structural information as the only input.

Machine-learning Based Screening of Lead-free Perovskites for Photovoltaic Applications — •ELISABETTA LANDINI^{1,3}, HARALD OBERHOFER², and KARSTEN REUTER¹ — ¹Fritz-Haber-Institut der Max-Planck-Gesellschaft, Faradayweg 4-6, D-14195 Berlin, Germany — ²Chair for Theoretical Physics VII, Physikalisches Institut Universität Bayreuth, 95440, Bayreuth, Germany — ³Chair for Theoretical Chemistry, Technische Universität München, Lichtenbergstr. 4, D-85747 Garching, Germany

Lead-free halide double perovskites are promising stable and non-toxic alternatives to methylammonium lead iodide in the field of photovoltaics. In this context, the most commonly used double perovskite is  $Cs_2AgBiBr_6$ , due to its favorable charge transport properties [1]. However, the maximum power conversion efficiency obtained for this material does not exceed 3%, as a consequence of its wide indirect gap and its intrinsic and extrinsic defects [2]. On the other hand, the materials space that arises from the substitution of different elements in the 4 lattice sites of this structure is large and still mostly unexplored.

In this work a neural network is used to predict the band gap of double perovskites from an initial space of 7056 structures and select candidates suitable for visible light absorption. Successive hybrid DFT calculations are used to evaluate the thermodynamic stability and the power conversion efficiency of the selected compounds, and propose novel potential solar absorbers.

**Equivariant graph neural network for linear scaling electron density estimation and applications in battery materials** — •Arghya Bhowmik and Peter Jorgensen — 301 Anker Engelunds vej, Kgs. Lyngby, DK-2800

We present a machine learning framework for the prediction of  $\rho(\mathbf{r})$  based on equivariant graph message passing neural networks. The electron density is predicted at special query point vertices that are part of the message passing graph, but only receive messages. The model is tested across multiple data sets of molecules (QM9), liquid ethylene carbonate electrolyte (EC) and LixNiyMnzCo(1-y-z)O2 lithium ion battery cathodes (NMC). The model is used to explore large materials phase space for safer battery materials and uncovering new understanding how redox mediated diffusion occurs and battery materials.

# O 44: Focus Session: Surfaces and Interfaces of (Incipient) Ferroelectrics (joint session O/KFM)

Ferroelectricity is a property of materials that allows spontaneous, switchable electric polarization. Recently, many surface-related applications have been proposed where ferroelectric or incipient-ferroelectric materials exhibit superior properties. These include catalysis, electron-hole separation in light harvesting, unique electronic properties such as a negative capacitance in heterostructures of ferroelectric materials, to name just a few. While (incipient) ferroelectrics clearly perform well in the aforementioned applications, there is very limited fundamental understanding of the processes involved on the surfaces of these materials.

O 44.1 Wed 15:00 H3 In search of electrostatic happiness at surfaces — • NICOLA SPALDIN — Materials Theory, ETH Zurich

We review the concept of surface charge in ionic insulators, first, in the context of the polarization in ferroelectric materials (traditionally discussed in the ferroelectrics community) and, second, in the context of layers of charged ions (traditionally discussed in the surface science community). In both cases, the surface charge leads to an electrostatic instability if it is not compensated, which is usually detrimental for the development of electronic devices based on ferroelectrics, but favorable for applications such as catalysis where surface reactivity is desirable.

Using the prototypical multiferroic bismuth ferrite, BiFeO3, as an example, we show how the spontaneous ferroelectric polarization and the charged ionic layers can in fact combine to yield stable, uncharged "happy" (100) surface geometries. Switching the polarization causes these (100) surfaces considerable electrostatic distress, which must be compensated by the introduction of charged point defects or adsorbates. We demonstrate that the relative happiness or unhappiness of the surfaces enables a cycle of alternating charged then neutral adsorbates on polarization switching, which can be exploited for water remediation and water splitting.

We close with a proposal that these physics can induce polarization in thin films of certain usually non-polar materials, and give a recipe for determining likely candidates.

#### Synthesis and Characterisation of Ultra-thin Aurivillius Phase Multiferroics •LYNETTE KEENEY — Tyndall National Institute, University College Cork, Lee Maltings Complex, Dyke Parade, Cork, Ireland, T12 R5CP

Multiferroic materials, possessing simultaneous ferroelectric and ferromagnetic memory states, have been road-mapped as promising multi-state architectures for memory scaling beyond current technologies. In recent years, my team reported the design of such a novel room temperature multiferroic material with an Aurivillius phase structure that could ideally be suited to future fabrication of revolutionary memory devices. Electrostatic strain and elastic energy variations close to defect regions increase the extent of magnetic partitioning and also influence the formation of exotic charged domain walls and polar vortices. This further initiates technology prospects in ultra-compact data storage, energy-efficient neuromorphic computing and ultrahigh speed data processing. As miniaturisation of electronic devices continues, a crucial requirement is the enhancement of their functional properties at very small dimensions. In this presentation, I will discuss how direct liquid injection chemical vapour deposition allows for frontier-development of ultra-thin films at fundamental thickness. Via a two-dimensional layer-by-layer growth mode, films equating to half of one unit-cell (2.5 nm) of the Aurivillius structure are grown. The persistence of stable ferroelectricity, even when pushed to ultra-thin thicknesses, demonstrates the recent progress in the optimisation of Aurivillius phase materials for utilisation in future miniaturised multiferroic-based devices.

## O 44.3 Wed 16:00 H3

Influence of Nb dopants on the polarization and screening on cleaved SrTiO₃(001) surfaces — •IGOR SOKOLOVIĆ¹, ALEXANDER HOHENEDER¹, JEsus Redondo², Dominik Wrana², Michael Schmid¹, Ulrike Diebold¹, and MARTIN SETVÍN² — ¹Institute of Applied Physics, TU Wien, Vienna, Austria ²Faculty of Physics and Mathematics, Charles University, Prague, Czech Republic

The incipient ferroelectric SrTiO₃ can turn ferroelectric even at room temperature under the application of strain, and this quantum phase transition can be utilized to cleave SrTiO₃ single crystals that otherwise posses no preferable cleavage planes [1]. This cleaving procedure creates truly bulk-terminated SrTiO₃(001) surfaces that come the closest to being pristine [2]. In this talk, I will present how the SrO- and TiO2-terminated surface domains of opposite polarity can be influenced by the small changes in the amounts of Nb doping. The cleaved SrTiO₃(001) surfaces with varying Nb doping levels were systematically studied

with atomic resolution using noncontact atomic force microscopy (ncAFM) and scanning tunneling microscopy (STM). It was observed that Nb doping does not affect the magnitude of the strain-induced polarization, yet still significantly affects the morphology, the electronic structure, and the domain-wall structure on cleaved SrTiO₃(001) surfaces. Beside demonstrating the interplay between the domain distribution and electrostatic screening, these results show how the properties of these heterogeneous surfaces can be tuned.

[1] Sokolović et al., Phys. Rev. Mater. 3, 034407 (2019)

## O 44.4 Wed 16:15 H3

Polaronic Properties of the weakly-polar  $SrTiO_3(001)$  Surface — •FLORIAN ELLINGER¹, MICHELE RETICCIOLI¹, IGOR SOKOLOVIĆ², ULRIKE DIEBOLD², MARTIN SETVÍN³, and CESARE FRANCHINI^{1,4} — ¹University of Vienna — ²Technische Universität Wien — ³Charles University Prague — ⁴Università di Bologna

The SrTiO₃(001) surface shows ferroelectric-like distortions on the bulk-like termination, an out-of-plane dipole moment, and so-called "weak polarity". Recent experiments propose that these effects are compensated by Sr-adatoms and -vacancies, stabilizing the unreconstructed surface. [1]

We investigate the 1×1 SrTiO₃(001) surface with TiO₂- and SrO-terminations by means of density functional theory (DFT) simulations. Our calculations confirm the experimental interpretation and show that these polarity-compensating surface defects introduce additional charge. Adsorbing Sr-adatoms and doping with Nb leads to excess electrons in the crystal, facilitating the formation of electron-polarons. On the other hand, by creating Sr-vacancies on the surface we introduce excess holes to the system, which can localize as hole-polarons. For both kinds of polarons we analyze their general properties, e.g., the preferred localization site or stability. Further, we compare results of different structural phases of this crystal to achieve a comprehensive understanding of mentioned physical phenomena.

#### O 44.5 Wed 16:30 H3

Ferroelectric domain imaging in barium titanate using infrared-visible sumfrequency generation microscopy — • DOROTHEE MADER¹, DANIEL LOURENS², MAARTEN KWAAITAAL², RICHARDA NIEMANN¹, SÖREN WASSERROTH¹, SANDY Gewinner¹, Marco De Pas¹, Wieland Schöllkopf¹, Martin Wolf¹, Andrei Kirilyuk², Sebastian F. Maehrlein¹, and Alexander Paarmann¹ ¹Fritz Haber Institute of the Max Planck Society, Berlin, Germany — ²Radboud Universiteit, Nijmegen, The Netherlands

Phonons exhibit a mostly unexplored leverage on the mechanisms and dynamics of domain formation in ferroics. Here, a new method is employed combining resonant phonon excitation and ferroelectric domain imaging of barium titanate (BTO) using infrared-visible (IR-VIS) sum-frequency generation (SFG) microscopy [1]. BTO is a non-centrosymmetric perovskite oxide with a strong ferroelectric polarization in its tetragonal phase. Typically, BTO samples exhibit a multi-domain structure. In this contribution, SFG microscopy is shown to naturally provide domain contrast due to the polarization-induced local variation of the nonlinear susceptibility. Additionally, our spectral analysis of the SFG response reveals the domain-selective phonon resonances for all high-frequency phonons in the IR spectral range of 500-800 cm⁻¹. By locally mapping phonon resonances in domains and domain walls, this approach may enable in-depth understanding of the underlying physics of domain formation and its dynamics. [1] R. Niemann et al., Appl. Phys. Lett. 120, 131102 (2022).

Water-oxidation catalysis on surfaces of ferroelectrics - •ULRICH Aschauer¹, Nathalie Vonrüti¹, Zhenyun Lan², Didrik R. Småbråten¹, TEJS VEGGE², and IVANO E. CASTELLI² - ¹University of Bern, Bern, Switzerland - ²Technical University of Denmark, Kgs. Lyngby, Denmark

Surfaces of ferroelectrics have unique properties for catalysis since the binding strength of reaction intermediates can be modulated by switching the fer-

roelectric polarization. This could allow to overcome the limitations of the Sabatier principle and enable dynamical catalysts operation. In this talk, we will focus on the interplay between screening charge transfer to surfaces, the adsorbate coverage and the (photo)electrochemical water-oxidation activity of ferroelectric surfaces. We will compare different ferroelectric materials such as BaTiO₃, strained LaTiO₂N and the hexagonal improper ferroelectric oxynitride InSnO₂N. Our results indicate that ferroelectric switching can indeed provide an economically interesting route to enhance the catalytic activity but that material-specific intricacies of the surface adsorbate coverage need to be understood and controlled to exploit the full potential of ferroelectric switching in (photo)electrocatalysis.

#### O 44.7 Wed 17:15 H3

The polar KTaO₃ (001) surface: Electronic structure and CO adsorption – Zhichang Wang¹, Michele Reticcioli², Zdenek Jakub¹, Michael Schmid¹, Gareth Parkinson¹, Ulrike Diebold¹, Cesare Franchini², and •Martin Setvin³ – ¹TU Wien, Vienna, Austria – ²University of Vienna, Vienna, Austria —  3 Charles University, Prague, Czech Republic

Polar surfaces offer intriguing physical and chemical properties applicable in electronics or catalysis. Cleaving the KTaO₃ perovskite along its polar (001) plane provides a well-defined, bulk-terminated surface with KO and TaO₂ terminations [1]. As-cleaved surfaces exhibit a high concentration of in-gap states; these electrons predominantly reside at the TaO2-terminated parts of the surface. These electrons can affect surface chemistry, as is demonstrated for CO molecules. CO has two adsorption configurations on the TaO₂ termination, and the CO differs in how it couples to the excess electrons. DFT calculations indicate that CO preferentially couples to electron bipolarons.

The work was supported by FWF project P32148-N36, by GACR 20-21727X and GAUK Primus/20/SCI/009.

Polarons and ferroelectricity: tip-induced phenomena on oxide perovskite surfaces — •Dominik Wrana¹, Igor Sokolović², Jesus Redondo¹, Pavel Kocán¹, Aji Alexander¹, Llorenç Albons¹, and Martin Setvin¹ -¹Department of Surface and Plasma Science, Charles University, Prague, Czech Republic — ²Institute of Applied Physics, TU Wien, Vienna, Austria

In this talk, I will present the similarities and differences between two representative perovskite oxide surfaces: KTaO₃(001) and BaTiO₃(001), showcasing the manifestation of the (incipient-) ferroelectricity on the atomic and electronic structure. Both surfaces were prepared by cleaving single crystals in situ and characterized by means of qPlus nc-AFM at temperatures ranging from 4K to 100K.

Bulk-terminated KTaO₃(001) develops two alternating domains of KO and TaO₂ [1]. Excess electrons injected from the AFM tip form quasiparticles called polarons (charges coupled with lattice distortions) which can be further shaped into 1D or 2D structures by emerging electric fields.

Different mechanism applies in the case of BaTiO₃(001), where at low temperatures titanium atoms can easily break the symmetry causing a spontaneous

polarization. Hence, a biased tip allows for reversible manipulation of individual atoms on the surface: writing and erasing polarized ferroelectric domains. [1] Setvin, Martin, et al. Science 359.6375 (2018): 572-575

O 44.9 Wed 17:45 H3

Optimisation and miniaturisation of naturally-layered multiferroic thin films — •LYNETTE KEENEY — Tyndall National Institute, University College Cork, Lee Maltings Complex, Dyke Parade, Cork, Ireland, T12 R5CP

Multiferroic materials, possessing simultaneous ferroelectric and ferromagnetic memory states, are road-mapped as promising multistate architectures for memory scaling beyond current technologies. In recent years, my team reported the design of such a novel room temperature multiferroic material with an Aurivillius phase structure that could ideally be suited to future fabrication of revolutionary memory devices. In this presentation, I will discuss how electrostatic strain and elastic energy variations close to bismuth oxide interfaces and defect regions are key to promoting magnetic cation partitioning and multiferroic behaviour. These also influence the formation of exotic charged domain walls and polar vortices, further initiating technology prospects in ultracompact data storage. As miniaturisation of electronic devices continues, a crucial requirement is the enhancement of their functional properties at very small dimensions. Direct liquid injection chemical vapour deposition allows for frontier-development of ultra-thin films at fundamental thickness. Via a twodimensional layer-by-layer growth mode, films equating to half of one unit-cell (2.5 nm) of the Aurivillius structure are grown. #### **Topical Talk**

O 45.1 Wed 15:00 H4 Addressing Electronic Effects in Catalysis by Intermetallic Compounds -•MARC ARMBRÜSTER — Chemnitz University of Technology

The catalytic properties of materials are determined by their electronic and geometric structure. A reliable development addresses both influences separately and then combines the ideal electronic and structural properties resulting in superior catalytic materials.

Unfortunately, this is only straightforward on paper. The implementation faces hurdles concerning the control of the materials. E.g. the electronic modification of metallic materials by addition of a second metal with a different electron count can result in substitutional alloys with (in theory) random distribution of

the elements. However, the sought-for electronic modification is not reachable due to segregation. Another intrinsic challenge is the geometric and electronic entanglement, i.e. when substituting one element by another, the structure might change and with it, the electronic properties.

Location: H4

A new approach is the partial substitution of main group elements in isostructural intermetallic compounds, enabling excellent electronic control with minimal geometric variation. Taking InPd2 and substituting In by Sn alters the valence electron count, while the distances are mostly not affected. Tuning the In/Sn ratio allows to address the electronic influence with very high resolution. Results in gas-phase hydrogenation and electrocatalysis are presented as examples of the broadly applicable approach.

# O 45.2 Wed 15:30 H4

Gallium droplets on nanostructured surfaces as matrix material for supported liquid metal solutions — •ANDRÉ HOFER, NICOLA TACCARDI, PETER WASSERSCHEID, and JULIEN BACHMANN — FAU Erlangen, Germany

A large variety of organic compounds are produced industrially using a dehydrogenation reaction which removes H₂ from a molecule and hence converts it into a more reactive and valuable product. Usually, such a reaction is endothermic and needs to be catalysed or performed at elevated temperatures. Our approach for improving the availability of the catalyst is the utilization of supported catalytically active liquid metal solutions (SCALMS). Here, the catalytically active material is dissolved in a dynamic liquid matrix, protecting it from undesired deactivation. Ga is used in our approach as the matrix material due to its outstanding properties. So far, SCALMS catalysis has been performed with very limited control of particle sizes. Here, we present a model system to determine the fundamental kinetic parameters of SCALMS reactions. We fabricate highly ordered, nanostructured substrates by electrochemical anodization of Al, generating indentations in a hexagonal arrangement with a tunable diameter. These substrates are coated with acidic or alkaline metal oxides by ALD to affect the surface tension and wetting behaviour of the Ga droplets. Subsequently, a Ga complex is spin-coated from organic solution on the surfaces and the elementary Ga droplets are obtained upon thermal treatment. Parameters relevant to SCALMS application of the surface fabricated are investigated systematically as they depend on the preparative parameters.

#### O 45.3 Wed 15:45 H4

**Extending the SCALMS catalytic concept to ternary systems** — •MICHAEL MORITZ¹, SVEN MAISEL¹, NARAYANAN RAMAN², HAIKO WITTKÄMPER¹, CHRISTOPH WICHMANN¹, NICOLA TACCARDI², PETER WASSERSCHEID², ANDREAS GÖRLING¹, HANS-PETER STEINRÜCK¹, and CHRISTIAN PAPP¹ — ¹Friedrich-Alexander-Universität Erlangen-Nürnberg, Department Chemie und Pharmazie, Egerlandstraße 3, 91058 Erlangen, Germany — ²Friedrich-Alexander-Universität Erlangen-Nürnberg, Department Chemie und Bioingenieurwesen, Egerlandstraße 3, 91058 Erlangen, Germany

Over the last few years, supported catalytically active liquid metal solutions (SCALMS) were shown to be remarkably efficient catalysts for alkane dehydrogenation. The active phase of these catalysts consists of a liquid metal matrix, in which catalytically active transition metals are dissolved. So far, only Gallium was used as a liquid matrix material, because of the low toxicity and low melting point. Since extensive research has already been made on Gallium-based SCALMS systems with different catalytically active transition metals, varying the matrix material is the logical next step to further improve the catalyst performance. These efforts are now extended to ternary systems such as GaInPt and GaSnPt. This extension opens up new questions as it increases the complexity, but also brings exciting new properties and insights into the dynamics of liquid SCALMS catalysts. In this talk, the most recent results regarding these ternary systems will be presented, with an emphasis on photoemission studies. Funded by SFB 1452.

Investigation of Pt-Ga SCALMS model particles using photoelectron spectroscopy — •Christoph Wichmann¹, Haiko Wittkämper¹, Micheal Moritz¹, Tzung-En Hsieh², Johannes Frisch², Mingjian Wu³, Marcus Bär², Erdmann Spiecker³, Hans-Peter Steinrück¹, and Christian Papp¹ — ¹Universität Erlangen, Physikalische Chemie II, Germany — ²Helmholtz-Zentrum Berlin, Germany — ³Universität Erlangen, Lehrstuhl für Werkstoffwissenschaften, Germany

Supported catalytically active liquid metal solutions (SCALMS) recently gained much attention as highly active and stable catalysts for the dehydrogenation of alkanes. SCALMS are metal solutions composed of low amounts of catalytically active transition metals like Rh, Pd, or Pt, alloyed with low melting metals like Ga, which act as matrix. Their stability is attested to a notable resistance against deactivation by coking, which is the prevalent deactivation route for dehydrogenation catalysts. To obtain a fundamental understanding, we make these complex materials systems accessible for a surface science approach. To gain insight in the catalytic properties of such nano-solutions, we work with supported PtGa particle systems. Herein, supported PtGa particle systems with low Pt content were investigated. The influence of the deposition sequence, the effects of annealing, and exposure to oxygen on the alloying and morphology of the resulting particle were studied with XPS using different excitation energies to obtain a depth-profile of the first few layers of the liquid.

Funded by SFB 1452.

# Topical TalkO 45.5Wed 16:15H4Understanding liquid metal catalysts for graphene synthesis using machinelearning interatomic potentials•HENDRIKH. HEENENFritz-Haber-Institut der MPG, Berlin, Germany

High-quality, near defect-free graphene can be synthesized on the levelled and uniform surfaces of liquid metal catalysts. This smoothness on the microscale is sometimes accompanied by seemingly different catalytic properties, the determination of which is, however, ambiguous. Assessing distinct catalytic properties of liquid metal catalysts by first principles atomistic simulations has so far been challenged due to the intractable long length and time scales necessary to model the liquid phase. Using computationally efficient machine learning interatomic potentials (MLIPs) trained to first principles data allows to extrapolate predictability to necessary scales and opens an avenue for obtaining the desired microscopic insight.

In this talk I will present strategies to train and employ MLIPs for the simulation of graphene synthesis on liquid metal catalysts. I will introduce the dataefficient training of MLIPs via fairly automatic workflows as a tool to extend the predictive accuracy of e.g. density functional theory to larger scales. On basis of these potentials, large-scale simulations can be performed to compute experimental observables and elucidate microscopic processes relevant to graphene synthesis. Further, one can identify trends between different metals and directly compare between the solid and liquid states of a catalyst. Findings based on these simulation approaches shed new light on the role of the liquid state of liquid metal catalysts.

Ionic liquids and deep eutectic solvents - sustainable media for selective molecular recognition and adsorption — •JAN BLASIUS, LEONARD DICK, and BARBARA KIRCHNER — Mulliken Center for Theoretical Chemistry, University of Bonn, Beringstrasse 4+6, D-53115 Bonn, Germany

The effective reduction of CO2 emission and chemical waste production are key disciplines on our way towards a more sustainable future. Ionic liquids (ILs) and deep eutectic solvents (DESs) offer new opportunities for addressing these challenges, as their properties can be adjusted in order to fulfill specific purposes. To efficiently optimize their usage for various applications, it is vital to understand the underlying molecular behavior and inherent structuring inside these liquids. Using state-of-the-art theoretical methods, we shed light on molecular adsorption and recognition mechanisms in ILs and DESs. This enables us to determine the reasons for specific capacities and allows a theoretical design of solvents with precisely tuned geometric, energetic and kinetic parameters in order to enhance the processes of interest. In this presentation, we will highlight our most recent research concerning molecular recognition and adsorption in ILs and DESs which can support the development of novel chemical processes that pave our way towards a more sustainable future.

Surfaces of ionic liquids studied by ARXPS and UHV Pendant Drop -•ULRIKE PAAP, FLORIAN MAIER, and HANS-PETER STEINRÜCK — Chair of Physical Chemistry II, FAU Erlangen-Nürnberg, Egerlandstr. 3, Erlangen, Germany Ionic liquids (ILs) are characterized by a low melting point, low vapor pressure and low surface tension. Many ILs exhibit high gas solubility along a high chemical and thermal stability. Such properties are beneficial in many areas such as gas absorbents, refrigerants, lubricants, antistatics and surfactants. In this work, we studied various imidazolium-based ILs with different functional PEG chains attached to the cation using angle-resolved X-ray photoelectron spectroscopy (ARXPS) and a new pendant drop setup, which enables to measure the surface tension also in ultrahigh vacuum (UHV). With ARXPS, we determine the surface composition of the topmost IL nanometers on the molecular level. We combine these results with our surface tensions studies in UHV and atmosphere. Our results allow for a deeper understanding of enrichment and molecular orientation processes at the outermost surface of these systems in a microscopic and macroscopic range.

This work was supported by the European Research Council (ERC) through an Advanced Investigator Grant (ILID 693398) to HPS and the Collaborative Research Center (CRC) 1452: Catalysis at Liquid Interfaces.

Mixed Films of protic and non-protic Ionic Liquids on Metal Surfaces – onsurface metathesis on Ag(111) — •STEPHEN MASSICOT¹, TOMOYA SASAKI², MATTHIAS LEXOX¹, SUNGHWAN SHIN¹, FLORIAN MAIER¹, SUSUMU KUWABATA², and HANS-PETER STEINRÜCK¹ — ¹Lehrstuhl für Physikalische Chemie 2, Friedrich-Alexander-Universität Erlangen-Nürnberg — ²Department of Applied Chemistry, Graduate School of Engineering, Osaka University

Ionic liquids (ILs) are salts that are composed of poorly coordinating ions and thus exhibit melting points typically well below 100°C. Thin films of ILs are of utmost interest in many applications such as in catalysis and electrochemistry. In this context, we investigate mixed ultrathin films of the protic IL diethylmethylammonium trifluoromethanesulfonate ([dema][TfO]) and the aprotic IL 1-methyl-3-octylimidazolium hexafluorophosphate ([C₈C₁Im][PF₆]) on a Ag(111) surface. The films are prepared by *in situ* physical vapor deposition in UHV. The molecular composition of the IL/solid and IL/vacuum interfaces is studied by angle-resolved and temperature-programmed X-ray photoelectron spectroscopy. We observe thermally induced phenomena of ion exchange and preferential enrichment at these interfaces. Furthermore, ions desorb selectively which leads to the on-surface formation of a new IL by metathesis at the IL/metal interface.

Supported through an ERC Advanced Investigator Grant (ILID 693398) to HPS and by the DFG through SFB 1452.

# O 45.9 Wed 17:45 H4

SCILL model catalysis - butadiene hydrogenation studied with molecular beam techniques — •LEONHARD WINTER, STEPHEN MASSICOT, AFRA GEZMIS, FLORIAN MAIER, and HANS-PETER STEINRÜCK - Lehrstuhl für Physikalische Chemie II, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Egerlandstr. 3, 91058 Erlangen

Ionic Liquids (ILs) are low temperature melting salts, often liquid even below room temperature. In "Solid Catalyst with Ionic Liquid Layer (SCILL)" systems, IL thin films are used to coat the catalytically active metal and therefore, modify the reactivity and the selectivity of the catalyst. Selectivity is crucial e.g., in the

Atomistic and coarse-grained modelling of liquid-liquid and liquid-gas interfaces — •JAKOB FILSER^{1,2}, KARSTEN REUTER^{1,2}, and HARALD OBERHOFER^{1,3} ¹Chair of Theoretical Chemistry, TU Munich — ²Theory Department, Fritz Haber Institute Berlin — ³Chair for Theoretical Physics VII, University of Bayreuth

Modelling of dielectric interfaces remains a central challenge in computational chemistry. Liquid-liquid and liquid-gas interfaces have so far received relatively little attention, compared to solid surfaces. We present a new method to incorporate solvation effects into density-functional theory calculations of large organic adsorbates at liquid-liquid and liquid-gas interfaces. Simulating a large number of solvent molecules explicitly at this first-principles level is not computationally tractable. We therefore resort to an implicit solvation approach, treating the solvent as a structureless dielectric medium. Specifically, we advance the multipole-expansion method, in which we model the interface as the boundary of two semi-infinite media with different permittivity. Additionally, we introduce a piecewise expansion of the dielectric response. While the previous version of the MPE method could solve the electrostatic problem only for small solute molecules up to  $\approx 10$  non-hydrogen atoms, this development now allows us to simulate larger solutes with an overall non-convex hull, with electrostatic interaction energies converged up to few meV. Validating first results of our model for octanoid acid at a water-gas interface by explicit force-field level molecular dynamics simulation provides insight into the role of the atomistic structure of the solvent in the adsorption.

#### O 46.2 Wed 15:15 H6

Quantum feedback at the solid-liquid interface: flow-induced electronic current and negative friction — •BAPTISTE COQUINOT^{1,2}, LYDÉRIC BOCQUET¹, and NIKITA KAVOKINE² - ¹Laboratoire de Physique de l'École Normale Supérieure, ENS, Université PSL, CNRS, Paris, France — ²Center for Computational Quantum Physics, Flatiron Institute, New York, NY 10010, USA

An electronic current driven through a conductor can induce a current in another conductor through the famous Coulomb drag effect. Similar phenomena have been reported at the interface between a moving fluid and a conductor, but their interpretation has remained elusive. Here, we develop a quantummechanical theory of the intertwined fluid and electronic flows, taking advantage of the non-equilibrium Keldysh framework. We predict that a globally neutral liquid can generate an electronic current in the solid wall along which it flows. This hydrodynamic Coulomb drag originates from both direct Coulomb interactions and interactions mediated by the solid's phonons. We derive explicitly the Coulomb drag current in terms of the solid's electronic and phononic properties, as well as the liquid's dielectric response, a result which quantitatively agrees with recent experiments at the liquid-graphene interface. Furthermore, we show that the current generation counteracts momentum transfer from the liquid to the solid, leading to a reduction of the hydrodynamic friction coefficient through a quantum feedback mechanism. Our results provide a roadmap for controlling nanoscale liquid flows at the quantum level, and suggest strategies for designing materials with low hydrodynamic friction.

#### O 46.3 Wed 15:30 H6

A fully periodic treatment of the chemisorption function for the analysis of adsorbate-substrate interactions — •SIMIAM GHAN¹, KARSTEN REUTER¹, and HARALD OBERHOFER² — ¹Fritz-Haber-Institut der MPG, Berlin, Germany. — ²University of Bayreuth, Bayreuth, Germany

We discuss the extension of our improved Projection-Operator Diabatization scheme POD2GS[1] to the study of electronic coupling on surfaces within periodic density-functional theory (DFT) simulations. Using POD2GS, we calculate diabatic electronic couplings  $H_{ab}$  between adsorbate and surface bands throughout k-space. It becomes thus possible to directly calculate the chemisorption function of Newns and Anderson[2], a weighted density of states which appears often in the theoretical description of surface interactions.

industrially important hydrogenation of 1,3-butadiene to butenes since further hydrogenation to *n*-butane must be suppressed.

We used a supersonic molecular beam to investigate the dynamical details of this reaction in a UHV model study. The method of King and Wells was used to measure sticking coefficients of 1,3-butadiene and 1-butene on bare Pt(111) and Pt(111) coated with ultrathin layers of the IL 1,3-dimethylimidazolium bis[(trifluoromethyl)sulfonyl]imide ([C1C1Im][Tf2N]). The hydrogenation reaction was also modelled by pre-adsorbing and co-feeding hydrogen gas.

Supported by the DFG through the Collaborative Research Center (CRC)/ Sonderforschungsbereich (SFB) 1452.

Location: H6

Interpreting the chemisorption function within the Fermi Golden Rule yields ultrafast (spin)electron transfer lifetimes directly comparable to experiment, as we demonstrate for the case of core-excited Argon monolayers on ferromagnetic substrates Fe(110), Co(0001) and Ni(111)[3]. Our scheme reveals the importance of sampling the Brillouin zone to gain accurate and convergent electron transfer rates, and offers an array of further applications.

A Revised Fourth-Generation Neural Network Potential for the Accurate Representation of Multiple Charge States — •ALEXANDER KNOLL, TSZ WAI Ko, and Jörg Behler - Georg-August-Universität Göttingen, Institut für Physikalische Chemie, Theoretische Chemie, Göttingen, Germany

Machine learning potentials (MLPs) have become a mature tool for large-scale atomistic simulations in chemistry and materials science. Recently, a fourthgeneration high-dimensional neural network potential (4G-HDNNP) has been introduced, in which the atomic charges are determined in a charge equilibration step enabling the description of long-range charge transfer. The quality of the charge prediction depends on environment-dependent electronegativities expressed by atomic neural networks, which poses a challenge for structures with differing total charges but nearly-identical nuclear positions. Here, we propose a generalized method applicable to these situations, and for a series of model systems we demonstrate that this extension leads to additional flexibility of the atomic electronegativities, ultimately resulting in more accurate atomic charges, energies, and forces.

O 46.5 Wed 16:00 H6

Machine learning potentials for complex aqueous systems made simple -•CHRISTOPH SCHRAN¹, FABIAN L. THIEMANN^{1,2}, PATRICK ROWE¹, ERICH A. MÜLLER², ONDREJ MARSALEK³, and ANGELOS MICHAELIDES¹ — ¹University of Cambridge, UK — ²Imperial College London, UK — ³Charles University, Czech Republic

Simulation techniques based on accurate and efficient representations of potential energy surfaces are urgently needed for the understanding of complex systems such as solid-liquid interfaces. Here we present a machine learning framework that enables the efficient development and validation of models for complex aqueous systems. Instead of trying to deliver a globally optimal machine learning potential, we propose to develop models applicable to specific thermodynamic state points in a simple and user-friendly process. After an initial ab initio simulation, a machine learning potential is constructed with minimum human effort through a data-driven active learning protocol. Such models can afterward be applied in exhaustive simulations to provide reliable answers for the scientific question at hand or to systematically explore the thermal performance of ab initio methods. We showcase this methodology on a diverse set of aqueous systems. Highlighting the accuracy of our approach with respect to the underlying ab initio reference, the resulting models are evaluated in detail with an automated validation protocol that includes structural and dynamical properties and the precision of the force prediction of the models. Finally, we demonstrate the capabilities of our approach for providing insight into the solid-liquid interface for various systems.

O 46.6 Wed 16:15 H6 Quantifying the breakdown of electronic friction theory during molecular scattering of NO from Au(111) — •CONNOR L. Box¹, YAOLONG ZHANG², RON-GRONG YIN², BIN JIANG², and REINHARD J. MAURER¹ — ¹Department of Chem-istry, University of Warwick, United Kingdom — ²Department of Chemical Physics, University of Science and Technology of China, Hefei, China

The Born-Oppenheimer approximation fails to capture the extent of multiquantum vibrational energy loss recorded during molecular scattering from metallic surfaces.[1] NO scattering on Au(111) has been one of the most studied examples in this regard, providing a testing ground for developing various nonadiabatic theories. The exact failings compared to experiment and their origin from theory are not established for any system, particularly since dynamic properties are affected by many compounding simulation errors, of which the quality of nonadiabatic treatment is just one. We use a high-dimensional machine learning representation of the energy and the electronic friction tensor to minimize errors that arise from quantum chemistry.[1,2] This allows us to perform a comprehensive quantitative analysis of the performance of molecular dynamics with electronic friction in describing state-to-state scattering. We find that electronic friction theory accurately predicts elastic and single-quantum energy loss, but underestimates multi-quantum energy loss and overestimates molecular trapping at high vibrational excitation. Our analysis reveals potential remedies to these issues. [1] C. L. Box & Y. Zhang et al, JACS Au, 2020 [2] R. Yin et al, J. Phys. Chem. Lett, 2019

O 46.7 Wed 16:30 H6

Accurate computation of chemical contrast in field ion microscopy — •SHALINI BHATT — Max Planck Institut für Eisenforschung GmbH Düsseldorf Germany

Field ion microscopy (FIM) was the first microscopy technique to image individual atoms on a metal surface with near atomic spatial resolution. In short an imaging gas (e.g. He, Ne) is ionized above a surface subject of a few field  $10^{10}$  V/m. The imaging contrast is dominated by the ionization probability at 5-10 Å above the surface. To simulate this within density-functional theory (DFT), we adapt the Tersoff-Hamann theory known from scanning tunneling microscopy (STM).

The gigantic electric field leads to very fast decay of wavefunctions into the vacuum. At the ionization height, they run into a regime that is dominated by numerical noise. To address this noise challenge inherent to any global-scale Kohn-Sham solver employed in DFT codes, wavefunction tails must be recom-

puted. To solve 3D Schrödinger equation at local scale we develop the extrapolated tail via reverse algorithm (EXTRA). The decaying tails are obtained by reverse integration (from outside in) using a Numerov-like algorithm. The starting conditions are then iteratively adapted to match the values of planewave DFT wavefunctions close to the surface. We demonstrate chemical contrast for Ta and W at Ni surface using this new technique.

O 46.8 Wed 16:45 H6

Designing Covalent Organic Frameworks Through Active Machine Learning – •YUXUAN YAO^{1,2}, CHRISTIAN KUNKEL³, KARSTEN REUTER³, and HAR-ALD OBERHOFER² - ¹Chair for Theoretical Chemistry and Catalysis Research Center, Technical University Munich — ²Fritz-Haber-Institut der Max-Planck-Gesellschaft —  3 Chair for Theoretical Physics VII, University of Bayreuth Covalent organic frameworks(COFs) are a class of materials with potential applications in many fields such as catalysis, sensing, or optoelectronics. It is well known that their design space is far too large to sample one by one. Focusing on their electronic properties, we modify an earlier active machine learning(AML) approach that explores the molecular design through the use of surrogate models for charge injection and transport descriptors. In this method, the Gaussian Process Regression(GPR) and AML are combined to train the molecular space. This way we ensure that only promising molecules or candidates that are very different from already explored ones have their descriptors evaluated on a comparatively expensive quantum mechanical level. Specifically, we modify molecular generation rules in order to produce three-fold rotational symmetric candidates molecules for use in COFs. In the future this approach can be generalized for any other symmetries, to potentially even allow for 3-dimensional network generation. The generation of a candidate space with well defined symmetries together with AML ensures a high efficiency in the detection of promising COFs with superior charge conduction properties and demonstrates the utility of this approach.

# O 47: Focus Session: Atomic-Scale Studies of Spins on Surfaces with Scanning Tunneling Microscopy 1

Magnetic single atoms and molecules are intensively studied as the smallest building blocks for potential applications in spintronic devices and quantum information processing. Detecting and controlling single spin states and their spin interactions require both high energy resolutions and atomic scale imaging capability. Scanning tunneling microscopes provide not only the spatial resolutions but also the bottom up approach to build magnetic structures atom by atom. Recently, unprecedented spin sensitivities have been reached by functionalizing the STM tips or by combining STM with electron spin resonance. The goal of this symposium is to highlight the recent developments in the rapidly evolving field of atomic scale sensing and quantum control of spins on surfaces. Researchers that use STM to investigate atomic or molecular spins on surfaces will present their most recent results. Sharing technical advances and addressing current issues will create synergies to foster future progress in this field and a deeper understanding of the underlying physics.

Organizer: Andreas Heinrich (Center for Quantum Nanoscience, Seoul, Republic of Korea)

Quantum control of multi-spin architectures on a surface — •YUJEONG BAE — Center for Quantum Nanoscience (QNS), Institute for Basic Science (IBS), 03760 Seoul, South Korea — Department of Physics, Ewha Womans University, Seoul 03760, South Korea

The spin-polarized scanning tunneling microscopy (STM) combined with electron spin resonance (ESR) [1] enables us to achieve single spin sensitivity with atomic precision. Employing ESR-STM, a single spin on a surface can be coherently probed and controlled [1,2], where the magnetic tip is positioned directly on the target spin. Here, we demonstrate a new approach to coherently control multi-electron spins in a quantum spin architecture crafted atom-by-atom. We found the remote spins, which are outside the tunnel junction, can be controlled by the local oscillating magnetic fields created by a single-atom magnet placed next to them in oscillating electric fields. The read-out of multi-electron spins is achieved by a sensor atom weakly coupled to them. The resonances of the sensor spin are separated in the frequency domain so that we can independently and simultaneously control the sensor and remote spins. Our work shows the enhanced coherent properties of the remote spins as well as fast controlled operations of multi-electrons in an all-electrical fashion. Our development widens the approaches to the multi-spin control in tailored spin structures on a surface.

O 47.2 Wed 15:30 S051 Longitudinal and transverse electron paramagnetic resonance in a scanning tunneling microscope — •Tom S. Seifert¹, Stepan Kovarik², Pietro Gambardella², and Sebastian Stepanow² — ¹FU Berlin — ²ETH Zürich Combining scanning tunneling microscopy (STM) with electron-paramagnetic resonance (EPR) allows for sensitive probing magnetic interactions at atomic scales [1]. However, the experimental requirements for driving the EPR transitions are not obvious [2,3]. In-depth understanding of what drives EPR-STM is mandatory to explore novel material systems with high sensitivity. Here, we acquire and model EPR spectra of single Fe and hydrogenated Ti atoms on bilayer MgO on Ag using a radio frequency (RF) antenna close to the STM junction [4]. We investigate in a systematic way the impact of RF excitation strength and tunneling parameters on the EPR signal and find strong evidence for a piezoelectric coupling mechanism [5]. Specifically, transverse magnetic field gradients drive the spin-1/2 hydrogenated Ti, whereas longitudinal magnetic field gradients drive the spin-2 Fe. Finally, we demonstrate how the choice of specific tipsample distances allows one to minimize the impact of tip magnetic fields on the EPR-STM measurements thereby excluding a major experimental uncertainty when determining single-atom magnetic moments [6].

**Experimental Determination of a Single Atom Ground State Orbital through Hyperfine Anisotropy** — •LAËTITIA FARINACCI¹, LUKAS M. VELDMAN¹, PHILIP WILLKE², and SANDER OTTE¹ — ¹Delft University of Technology, Delft, The Netherlands — ²Karlsruhe Institute of Technology, Karlsruhe, Germany Electron spin resonance has long been a powerful tool for electronic analysis. Its

recent combination with scanning tunneling microscopy [1] gives exceptional energy resolution for the investigation of the magnetism of single atoms in addition to a very good characterization of their spatial surroundings.

Here, we provide a full angle-dependent investigation of the anisotropy of the hyperfine splitting of single Ti atoms on MgO/Ag(100). We find that the anisotropy of the hyperfine splitting is related to that of the g factor: spin-orbit coupling leads to a partially unquenched angular momentum which couples to the electron spin and thereby affects its interaction both with an external magnetic field and the nuclear spin of the nucleus. Combining the symmetry properties of the atoms binding site with a simple point charge model, we provide a method to predict the shape of the ground state orbital of the Ti atom. Relying on experimental values only, this analysis paves the way for a new protocol for electronic structure analysis for spin centers on surfaces.

#### O 47.4 Wed 16:00 S051

Anisotropic hyperfine interaction of surface-adsorbed single atoms — •JINKYUNG KIM^{1,2}, KYUNGJU NOH^{1,2}, YI CHEN^{1,3}, CHRISTOPH WOLF^{1,3}, AN-DREAS HEINRICH^{1,2}, and YUJEONG BAE^{1,2} — ¹Center for Quantum Nanoscience (QNS), Institute for Basic Science (IBS), Seoul 03760, South Korea — ²Department of Physics, Ewha Womans University, Seoul 03760, South Korea — ³Ewha Womans University, Seoul 03760, Republic of Korea

Hyperfine interactions between electron and nuclear spins provide sensitive probes to the chemical environment of atoms, molecules, and crystal defects as well as an alternative way to control the nuclear spins. While a variety of experimental techniques have been applied to the detection and control of single nuclear spins in various environments, simultaneous investigations of the single nuclear spin*s resonance and the atomic scale imaging are more demanding. Using the electron spin resonance (ESR) technique in a scanning tunneling microscope (STM), we investigated hyperfine interaction of hydrogenated titanium (Ti) on MgO/Ag(100) and its local environment at the atomic scale. By means of atom manipulation in vector magnetic fields, we identified the hyperfine interaction of Ti along three principal axes, which shows a large anisotropy of hyperfine interaction reflects the anisotropic orbital configuration of the electronic ground state, which is further supported by the density functional theory calculations.

#### O 47.5 Wed 16:15 S051

**Electron Paramagnetic Resonance of individual Alkali Metal Atoms and Dimers on Ultrathin MgO** — •STEPAN KOVARIK¹, ROBERTO ROBLES², RICHARD SCHLITZ¹, TOM SEBASTIAN SEIFERT^{1,3}, NICOLAS LORENTE^{2,4}, PIETRO GAMBARDELLA¹, and SEBASTIAN STEPANOW¹ — ¹Department of Materials, ETH Zurich, Switzerland — ²Centro de Física de Materiales, San Sebastian, Spain — ³Department of Physics, FU Berlin, Germany — ⁴Donostia International Physics Center, San Sebastian, Spain

Electron paramagnetic resonance (EPR) provides unique insight into the chemical structure and magnetic properties of dopants in oxide and semiconducting materials that are of interest for applications in electronics, catalysis, and quantum sensing. We demonstrate that EPR in combination with scanning tunneling microscopy (STM) [1, 2] allows for probing the spin and charge state of alkali metal atoms on an ultrathin magnesium oxide layer on a Ag(100) substrate. We identify a magnetic moment of 1  $\mu_B$  for Li₂, LiNa, and Na₂ dimers corresponding to spin radicals with a charge state of +1e [3]. Individual alkali atoms have the same charge state and no magnetic moment. The ionization of the adsorbates is attributed to the charge transfer of one electron through the oxide to the metal substrate. Our work highlights the potential of EPR-STM to provide insight into dopant atoms, which are relevant for the control of the electrical properties of surfaces and represent a suitable platform for studying quantum nanomagnets.

#### **Topical Talk**

O 47.6 Wed 16:30 S051

Free coherent evolution of a coupled atomic spin system initialized by electron scattering — •SANDER OTTE¹, LUKAS VELDMAN¹, LAETITIA FARINACCI¹, RASA REJALI¹, RIK BROEKHOVEN¹, JEREMIE GOBEIL¹, DAVID COFFEY¹, and MARKUS TERNES^{2,3} — ¹Delft University of Technology, Delft, The Netherlands — ²RWTH Aachen University, Aachen, Germany — ³Forschungszentrum Jülich, Jülich, Germany

Full insight into the dynamics of a coupled quantum system depends on the ability to follow the effect of a local excitation in real-time. Here, we trace the free coherent evolution of a pair of coupled atomic spins by means of scanning tunneling microscopy. Rather than using microwave pulses, we use a direct-current pump-probe scheme to detect the local magnetization after a current-induced excitation performed on one of the spins. By making use of magnetic interaction with the probe tip, we are able to tune the relative precession of the spins. We show that only if their Larmor frequencies match, the two spins can entangle, causing angular momentum to be swapped back and forth. These results provide insight into the locality of electron spin scattering and set the stage for controlled migration of a quantum state through an extended spin lattice.

#### O 47.7 Wed 17:00 S051

Controlled migration of a coherent spin excitation through atomically assembled nanomagnets — •LUKAS VELDMAN¹, LAËTITIA FARINACCI¹, RASA REJALI¹, RIK BROEKHOVEN¹, JEREMIE GOBEIL¹, DAVID COFFEY¹, MARKUS TERNES^{2,3}, and SANDER OTTE¹ — ¹TU Delft, Delft, The Netherlands — ²RWTH Aachen, Aachen, Germany — ³Forschungszentrum Jülich, Jülich, Germany

Tracing single coherent spin excitations in low dimensional nanomagnets has been a long standing goal in experimental solid state physics. Scanning tunneling microscopy offers a promising platform to chase this goal due to its capability to build nanomagnets atom-by-atom and address each atomic spin individually. Here, we show the possibility of inducing a single spin-flip excitation using electron scattering and the measurement of the resulting flip-flop interaction between two atomic spins [1]. Next, we use the same principle to observe coherent spin dynamics in multiple atomically assembled nanomagnets. By tuning the interaction between tip and nanomagnet, we are able to address different magnetic resonances in each atomic structure. In engineered branched structures, the spin excitation can be sent to different directions using the tip interaction. These techniques can serve as a platform for dynamical quantum simulation and can form a foundation for atomically assembled spintronic applications.

#### O 47.8 Wed 17:15 S051

Electric field control of spin transitions in a single molecule using ESR-STM — •MANEESHA ISMAIL, PIOTR KOT, and CHRISTIAN R. AST — Max-Planck-Institute for Solid State Research, Heisenbergstr. 1, 70569 Stuttgart, Germany Since the demonstration of the control of spins on the atomic scale, the technique of ESR-STM has been used extensively to explore the field of spintronics. Here, we present an extension to the ESR-STM parameter space, which uses the bias voltage to tune the energy of the Zeeman transition. We emonstrate electronic control of spin resonance transitions in a single TiH molecule. We were able to observe a strong dependency of the g-factor along with a tip-field shift as function of the electric field. Finally, we manipulate a TiH dimer by continuously changing the bias voltage such that the dimer moves through an avoided crossing of the energy levels. This could be an important step towards pump-probe control of spin states through the bias voltage and opens new possibilities for coherent manipulation.

#### O 47.9 Wed 17:30 S051

Isotope detection inside single molecules in scanning-probe based electron spin resonance — •LISANNE SELLIES, RAFFAEL SPACHTHOLZ, PHILIPP SCHEUERER, and JASCHA REPP — University of Regensburg, Regensburg, Germany

Electron spin resonance (ESR), a versatile technique to study materials with unpaired electrons, was recently combined with scanning tunneling microscopy (STM), bringing atomic-scale spatial resolution to ESR [1]. ESR-STM even allowed detecting strong hyperfine interactions between the single electron spin under study with the atom's nuclear spin [2], due to its largely improved energy resolution compared to conventional STM, reaching the nano-electron-volt regime. This energy resolution could even be improved further if the tunneling current as a read-out was avoided, since this current is the dominating decoherence source for the probed electron spin.

We propose, therefore, a new ESR scanning probe method based on atomic force microscopy (AFM). Since our technique does not rely on the tunneling current to read-out the ESR signal, we increase the coherence times of the electron spins and, consequentially, the energy resolution. Therefore, we can resolve the hyperfine interaction inside organic molecules and distinguish molecules only differing in the isotopic composition. Thus, our technique allows the chemical fingerprinting of molecules and their surroundings.

A home-built scanning tunneling microscope combined with electron spin resonance — •ANDREAS HEINRICH — Center for Quantum Nanoscience, Institute for Basic Science, Seoul, Korea

Scanning tunneling microscopy is a powerful tool to characterize the electronic and magnetic properties of atomic scale structures on a surface. Recently, improved spectral energy resolution has been achieved by functionalizing the STM tip with a well-characterized molecule at the apex [1,2] or by combining electron spin resonance with STM (ESR-STM) [3]. Here, we present the design and operation of an optimized, home-built ESR-STM with a specially designed me-

chanical damper, a Joule-Thomson refrigerator, and 2-axes vector magnets. This system provides outstanding performance of STM for nanoscale measurements. We further describe a new design of a microwave antenna to increase the transmission of RF voltages to the junction, which performs better than the direct connection to the tip. Applying RF power through the antenna terminated at

50 Ohm results in the reduction of standing waves and increases the available frequency range (5-40 GHz), which allows us to measure ESR of surface spins at elevated temperatures up to 10 K. the stability of point defects in 2D monolayer transition metal dichalcogenides and their impact on the electronic structure — •ALAA AKKOUSH^{1,2} and MARIANA ROSSI^{1,2} — ¹Fritz Haber Institute of the Max Planck Society, Faradayweg 4-6, Berlin — ²MPI for the Structure and Dynamics of Matter, Luruper Chaussee 149, 22765 Hamburg

Defects can strongly influence the electronic, optical and mechanical properties of 1D materials. However, their stability and distribution under different conditions of temperature, pressure and strain are not well characterized from an atomistic perspective. We have investigated the structural and electronic properties, as well as the thermodynamic stability of point defects (vacancies and adatoms) in monolayer transition metal dichalcogenides MX₂ with M=Mo/W and X= S/Se, through density-functional theory (DFT) simulations with hybrid exchange correlation functional, as implemented in the all-electron package FHI-aims [1]. These calculations are carried out using a supercell approximation to model localised defects using periodic boundary conditions. We show quantitatively that X adatom is most favorable in rich X conditions while in poor X environment X monovacancy is most favorable. Interestingly, an interplay between adatom and divacancies takes place as temperature increases. To gauge the importance of vibrational free energy contributions on the engineering of gap states in the 2D monolayers, we compare the formation energies of point defects with an adsorbed F6TNAP at various thermodynamic conditions.

Non-linear optical response of TMD Nanotubes using Wannier interpolation — •JYOTI KRISHNA and JULEN IBAÑEZ-AZPIROZ — Centro de Fisica de Materiales (CSIC-UPV/EHU), Donostia-San Sebastian, Spain

Single crystals lacking an inversion center display a non-vanishing second-order response known as shift current- a dominant contribution to the bulk photovoltaic effect. There has been a renewed interest in novel materials with large non-linear absorption capabilities[1]. Here we focus on transition metal dichalcogenide nanotubes, which have recently exhibited a short-circuit intensity showing orders of magnitude enhancement over the monolayer value[2]. We systematically explore the implications of the different chiral indexes on both linear and quadratic optical responses for single-walled TMD NT employing the Wannier interpolation technique. We classify the allowed symmetry and calculate the dependence of the magnitude of the response as a function of NT diameter and chirality. Finally, we discussed our results in the context of the experimental measurements.

Structural, electronic and optical properties of strained  $MoS_2 - \bullet$ JAN-HAUKE GRAALMANN and MICHAEL ROHLFING — Institute of Solid State Theory, University of Münster, 48149 Münster, Germany

Experimental and theoretical studies have shown that the spectrum of  $MoS_2$  changes when the system gets strained. Stretching a monolayer leads to a shift of the optical absorption spectrum to lower energies. In case of the bilayer under hydrostatic stress, the interlayer interaction plays a major role.

In this talk we investigate the behaviour of a  $MoS_2$  monolayer and bilayer theoretically using DFT, GdW and the Bethe-Salpeter equation. Our results show a transition of the monolayer from a direct semiconductor to an indirect one when the in-plane lattice constant is increased. Furthermore, the fundamental gap at the K point is reduced while the binding energies of the A and B excitons remain approximately constant. These effects lead to an effective shift of the excitation energies of both excitons towards lower energy with similar gauge factors.

We also find a significant influence of interlayer interaction within the bilayer. The effect of a decreasing gap by biaxial shrinking of each single layer under an external hydrostatic pressure gets counterbalanced by the reduction of the interlayer distance. Location: S052

**Excitons in TMDC Bilayers** — •JAN NELLESEN and MICHAEL ROHLFING — Westfälische Wilhelms-Universität, Münster, Germany

Semiconducting Transition-Metal-Dichalcogenides (TMDCs) have gained a lot of attention in the past few years due to possible new applications in optoelectronics. In particular, the excitonic properties of TMDC mono- and bilayers have been studied extensively.

This work focuses on interlayer excitons in TMDC heterostructures which combine large binding energies with relatively long lifespans. The exciton energies are investigated in different systems using the Bethe-Salpeter-Equation.

In order to describe excitons in twisted bilayers, which exhibit long-range moiré structures, *ab initio* approaches are no longer feasible because of their high computational demand. With the goal of studying excitons in such systems in mind, the TMDC bandstructure is modeled within a tight-binding approximation. For describing the electron-hole interaction, a model potential is used.

O 48.5 Wed 16:00 S052

Unoccupied electronic states of 1T-TiSe₂: Band dispersions and CDW-induced changes at  $\overline{\Gamma}$  – •PATRICK GEERS, MARCEL HOLTMANN, and MARKUS DONATH – University of Münster, Germany

The transition metal dichalcogenide 1T-TiSe₂ shows a phase transition into a charge density wave (CDW) below a critical temperature  $T_{CDW}$  [1]. This transition leads to a half-sized Brillouin zone and backfolded electronic bands. For the occupied electronic structure, photoemission results show a backfolding of Se-4p_{x,y} valence bands below  $T_{CDW}$  from  $\overline{\Gamma}$  to  $\overline{M}$  [2].

We present angle-resolved inverse-photoemission (IPE) measurements for the unoccupied electronic structure above and below  $T_{CDW}$ . Our data for the  $\overline{\Gamma} \overline{M}$  azimuth resemble literature data for the energy vs. momentum dispersion of Ti-3d states as well as an image-potential-induced surface state [3]. In addition, we report on IPE measurements for the  $\overline{\Gamma} \overline{K}$  azimuth. Finally, we give special attention to the changes in the electronic structure, which are caused by the CDW phase transition. Measurements around  $\overline{\Gamma}$  below  $T_{CDW}$  show modifications in the spectra which are attributed to backfolded electronic bands from  $\overline{M}$  to  $\overline{\Gamma}$  as a direct consequence of the CDW phase.

**Nontrivial Doping Evolution of Electronic Properties in Ising-Superconducting Alloys** — •WEN WAN¹, DARSHANA WICKRAMARATNE², PAUL DREHER¹, RISHAV HARSH¹, IGOR I. MAZIN³, and MIGUEL UGEDA¹ — ¹Donostia International Physics Center (DIPC), Paseo Manuel de Lardizábal 4, 20018 San Sebastián, Spain — ²Center for Computational Materials Science, U.S. Naval Research Laboratory, Washington, DC 20375, USA — ³Department of Physics and Astronomy, George Mason University, Fairfax, VA 22030, USA

TMDs offer unprecedented versatility to engineer 2D materials with tailored properties to explore novel structural and electronic phase transitions. Here, we present the atomic-scale evolution of the electronic ground state of a monolayer of Nb1- $\delta$ Mo $\delta$ Se2 (0< $\delta$ <1) using STM/STS measurements at 300 mK. We investigate the atomic and electronic structure of this 2D alloy throughout the metal to semiconductor transition (NbSe2 to MoSe2). Our measurements let us extract the effective doping of Mo atoms, the bandgap evolution and the band shifts, which are monotonic with  $\delta$ . Furthermore, we demonstrate that collective phases (CDW and superconductivity) are remarkably robust against disorder. We further show that the superconducting TC changes non-monotonically with doping. This contrasting behavior in the normal and superconducting state is explained using first-principles calculations. We show that Mo doping decreases the DOS at EF and the magnitude of pair-breaking spin fluctuations as a function of Mo content. (1) W. Wan, et al. Advanced Materials, accepted (2022).

O 48.7 Wed 16:30 S052 Surface spin texture derived from a single mirror plane of WTe₂ – TRISTAN HEIDER¹, GUSTAV BIHLMAYER², JAKUB SCHUSSER^{3,4}, FRIEDRICH REINERT⁴, JAN MINAR³, STEFAN BLÜGEL², CLAUS M. SCHNEIDER¹, and •LUKASZ PLUCINSKI¹ – ¹PGI-6 Forschungszentrum Jülich – ²PGI-1 Forschungszentrum Jülich – ³University of West Bohemia, Pilsen, Czech Republic – ⁴Experimentelle Physik VII, Universität Würzburg  $WTe_2$  is an important semi-metallic quantum material that exhibits nonsaturating magnetoresistance and potentially hosts Weyl type-II nodes [1]. Through the laser-driven spin-polarized ARPES Fermi surface mapping, we demonstrate highly asymmetric spin textures of electrons photoemitted from the surface states of  $WTe_2$ . Such asymmetries are not present in the initial state spin textures, which are bound by the time-reversal and crystal lattice mirror plane symmetries. The findings are reproduced qualitatively by theoretical modeling within the one-step model photoemission formalism, while a simple toy-model suggests that a similar effect shall be observed in other materials with low symmetry.

Our spin-polarized maps with detail comparable to the previous spinintegrated maps [2] have been measured using the newly developed highresolution instrument at PGI-6 in Jülich that is based on a hemispherical analyzer with the scanning lens, an exchange-scattering spin detector, and a cw 6 eV laser.

Effect of gold substrate on the excitonic properties of MoS₂: a final state sum frequency spectroscopy study — • TAO YANG, ERIK POLLMANN, STEPHAN SLEZIONA, MARIKA SCHLEBERGER, RICHARD KRAMER CAMPEN, and YUJIN TONG — Fakultät für Physik Universität Duisburg-Essen, Duisburg, Germany Monolayer transition metal dichalcogenides(TMDCs) are promising candidates for applications in electronics, optoelectronics, and photocatalysts due to their good thermodynamic stability, ease of preparation, tunable bandgap in the visible region, and pronounced activity for photoelectrochemical water splitting. To take advantage of their excellent properties to build the devices and catalysts, a metallic surface is required to combine them. However, compared to the wellexplored properties of monolayer TMDCs on dielectric substrates, less attention has been paid to these properties on metal substrates due to the challenges associated with linear spectroscopies probing, such as quenching. Here we use a final state sum frequency spectroscopy(FSSFG) to study the optical properties of MoS₂ exfoliated on a gold surface. Relative to the well-known six-fold symmetry of MoS₂ on SiO₂, the azimuthal dependent FSSFG show significantly different patterns at different polarization combinations. The current study provides important insights into the significant changes in electronic structure when MoS₂ comes into contact with gold, and the possibility to selectively switch resonance on and off through azimuthal tuning, as revealed by the robust FSSFG.

Revised Chen's derivative rule for efficient simulations of scanning tunneling microscopy: New results on surface oxides — •KRISZTIÁN PALOTÁS¹, YUN-JAE LEE², TAEHUN LEE², and ALOYSIUS SOON² — ¹Wigner Research Center for Physics, Budapest, Hungary — ²Yonsei University, Seoul, Republic of Korea Advanced simulation tools of scanning tunneling microscopy (STM) are vital for the proper understanding of various physical and chemical processes at material surfaces. For this reason Chen's derivative rule for electron tunneling has been revised [1] to build a computationally efficient STM simulation tool, based on ab initio electronic structure. This STM simulation method enables (i) the weighting of tunneling matrix elements of arbitrary tip-orbital composition, (ii) arbitrary tip geometrical orientations to mimic asymmetric tip-sample relations, and (iii) the possibility of quantitative analysis of tip-orbital interference contributions to the tunneling current. Recently, this method has been applied to diverse complex surface oxides [2,3,4], where a better agreement with STM experiments has been achieved than obtained with the Tersoff-Hamann (spherical tip orbital) model.

Transition metal dichalcogenides (TMDs) are extensively studied because of their exceptional material properties. The stacking of different TMDs can lead to even more intriguing electronic properties: In type-II band aligned TMD stacks, novel excitonic states can be created where the electron and the hole contribution to the exciton are separated between the van-der-Waals-coupled TMDs. A twist angle between these layers allows further manipulation of the electronic properties and gives rise to moiré-patterns which leads to distinct patterns in momentum space. Here, we make use of our setup for time-resolved momentum microscopy that is perfectly suited to probe these excitonic features with energy- and in-plane momentum resolution. We present femtosecond evaluation of the momentum-fingerprints of the excitonic features that are created on a type II aligned heterostructure. Schmitt *et al.*, arXiv:2112.05011 (2021).

Engineering and Information Techn., TU Ilmenau, 98684 Ilmenau, Germany — ⁵Jožef Stefan Institute, 1000 Ljubljana, Slovenia — ⁶DESY, 22607 Hamburg, Germany Layered transition-metal dichalcogenides (TMDCs) are a particularly promising platform for low-dimensional electronic devices due to their two-dimensional nature and richness regarding physical phenomena. This includes non-linear conductance behavior due to, e.g., metal-insulator transitions and memristive behavior, which is of particular interest to in-memory computing designs for neuromorphic systems. By combination of micrometer position- and angleresolved photoemission spectroscopy ( $\mu$ -ARPES) in the soft X-ray range with in operando electrical control, we attempt to study the electronic structure changes concomitant with thickness changes and non-equilibrium conditions in devicelike structures based on TMDCs. A portrayal of conductance-governing mechanisms at a fundamental level could help to evolve towards the understanding and engineering of novel band structures, transport phenomena, and device functionality.

which allows us to include the full-dimensional thermal motion of the surface atoms, we are able to calculate a large number of trajectories with the accuracy of density-functional theory at a small fraction of the computational costs. Investigating different kinetic energies, surface temperatures and incident angles, we are able to characterize the scattering process in detail.

O 49.3 Wed 15:30 S053 Adsorption of Gases on  $\beta$ -Ga₂O₃ Surfaces — •JONATHAN K. HOFMANN^{1,2}, CELINA S. SCHULZE¹, MARTIN FRANZ¹, NIPIN KOHLI¹, DOROTHEE ROSENZWEIG¹, ZBIGNEW GALAZKA³, and HOLGER EISELE¹ — ¹Technische Universität Berlin, Institut für Festkörperphysik, Germany — ²Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, Germany — ³Institut für Kristallzüchtung, Germany

 $\beta$ -Ga₂O₃ is a wide band gap material, which is promising for high power and UV (opto-)electronics. The typical *n*-type doping is controllable via the growth parameters, intentional doping, or post-growth heat treatment. In this contribution, we address the question of its surface properties under typical ambient conditions, i. e., under H₂O and O exposure. The  $\beta$ -Ga₂O₃ single crystals were grown with the Czochralski method [1]. Using Auger electron spectroscopy (AES), and scanning tunnelling microscopy/spectroscopy (STM/STS), we show how the different adsorbed atoms/molecules change the structure and electronic properties of  $\beta$ -Ga₂O₃ (100) and (001) surfaces under UHV-conditions. On the (100) surface, large clusters of H₂O with an undisturbed surface in between were observed. However, STS showed no change in the electronic states. On the (001) surface, oxygen covered almost the complete surface. STS showed that O lifts the band bending inherent in clean  $\beta$ -Ga₂O₃ surfaces.

The project was supported by the Leibnitz Association, Leibnitz Science Campus GraFOX, project C2-3.

Atomic scale studies of chromium species on  $Fe_3O_4(001) - \bullet$ MORITZ EDER¹, PANUKORN SOMBUT¹, CHUNLEI WANG¹, MATTHIAS MEIER², JIRI PAVELEC¹, CESARE FRANCHINI^{2,3}, MICHAEL SCHMID¹, ULRIKE DIEBOLD¹, and GARETH PARKINSON¹ - ¹Institute of Applied Physics, TU Wien, Austria - ²Faculty of Physics and Center for Computational Materials Science, University of Vienna, Austria - ³Department of Physics and Astronomy, Alma Mater Studiorum, Università di Bologna, Bologna, Italy

Chromium (Cr) ferrite catalysts are industrially employed for the water gas shift reaction in order to provide large amounts of molecular hydrogen.[1] However, the European REACH legislation requires the removal of hexavalent Cr from all catalysts used in industrial processes due to its toxicity. Consequently, alternative metals are sought to fulfill the role of Cr species in the corresponding compounds.[2] To this end, one needs a fundamental understanding of Cr on iron oxides. We present the investigation of Cr species on Fe₃O₄(001) by means of STM and XPS at room temperature. We show the behavior during exposure to water gas shift reactants and upon high-temperature treatment. The results are compared to the behavior of other transition metals[3] and discussed with respect to implications for applied catalysis.

O 49.5 Wed 16:00 S053 Adsorption and structural behaviour of thymine on Ce2O3 and Ce6WO12 — •SASCHA MEHL — Elettra Sincrotrone, Trieste, Italy

Reducible oxides are of particular interest in the field of biological systems and nanotechnology application for instance in biosensors, bio medicine and catalysis. The aim is to design novel nano-size structured thin cerium oxide films that possess bio recognition and bio catalytic properties to detect macro molecules e.g. nucleic acids. Model studies of simplified systems such as nucleobases on well-defined oxide surfaces play a major role for understanding and development of these highly promising bio analytical devices. We utilized synchrotron radiation photo electron spectroscopy (SRPES), resonant photo electron spectroscopy (RPES) and X-ray absorption spectroscopy (XAS) which provide ideal conditions to obtain oxidation states, structural and geometrical information on thin organic ad layers. Furthermore, the focus was on the adsorption behavior, electronic structure and thermal stability in the temperature range of 25 * 250 °C of thymine on reduced cerium oxide model systems: thymine/Ce2O3(111)/Cu(111) and thymine/Ce6WO12(100)/W(110). We distinguished two different adsorbed species of thymine on cerium oxide: one strongly bound chemisorbed type and a second weakly bound physisorbed species in the multi layer regime which desorbs at 75 °C. Further investigations have shown that chemisorbed thymine binds to the surface via N-atoms independent of elementary composition and stoichiometry of the substrate.

Interaction of organic acids with magnetite surfaces - the DFT perspective — KAI SELLSCHOPP¹, WERNFRIED MAYR-SCHMÖLZER¹, SOMAK BANERJEE¹, JOHANN FLEISCHHAKER¹, ROBERT MEISSNER², and •GREGOR VONBUN-FELDBAUER¹ — ¹Institute of Advanced Ceramics, TU Hamburg, Germany — ²Institute of Polymers and Composites, TU Hamburg, Germany

Magnetite nanoparticles have a high potential for diverse applications like wastewater treatment, catalysis, and hybrid materials. Formic acid and phosphoric acid can be viewed as the smallest representatives of the acids, which are used to functionalize magnetite nanoparticles. Here, we present results from density functional theory (DFT) calculations on the adsorption of such acids on magnetite low index surfaces. For modelling the adsorption, the configuration space is a challenge and here an approach is presented which allows to sample the adsorption configuration space and to select configurations as input for DFT calculations using unsupervised machine learning approaches. The resulting structures allow for in-depth analyses of the systems including structural and electronic effects.

#### O 49.7 Wed 16:30 S053

Role of surface termination and orientation on the activity of  $CoFe_2O_4(001)$ and (100) surfaces for water oxidation — •SHOHREH RAFIEZADEH and ROSSITZA PENTCHEVA — Department of Physics and Center for Nanointegration Duisburg-Essen (CENIDE), University of Duisburg-Essen, 47057 Duisburg  $CoFe_2O_4$  plays an important role as an anode material for electrochemical water splitting, necessitating detailed understanding of the mechanism of oxygen evolution reaction (OER). This inverse spinel contains alternating layers of octahedral Co and Fe in the (001) direction and mixed Co and Fe layers along the (100) orientation. Here, we employ density functional theory calculations with an onsite Hubbard U term (DFT+U) to investigate the OER performance of  $CoFe_2O_4(100)$  and iron-rich (001) surfaces and compare to the cobalt-rich (001) surface [1]. While the overpotentials of Fe reaction sites are above 0.44 V, octahedral Co shows the lowest overpotential: 0.38 V at the Co-rich (001) surface and even 0.20 V at the mixed Co-Fe (100) surface when terminated with an additional tetrahedral Fe-layer. This reduction of overpotential correlates with a Co²⁺ oxidation state at the surface and a stabilization of the *OOH intermediate due to hydrogen bonding to neighboring sites. Support by the German Science Foundation (DFG), CRC/TRR 247, project B04 and a computational grant at MagnitUDE are gratefully acknowledged.

**Complexion Induced Active Phase Evolution in High-Temperature Solid Oxide Cells** — •HANNA TÜRK, FRANZ-PHILIPP SCHMIDT, THOMAS GÖTSCH, ROBERT SCHLÖGL, AXEL KNOP-GERICKE, THOMAS LUNKENBEIN, CHRISTOPH SCHEURER, and KARSTEN REUTER — Fritz-Haber-Institut der MPG, Berlin, Germany

Solid oxide cells (SOCs) are among the most efficient technologies for energyto-hydrogen conversion from fluctuating renewable electricity sources. While SOCs are in principle well adapted to intermittent operation, cell performance and lifetime in electrolysis mode is severely limited by degradation of the anode. This degradation goes hand in hand with the oxygen evolution reaction (OER) taking place at the triple-phase boundary (TPB) between the anode, the solid electrolyte and the gas phase. Up to now, the atomistic structure of this active catalyst region is essentially unknown though, which prevents a detailed analysis of the actual degradation mechanisms.

Recently, we took the first step in elucidating the TPB structure by revealing a complexion at the underlying solid|solid interface of the sintered anode[1], featuring partial amorphization and varying elemental distributions deviating from the confining bulk phases. Based on this finding, we now expand our force field based Monte-Carlo simulations to the OER active site. Our experimentally validated results show unexpected compositional changes with respect to the thermodynamic equilibrium, that combined with a spatially resolved diffusion study indicate a hitherto unknown deactivation mechanism of the anode.

Synergistic Effects of Co and Fe on the Oxygen Evolution Reaction Activity of  $LaCo_x Fe_{1-x}O_3 - \bullet$ ACHIM FÜNGERLINGS and ROSSITZA PENTCHEVA — Universität Duisburg-Essen, Fakultät für Physik, Lotharstr. 1, 47057 Duisburg

The efficiency of the perovskite  $LaCo_xFe_{1-x}O_3$  as a catalyst for the oxygen evolution reaction was investigated by DFT+U calculations. The overpotential required to drive the reaction is significantly reduced upon Co incorporation, with a subsequent nonmonotonic behaviour for larger amounts of Co. This is supported by electrocatalytic measurements of phase-pure  $LaCo_xFe_{1-x}O_3$  samples [1]. With the deprotonation of adsorbed *OH being the potential determining step in all cases, the reason for the observed trend is twofold: Co turns out to be a more favorable reaction site than Fe, whereas the overpotential of the latter is decreased upon Co substitution. Variations of the magnetic moments of the Co and Fe cations during OER reveal the participation of several, particularly Co, cations up to several layers below the surface. This extends the concept of the active site.

 A. Füngerlings, A. Koul, M. Dreyer, A. Rabe, D. M. Morales, W. Schuhmann, M. Behrens, R. Pentcheva, Chem. Eur. J. 27, 17145-17158 (2021)

 $O\ 49.10 \quad Wed\ 17:15 \quad S053$  Hydrophobic pockets on an oxide surface: In₂O₃(111) — Hao Chen^{1,2}, Matthias Blatnik^{1,3}, Michael Schmid¹, Bernd Meyer⁴, Ulrike Diebold¹, and •Margareta Wagner^{1,3} — ¹TU Wien, Vienna, Austria — ²University of the Chinese Academy of Sciences, Beijing, China — ³CEITEC BUT, Brno, Czechia — ⁴FAU Erlangen-Nürnberg, Erlangen, Germany

Indium oxide, a transparent conductive oxide (TCO), is widely used in semiconductor industry but it also displays promising performance in electro- and photocatalytic reactions. In all applications, surrounding water molecules may influence chemical processes at the atomic scale, and understanding the interaction of water with  $In_2O_3$  is important.

We focus on  $In_2O_3(111)$ , which has an intrinsically large unit cell composed of a hydrophilic and a hydrophobic area. We test the reactivity of these areas by unraveling the interfacial water structures for the whole range of water coverages in UHV, from single dissociated molecules to multilayers, employing TPD, XPS, STM and AFM. Even at high coverages we clearly see hydrophilicity and hydrophobicity within the unit cell, both in experiments and calculations. Local accumulation and depletion of water is confirmed by DFT calculations and ab initio molecular dynamics (MD) simulations for ordered structures consisting of up to 18 water molecules per unit cell. This first water layer shows ordering into nanoscopic 3D water clusters separated by hydrophobic pockets. Going beyond UHV conditions, our MD simulations of a liquid layer show the robustness of the strongly hydrophobic area in the unit cell.

Automating the Generation of Linearized Augmented Planewave Basis Functions — •HANNAH KLEINE¹, SVEN LUBECK¹, ANDRIS GULANS², and CLAUDIA DRAXL¹ — ¹Humboldt-Universität zu Berlin — ²University of Latvia

The linearized augmented planewave (LAPW) and local orbitals (LO) method is known to be a highly precise scheme for solving the Kohn-Sham equations of density-functional theory (DFT) for solids. One drawback, however, is that the LAPW and LO basis functions depend on linearization energies which are material dependent. We propose an approach that allows us to compute the linearization energies from the number of nodes of the respective atomic function. It is implemented in the all-electron full-potential computer package exciting [1]. Following this prescription, we are able to automatize the generation of linearly independent basis functions for any material. This approach not only improves the usability of the method, it also leads to better reproducibility of results, and prepares the code for high-throughput calculations.

Hybrid Density-Functional Theory at the Limit: All-electron Exact Exchange beyond 10,000 Atoms — FLORIAN MERZ¹, •SEBASTIAN KOKOTT², CHRISTIAN CARBOGNO², YI YAO³, MARKUS RAMPP⁴, MATTHIAS SCHEFFLER², and VOLKER BLUM³ — ¹Lenovo HPC Innovation Center, Stuttgart — ²The NOMAD Laboratory at the FHI-MPG and HU, Berlin — ³Duke University, North Carolina, USA — ⁴Max Planck Computing and Data Facility, Garching

The computational bottleneck of hybrid density functionals, such as HSE [1], is the evaluation of the exact exchange (EXX) contribution. In this work, we present algorithmic advances in the resolution-of-identity [2] based, real-space implementation of EXX in *FHI-aims* [3,4]. By exploiting MPI-3 intra-node shared memory and enhancing the parallelization scheme, scalability and work-load distribution has been drastically improved, which results in memory efficiency and performance increases of up to two orders of magnitude compared to the original implementation, for both total energies and forces/stresses. [3,4] We discuss the details of our implementations and demonstrate the performance as well as scalability for a balanced test set covering inorganic solids, large molecules, and organic crystals with up to 10,000 atoms. Eventually, we show how these advancements enable insights for the design and optimization of hybrid organic/inorganic perovskites.

Studying nuclear quantum effects on water splitting at a charged interface — •KAREN FIDANYAN and MARIANA ROSSI — Max Planck Institut for the Structure and Dynamics of Matter

Interfaces of water with charged metallic surfaces are relevant for multiple technological processes.¹ In particular, in electrolyzers, the water splitting reaction happens at charged metallic electrodes. The atomistic mechanisms of this fundamental reaction is determined not only by the surface charge induced by the potential bias, but also by nuclear quantum effects (NQE), which are known to impact such reactions strongly.² In this work, we present steps towards a framework for an *ab initio* evaluation of the interplay between these two effects. By making use of a new implementation of the nudged-elastic-band method in the i-PI software,³ we are able to calculate forces for this reaction from a variety of electronic-structure codes. At first, we approximate the electrode by a slab using density-functional theory with an applied homogeneous electric field and study how NQEs are changed through the water dissociation paths under different field strengths. Taking advantage of the capabilities of i-PI to connect to other codes, our framework can be extended to more accurate models of the potential bias, as for example grand-canonical electronic structure methods.

#### O 50.4 Wed 15:45 S054

All-Electron BSE@GW Method for K-Edge Core Electron Excitation Energies — •YI YAO^{1,2}, DOROTHEA GOLZE^{3,4}, PATRICK RINKE⁴, VOLKER BLUM^{2,5}, and YOSUKE KANAI¹ — ¹Department of Chemistry, University of North Carolina at Chapel Hill, Chapel Hill, North Carolina 27599, United States — ²Thomas Lord Department of Mechanical Engineering and Materials Science, Duke University, Durham, North Carolina 27708, United States — ³Faculty of Chemistry

and Food Chemistry, Technische Universität Dresden, 01062 Dresden, Germany —  4 Department of Applied Physics, Aalto University, P.O. Box 11100, FI-00076 Aalto, Finland —  5 Department of Chemistry, Duke University, Durham, North Carolina 27708, United States

We present an accurate computational approach to calculate K-edge core electron excitation energies, achieved by combining all-electron GW and Bethe-Salpeter equation (BSE) methods. We assess the BSE@GW approach for calculating K-edge X-ray absorption spectra using a set of small organic molecules and also a medium-sized sulfur-containing molecule, which was used in a past benchmark of an equation-of-motion coupled-cluster (EOM-CC) method by Peng and coworkers [Peng et al., J. Chem. Theory Comput., 11, 4146 (2015)]. We present the influence of different numerical approximations. We assess the basis set dependence and convergence. We identify the importance of core-correlation basis functions as well as the augmenting basis functions. Compared to the experimental values, the predicted mean absolute error by BSE@GW is as low as 0.6-0.7 eV.

Hybrid excitations at the interface between  $MoS_2$  monolayer and organic molecules from first-principle calculation — •IGNACIO GONZALEZ OLIVA¹, FABIO CARUSO^{1,2}, PASQUALE PAVONE¹, and CLAUDIA DRAXL¹ — ¹Institut für Physik and IRIS Adlershof, Humboldt-Universität zu Berlin, 12489 Berlin, Germany — ²Institut für Theoretische Physik und Astrophysik, Christian-Albrechts-Universität zu Kiel, 24118 Kiel, Germany

Hybrid materials composed of organic and two dimensional (2D) inorganic semiconductors are receiving increasing attention due to the interesting physical processes happening at the interface. We present a first-principles investigation of the electronic and optical properties of hybrid organic-inorganic interfaces consisting of a MoS₂ monolayer and the  $\pi$ -conjugate molecules pyrene and pyridine. Employing the  $G_0 W_0$  approximation to obtain the quasi-particle band structures, and solving the Bethe-Salpeter equation, we compute the absorption spectra. The latter reveal intralayer excitons on the MoS₂ side, and also hybrid as well as charge-transfer excitons at the interface. Our findings indicate that hybrid systems consisting of semiconducting transition-metal dichalcogenides and organic  $\pi$ -conjugate molecules can host a rich variety of optical excitations and thus provide a promising venue to explore exciton physics in low dimensionality.

#### O 50.6 Wed 16:15 S054

Mott Metal-Insulator Transition from Steady-State Density Functional Theory — •DAVID JACOB^{1,2}, GIANLUCA STEFANUCCI³, and STEFAN KURTH^{1,2,4} — ¹Universidad del País Vasco UPV/EHU, San Sebastian, Spain — ²Ikerbasque Foundation, Bilbao, Spain — ³Università di Roma Tor Vergata, Rome, Italy — ⁴Donostia International Physics Center, San Sebastian, Spain

We present a computationally efficient method to obtain *many-body* spectral functions of bulk systems in a *density functional theory* framework [1]. To this end we generalize a recently developed method for computing many-body spectral functions of nanoscale systems [2], based on steady-state density functional theory (i-DFT) and using an idealized scanning tunneling microscope (STM) setup, to the case of bulk systems. In this setup the spectral function can be obtained from the finite-bias differential conductance of the current through the STM tip. The fictitious noninteracting system of i-DFT features an exchange-correlation (XC) contribution to the bias which guarantees the same current as in the true interacting system. Exact properties of the XC bias are established using Fermi-liquid theory and subsequently implemented to construct approximations for the Hubbard model. We show for two different lattice structures that our method captures the Mott metal-insulator transition.

Network of 1d edge channels and localized states emerging in moiré system — •JEYONG PARK, JINHONG PARK, and ACHIM ROSCH — Institute of theoretical physics, University of Cologne, Germany

For the general moiré system, we theoretically study the effective Hamiltonian for single layer considering the smooth periodic moiré potential induced by other layer, which appears because of distance difference between each pair of atoms located on different layer. For moiré potential larger than tunable moiré energy scale, we find the coexistence of 1D channels and localized state in real space. The 1D channels emerge along the three 1D lines where the mass gap of single layer coming from moiré potential becomes zero, which is showing that these channels are the edge states. Localized states emerge at the crossing point of three 1d lines. We construct the toy model which describes the coexistence of these states by symmetry analysis and consider the RKKY interaction between

O 50.5 Wed 16:00 S054

localized states which is mediated by 1D channels by including whole spin and valley degrees of freedom. Expanding the effective action for the toy model and controlling chemical potential to suppress oscillation coming from fermi momentum gives three spin interaction  $S \cdot (S \times S)$ , which can give chiral spin liquid phase. We show how the analytical result can be seen in our model numerically and propose the graphene on top of AB stacking bilayer with twist as the candidate material for realization.

#### O 50.8 Wed 16:45 S054

**Incorporating First-Principles Electronic Friction in Instanton Rate Theory** — •YAIR LITMAN¹, ESZTER S. POS¹, CONNOR L. BOX², ROCCO MARTINAZZO³, REINHARD J. MAURER², and MARIANA ROSSI¹ — ¹MPI for the Structure and Dynamics of Matter, Hamburg, Germany. — ²Department of Chemistry, University of Warwick, Coventry, United Kingdom — ³Department of Chemistry, Università degli Studi di Milano, Milano, Italy

Reactions involving impurities in bulk metals are ubiquitous in a wide range of technological applications. The theoretical modelling of such reactions present a challenge for theory because nuclear quantum effects (NQEs) can play a prominent role and the coupling of the atomic motion with the electrons in the metal gives rise to important non-adiabatic effects (NAEs). In this work, we present a theoretical framework for the calculation of reaction rates capable of capturing both NQEs and NAEs for high-dimension realistic systems [1,2]. This is achieved by combining the ring polymer instanton (RPI) formalism with ab initio electronic friction from Ref. [3]. We derive equations that incorporate the spatial and frequency dependence of electronic friction, and name the new method RPI with explicit friction (RPI-EF). We validate RPI-EF against numerically exact results and find, quantitatively, how the friction modifies reaction rates and tunnelling pathways. Finally, we present ab initio results for H-hopping in selected bulk metals. [1] Y. Litman, E. S. Pós, C. L. Box, R. Martinazzo, R. J. Maurer, and M. Rossi, JCP 156, 194106 (2022) [2] id. #### O 50.9 Wed 17:00 S054

**Real-Time Time-Dependent Density Functional Theory within the FHI-aims code** — JOSCHA HEKELE¹, YI YAO², VOLKER BLUM², YOSUKE KANAI³, and •PETER KRATZER¹ — ¹Faculty of Physics, University Duisburg-Essen, 47057 Duisburg, Germany — ²Thomas Lord Department of Mechanical Engineering and Materials Science, Duke University, Durham, North Carolina 27708, USA — ³Department of Chemistry, University of North Carolina, Chapel Hill, North Carolina 27599, USA

We present a high-precision all-electron RT-TDDFT implementation using numerical atom-centered orbital (NAO) basis functions into FHI-aims. First, RT-TDDFT results are validated against linear-response TDDFT results for the molecules of Thiel's test set and the importance of basis augmentation for adequate convergence is confirmed. Adopting a velocity-gauge formalism, dielectric properties of crystalline materials are calculated. Taking advantage of the all-electron full-potential implementation, we present applications to soft X-ray spectra of  $H_2O$  using hybrid functionals. Moreover, numerical performance tests are presented showing almost linear scaling on parallel computers.

#### O 50.10 Wed 17:15 S054

Ab initio study of many-body interacting nonlinear optical photoconductivity tensors — •PEIO GARCIA-GOIRICELAYA¹, JYOTI KRISHNA¹, and JULEN IBAÑEZ-AZPIROZ^{1,2} — ¹Centro de Física de Materiales, University of the Basque Country UPV/EHU, Spain — ²IKERBASQUE Basque Foundation for Science, Spain We present a general scheme for calculating the many-body interacting second-order optical photoconductivity tensor from first-principles. Our practical implementation starts from the length-gauge formulation of the single-particle non-interacting second-order response tensor [1] that is efficiently calculated using Wannier interpolation [2]. In a second step, we make use of the TD-CDFT in

order to extract the many-body interacting response tensor, taking into account collective excitations, i.e. excitonic effects for semiconductors and plasmonic effects for metals. We employ this scheme to assess the impact of many-body excitations on second harmonic generation and benchmark our results with experiments on the semiconducting GaAs [3] and the semimetal TaAs [4], as well as with early calculations [5].

Electron-phonon drag in  $MgB_2 - \bullet$ NAKIB PROTIK and CLAUDIA DRAXL — Institut für Physik and IRIS Adlershof, Humboldt-Universität zu Berlin, Berlin, Germany

MgB₂ is a well known phonon-mediated superconductor with a transition temperature around 40 K. The strong electron-phonon interactions present in the material also give rise to strong drag phenomena, as has been demonstrated experimentally in Refs. [1, 2]. While the measured thermopower in the normal phase shows hole-like transport, there is, however, no consensus regarding the sign and temperature dependence of the drag contribution. In this work, we carry out anisotropic and band-resolved *ab initio* transport calculations to investigate this puzzle. Our findings will shed light on the roles of the microscopic interactions on the strong drag behavior in metals.

*Ab initio* simulations of vibrational sum frequency generation without molecular decomposition — •PAOLO LAZZARONI, ALAN LEWIS, and MARIANA ROSSI — Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany

Hydrogen evolution through heterogeneous catalysis is an increasingly popular solution for storage of energy generated from renewable sources, and as such is becoming a central part of green energy grids. Understanding the structure of water at solid interfaces is vital to find more efficient and cost-effective catalysts of this reaction, and sum-frequency generation spectroscopy provides a surfacespecific method of investigating these structures [1]. In this work we present a new framework for ab initio calculations of the sum-frequency response which avoids the need for an arbitrary molecular decomposition of the polarizability and dipole moment. Within this approach, based on Density Functional Theory, the observables are evaluated using real space integrals directly on the whole system [2]. This allows us, for example, to unravel the effect of this decomposition on the sum-frequency response of the much-studied water/vacuum interface. This scheme also enables us, in the context of water-solid interfaces, to account explicitly for the contribution of the solid to the polarizability and dipole moment of the interface, which are commonly neglected. # O 51: Poster Wednesday: Atomic-Scale Studies of Spins on Surfaces with Scanning Tunneling Microscopy

Time: Wednesday 18:00–20:00

O 51.1 Wed 18:00 P4

Nickelocene molecule as an STM magnetic sensor — •ANDRES PINAR SOLE, OLEKSANDR STETSOVYCH, PAVEL JELINEK, ALES CAHLIK, CHRISTIAN WAKER-LIN, and JINDRIC KOLORENC — Czech Institute of Physics, Prague, Czech Republic, Email: pinar@fzu.cz

Functionalization of the scanning probe of a scanning tunnelling microscopy (STM) with metallocene molecule allows performing spin-sensitive measurements on magnetic systems. Here, we used a nickelocene molecule (NiCp2), consisting of a Ni atom sandwiched between two cyclopentadienyl rings. As an S=1 system, it presents magnetic-induced spectral features due to the inelastic electron spin-flip.

Location: P4

First, we examined 1D metallorganic coordination polymers (2,5-diamino-1,4-benzoquinonediimines) on Au(111) with Co or Cr atoms as metal sites respectively. Nickelocene IETS conductance spectrum deformation was only sensitive to the out-of-plane magnetic anisotropy of the Cr.

Secondly, the Nc functionalized probe was also used to measure the magnetism emerging from the unpaired electron on the edge of a wave-like graphene nanoribbon (GNR) on Au(111). Here, we observed spectral convolution between a Kondo feature from the edge-state and the nickelocene spectrum.

To understand the IETS from the magnetic sensor, a many-body Hubbard model was proposed, and the system was simplified to a two-site model consisting of the partially filled 3d shell of the nickelocene and a 3d shell in the probed magnetic center.

# O 51.2 Wed 18:00 P4

Yu-Shiba-Rusinov band dispersion of infinite Mn chains on top of a semiinfinite Nb(110) surface — •Rik Broekhoven, Artem Pulkin, Antonio Manesco, Sander Otte, Anton Ahkmerov, and Michael Wimmer — Delft University of Technology, Delft, The Netherlands

Chains of magnetic atoms on s-wave superconductors have been proposed to have a topological non-trivial phase, when the induced in-gap Yu-Shiba-Rusinov (YSR) bands are p-wave gapped by for example spin-orbit coupling. In order to determine the topological phase diagram, experiments were previously limited to probing local quantities of the chain. Recent improvements in STM methodology have made it possible however to now also probe the YSR band dispersion relation. It was found to be highly dependent on the chain spacing and orientation with respect to the superconductor lattice.

Motivated by this discovery, here we present a method to evaluate the in-gap dispersion relation of chains with different orientations and spacing. In contrast to previous works, we work with infinite chains on a semi-infinite surface to make sure the system is larger than the superconductor coherence length. We focus on Mn atoms on top of superconducting Nb(110). First, we derive an effective tight-binding model from ab initio calculation, and subsequently we use the multidimensional Green's function formalism to extend to a semi-infinite system and solve for the corresponding in-gap YSR bands.

O 51.3 Wed 18:00 P4

Unravelling the Magnetic Ground State of All-Organic Diradicals on Au Substrates — •ALESSIO VEGLIANTE¹, SALETA FERNANDEZ², RICARDO ORTIZ³, NIKLAS FRIEDRICH¹, ANDREA AGUIRRE¹, FRANCISCO ROMERO¹, DIEGO PEÑA², and THOMAS FREDERIKSEN³ — ¹CIC NanoGUNE, San Sebastian, Spain — ²CiQUS-USC, Santiago de Compostela, Spain — ³Donostia International Physics Center, San Sebastian, Spain

Open-shell organic molecules have received considerable interest as potential candidates for molecular spintronics. Magnetism can emerge in all-organic molecules due to the presence of one or more unpaired  $\pi$ -electrons. Organic diradicals, hosting two spin centers, are particularly interesting as model systems for investigating and manipulating magnetic interactions at the atomic scale.

Here we study the magnetic state of a Chichibabin*s hydrocarbon diradical deposited on a gold substrate, by using scanning tunneling microscopy (STM) and spectroscopy (STS). We investigate the interaction between the two spin centers of the molecule, focusing on the influence of the molecular geometry. With the support of theoretical simulations, we show that the adsorption on the metal surface changes the ground state of the molecule from a triplet, expected in the gas phase, to a singlet state. Furthermore, we demonstrate that it is possible to modify the magnetic state of the diradical through conformational changes induced by the STM tip. These findings represent an important step towards the control of magnetic interactions within purely organic molecules.

# O 51.5 Wed 18:00 P4

Magnetic molecule as a parity sensor in entangled spin and YSR excitation on a superconductor — •JON ORTUZAR¹, STEFANO TRIVINI¹, KATERINA VAXEVANI¹, JINGCHEN LI⁵, ANE GARRO¹, MIGUEL ANGEL CAZADILLA³, SEBASTIAN BERGERET^{2,3}, and JOSÉ IGNACIO PASCUAL^{1,4} — ¹CIC nanoGUNE-BRTA, San Sebastián, Spain — ²Centro de Física de Materiales (CFM-MPC), San Sebastián, Spain — ³Donostia International Physics Center (DIPC), San Sebastián, Spain — ⁴Ikerbasque, Bilbao, Spain — ⁵School of Physics, Sun Yat-sen University, Guangzhou, China

A magnetic molecule coupled to a superconductor induces Yu-Shiba-Rusinov (YSR) bound states, detected by tunneling spectroscopy as long-lived quasiparticle excitations inside the superconducting gap [1]. The degeneracy of the system can be lifted by intrinsic magnetic anisotropy so that entangled spin and YSR excitations are possible [2]. We tune the exchange coupling between a FeTPP-Cl molecule and the proximitized Au(100)/V substrate to go through a Quantum Phase Transition from an unscreened half-integer spin (even parity) system to a screened integer spin (odd parity) system [3]. We use a single site superconductor model [4] to prove the capability to detect the parity of the system, getting fundamental insight into the interplay of YSR and spin excitation.

#### O 51.6 Wed 18:00 P4

Electronic Properties of Dysprosium-based Fe-Porphyrins Metal-Organic Coordination networks on Au(111) and Ag(100) Substrates — •SERIM JEON^{1,3}, LUKAS SPREE^{1,2}, CORINA URDANIZ^{1,2}, CAROLINE HOMMEL^{1,2}, ANDREAS HEINRICH^{1,2}, CHRISTOPH WOLF^{1,2}, and LUCIANO COLAZZO^{1,2} — ¹Center for Quantum Nanoscience, Institute for Basic Science, Seoul, Republic of Korea — ²Ewha Womans University, Seoul, Republic of Korea — ³Department of Physics, Ewha Womans University

Dy has become the cornerstone for many investigations on lanthanide-directed molecular-magnetism, thanks to its strong magnetic anisotropy. Iron Tetrapyrrole complexes, on the other hand, have shown promise as materials for quantum information processing. Creating a platform that incorporates both might have a way for the realization of multiqubit architectures. The presented study describes electronic properties within a metal-organic network MOF consisting of Iron-Tetrakis-(4-Cyanophenyl) Porphyrin Fe-TCPP and Dysprosium. Fe-TCPP was deposited on Au(111), Ag(100), and MgO/Ag(100). The deposition of Dy induces coordination between the cyano groups and the lanthanide atoms and gives rise to ordering and the formation of large islands of 2D MOF. The lanthanide-based organic network was examined by scanning tunneling microscopy STM on the substrates. Significant shifts in the energy of LUMO of the MOFs were observed via scanning tunneling spectroscopy STS after deposition of Dy. The results were combined with ab initio calculation to further elucidate the electronic structure of the deposited materials.

Long-lived spin states of Fe atomic chains on Cu₂N via Hamiltonian engineering — ROBBIE J. G. ELBERTSE¹, •TAEHONG AHN^{2,3}, JIYOON HWANG^{2,3}, JEONGMIN OH^{2,3}, JORN C. RIETVELD¹, SANDER OTTE¹, ANDREAS J. HEINRICH^{2,3}, and YUJEONG BAE^{2,3} — ¹Department of Quantum Nanoscience, Kavli Institute of Nanoscience, Delft University of Technology, Lorentzweg 1, Delft 2628 — ²Center for Quantum Nanoscience, Institute for Basic Science, Seoul, Korea — ³Department of Physics, Ewha Womans University, Seoul, Korea

A spin-polarized scanning tunneling microscope (STM) operating at various magnetic fields allows us to characterize the spin relaxation time of atomic structures on a surface, enabling Hamiltonian engineering. Here, we introduce 1D Fe atomic chains built on Cu₂N/Cu(100) using a home-built STM and the evolution of their spin lifetime depending on the length of chains and the direction and magnitude of magnetic fields. To measure the spin lifetime ranging from  $10^{-6}$  to 10 seconds, we used two different detection schemes; pump-probe [Science 329, 1628-1630 (2010)] and two state switching [Science 335, 196-199 (2012)]. We observed the spin lifetime of Fe chains changes non-monotically as passing through a diabolic point with varying magnetic fields changes the degree of superposition of the two Neél states in the lowest energy eigenstates. To control the spin lifetime of Fe chains, we use magnetic fields as a control knob. Our work shows a capability of the spin lifetime in a large time scale and the precise control of spin dynamics in engineered atomic structures.

#### O 51.8 Wed 18:00 P4

Local characterization of Yu-Shiba-Rusinov excitations in magnetic field — •NIELS P.E. VAN MULLEKOM¹, BENJAMIN VERLHAC¹, WERNER M.J. VAN WEERDENBURG¹, HERMANN OSTERHAGE¹, MANUEL STEINBRECHER¹, KATHA-RINA J. FRANKE², and ALEXANDER A. KHAJETOORIANS¹ — ¹Institute for Molecules and Materials, Radboud University Nijmegen, the Netherlands — ²Fachbereich Physik, Freie Universität Berlin, Germany.

An isolated spin, typically derived from an atomic or molecular adsorbate, can interact with a BCS superconductor leading to so-called Yu-Shiba-Rusinov (YSR) excitations. These excitations can be probed with scanning tunneling microscopy/spectroscopy (STM/STS), which are often characterized by resonances that reside in the superconducting gap and are linked to the excitation energies. These spin-based excitations to date have been poorly studied in magnetic fields, due to influence of magnetic fields on typical BCS superconductors. Here, utilizing STM/STS at milliKelvin temperatures, we report on a study of the YSR excitations of individual adsorbates in variable magnetic field.

# O 51.9 Wed 18:00 P4

Extending the spin excitation lifetime of a magnetic molecule on a proximitized superconductor — •Katerina Vaxevani¹, Stefano Trivini¹, JINGCHENG LI¹, JON ORTUZAR¹, DONGFEI WANG¹, DANILO LONGO¹, and JOSE IGNACIO PASCUAL 1,2  —  1 CIC nanoGUNE-BRTA, 20018 Donostia-San Sebastian, Spain — ²Ikerbasque, Basque Foundation for Science, 48013 Bilbao, Spain Magnetic molecules adsorbed on surfaces have been used as a platform to individually address and manipulate spins. Long spin-relaxation times are required in order to be able to use atomic spins in quantum information processing and data storage. Normally, coupling of the spin with the conduction electrons of metallic substrates can quench the excited state lifetime and lead to short relaxation times, but the presence of superconducting paring effects in the metal substrate can protect the excited spin from relaxation[1]. Here, we use a substrate of a few monolayers of gold epitaxially grown ontop of an oxygen reconstructed 1x5-V(100) surface to decouple the molecular spin of an ironporphyrin-chloride from itinerant electrons. The gold film exhibits a proximitized superconducting gap with in-gap de Gennes-Saint James resonances, which protects molecular spin excited states and results into a lifetime of  $\tau$ =80ns. The spin lifetime decreases with increasing the film thickness due to the gradual gap-

closing by the in-gap states. Our results elucidate the use of proximitized gold electrodes for addressing quantum spins on surfaces, envisioning new routes for tuning the value of their spin lifetime. [1] B. W. Heinrich et al., Nature Physics 9, 765 (2013).

The Emergence of Magnetism in [5]-Aza-Triangulene – •LORENZ MEYER¹, Francisco Romero Lara¹, Niklas Friedrich¹, Alessio Vegliante¹, Manuel Vilas Varela², Unai Uriarte Amiano¹, Natalia Koval¹, Emilio ARTACHO CORTÉS¹, DIEGO PEÑA GIL², and JOSE IGNACIO PASCUAL¹ - ¹1 CIC nanoGUNE, San Sebastian (Spain) — ²Centro Singular de Investigación en Química Biológica y Materiales Moleculares (CIQUS), Santiago de Compostela (Spain)

Zigzag-edged Graphene triagulenes are known to host a magnetic ground state due to sublattice imbalance. The magnetic properties of these structures can be tuned by the size of the triangulene or via heteroatom substitution. This makes them intriguing for future spintronic applications paving the way towards organic logical devices. So far, the influence of heteroatoms in larger triangulenes seems to be unknown. In our work, we report the bottom-up synthesis of [5] aza-Triangulene by means of surface-assisted cyclodehydrogenation on a Au(111) surface. Electronic transport measurements carried out with a scanning tunneling microscope reveal the high-spin ground state of this molecule via low energy phenomena. Additionally, we shine light on not only the influence of heteroatoms but also of additional Hydrogen atoms and defects which are able to tune the magnetic ground state. Density functional theory and Mean-Field-Hubbard calculations confirm the spin texture and the electronic structure of the observed molecules.

# 0 52: Poster Wednesday: Adsorption and Catalysis 2

Time: Wednesday 18:00-20:00

O 52.1 Wed 18:00 P4 Investigation of the influence of the spin in adsorption structures of oxygen on a cerium chloride catalyst surface in the Deacon process using computational methods — •KATHRIN NIESWIEC and FRANZISKA HESS — Technische Universität Berlin, Institut für Chemie, Straße des 17. Juni 124, 10623 Berlin, Germany

CeO2-based catalysts in the HCl oxidation undergo reversible deactivation by forming CeCl₃. This works examines the interaction of the CeCl₃-(110)-surface with O2 during the reoxidation of CeCl3. CeCl3 is an insulator, where Ce is 9-fold coordinated that exposes different adsorption sites at the surface. Different adsorption structures of atomic and molecular oxygen on the CeCl₃-(110)-surface are examined in terms of energy, electronic state and magnetization. Ceriumbased catalyst systems are investigated by DFT calculations in the PAW approach with the PBE functional including Hubbard-U correction. Ab-initio thermodynamics are employed to analyze temperature and pressure-dependency of oxygen adsorption on the surface. Upon adsorption of oxygen on the surface, Ce³ can be locally oxidized to Ce⁴⁺, resulting in different spin and charge density distributions. Consequently, the adsorption energies of oxygen can variate by over 1 eV, depending on the initial spin state. The ab-initio thermodynamics analysis based on the obtained oxygen adsorption energies suggests that the CeCl₃ surface is expected to be covered by oxygen due to the strong Ce-O bond. These results suggest that spin must be explicitly included when examining adsorption on CeCl₃ surfaces in order to obtain correct adsorption energies for catalysis applications.

#### O 52.2 Wed 18:00 P4

Influence of the Substrate Orientation Dependent Reactivity on the Onsurface Ullmann Coupling Reaction of 2,2-Dibromobiphenyl Studied by XPS - •PAUL SCHWEER and KARINA MORGENSTERN — Chair of Physical Chemistry I, Ruhr-University of Bochum, Germany

The Ullmann coupling reaction is considered the leading approach for accessing low dimensional covalent organic structures in the context of on-surface synthesis. Despite extensive studies on the influence of the halogen substitution pattern of the halogen-aryl precursor on the reaction mechanism and product formation, the impact of ortho-substitution is barely investigated. Hence, this work aims to reveal the temperature-induced reaction steps for 2,2-dibromobiphenyl on low-index Cu surfaces. For this purpose, the precursor is deposited in ultrahigh vacuum at 86 K and stepwise annealed to 600 K. By using X-ray photoelectron spectroscopy, chemical changes of the organic species and the bromine atoms are identified and assigned to the typical Ullmann reaction steps: dissociation of the halogen-carbon bond, surface bonding, and C-C coupling. Here, we further discuss different precursor reactivities on Cu(111) and Cu(110) and an additional binding energy shift on Cu(110), indicating a structural change of the surface bound biphenyl before C-C coupling at a higher temperature.

O 52.3 Wed 18:00 P4 Surface Chemistry of the MOST Energy Storage System 2-Carbethoxy-3-Phenyl-Norbornadiene/Quadricyclane — •Felix Hemauer, Cornelius WEISS, JOHANN STEINHAUER, VALENTIN SCHWAAB, HANS-PETER STEINRÜCK, and CHRISTIAN PAPP — Friedrich-Alexander-Universität, Erlangen, Germany The intermittent character of renewable energy sources gives the necessity for novel energy storage technologies. So-called molecular solar thermal (MOST) energy systems directly combine the light-harvesting process with storing the gained energy as molecular strain. In a photoconversion reaction, the energylean norbornadiene (NBD) is converted to its energy-rich valence isomer quadricyclane (QC). By derivatization of the molecular framework, the light-harvesting properties of the molecules are optimized.

The pair 2-carbethoxy-3-phenyl-NBD/QC was investigated as model system for heterogeneously catalyzed energy release. X-ray photoelectron spectroscopy was employed to study the adsorption and thermal evolution on a Ni(111) and Pt(111) surface, respectively. An unambiguous identification of the QC and NBD derivatives at low temperature was possible on both surfaces. In case of nickel, no cycloreversion of the QC derivative to NBD was found, but individual decomposition routes setting in at about 170 K. For platinum, the back conversion under energy release was found to start at 150 K and being completed at 230 K. Above 300 K, a fragmentation into carbonaceous species occurred. The work was supported by the DFG (Project No. 392607742) and the HZB for allocation of synchrotron radiation beamtime.

#### O 52.4 Wed 18:00 P4

Temperature-induced surface reactions of 1-cyclohexylethanol and acetophenone on Pt(111) — •VALENTIN SCHWAAB, FELIX HEMAUER, EVA MARIE FREIBERGER, NATALIE WALESKA, HANS-PETER STEINRÜCK, and CHRISTIAN PAPP — Friedrich-Alexander-Universität, Erlangen, Germany

1-Cyclohexylethanol (1-CHE) is an interesting candidate when it comes to molecular energy storage systems. Such secondary alcohols can function as electrofuel, whereby their oxidation over a platinum electrode yields the respective ketone together with two electrons and two protons. Additionally, 1-CHE and acetophenone (APH) represent an attractive liquid organic hydrogen carrier (LOHC) pair, as the complete dehydrogenation of the former leads to the release of four equivalents of H₂.

To gain fundamental insights into the surface reaction of both molecules, high-resolution temperature-programmed X-ray photoelectron spectroscopy experiments (HR-TPXPS) were carried out on a Pt(111) model catalyst. Based on the obtained C 1s and O 1s data, the dehydrogenation reaction of the alcohol and the formation of potential catalyst poisoning decomposition products are discussed.

We acknowledge financial support by the Bavarian Ministry of Economic Affairs, Regional Development and Energy, and by the DFG (Project No. 419654270). We thank HZB for the allocation of synchrotron radiation beamtime.

# O 52.5 Wed 18:00 P4

Force-induced single-molecular switch of graphene-nanoribbon-fused helicene by atomic force microscopy — •AKITOSHI SHIOTARI^{1,2}, AYUMU ISHII¹, and YOSHIAKI SUGIMOTO¹ — ¹The University of Tokyo, Kashiwa, Japan — ²Fritz-Haber Institute of the Max-Planck Society, Berlin, Germany

On-surface synthesis is an effective bottom-up method to fabricate nanocarbon materials, such as graphene nanoribbons (GNRs), in an atomically precise manner. In this study, using the on-surface method with multiple precursors, we successfully synthesized new helicene-derivative molecule fused by seven-atom-wide armchair GNRs on an Au(111) surface. Atomic resolution imaging with non-contact atomic force microscopy (AFM) identified the molecular structure and the helicity (i.e., chirality of the twisted terminal of the GNR). Although the helicities of individual GNRs on the surface remained stable during observation, the approach of the AFM tip to the helicene-type terminal caused repulsive interactions, leading to the inversion of the twisted structure in a selective and reversible manner. This finding would contribute to the advanced design of switchable molecules and control of chiral-molecule-based devices and machines.

#### O 52.6 Wed 18:00 P4

**On-Surface Synthesis of Kekulene and Isokekulene** – •TIM NAUMANN, QI-TANG FAN, LUKAS HEUPLICK, LUKAS RUPPENTHAL, SIMON WERNER, TOBIAS VOLLGRAFF, JÖRG SUNDERMEIER, and J. MICHAEL GOTTFRIED — Fachbereich Chemie, Philipps-Universität Marburg, Marburg (Germany)

The concept of aromaticity explains the exceptional stability of monocyclic, planar, conjugated molecules. When extending this concept on cycloarenes, however, the question arises whether the  $\pi$ -electron system is best described by the Clar model or rather by annulenoid aromaticity, i.e. delocalization in the inner and outer annulene ring. This question has been discussed especially in the context of kekulene, an alternant benzenoid cycloarene. On-Surface techniques offer the possibility to synthesize kekulene and to investivate its resonance stabilisation. To create complete monolayers of kekulene for further spectroscopic studies, we developed a high-yield on-surface synthesis of kekulene on Cu(111) from vapor-deposited 1,4,7(2,7)-triphenanthrenacyclononaphane-2,5,8-triene, which undergoes cyclodehydrogenation upon annealing, resulting in extended (up to 100 nm) well-ordered domains of kekulene. While the reaction is highly selective towards kekulene on Cu(111), reaction on Cu(110) leads to an isomer of kekulene with a lower symmetry, named isokekulene. The precursor and the products were analyzed with scanning tunneling microscopy (STM), X-ray photoelectron spectroscopy (XPS) and other methods. Further annealing leads to peripheral C-H bond activation and linking towards chains and islands.

#### O 52.7 Wed 18:00 P4

**2D** arrays of reaction centers for CO oxidation over Pt/SiO2/Si interface — •ARTUR BÖTTCHER¹, DAVID RETTINGER¹, JAKOB HAUNS¹, MANFRED KAPPES¹, DANIELA EXNER², RAHUL PARMER³, MATTEO AMATI³, and LUCA GREGORATTI³ — ¹Institute of Physical Chemistry, KIT, 76131 Karlsruhe, Germany — ²Institute for Applied Materials, KIT, 76344 Karlsruhe, Germany — ³Elettra - Sincrotrone Trieste SCPA, Area Science Park, 34149 Basovizza-Trieste, Italy

We created arrays of tailored reaction centers on the SiO2/Si-wafer by annealing thin Pt layers deposited on He+-beam patterned Graphene/SiO2/Si substrates.[1] The resulting spots have been identified as amorphous areas consisting of silicon carbides and silicon oxycarbides. These defected surface regions are expected to act as pinning sites for migrating Pt atoms. By thermally activating the surface diffusion of Pt adatoms (1h, 600°C, UHV), the migrating atoms become immobilized thus forming chemical bonds with compounds created in the defected surface regions, resulting in 2D arrays of tailored Pt-based islands. The chemical state of individual islands has been studied by monitoring core level states (ESCA microscopy). The islands consist of Pt, PtSix and PtOx compounds and appear to be chemically resistant under exposure to molecular oxygen and carbon monoxide at T=550°C, p=0.4 mbar, 0.5 h. The CO2-light-off curves enable to estimate the contribution of the artificial reaction centers to the total CO->CO2 conversion yield.

#### O 52.8 Wed 18:00 P4

 $CO \rightarrow CO_2$  conversion over Pt/SiO₂/Si model catalyst — •ARTUR BÖTTCHER¹, PASCAL WEISENBURGER¹, DAVID RETTINGER¹, JAKOB HAUNS¹, RAHUL PARMER², MATTEO AMATI², LUCA GREGORATTI², and MANFRED KAPPES¹ — ¹Institute of Physical Chemistry, KIT, 76131 Karlsruhe, Germany — ²Elettra - Sincrotrone Trieste ScPA, Area Science Park, 34149 Basovizza-Trieste, Italy We studied the thermal stability of the Pt/SiO₂/Si interface as the model catalyst for CO oxidation reaction. The 2D catalysts were prepared under UHV conditions by growing very thin Pt films on the SiO₂/Si wafer and subsequently performing a long-term annealing of the interface at elevated temperatures, T*(700-900K). Such a treatment results in the formation of the submicron-sized islands. The size/shape distribution of the islands scales primarily with the thickness of the Pt film. The chemical state of the islands as probed by ESCA microscopy (Elettra) evidences the formation of PtSinOm alloys as the dominating component of the islands. The CO₂ light-off curves taken for Pt/SiO₂/Si interfaces fabricated at room temperature reveal the highest CO/CO₂ conversion yield, Y, and the lowest activation temperature, T_A ~400 K. Increasing alloying degree considerably quenches the conversion yield and shifts up the CO/CO₂ conversion onset.

# O 52.9 Wed 18:00 P4

Adsorption and photocatalytic inactivation of Corona-virus like particles by anatase TiO2(101) — •MONA KOHANTORABI, MICHAEL WAGSTAFFE, HESHMAT NOEI, and ANDREAS STIERLE — Centre for X-ray and Nano Science (CXNS), Deutsches Elektronen-Synchrotron (DESY), 22607 Hamburg, Germany

The adsorption of corona-virus like particles (VLPs), on the surface of the model catalyst TiO2(101) was investigated using different spectroscopic and microscopic techniques.

Two different methods were employed to inactivate the virus after it was loaded on the surface of TiO2: 1) UV light and 2) thermal treatment. The adsorbed virus morphology and virus particle arrangement on the surface of TiO2 were investigated using grazing-incidence small-angle scattering. Microscopic studies demonstrate that the denatured spike proteins and other virus proteins dissociate from VLPs and adsorb on the surface of TiO2.

Clarification of the interaction of the virus with the surface of semiconductor oxides will aid in obtaining a deeper understanding of the chemical processes involved in photo-inactivation of microorganisms which is important for the design of effective photocatalysts for air purification and self-cleaning materials.

Calculation of XPS Core-Level Fingerprints of Intermediates in Methanol Synthesis on Cu Surfaces — •MATTIS GOSSLER, AZAD KIRSAN, and BERND MEYER — Interdisciplinary Center for Molecular Materials and Computer Chemistry Center, FAU Erlangen-Nürnberg, Germany

Cu/ZnO/Al₂O₃ is used as a highly efficient catalyst in industry for the synthesis of methanol from syn gas, i.e. H₂, CO and CO₂. Despite intensive research efforts over the past decades, the precise reaction pathway and the relevant intermediates in the synthesis process are still under debate. New insights can be provided by recently performed ambient pressure x-ray photoelectron spectroscopy (AP-XPS) measurements on ZnO-supported Cu clusters with well-defined crystal terminations [1]. In order to assist the interpretation of the measured AP-XP spectra, we determined the C-1s and O-1s core level shifts for a series of intermediates in the methanol synthesis process on a variety of Cu surfaces using DFT calculations. First, a careful search for the most stable structure of all intermediates on each surface was performed. Core-level shifts were then calculated by an  $\Delta$ SCF approach after removing a core electron. This fingerprint data allows us to identify the most relevant intermediates present in the AP-XPS experiments and to assess the importance of different Cu surfaces for the overall reactivity. [1] R. Gleissner, H. Noei, S. Chung, G.D.L. Semione, E.E. Beck,

The relation between structure sensitivity and doping of ceria(111) vs. ceria(100) — EMILIA POZAROWSKA¹, LINUS PLEINES², MAURICIO J. PRIETO³, LIVIU C. TĂNASE³, LUCAS DE SOUZA CALDAS³, AARTI TIWARI³, THOMAS SCHMIDT³, JENS FALTA², CARLOS MORALES¹, and •JAN INGO FLEGE¹ — ¹Applied Physics and Semiconductor Spectroscopy, BTU Cottbus-Senftenberg, Cottbus, Germany — ²Institute of Solid State Physics, University of Bremen, Bremen, Germany — ³Department of Interface Science, Fritz-Haber Institute, Berlin, Germany

 $CeO_x$ -Cu inverse catalysts have been shown to convert  $CO_2$  into valuable chemicals through catalytic hydrogenation. The catalytic activity may further be enhanced by alloying ceria with trivalent, catalytically active metals, such as Sm, promoting the formation of  $Ce^{3+}$  active sites. In this work, the structural and chemical properties of (111)- and (100)- oriented  $CeO_x$  islands alloyed with samarium were explored by low-energy electron microscopy and X-ray photoemission electron microscopy. After Sm deposition on the as-grown  $CeO_x$  islands, the near-surface region of (100)-oriented  $CeO_x$  is reduced after exposure to  $H_2$  at 470 °C, whereas the deeper layers as well as the whole (111)-oriented islands retain the  $Ce^{4+}$  state. Subsequent reoxidation with  $O_2$  leads to the complete  $Ce^{4+}$  state recovery, suggesting the healing of oxygen vacancies. Additional annealing at 470 °C induces samarium diffusion into the creia matrix. Yet, subsequent exposure to  $H_2$  reduces neither the (111)- nor the (100)-oriented  $CeSmO_x$  islands, suggesting a quite unexpected stability of this system.

Location: P4

duction uses a ternary Cu/ZnO/Al₂O₃ catalyst. Especially the interaction between Cu and ZnO is critical for a high activity of the catalyst. Multiple model catalysts were synthesized to target different aspects of this system, but particularly the Cu-ZnO interactions. In-situ and operando spectroscopy methods (XAS, XPS, Raman) together with microscopy and measurements of the catalytic performance allow us to follow the chemical and structural changes of the catalysts under reaction conditions. We investigated size-selected Cu and CuZn nanoparticles on multiple support materials (SiO₂, Al₂O₃ and ZnO/Al₂O₃) to obtain a better insight into particle-support interactions. These studies show that the formation of metallic Zn for CuZn particles on SiO₂ is detrimental for the catalysts activity, as it coincides with a deactivation. On Al₂O₃ in contrast, ZnO is incorporated into the support and forms a spinel structure similar to ZnAl₂O₄. In another catalyst shaped Cu particles are used to create preferential facets on the surface of our catalysts. These unalike surface structures will then lead to different catalytic behavior. Here, a higher activity was observed for cubic particles.

Ferroelectric BaTiO3 (001): Atomic-level characterization and polarization by combined STM/AFM — •LLORENÇ ALBONS CALDENTEY¹, DOMINIK WRANA¹, IGOR SOKOLOVIĆ², AJI ALEXANDER¹, and MARTIN SETVIN¹ — ¹Department of Surface and Plasma Science, Faculty of Mathematics and Physics, Charles University, 180 00 Prague 8, Czech Republic — ²Institute of Applied Physics, TU Wien, 1040 Vienna, Austria

Perovskites attract strong interest thanks to their catalytic properties, efficient electron-hole separation in light harvesting, or the frequent occurrence of ferroelectricity. In this work we show that BaTiO3 single crystals can be cleaved along the (001) plane to obtain flat surfaces with domains of either BaO or TiO2 termination. Using low temperature (4K) qPlus nc-AFM we have characterized the surface atomic structure and studied the tip-induced ferroelectric polarization of the material. The impact of ferroelectric poling on adsorbed species is discussed.

O 53.2 Wed 18:00 P4 DFT based analysis of surface reactions of stainless steels through degradation in aqueous media — •VAHID JAMEBOZORGI — Bielefeld University and Bielefeld University of applied science

Stainless steels (SSs) are widely used in industry due to their outstanding mechanical and physical properties plus their durability in corrosive media. The corrosion resistance of SSs is caused by the formation of a thin passive layer which mainly consists of chromium oxides. However, the passive layer makes SSs more vulnerable to localized corrosion including pitting corrosion. Pitting corrosion occurs when the passive layer interacts locally with bond-forming atoms and molecules dissolved in the aqueous media, e.g. halides or hydroxide. However, the process of bond formation, erosion of the passive layer, and consequently the degradation of SSs is still not completely understood. Amongst other parameters, the adsorption energy and work function seem to play a key role in pitting corrosion. The experimental determination of the work function is challenging since the surface texture, crystal defects and impurities can increase or decrease work function value significantly. Here, we show how densityfunctional theory (DFT) computation techniques can be used to obtain adsorption energies and work function values for different crystallographic orientations on the surfaces of Fe, Cr and Ni. As a result we will provide insight into the degradation mechanisms of SSs surfaces in aqueous media.

#### O 53.3 Wed 18:00 P4

**Thermally-induced magnetic order from glassiness in elemental neodymium** — •BENJAMIN VERLHAC¹, LORENA NIGGLI¹, ANDERS BERGMAN², UMUT KAMBER¹, ANDREY BAGROV^{1,2}, DIANA IUŞAN², LARS NORDSTRÖM², MIKHAIL I. KATSNELSON¹, DANIEL WEGNER¹, OLLE ERIKSSON^{2,3}, and ALEXANDER A. KHAJETOORIANS¹ — ¹Institute for Molecules and Materials, Radboud University, Nijmegen, The Netherlands — ²Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden — ³School of Science and Technology, Örebro University, SE-701 82 Örebro, Sweden

In thermodynamic systems, temperature is synonymous with disorder as phase transitions between order to disorder occur when temperature is increased. Re-

cently, the first example of a spin-Q glass was found in elemental neodymium between 30mK and 4K(1). This phase originated from magnetic frustration within the dhcp lattice of neodymium. In this study, we show by means of spin-polarized scanning tunneling microscopy that neodymium undergoes an unusual magnetic transition, where long range multi-Q order emerges from the spin-Q glass phase as temperature is increased from 5 K to 15 K(2). We also developed a new analysis method, which analyzes the experimental data and extracts the phase transition temperature. These findings are supported by atomistic spin dynamics simulations, in which the phase transition is qualitatively explained by destroying spin frustration due to various exchange contributions of the different sublattices.

Yu-Shiba-Rusinov states of Mn on Pb(110) — •BHARTI MAHENDRU, MARTINA TRAHMS, GAËL REECHT, and KATHARINA J. FRANKE — Fachbereich Physik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany

Unpaired electron spins exchange coupled to a superconductor give rise to bound states inside the superconducting energy gap and are called Yu-Shiba-Rusinov (YSR) states. Previously, it has been shown that the crystal-field splits singly-occupied d levels of Mn atoms on Pb surfaces, which leads to distinct YSR states inheriting the symmetry of the spin-carrying orbital [1,2].

Here we investigate single atoms and chains of Mn on a Pb(110) surface using scanning tunneling microscopy and spectroscopy. We find different adsorption sites of the individual Mn atoms and chains, which can be distinguished by different YSR states. Some of the Mn sites show a bistability in the presence of the STM tip, while some of the YSR states are also influenced by the tip position.

Imaging fast magnetization dynamics by Lorentz microscopy with eventbased electron detectors — •ALEXANDER SCHRÖDER, CHRISTOPHER RATHJE, XINLAI XING, and SASCHA SCHÄFER — Institute of Physics, University of Oldenburg, Germany

In recent years, ultrafast transmission electron microscopy (UTEM) [1] has successfully enabled the imaging of ultrafast dynamics on the nanoscale by utilizing femtosecond electron pulses in an optical-pump/electron-probe approach. In a potentially more flexible approach, instead of femtosecond electron pulses, a continuous electron beam could be used to map the optically induced dynamics provided sufficiently fast, event-based electron detectors are employed.

Here, we present Lorenz microscopy of nanoscale magnetic dynamics observed with a Timepix3 hybrid pixel electron detector. In particular, we study the distortion of magnetic vortices triggered by femtosecond optical pulses, accessing reversible processes on time scales ranging from nanoseconds to milliseconds.

**Growth and characterization of WSe**₂ **on epitaxial graphene on SiC(0001)** — •ADRIAN SCHÜTZE, PHILIP SCHÄDLICH, and THOMAS SEYLLER — Institute of Physics, TU Chemnitz, Chemnitz, Germany

2D materials such as, for example, graphene, hexagonal boron nitride or transition metal dichalcogenides have recently received much interest as building blocks for electronic devices. For a successful integration of these materials, scalable growth methods are essential. In this work we investigate the growth of WSe₂ by metal organic molecular beam epitaxy (MOMBE) [1] on epitaxial graphene on SiC(0001). In that process W(CO)₆ is used as a precursor in conjunction with selenium vapor produced by decomposition of SnSe₂ in a thermal evaporator. Using MOMBE we were able to grow ultra-thin films of WSe₂ on epitaxial graphene which were characterized by a combination of X-ray photoelectron spectroscopy (XPS), angle resolved photoemission spectroscopy (ARPES), low-energy electron diffraction and microscopy (LEED, LEEM) and atomic force microscopy (AFM). The films were observed to consist of triangular domains. We discuss the influence of the growth parameters such as the substrate temperature on the structural and electronic properties of the layers.

Vanadyl phthalocyanine: study of the formation of a characteristic molecular spin pattern on a diamagnetic template — •CORINA URDANIZ, KYUNGJU NOH, LUCIANO COLAZZO, JAEHYUN LEE, ANDREAS HEINRICH, CHRISTOPH WOLF, FABIO DONATI, and YUJEONG BAE — Center for Quantum Nanoscience (QNS), IBS, Ewha Womans University, Seoul, Republic of korea

Achieving quantum coherent control of spins on surfaces at the atomic scale is the goal for quantum coherent nanoscience. A good surface spin system requires two components: a localized spin and a buffer layer to isolate that spin from the metallic substrate. The use of magnetic molecules as hosts for spin qubits is a promising pathway towards quantum information processing.

In this work, we used Vanadyl phthalocyanine (VOPc), a well-known spin = 1/2 molecule with long coherence times up to one microsecond in its crystalline form, and the non-magnetic Titanyl phthalocyanine (TiOPc) as a buffer layer from the metal. We found that TiOPc is an effective buffer layer, preserving vacuum-like electronic structure of VOPc. We present compelling arguments for using TiOPc as self-assembling templates with long-range order for adsorbed VOPc molecules. Our results suggest that the TiOPc/VOPc system is a potential candidate for long-lived molecular spin states on surfaces for the study of quantum information processing.

#### O 54.4 Wed 18:00 P4

Competing Processes as Quality Limitation: New Insights into Microscopic Growth Mechanism of hexagonal Boron Nitride on  $Ir(111) - \cdot MARKO$  KRIEGEL¹, KARIM OMAMBAC¹, MARIN PETROVIC², BIRK FINKE¹, FRANK MEYER ZU HERINGDORF^{1,3}, and MICHAEL HORN-VON HOEGEN¹ - ¹Faculty of Physics, University of Duisburg-Essen, D-47057 Duisburg, Germany - ²Center of Cxcellence for Advanced Materials and Sensing Devices, Institude of Physics, HR-10000 Zagreb, Croatia - ³Interdisciplinary Center for Analytics on the Nanoscale (ICAN), D-47057 Duisburg, Germany

Despite the tremendous research effort targeting industrial growth of twodimensional hexagonal boron nitride (hBN), especially on transition metal surfaces, until today no superior growth recipe was developed, promising large domain sizes, homogeneous lattice constants and a matching orientation of layer and substrate. Here we study single layer hBN grown on Ir(111) via conventional chemical vapor deposition (CVD) using borazine as precursor. We found two competing processes governing the density of hBN domains on a microscopic scale: Kinetic limitations at low T and the disintegration of B₃N₃ rings as well as the grown layer at high T. The interplay of both processes sets a fundamental limit to the achievable quality in this and other 2D material systems. Our study combines data from high-resolution reciprocal space mapping, using Spot Profile Analyzing Low Energy Electron Diffraction (SPA-LEED), allowing us to determine the complete distribution of domain orientations, and Low Energy Electron Microscopy (LEEM), for the measure of domain densities.

#### O 54.5 Wed 18:00 P4

Tuning  $MOS_2$  doping by switching its support material — •MARCO BIANCHI¹, DANIEL LIZZIT⁴, PAOLO LACOVIG², CHARLOTTE SANDERS³, DAVIDE CURCIO¹, EZEQUIEL TOSI², MONIKA T. SCHIED², JILL MIWA¹, SILVANO LIZZIT², and PHILIP HOFMANN¹ — ¹Dep. of Physics and Astronomy, ASTRID2, iNANO, Aarhus University, DK. — ²Elettra Sincrotrone Trieste S.C.p.A., Trieste, IT — ³Artemis Program, UK Central Laser Facility, Harwell, STFC, UK — ⁴DPIA - University of Udine, IT

Tuning the electronic properties of a 2D crystal by the interaction with its support is the key to design well-controlled nanoelectronic devices based on transition metal dichalcogenides (TMDCs). In particular, the establishing of a low resistance between a metallic contact and the TMDC has been challenging and different strategies for this have been introduced. It was suggested that a low Schottky barrier could be achieved not only by choosing contact materials with the suitable work function but also by introducing interface defects that can contribute independent of the metal contact work function.

Here we present a combined ARPES, STM, LEED and XPS study of  $MoS_2$  grown on Au(111) using well established methods. After intercalation of Bi, which is semimetallic, and its further treatment we observe a doping consistent with what was inferred from recent transport measurements. The results shown here sheds light on a potential way for tuning the effects of contacts of a 2D layer and their influence on the TMDC electronic structure.

Subnanoscale Engineering of 2D Magnetism in van der Waals Heterostructures — •KEDA JIN^{1,2}, JOSE MARTINEZ-CASTRO^{1,2}, STEFAN F. TAUTZ^{1,3}, and MARKUS TERNES^{1,2} — ¹Institute of Physics II B, RWTH Aachen University, 52074 Aachen, Germany — ²Peter Grünberg Institute (PGI-3), Forschungszentrum Jülich and Jülich- Aachen Research Alliance (JARA), Fundamentals of Future Information Technology, 52425 Jülich, Germany — ³Institute of Physics IV A, RWTH Aachen University, 52074 Aachen, Germany

The dry transferred method paves a way to investigate exotic properties and emerging new phenomena in van der Waals heterostructures. Polycarbonate (PC) is commonly used as a polymer for the dry transfer of 2D materials. A limitation of PC is the contamination of chemical residues on the surface and the difficulty to fabricate complex heterostructures. Here, we show the study of different polymers, including polyvinyl chloride (PVC) and nitrocellulose for an effective and clean way to assemble 2D heterostructures. In addition, based on our previous method of studying encapsulated air-sensitive 2D materials (Nano Lett. 18, 6696 (2018)), we show our current development in a new technique to study air-sensitive materials in heterostructures compatible with ultra-high vacuum: in-situ de-encapsulation. This technique aims to provide the required cleanliness of mechanical assembled air-sensitive van der Waals heterostructures for their study by scanning tunneling microscopy at ultra-high vacuum and low temperature.

#### O 54.7 Wed 18:00 P4

**Growth and characterization of monolayer**  $MnSe_2$  on  $Au(111) - \bullet$ SEBASTIEN ELIE HADJADJ¹, EVANGELOS GOLIAS², JACK HAYES¹, MARCEL WALTER¹, CHRIS-TIAN LOTZE¹, SANGEETA THAKUR¹, IVAR KUMBERG¹, ISMET GELEN¹, JORGE TORRES¹, and WOLFGANG KUCH¹ - ¹Institut für Experimentalphysik, Freie Universität Berlin, Arnimallee 14, 14195 Berlin, Germany - ²MAX IV Laboratory, Lund University, Fotongatan 2, Lund, Sweden

During the last couple of years, there has been a rising interest in novel twodimensional magnetic materials. Most recently, several groups have shown that magnetic order in two-dimensional materials can be stable. Among them, MnSe₂ is interesting, since it has shown magnetic properties at room temperature [1], making it an ideal candidate for applications. However, magnetic order so far has been reported for MnSe2 grown on GaSe or SnSe2, and the role of the interface in the stabilization of magnetic order is not yet clear. We use molecular beam epitaxy to co-deposit Se and Mn on Au(111) to ascertain if the magnetic ordering of monolayer MnSe2 is an intrinsic effect of the material or an interface-induced phenomenon. We examine the films chemically by X-ray photoelectron spectroscopy (XPS) and X-ray absorption spectroscopy (XAS) as well as structurally by scanning tunneling microscopy (STM) and low-energy electron diffraction (LEED). The latter shows a near -  $3 \times 3$  pattern. The XPS measurements show chemical shifts in the Mn and Se binding energies for the MnSe₂ sample in comparison to pure Mn and Se that confirm that the Mn has bonded to Se. [1] D. J. O'Hara et al., Nano Letters 18, 3125 (2018).

Towards Shot-Noise Spectroscopy of Majorana Modes in 2D Systems — •JAN CUPERUS, FLORIS KOOIJ, and INGMAR SWART — Condensed Matter & Interfaces, Utrecht University, Utrecht, The Netherlands

The quasiparticles known as Majorana zero modes (MZMs) are particles that have the peculiar properties to be their own antiparticle and to obey non-Abelian statistics. Because of the latter, MZMs are predicted to be the building blocks of topological quantum computing. Over the past years, many signatures of what could be MZMs have been reported. Examples are the end modes of 1D atomic line defects in ML FeSe [1], or the edge modes found on CrBr3 island grown on NbSe2 [2]. Conclusive observations are however, still to be made. One reason for this is the similarity of MZMs to other (close-to-)zero-energy states, e.g. Yu-Shiba-Rusinov states or Andreev bound states. Scanning tunnelling microscopy (STM) has already shown to be a key tool in the field of condensed matter physics because of its extreme spatial resolution and spectroscopic abilities. Via a new STM-based tool, namely shot-noise spectroscopy, we aim to provide a new point of view onto the matter of MZMs.

The tellurization of Cu(111): From incorporated Te atoms via 1D-like surface reconstructions to closed films - •ANDREAS RAABGRUND, TILMAN KISSLINGER, MAXIMILIAN AMMON, LUTZ HAMMER, and M. ALEXANDER SCHNEIDER — Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen, Germany

We investigated the tellurization of Cu(111) from low Te coverages up to thick films both structurally and electronically by STM, STS, LEED-IV structural analysis, and DFT. For  $\Theta$  < 0.14 ML Te forms a substitutional surface alloy with short-range ordered patches of a  $(\sqrt{7} \times \sqrt{7})$ R19.1° structure. Increasing the Te coverage leads to coexisting islands of a  $(3 \times \sqrt{3})_{rect}$  superstructure which is well-ordered and fully developed at  $\Theta = 0.33 \text{ ML}$  [1]. In the range 0.33 ML <  $\Theta$  < 0.40 ML, the  $(3 \times \sqrt{3})_{\text{rect}}$  structure coexists next to a well-ordered  $(5 \times \sqrt{3})_{rect}$  phase which is completely developed at  $\Theta = 0.40$  ML [2]. Our LEED-IV analyses reveal arrangements of Cu₂Te₂ chains, whereby for the  $(5 \times \sqrt{3})_{rect}$ phase a substantial reorganization of the surface into troughs allows to incorporate more Te. STS finds an unoccupied chain state, that has lower energy on the  $(3 \times \sqrt{3})_{rect}$  which we interpret as an indication of delocalization with decreasing interchain distance. By further tellurization beyond  $\Theta = 1.1$  ML closed Cu_{2-x}Te films develop. For  $\Theta > 4$  ML, a phase transition takes place below 300 K that results in a wrinkled appearance at low temperatures. On the surface two different reconstructions with distinct electronic fingerprint occur side-by-side.

Fabrication of nanostructured van der Waals heterostructures - •KHAIRI F. Elyas¹, Johanna Richter³, Kirill Bolotin³, Hannah C. Nerl², and Катја Нöflich 1  —  1 Ferdinand Braun Institut gGmbH, Berlin, Germany — ²Humboldt Universität zu Berlin, Institute of Physics, Berlin, Germany — ³Freie Universität Berlin, Institute of Experimental Physics, Berlin, Germany

Two-dimensional (2D) materials can exhibit a significantly enhanced lightmatter interaction making them interesting for highly-confined and low-loss light transport. When combining different 2D materials, the different polaritonic modes may hybridize to combine the strong localization of plasmonic excitations with the long propagation distances of phonon modes. Here we report on the fabrication of heterostructures of the (semi)metallic graphene and the wide-bandgap material hexagonal boron (hBN) nitride. The dry-release transfer of graphene and hBN makes use of polydimethylsiloxane(PDMS) and poly(propylene) carbonate (PPC) films. Due to the strong adhesion between PPC and 2D materials at room temperature, we show that single-layer to fewlayer graphene as well as few-layer hBN can be produced on a spin coated PPC film/SiO2/Si substrates by mechanical exfoliation. Using He ion beam patterning we further modify the geometry of the heterostructures on the nanoscale with the specific aim to tune hybrid polaritonic modes. The optical properties of the fabricated heterostructures are then mapped using monochromated low-loss scanning transmission electron microscopy (STEM) electron energy-loss spectroscopy (EELS) and outcomes compared to optical methods.

Interlayer charge transport anomalies in 1T-TaS₂ and 2H-NbS₂ — EDOARDO MARTINO, LÁSZLÓ FORRÓ, and •KONSTANTIN SEMENIUK — Institute of Physics, École Polytechnique Fédérale de Lausanne (EPFL), CH-1015 Lausanne, Switzerland

Lavered van der Waals materials, such as transition metal dichalcogenides, have emerged as promising platforms for realising functional materials for practical applications. Tuning interlayer coupling in these systems via twist, intercalation, exfoliation, etc. opens up a vast parameter space for inducing exploitable properties. Probing of the out-of-plane conduction is a useful tool for gauging the subtle interactions between the atomic planes, particularly in bulk crystals of TMDs.

We present comprehensive studies of charge transport anisotropies of bulk 1T-TaS₂ and 2H-NbS₂. The samples were tailored using focused ion beam in order to ensure homogeneous current flow across the principal crystallographic directions. We find that resistivity anisotropy of 1T-TaS₂ is, paradoxically, of the order of unity, with the out-of-plane conduction becoming more preferred at lower temperatures due to a formation of c-axis-oriented quasi-one-dimensional orbital chains. In 2H-NbS₂, we observe a pronounced upturn of the out-of-plane resistivity upon cooling. We attribute the anomaly to a unidirectional Kondo scattering, caused by inherent inclusions of 1T-NbS₂ layers, which host a lattice of singly occupied orbitals.

Carbon Embedding of Pt Cluster Superlattices Templated by Hexagonal Boron Nitride on Ir(111) — •TOBIAS HARTL¹, MORITZ WILL¹, PANTELIS BAMPOULIS^{1,2}, VIRGINIA BOIX DE LA CRUZ³, PAOLO LACOVIG⁴, VEDRAN VONK⁵, SIMON CHUNG⁵, ANDREAS STIERLE⁵, JAN KNUDSEN³, SILVANO LIZZIT⁴, and Thomas Michely¹ - ¹Universität zu Köln - ²University of Twente - ³MAX IV Laboratory and Division of Synchrotron Radiation Research - ⁴Elettra-Sincrotrone Trieste S.C.p.A — ⁵DÉSY Hamburg

With the goal to delevop the fabrication of a new type of Pt-nanoparticle carbon support electrocatalyst, we investigate the carbon embedding of Pt cluster superlattices grown on the moiré of a monolayer of h-BN on Ir(111). Using STM and XPS we find that carbon embedding is conformal and does not deteriorate the excellent order of the clusters. The thermal and mechanical stability of the embedded clusters is greatly enhanced by the C forming a strong binding to the Pt clusters. Sintering as well as single cluster pick-up by the STM tip, are both suppressed. (Hartl, T. et al., J. Phys. Chem. C, 2021)

The only cluster decay path left takes place at an elevated temperature above 850 K. Cluster material penetrates through the h-BN sheet, whereby it becomes bound to the underlying metal. There are indications that while the a-C matrix and the Pt clusters bind strongly to each other, upon annealing both weaken their binding to h-BN.

We discuss how the binding between the membrane and the substrate can be weakened, such that it is possible to be split-off via a combination of hydrogen bubbling and dry transfer approaches.

Self-assembly and debromination of a functionalized borazine on Ag(111) •BIRCE SENA TÖMEKCE¹, MARC G. CUXART¹, MARTINA CROSTA², MARCO FRANCESCHINI², DANIELE POLETTO², DAVIDE BONIFAZI², and WILLI

Location: P4

 $AUWÄRTER^1 - {}^1$ Physics Department E20, Technical University of Munich, Germany — ²Institute of Organic Chemistry, University of Vienna, Austria

On-surface synthesis is a promising route towards the generation of doped graphene nanoarchitectures with tunable electronic properties [1]. To fabricate atomically precise hybrid BNC materials, distinct precursors incorporating BN units can be used [2]. In this study, we employed a precursor with a borazine core and Br and OH functionalization. We report on a low-temperature scanning tunneling microscopy/spectroscopy and X-ray photoelectron spectroscopy characterization of well-ordered phases of this precursor on Ag(111). At low temperatures, the molecules adsorb intact. At moderate temperatures, debromination is activated and the self-assembly of a chiral kagomé lattice coexisting with a hexagonal packing is observed. At elevated temperatures, completion of cyclodehydrogenation leads to full planarization of the molecules, followed by covalent intermolecular coupling, thereby forming random BNC-based networks. We further investigated the electronic structure of the kagomé lattice on the single molecule level. Our findings constitute a step towards exploiting the structural and electronic properties of BNC architectures.

O 55.2 Wed 18:00 P4 The investigation of self-assembly molecule on metal substrate — •Yong-HE PAN and GERMAR HOFFMANN — Department of Physics, National Tsing Hua

University Field-effect transistors (FETs) made out of organic materials are lighter, mechanically more flexible, have lower costs and have higher field-effect mobility. For picene- $(C_{14}H_{29})_2$  the highest field-effect mobility in all FETs was recorded. Here, phenacene- $(C_{14}H_{29})_2$  is deposited on Au(111) by thermal evaporation and is investigated by STM and Scanning Tunneling Spectroscopy (STS) at 70 K under UHV conditions. The self-assembly molecule forms a rhombohedral unit cell with a two molecular basis, and the alkyl chain, flexible up to 15 degrees, is nearly parallel with the nearby molecules. Scanning close to the bandgap region of the phenacene( $C_{14}H_{29}$ )₂ leads to imaging of the LUMO-state, which also shows the pronounced electronic state on the phenacene core and energetically broad state on the alkyl chain.

O 55.3 Wed 18:00 P4

adsorption structure and mechanical properties of single nonahelicene molecules on Ag(110) — •MAX HALBAUER^{1,2}, AKITOSHI SHIOTARI¹, TAKASHI KUMAGAI³, KYOKO NOZAKI², and MARTIN WOLF¹ — ¹Department of Physical Chemistry, Fritz-Haber-Institute of the Max-Planck-Society, Faradayweg 4-6, 14195 Berlin, Germany — ²Department of Chemistry and Biotechnology, School of Engineering, The University of Tokyo, 7-3-1 Hongo, Bunkyo-ku, 113-8656 Tokyo, Japan — ³Center for Mesoscopic Sciences, Institute for Molecular Science, 38 Nishigo-Naka, Myodaiji, 444-8585 Okazaki, Japan

Helicenes are a class of compounds that has received great attention due to their chiroptical properties, while the single-molecule mechanical behavior has often been overlooked. Scanning tunneling microscopy (STM) and atomic force microscopy (AFM) measurements of nonahelicene ([9]H) molecules on Ag(110) were performed in order to address this issue. The adsorption structure of isolated and aggregated [9]H molecules on the surface is revealed by high-resolution imaging. Interactions of the molecule with a probe tip are quantified by force curve measurements and a comparison with co-adsorbed coronene gives insights into the impact of the helical backbone on the mechanical properties.

#### O 55.4 Wed 18:00 P4

Changes in the coupling of a single-molecule magnetic moment to a Cooper pair condensate by the sequential removal of molecular moieties — •STEFAN SCHULTE¹, NICOLAS NÉEL¹, KRISZTIAN PALOTAS², and JÖRG KRÖGER¹ — ¹Institut für Physik, Technische Universität Ilmenau, Ilmenau, Germany — ²Institute for Solid State Physics and Optics, Wigner Research Center for Physics, Budapest, Hungary

Using the tip of a STM chemical reactions are induced in organic 5, 10, 15, 20tetrakis(4-bromophenyl)-porphyrin-cobalt molecules adsorbed on superconducting Pb(111). Two chemical reactions, the dehalogenation and dephenylation of the molecules are presented. Yu-Shiba-Rusinov bound states occur in the superconductor energy gap only after the entire dephenylation of the molecule. The presence of the intragap resonances is related to an unoccupied molecular orbital that is confined to the atomic magnetic center (Co) of the porphyrin. From the energy position and spectral weight of these intragap resonances, a weak interaction between the molecular magnetic moment and the Cooper pair condensate is inferred. The electron-hole asymmetry of the bound states exhibits a spatial oscillation with a wavelength that evidences the exchange coupling of the molecular magnetic moment to the sp-sheet of the Fermi surface. The very low binding energy of the Yu-Shiba-Rusinov levels is consistent with the observed absence of the Kondo effect. Funding by the DFG through KR 2912/10-1 and KR 2912/10-3 is acknowledged.

## O 55.5 Wed 18:00 P4

Pentacene on prototypical antiferromagnets: A photoemission study — •VALENTIN MISCHKE, DAVID JANAS, GIOVANNI ZAMBORLINI, JONAH E. NITSCHKE, and MIRKO CINCHETTI — Department of Physics, TU Dortmund University, Otto-Hahn-Straße 4, 44227 Dortmund, Germany In the last years, so-called molecular spinterfaces have been intensively studied because of the novel spin properties raising from the molecule-metal hybridization [1]. Recently, antiferromagnets have been considered as an alternative to their ferromagnetic counterparts for the engineering of spinterfaces with novel spin properties. Here, we present the preliminary characterization of a single layer of pentacene atop two prototypical antiferromagnets, namely nickel oxide NiO(111) and iron oxide FeO(100). Both thin films have been grown in-situ, under UHV conditions, by depositing Ni and Fe in a  $O_2$  background atmosphere onto Au(111) and oxygen-passivate Fe(100), respectively. The resulting interfaces have been characterized with low energy electron diffraction and momentum microscopy. In addition, photoemission tomography was employed to determine the energy level alignment of the molecular orbitals at the interface.

#### O 55.6 Wed 18:00 P4

Systematically mapping the distance-dependent tip-sample interaction for the PTCDA/Ag(111) system — •TIM DIERKER and PHILIPP RAHE — Fachbereich Physik, Universität Osnabrück, Barbarastraße 7, 49076 Osnabrück, Germany Scanning probe microscopy (SPM) has been continually improved by establishing a number of controlled tip functionalizations [1]. In particular, the attachment of a single 3,4,9,10-perylene-tetracarboxylic-dianhydride (PTCDA) molecule to the apex of a metallic tip enables mapping of the electrostatic potential near sample surfaces by so called scanning quantum dot microscopy [2,3]. In order to reliably apply this technique, the expedient pick-up of a single molecule is required [4]. Here, the tip-molecule interaction between a metallic tip and surface-adsorbed molecules is investigated by means of systematic scanning tunneling (STM) and atomic force (AFM) microscopy measurements. In particular the vertical dependencies of the STM tunneling current and the AFM frequency shift are mapped along different axes of single PTCDA molecules embedded in the molecular film on Ag(111). Fingerprints for the dynamic behavior of the molecules are clearly revealed and guide the vertical manipulation for molecular pick-up.

Photoemission and Raman Spectroscopic Studies of n-GaAs(100) Surface Passivation with Thioglycolic Acid — •ALEXANDER EHM, OLEKSANDR SELYSHCHEV, and DIETRICH R. T. ZAHN — Semiconductor Physics, TU Chemnitz, Chemnitz D-09107, Germany

Gallium arsenide is one of the most investigated inorganic semiconductors and used in a vast variety of applications and prospective for new high-performance devices. A challenge in constructing such devices is a surface of native oxides causing a high surface density of states, which leads to the mid-gap pinning of the surface Fermi level, band bending, and the formation of a surface depletion layer. Sulphur passivation yields a significant reduction of the depletion layer and related effects but requires several treatment steps [1].

We report a new simple approach utilizing thioglycolic acid (TGA) to provide a one-step effective removal of surface oxides and protection from reoxidation compared to etching with inorganic acids. This effect is confirmed by X-ray photoemission spectroscopy and the reduction of the depletion layer is confirmed by Raman spectroscopy results. n-GaAs(100)/poly(3,4-ethylenedioxythiophene) polystyrene sulfonate (PEDOT:PSS) solar cells show improved performance for such passivated n-GaAs(100) surfaces.

The different effects of the topology of pyrene and cyclohepta[*fg*]acenaphthylene (acepleiadylene) on the occupied and the unoccupied electronic states as well as on the desorption process from the Cu(111) surface are studied using PES, NEX-AFS and TPD. Both molecules are aromatic but differ in their topology. While pyrene has an alternating structure, its constitutional isomer acepleiadylene has a non-alternating one. With TPD, we showed that the desorption of acepleiadylene begins at about 340 K, 40 K higher than for pyrene, indicating a stronger bond to the Cu(111) surface. Using the modified leading edge analysis we find a desorption energy of 152 kJ/mol for acepleiadylene compared to 108 kJ/mol for pyrene, each at monolayer coverage. Furthermore, combining PES and NEX-AFS, we were able to assess the energy needed in the excitation process of electrons originating from occupied valance orbitals into unoccupied ones. Here we find a 0.5 eV smaller energy difference for the non-alternating species in comparison to the alternating species.

# O 55.11 Wed 18:00 P4

New Photon Scanning Tunnelling Microscope for studying electrically driven single photon emitters in the GHz range — •ANDREAS REUTTER^{1,2}, MIKE STUMMVOLL^{1,2}, NEDA NOEI¹, MARKUS ETZKORN^{1,2}, and UTA SCHLICKUM^{1,2} — ¹Institut für Angewandte Physik, Technische Universität Braunschweig, Mendelssohntraße 2, 38106 Braunschweig — ²Laboratory for Emerging Nanometrology, Langer Kamp 6a/b, 38106 Braunschweig

Single atoms and molecules have always been an interesting research area. An important tool for investigating such is scanning tunnelling microscopy (STM) which has become a widely used method to characterize not only the surface density states and vibrational excitations but also electrical excitations and recombination processes of individual atoms and molecules by STM-induced luminescence (STML).

We would like to present a state-of-the-art, self-build, low-temperature, ultrahigh vacuum STM with the possibility for STML measurements and for the timeresolved probing of electrically driven single photon emitters with a band width of up to around 20 GHz. This allows for instance the investigation of charge transfer in molecules below the nanosecond range and further insight into its exciton decay.

Anchoring *p*-terphenyl-based thiols to top-layer sulphur defects on  $MoS_2/Au(111) - J$ . Rika Simon¹, Dmitrii Maksimov², •Juan Pablo Guerrero Felipe¹, Paul Wiechers¹, Christian Lotze¹, Ana M. Valencia^{3,4}, CATERINA COCCHI^{3,4}, BJÖRN KOBIN⁴, STEFAN HECHT⁴, MARIANA ROSSI², and Katharina J. Franke $^1 - {}^1$ Freie Universität Berlin, Germany  $- {}^2$ MPI for the Structure and Dynamics of Matter, Hamburg, Germany — ³Carl von Ossietzky Universität Oldenburg, Germany — ⁴Humboldt-Universität zu Berlin, Germany Systems consisting of transition metal dichalcogenides (TMDCs) and organic molecules is a field gathering much interest in recent years. By using a scanning tunneling microscope (STM), it is possible to explore these systems in detail, where the TMDC layer works as a decoupling layer between the adsorbate and metal substrate. In our experiments, we investigate a monolayer of MoS₂ on Au(111) where interesting results occur once a sulphur defect on the top-layer is created. It gives rise to a localized resonance around the Fermi energy, not present in pristine MoS2. Here we show experimental and theoretical comparisons where the thiol-based molecule CF3-3P-SH (4"-(trifluoromethyl)-[1,1':4',1"-terphenyl]-4-thiol) is anchored to a sulphur top-layer defect, creating a chemical bond between the molecule and MoS2. We observe a characteristic Kondo resonance due to the interaction between molecule and substrate. Additionally, we have mapped out the spatial distribution of the electronic states as well as explored the vibronic states of the molecule.

**On-Surface Transmetalation of a Lead-Porphyrin on the Cu(111) surface** – •JAN HERRITSCH, STEFAN R. KACHEL, QITANG FAN, MARK HUTTER, LUKAS J. HEUPLICK, FLORIAN MÜNSTER, and J. MICHAEL GOTTFRIED — Philipps-Universität Marburg

Starting from porphyrin complexes, highly ordered nanostructures can be assembled on surfaces in which reactive metal centers are firmly anchored in a defined environment. Such structures have enormous potential in various areas of modern technology. A reaction in which there is an exchange of the central atom by another element leads to a drastic change in the properties of the functionalized surface. Here, we report on a thermally induced Pb/Cu metal exchange of lead(II)-tetraphenylporphyrin (Pb(TPP)) on the Cu(111) surface. Using temperature-dependent XPS, we were able to track this exchange reaction and the accompanying change of the Pb oxidation state by probing the Pb 4f level. The reaction starts already below 380 K and is completed at 600 K. In parallel, partial desorption of a monolayer occurs above 430 K. In a temperatureprogrammed reaction experiment (TPR), the desorbing species are unambiguously identified as the product, Cu(TPP), of the metal exchange by mass spectrometry. By STM, the adsorbate structure of Pb(TPP) on Cu(111) were revealed and individual free Pb atoms, which are formed in the course of the Pb/Cu metal exchange, were observed. Moreover, side-reactions of the peripheral phenyl substituents occur due to dehydrogenative coupling reactions.

**Tip-enhanced Raman Spectroscopy of a lifted single PTCDA molecule** – •RODRIGO CEZAR DE CAMPOS FERREIRA¹, JIŘÍ DOLEŽAL^{1,2}, SOFIA CANOLA¹, PROKOP HAPALA¹, PABLO MERINO³, and MARTIN ŠVEC¹ – ¹Institute of Physics,Czech Academy of Science;, Czech Republic – ²Faculty of Mathematics and Physics, Charles University; Czech Republic – ³Instituto de Ciencia de Materiales de Madrid; CSIC, Madrid, Spain

Advanced scanning probe techniques in the research of molecular adsorbates on surfaces have been instrumental in unveiling fundamental quantum phenomena with high sensitivity and spatial resolution at the nanoscale level. Such advances impact areas of molecular electronics, nanophotonics, and near-field spectroscopies. Tip-enhanced Raman spectroscopy (TERS) is a technique that provides access to vibrational modes of individual molecules via the extremely confined plasmonic field at the STM tip apex. This can be also used as a probe to chemically scrutinize single bonds with subnanometer precision. In this work, the STM-controlled TERS technique in a UHV environment at low temperature was performed for the perylene tetracarboxylic dianhydride molecule (PTCDA), in which we measured the Raman fingerprint for an array of PTCDAs on Ag(111) as well as for a single molecule. Moreover, we were able to simultaneously follow the conductance spectrum of the system while lifting a single PTCDA from the surface. The observed transition in the Raman spectra correlates with the differential conductance showing the transition of the system from S=0 neutral to S=1/2 anion state.

Electronic properties of CuPc/TiSe2 heterostructures — •HIBIKI ORIO^{1,2}, KIANA BAUMGÄRTNER^{1,2}, CHRISTIAN METZGER^{1,2}, MARKUS SCHOLZ^{3,4}, KAI ROSSNAGEL^{4,5}, and FRIEDRICH REINERT^{1,2} — ¹Universität Würzburg Experimentelle Physik VII, Würzburg, Germany — ²Würzburg-Dresden Cluster of Excellence ct.qmat, Würzburg Dresden, Germany — ³European XFEL Facility, Schenefeld, Germany — ⁴Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany — ⁵KiNSIS, Universität Kiel, Kiel, Germany

Transition metal dichalcogenides (TMDC) are a class of quasi-2D materials that exhibit a variety of electronic properties including superconductive, excitonic insulator, and charge-density wave (CDW) phases. TiSe2 is one of the most prominent TMDC because it has intriguing CDW properties. The physical process of the CDW is not fully understood, however, and is attributed to either be purely electron-electron or jointly electron-electron and electron-phonon mediated. To gain more insight into the CDW buildup, modulating the intrinsic physical properties is useful [1]. For this purpose, we have used organic molecules as several interactions such as charge transfer or a rearrangement of the electron density can modulate the electronic properties at the organic/TMDC interface. We have evaporated copper phthalocyanine (CuPc) on TiSe2 single crystals. We report the perturbed electronic characteristics of the resulting CuPc/TiSe2 heterostructure examined with angle-resolved and X-ray photoelectron spectroscopy.

Chirality-induced electron spin filtering in chiral helicene mono-, doubleand multilayers — •Ruwen Quenter¹, Paul Valerian Möllers¹, Karl-Heinz Ernst², and Helmut Zacharias¹ — ¹Center for Soft Nanoscience, WWU Münster, Germany — ²Empa, Dübendorf, Switzerland

The transmission yield of electrons through molecules with chiral structure can depend on the electron spin. This phenomenon is established as chirality-induced spin selectivity (CISS).¹ While initial demonstrations of CISS were conducted with, e.g., short DNA strands,² studies with simpler molecules such as

Location: P4

helicene potentially allow for a better insight into the mechanism. Previous work³ on CISS in ordered monolayers of heptahelicene ([7]H) demonstrated that while the preferentially transmitted spin orientation depends on the helicity of the molecules, no major influence of the substrate is evident. Since the CISS increases with the number of helical turns, we investigate how it evolves for double and multilayers of [7]H adsorbed on a Cu(332) surface. Photoelectrons were excited from the substrate by deep-UV laser pulses and transmitted through [7]H

mono-, double or multilayers. Subsequently, the average spin polarization of the photoelectrons was measured via Mott scattering. With a [7]H monolayer a spin polarization of  $P \approx 8\%$  was shown earlier³ and reproduced now. For the double and multilayers no increased spin polarization magnitude was found. ¹ D. H. Waldeck et al., APL Mater. **9**, 040902 (2021) ² B. Göhler et al., Science **331**, 894 (2011) ³ M. Kettner et al., J. Phys. Chem. Lett. **9**, 2025 (2018)

Pt Wedge on h-BN/Rh(111): Structural Analysis by HR-XPS — •NATALIE J. WALESKA, FABIAN DÜLL, FLORIAN SPÄTH, UDO BAUER, PHILIPP BACHMANN, JOHANN STEINHAUER, and CHRISTIAN PAPP — Friedrich-Alexander-Universität, Erlangen, Germany

An approach to overcome the material gap to commercial catalysts is the investigation of metal nanoclusters on 2D materials (e.g. h-BN). To date, mostly 3D metal clusters with a narrow size distribution on such support materials were studied. However, the clusters' structure and thus the available adsorption sites, as well as the catalytic activity varies strongly from 3D to monolayer clusters or even single atoms.

To investigate the structural differences of clusters with varying sizes, a Pt wedge was prepared in a single preparation step on the h-BN/Rh(111) substrate, ranging from 0.21 to 0.001 ML Pt coverage. The analysis was performed using HR-XPS and CO as a probe molecule. From the data, we were able to determine the transition from monolayer to 3D cluster formation for the as-prepared Pt wedge. Upon heating to 550 K, structural changes of the Pt clusters were observed as a result of cluster ripening and sintering.

We thank Helmholtz-Zentrum Berlin for allocation of synchrotron-radiation beamtime and BESSY II staff for support during beamtime. This work was funded by the DFG within SFB 953 "Synthetic Carbon Allotropes" (Project #182849149).

#### O 56.2 Wed 18:00 P4

Charge effects on the (de-)Hydrogenation activity of  $Pt_n$ -clusters on *a*-SiO₂ thin films — •TOBIAS HINKE¹, ANDREW CRAMPTON¹, MARIAN RÖTZER¹, MAXIMILIAN KRAUSE¹, FLORIAN SCHWEINBERGER¹, BOKWOON YOON¹, UZI LANDMAN², and UELI HEIZ¹ — ¹Physical Chemistry, Department of Chemistry & Catalysis Research Center, Technical University of Munich, 85748 Garching, Germany — ²School of Physics Georgia Institute of Technology, Atlanta GA, U.S.A.

Catalytic model systems facilitate the gain of fundamental insights on molecular mechanisms and enable atom-precise manipulation of catalytic processes. Besides the size-effects of clusters with less than 100 atoms, the influence of the supporting material and the substrate are of special interest when steering reactivity. The catalyst's local electron density can be altered by varying the underlying metal. A high local work function of the substrate, Mo(112), yields clusters of positive charge while a low local work function , Pt(111), results in a negative charge. This allows for specifically altering the reactivity as well as the coking stability of the catalytic system.

In order to elucidate the impact of different support materials as well as cluster size-effects the change in activity of a-SiO₂ thin-film supported Pt_n-clusters towards ethylene (de-)hydrogenation was investigated.

The catalytic samples were characterized in a UHV setup with base pressures below  $5 * 10^{-10}$  mbar through IRRAS and electron spectroscopy (XPS, MIES, UPS), while reactivity was monitored with TPD and pulsed valve experiments (*p*-MBRS).

#### O 56.3 Wed 18:00 P4

**Design of an Enhanced Ce-Evaporator for Ce_xO_y Thin Film Synthesis** — •FLORA SIEGELE, KEVIN BERTRANG, TOBIAS HINKE, and UELI HEIZ — Physical Chemistry, Department of Chemistry and Catalysis Research Center, Technical University of Munich

In today's industry, the importance of sustainability regarding resource consumption and waste management is strongly increasing and hence, the contribution of catalysis-based processes is becoming more and more important. Substantial advances can be achieved by investigating catalytic model systems to facilitate the understanding of basic mechanisms on a molecular level. These model catalysts comprise a metal single crystal substrate with metal clusters (1-100 atoms), deposited on a metal oxide thin film (2-20 ML). Especially the lewis acidic and basic properties of metal oxidic compounds showed promising results in terms of controlled tuning of the catalytic performance. However, the reducibility of thin film materials like  $CeO_2$  offers an additional possibility of adjusting catalytic properties. Due to the lack of experimental results focusing on the influence of  $CeO_2$  thin films on the reactivity and selectivity of clusters, the poster presents the implementation of an optimized  $CeO_2$  thin film generation procedure with a home-built ribbon evaporator. With this evaporator design, including a self-built quartz crystal microbalance, deposition rates of multiple monolayers per minute could be achieved and tracked with high accuracy. Electron emission spectroscopy (x-ray photoelectron spectroscopy and Auger electron spectroscopy) was performed to investigate the composition of the deposited film.

O 56.4 Wed 18:00 P4

**CO** Adsorption on PdPt Alloy Nanoparticles — •Daniel Silvan Dolling^{1,2}, Jan-Christian Schober^{1,2}, Marcus Creutzburg¹, Heshmat Noei^{1,2}, and Andreas Stierle^{1,2} — ¹Universität Hamburg — ²DESY

Platinum palladium alloy nanoparticles are of high interest because of their role as catalysts for different processes, including exhaust control and methane oxidation. Catalyst behavior is determined by the shape, structure and alloy composition of the particles. To enhance catalyst efficiency, it is thus necessary to improve our understanding of the structure of the nanoparticles and the active adsorption sites. In order to access detailed structural and morphological information, we employ the use of a model catalyst. In this work, platinum and palladium are co-deposited via molecular beam evaporation on  $\alpha$ -Al2O3 (0001). The nanoparticles are grown epitaxially and have a well defined height to diameter ratio and alloy composition. By investigating the particle surface with the probe molecule CO using polarized infrared reflection absorption spectroscopy (IRRAS), we determined the surface species on top and side facets of the particles. The morphology was further identified with X-ray diffraction and X-ray reflectivity. The effect of the Pd/Pt alloy composition on the adsorption was investigated by comparing the IRRAS reflectivity. Moreover, the difference in the adsorption of CO was studied for samples annealed in hydrogen and oxygen.

O 56.5 Wed 18:00 P4

Methane activation with small Ta clusters — •KEVIN BERTRANG, TOBIAS HINKE, NIKITA LEVIN, MARTIN TSCHURL, and UELI HEIZ — Physical Chemistry, Department of Chemistry and Catalysis Research Center, Technical University of Munich

With the exhaustion of petroleum reserves, methane will become an important feedstock for the synthesis of fuels and fine chemicals. The challenge is to find an efficient way to activate the highly inert molecule under mild conditions and steer the reaction towards the formation of chemically precious products while preventing coking.

Studies of small cationic Ta-clusters in the gas phase and their oxides were found to exhibit high activity towards non-oxidative C-C-coupling of methane, yielding dehydrogenated carbohydrate species and ethane. The cluster charge was identified as a key parameter for activity. These studies are extended to their supported analogues. To replenish the cluster charge acidic (SiO₂) and reducible (CeO₂) thin metal-oxide films are employed and cluster oxygen content is tuned.

Characterization is performed by means of vibrational (IRRAS) and electron spectroscopy (XPS) and reactivity is studied via TPD and pulsed valves experiments.

**3d-Nanoparticles on Graphene: Influence of Temperature** — •КАІ ВЕSOCKE, Манвоовен Ravankнан, and Mathias Getzlaff — Institut für Angewandte Physik, Heinrich-Heine-Universität Düsseldorf

With its unique properties, such as high quality crystal structure, excellent electrical conductivity and high tensile strength, graphene is a promising substrate for fabricating nanocomposites. In this context we are investigating the influence of graphene as substrate for the deposition of metallic nanoparticles and the influence of susequent heating. In this contribution we present our results concerning the mobility and distribution of Fe_{0.5}Ni_{0.5}-Nanoparticles on graphene surfaces.

A W (110) single crystal serves as the substrate being coated with a Co thin film of about 20 ML and annealed at temperatures up to 500  $^{\circ}$ C. Surfaces prepared in such a way exhibit elongated Co-islands with a width of several hundred

524

nm and height up to 10 nm, which are coated with graphene subsequently. For graphene synthesis the samples are heated in a Propene atmosphere of  $10^{-6}$  mbar for several minutes. The nanoparticles are produced by means of Ar magnetron sputtering in a Haberland source and aggregation takes place in a He atmosphere.

The spherical particles under investigation have diameters of several nm. Particle distributions are analyzed via STM, both as-prepared as well as after heating. It will be discussed, whether the nanoparticles are more mobile on graphene compared to other surfaces.

Josephson effect in the two-band superconductor Niobium Diselenide — •XIANZHE ZENG¹, HAONAN HUANG¹, SUJOY KARAN¹, KLAUS KERN^{1,2}, and CHRISTIAN AST¹ — ¹Max-Planck-Institut für Festkörperforschung, Heisenbergstraße 1, 70569 Stuttgart, Germany — ²Institut de Physique, Ecole Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland

Niobium Diselenide is a two-dimensional (2D) van der Waals s-wave superconductor that can be described by a two-band model. The Josephson effect between Niobium Diselenide and another known BCS superconductor is non-trivial since it involves Copper pair tunneling of two bands with different order parameters. Here, we measure quasiparticle tunneling as well as the Josephson current between a clean superconducting Niobium Diselenide surface and a superconducting Vanadium tip using low-temperature scanning tunneling microscopy and spectroscopy. We analyze our results with the McMillan formula for a two-band superconductor. Our observations present a first step towards understanding more complicated scenarios, such as the predicted p-wave triplet superconductivity in Chromium Tribromide islands on Niobium Diselenide.

O 57.2 Wed 18:00 P4 Bulk Ion Conductivity and Near Surface Composition of Ionic Liquid and Zwitterionic Salt Based Electrolytes for Lithium Battery Applications -•FABIAN ULLMANN, JOEL TAYO, ANNA DIMITROVA, and STEFAN KRISCHOK — Institut für Mikro und Nanotechnologien, Institut für Physik, TU Ilmenau In this contribution we focus on the bulk conductivity and the near surface composition of several tertiary electrolytes which consist of Ionic Liquid (IL), Zwitterionic salt (ZwS) and lithium salt. Two ILs and ZwSs are chosen: IL: 1-ethyl-3-methyl-imidazolium bis-(trifluoromethylsulfonyl)imide - [EMIm][Tf2N] and 1-butyl-1-methylpyrrolidinium bis-(trifluoromethylsulfonyl)imide [BMP][Tf2N]; ZwS: 3-(3-methylimidazolium-1-yl)Propane-1- sulfonate and 3-(3-vinylimidazolium-1-yl)Propane-1-sulfonate. As lithium precursor bis(trifluoromethylsulfonyl)imide - Li[Tf2N] was used. Different Li[Tf2N]/ZwS ratios are considered and studied. Electrochemical Impedance Spectroscopy (EIS) enables us to determine the ion conductivity of the electrolytes. The results reveal that the presence of ZwSs enhances the ion conductivity, although they itself are not ion conductive. Further, by using X-Ray Photoelectron Spectroscopy (XPS) we analyze the near surface chemical composition at UHV-conditions. The XPS analysis displays a cation/anion/ZwS distribution as depended on the concentration of Li[Tf2N] and the type of IL and ZwS used. The spectroscopic results revealed solute-solvent interactions which modify the ion mobility.

Line shape analysis of the resonant eigenstates in a quantum corral by means of tunneling spectroscopy and non contact AFM — •MARCO WEISS, MICHAEL ROESSNER, FABIAN STILP, and FRANZ J. GIESSIBL — Institute of Experimental and Applied Physics, University of Regensburg, Germany

Back in 1993 Crommie et al. [1] arranged 48 Fe adatoms on a Cu(111) surface in a circle with a diameter of 14.26 nm. This quantum corral confines surface electrons in a circular potential well. Past investigations with scanning tunneling microscopy revealed energetically discrete eigenstates that spatially appear as Bessel functions. But these studies on the Fe quantum corral showed unwanted movement of the corral walls during spectroscopic measurements. [1]

Instead of Fe, we used CO molecules to provide the corral with more stable walls. This permitted us to access a larger voltage window and allowed for a detailed line shape analysis of the corrals eigenenergy levels. Surprisingly, we discovered a large Gaussian broadening of the eigenstates.

We also acquired nc-AFM data of the corral. As we have previously done, we determined the occupation of electronic states that cross the Fermi level [2]. Similar to our previous work, we observed that the presence of the probe tip shifts the energy of the electronic states under study. In this work, we show that we can also use the AFM data to estimate the lifetime (i.e. the spectral width) of these states.

O 57.4 Wed 18:00 P4 Interaction between an artificial and a natural atom — •FABIAN STILP, MARCO WEISS, and FRANZ J. GIESSIBL — University of Regensburg, Regensburg, Germany The surface state of Cu (111), a quasi-2-dimensional electron gas, is trapped to a small surface area of about 15 x 15  $\text{nm}^2$  by placing 48 CO-molecules in a circular shape on the surface via atomic manipulation. By doing so, one creates a quantum corral with discrete electronic states forming an artificial atom. This structure can be described reasonably well by an infinitely high circular potential well leading to corral states with Bessel-type radial functions and an angular momentum normal to the surface. To investigate the interaction between this artificial atom and a natural atom we bring Fe atoms inside the corral and measure the response of the corral states.

Thanks to the large size, one can study the structure of the wave functions within that artificial atom by nc-AFM showing an angular dependence of the corral states after placing the atoms inside the corral. This change of the wave functions leads to an energy shift of a few meV confirmed by tunneling spectroscopy measurements. By investigating the change of the wave functions and the energies of the corral states when placing the adatom inside, one can draw conclusion about the interaction between this artificial atom and a natural atom. Here we expand the interpretation of the adatom acting repulsively on the corral states as stated by Stilp et al. [1].

**Spontaneous Charge Localization on Polar Surfaces** — •MICHELE RETICCIOLI¹, ZHICHANG WANG^{2,3}, ZDENEK JAKUB², IGOR SOKOLOVIC², MATTHIAS MEIER^{1,2}, GARETH S. PARKINSON², MICHAEL SCHMID², DOMINIK WRANA⁴, LYNN A. BOATNER⁵, ULRIKE DIEBOLD², MARTIN SETVIN^{2,4}, and Cesare FRANCHINI^{1,6} — ¹Faculty of Physics and Center for Computational Materials Science, University of Vienna, Austria — ²Institute of Applied Physics, TU Wien, Vienna, Austria — ³State Key Laboratory for Physical Chemistry of Solid Surfaces, Xiamen University, China — ⁴Department of Surface and Plasma Science, Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic — ⁵Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, USA — ⁶University of Bologna, Italy

Excess charge on polar surfaces of ionic compounds is commonly described by the two-dimensional electron gas (2DEG) model, a homogeneous distribution of charge confined in a few atomic layers. Conversely, our density functional theory calculations and scanning-probe microscopy measurements on KTaO₃(001) show spontaneous localization of the excess charge in the form of polarons, bipolarons and charge density waves. These electronic reconstructions form on the defect-free surface, and alter the material properties and functionalities to different degrees. Controlling the degree of charge ordering could be of great benefit for a wide range of applications: in our study, we analyze the impact on the surface reactivity by considering the interaction with CO molecules.

#### O 57.6 Wed 18:00 P4

**Evolution of Property and Bonding Maps** — •CARL-FRIEDRICH SCHÖN and MATTHIAS WUTTIG — RWTH Aachen University, Aachen, Germany

Since picking up the first tool, it has been the goal of mankind to create materials that best suit human needs. While for the longest time any development in this field was driven by an empirical approach, modern means of physics and chemistry gave rise to the concept of material and property maps based on chemical bonding. We have composed a database of elemental and binary compounds. For all compounds, the corresponding values of a set of properties were included, containing the conductivity, the Born Effective Charge, the Effective Coordination Number (ECoN) and the Bandgap, the melting point, the density and the atomic density. A Gaussian mixture algorithm was utilized to separate the compounds in the database into n clusters. With the number of allowed clusters set to 4, the algorithm nicely separates materials which employ metallic, ionic and covalent bonding. This implies that properties can be used to distinguish bonding mechanisms. Interestingly, a fourth class of materials is identified, characterized by a property portfolio neither found in metals, or materials employing ionic or covalent bonding. This is further support for the concept of metavalent bonding, a novel bond type characterized by the competition between localization and delocalization. This classification provides a close link between chemical bonding mechanisms and properties enabling novel routes to material's design with material maps.

Fully Atomistic Modelling of Tip-enhanced Raman Spectra from First Principles — •YAIR LITMAN, FRANCO BONAFE, ALAA AKKOUSH, HEIKO APPEL, and MARIANA ROSSI - MPI for the Structure and Dynamics of Matter, Hamburg, Germany.

Tip-enhanced Raman scattering (TERS) has emerged as a powerful tool to study surfaces with subnanometer spatial resolution [1]. In particular, single-molecule TERS studies have shown the capability to visualize high-resolution images of individual molecular normal modes in real space [2]. Theoretical simulations that can provide an unambiguous interpretation and atomic description of obtained TERS images often rely on crude approximations of the local electric field [3]. In this work, we present a novel method to compute TERS images by combining Time Dependent Density Functional Theory (TDDFT) and Density Functional Perturbation Theory (DFPT) to calculate Raman cross sections with realistic local fields. The new approach allows for a fully ab initio atomistic description of the tip-molecule-surface system, and naturally incorporates chemical effects arising from the molecule-surface interaction. We show results for benzene and pyridine and discuss the importance of a realistic description of the local field, and self consistent evaluation of the electronic density response. Finally, we evaluate the use of 2D TERS imaging as an identification tool for defects in 2D materials. [1] M. Richard-Lacroix, et al., Chem. Rev. 56, 3922 (2017) [2] L. #### O 58.2 Wed 18:00 P4 Deep learning based signal processing for touch-sensitive surfaces — •JAKOB ELSNER, VIKTOR FAIRUSCHIN, and THORSTEN UPHUES - Institute for Sensor and Actuator Technology, Coburg, Germany

Touch-sensitive surfaces enable intuitive and efficient operation of electronic devices and eliminate the need for external peripherals and mechanical components, making touch technology increasingly important in the modern society. However, conventional touch technologies, i.e. capacitive, resistive or optical, are usually limited to non-metallic materials that hardly meet the stringent requirements for robustness and hygiene in a medical environment. Stainless steel is one of the most commonly used materials in medical fields due to its high strength, chemical resistance and excellent hygienic properties. In this work, we present a novel approach based on Lamb wave technology and deep learning analytics, and apply this new principle to design a stainless steel touch-sensitive surface. Compared to Rayleigh wave-based touch technology, our approach requires no additional reflective structures and involves only a single piezoelectric transducer used to monitor the entire surface, while position-sensitive information is extracted from raw Lamb wave signals using a trained deep neural network.

#### O 58.3 Wed 18:00 P4

Enhanced Sampling of Surface Reactions Using Boltzmann Generators -•DAVID HERING, JOHANNES T. MARGRAF, and KARSTEN REUTER - FHI Theory Department, Berlin, DE

Computational surface science and catalysis research is still mainly conducted with static density functional theory (DFT) calculations. This approach is computationally convenient, but misses important aspects of surface chemistry, such as anharmonic free energy contributions. In principle, DFT-based molecular dynamics (MD) simulations (ideally combined with enhanced sampling algorithms) would allow a much more accurate description of these processes. Unfortunately, these are far too expensive to be routinely applied to complex surface/adsorbate systems. This is due to the fact that configurations in MD are generated sequentially. As a consequence, MD configurations are not statistically independent so that a very large number of samples is required to obtain converged ensemble properties. To overcome this limitation, Noé and co-workers recently proposed a generative machine learning model called the Boltzmann Generator, which was used to generate independent configurations of biomolecules. In this contribution, we explore how Boltzmann Generators can also be used to sample the free energy surface of surface/adsorbate systems relevant for heterogeneous catalysis. In particular, training protocols and validation metrics of generated ensembles will be discussed.

ing image nudged elastic band method. Both reactions exhibit two transition states. One of them is related to the rotation of OH groups, and the other one is related to the breaking and forming of bonds. The gallic acid pyrolysis as a whole is judged to be endothermal, and it changes from endergonic to exergonic between 500 K and 750 K. The second reaction step, the dehydrogenation of pyrogallol, is identified as the limiting step of gallic acid pyrolysis, with reaction rate constants below 1 s⁻¹ for temperatures below 1250 K.

#### O 58.5 Wed 18:00 P4

Assessment of Structural Descriptors for the Construction of High-**Dimensional Neural Network Potentials** — •MORITZ R. SCHÄFER¹, JONAS FINKLER², STEFAN GOEDECKER², and JÖRG BEHLER¹ – ¹Georg-August-Universität Göttingen, Institut für Physikalische Chemie, Theoretische Chemie, Tammannstraße 6, 37077 Göttingen, Germany<br/>  $-\,^2 \mathrm{Basel}$  University, Department of Physics and Astronomy, Klingelbergstrasse 82, 4056 Basel, Switzerland

High-dimensional neural network potentials (HDNNPs) can be used to efficiently compute close-to ab initio quality energies and forces for performing large-scale molecular dynamics simulations of complex systems. In this method, the total energy is constructed as a sum of environment-dependent atomic energy contributions. Also electrostatic interactions based on environmentdependent charges can be included. Hence, a set of reliable structural descriptors for the atomic local environments is crucial to develop accurate potentials. Often, atom-centered symmetry functions (ACSFs) are used for this purpose in HDNNPs. In this work, we benchmark the accuracy and transferability of HDNNPs with respect to alternative descriptors like the recently proposed overlap matrix descriptor.

#### O 58.6 Wed 18:00 P4

Fortnet, a software package for training Behler-Parrinello neural networks — •TAMMO VAN DER HEIDE¹, JOLLA KULLGREN², PETER BROQVIST², VLADIMIR BAČIĆ³, THOMAS FRAUENHEIM^{4,5,1}, and BÁLINT ARADI¹ — ¹BCCMS, University of Bremen, Bremen, Germany — ²Dept. of Chemistry - Ångström Laboratory, Uppsala University, Uppsala, Sweden — ³Dept. of Physics and Earth Sciences, Jacobs University Bremen, Bremen, Germany — ⁴Beijing CSRC, 100193 Beijing, P. R. China — ⁵Shenzhen JL CSAR Institute, Shenzhen 518110, P. R. China A new, open source, parallel, stand-alone software package (Fortnet) has been developed, which implements Behler-Parrinello neural networks. It covers the entire workflow from feature generation to the evaluation of generated potentials, coupled with higher-level analysis such as the analytic calculation of atomic forces. The functionality is demonstrated by driving the training for the fitted correction functions of the density functional tight binding (DFTB) method, which are commonly used to compensate the inaccuracies resulting from the DFTB approximations to the Kohn-Sham Hamiltonian. Their usual two-body form limits the transferability of parameterizations between very different structural environments. After investigating various approaches, we have found the combination of DFTB with a near-sighted artificial neural network, acting ontop of baseline correction functions, the most promising one. It allows to introduce many-body corrections on top of two-body parametrizations, while excellent transferability to deviating chemical environments could be demonstrated.

**Machine learning enhanced DFTB method for periodic systems** — •WENBO SUN, GUOZHENG FAN, TAMMO VAN DER HEIDE, ADAM MCSLOY, THOMAS FRAUENHEIM, and BÁLINT ARADI — Bremen Center for Computational Materials Science, University of Bremen, Am Fallturm 1, Bremen 28359, Germany.

The Density Functional based Tight Binding (DFTB) is an approximative density functional based quantum chemical simulation method with low computational costs. In order to increase its accuracy, we have introduced a machine learning algorithm to optimize several parameters of the DFTB method, concentrating on solids with defects. The backpropagation algorithm was used to reduce the error between DFTB and DFT results w.r.t. the training dataset and to obtain adjusted DFTB Hamiltonian and overlap matrix elements. Afterwards, the generalization capability of the trained model was tested for geometries not being part of the training set. In the current work, we have focused on defective periodic silicon and silicon carbide systems as target materials and the density of states (DOS) as target property to demonstrate the feasibility of our approach. The trained model was able to reduce the differences between the DFTB and the DFT DOS significantly, while other derived properties (e.g. charge distribution, partial DOS) remained physically sound. Also, the transferability of the obtained model could be verified. Our method allows to carry out relatively fast simulations with high accuracy and only moderate training efforts, and represents a good compromise for cases, where long range effects make direct machine learning predictions difficult.

**Electronic properties of Density Functional Tight Binding by Machine Learning** – •GUOZHENG FAN¹, ADAM MCSLOY¹, BALINT ARADI¹, CHI-YUNG YAM², and THOMAS FRAUENHEIM^{1,2} – ¹Bremen Center for Computational Materials Science (BCCMS), University of Bremen, Bremen, Germany – ²Beijing Computational Science Research Center (CSRC), Beijing, China

We have introduced a machine learning workflow, which could optimize electronic properties in density functional tight binding method. With this workflow, we can train and predict electronic properties in a cheap, accurate and transferable way. The implementation features of batch calculations greatly improve the calculation efficiency, especially for high throughput calculations. This workflow could optimize electronic properties by train basis functions or train a spline model to generate two center integrals for off-diagonal and onsite for diagonal Hamiltonian and overlap. The results show that compared with previous Slater-Koster parameters, the dipole moments, charges, the ratios of the on-site populations and the atomic numbers in charge population analysis method can be improved by both tuning basis function parameters or optimizing integrals in spline model directly. The training on basis functions could prevent the two center integrals go randomly and keep Hamiltonian and overlap in reasonable range. Besides, the multiple electronic properties could be improved simultaneously.

Unsupervised regression-based measures for applications on atomistic features — •ALEXANDER GOSCINSKI¹, GUILLAUME FRAUX¹, GIULIO IMBALZANO¹, FÉLIX MUSIL^{1,2}, SERGEY POZDNYAKOW¹, and MICHELE CERIOTTI¹ — ¹Laboratory of Computational Science and Modeling, Institute of Materials, École Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland — ²National Center for Computational Design and Discovery of Novel Materials (MARVEL), Lausanne, Switzerland

The quality of the features as input for a machine learning model is a crucial factor for the prediction quality and the computational efficiency. Commonly, to assess the quality of features, they are compared by benchmarking the regression performance on several properties. Complementary to such a quality assessment, this work presents certain measures for direct feature-to-feature comparisons without the need of a target property. These measures are used to quantify the capacity of features representing geometrical space in atomistic applications and derive an understanding of the information encoded in features.

Accelerating plane-wave-based *ab initio* molecular dynamics by optimization of Fast-Fourier transforms for modern HPC architectures — •CHRISTIAN RIT-TERHOFF, TOBIAS KLÖFFEL, SAGARMOY MANDAL, and BERND MEYER — Interdisciplinary Center for Molecular Materials and Computer Chemistry Center, FAU Erlangen-Nürnberg, Germany

The most important advantage of plane-wave basis sets is that wave functions can be transformed efficiently from reciprocal to real space and back by using the Fast-Fourier transform (FFT) algorithm. This allows to evaluate the kinetic and potential energy in reciprocal and real space, respectively, where both operators are diagonal. This reduces the computational cost for applying the Hamilton operator from  $N^2$  to  $N \log N$ . However, the scalability of current FFT libraries is rather limited on today's HPC systems, which offer large numbers of compute nodes, each of them with many cores. Here we present our optimization of the FFTX library of the Quantum Espresso software package. Data distribution and communication patterns have been revised to make optimal use of combined

MPI and OpenMP parallelization. Scalability is further increased by combining FFTs into batches and by introducing overlapping computation and communication. We implemented the revised FFTX library in our optimized version of the CPMD code [1], and we demonstrate the achieved acceleration by a series of benchmark simulations.

Surface tension measurement of pure water in vacuum — •PAUL T. P. RYAN, JIRI PAVELEC, JAN BALAJKA, MICHAEL SCHMID, and ULRIKE DIEBOLD — Institute of Applied Physics, TU Wien, Austria

Very little is known about the surface tension of pure liquids in contact with their pure gaseous phases, i.e. without the presence of other gases or liquid phase contaminants. This is surprising given that contaminants are known to greatly affect surface tensions values[1]. Recently we have developed a method to dose liquid water onto pristine surfaces in UHV using a small cryostat [2,3]. We combine this approach with the pedant drop method [4] to measure the surface tension of ultra-clean liquids in contact with their pure gaseous phases. The upgraded version of the small cryostat, replaces the syringe typically used in the pendantdrop method. The ultra-clean liquid is condensed onto a small cryostat placed in a vacuum chamber. A pendant drop is formed and carefully photograph allowing the surface tension of the liquid to be directly determined. The design of the apparatus will be discussed and preliminary measurements of ultra-clean water will be presented. **Home-Built UHV Suitcase** — •LUCA LEZUO¹, LUCIE DOCKALOVÁ², GARETH PARKINSON¹, ULRIKE DIEBOLD¹, and JIRI PAVELEC¹ — ¹Institute of Applied Physics, TU Wien, Wiedner Hauptstrasse 8-10/134, Vienna, Austria — ²Institute of Physical Engineering, Brno University of Technology

Due to their extreme sensitivity to adsorbing molecules, most surface experiments have to be carried out in ultra-high vacuum (UHV). Ideally, multiple different techniques are used to explain and understand the phenomena happening on an atomic scale. To this end, it is often necessary to transfer a sample from one chamber to another.

As a showcase, we discuss the analysis of perovskite oxides, produced by pulsed laser deposition (PLD) as thin films, in another UHV chamber that allows atomically resolved STM/AFM imaging with a Q+-sensor at liquid  $N_2/He$  - temperatures. The home built UHV suitcase consists of three stages divided by gate valves. It has a scroll pump for rough vacuum, a turbo pump to reach high vacuum, a NEG pump and a cryopump to ensure a clean transfer and an ION/NEG combination to provide UHV conditions long term in the storage stage, where the sample is transported.

#### O 58.13 Wed 18:00 P4

Wettability investigation of microscale water droplets on silicon substrate using atomic force microscopy — •MOHAMMADALI HORMOZI¹, MARVIN HOFFER^{1,2}, PAULINE BRUMM², and REGINE VON KLITZING¹ — ¹Soft Matter at Interfaces, Department of Physics, Technical University of Darmstadt, 64289 Darmstadt, Germany — ²Institute of Printing Science and Technology (IDD), Technische Universität Darmstadt, Magdalenenstraße 2, 64289 Darmstadt, Germany

The wettability of a particular substrate by a liquid drop is of interest in many scientific fields. This phenomenon is often described by the contact angle between the considered liquid and substrate. This parameter is an important boundary condition, especially for the wetting of mixtures and solutions. This study shows a methodology for evaluating the contact angle of different droplets with a base diameter down to 0.5 micrometers. 3D topography of water droplets -generated through condensation and Inkjet printing on a silicon substrate- has been determined using Atomic Force Microscopy. Also, the topography of printed mixture droplets including water-glycerol and water-glycerol-isopropanol has been measured. Different curves have been fitted to a 2D cross-section of each droplet, which provides information about their contact angle. The contact angle of the mixtures deviates from the macroscale contact angle at the vicinity of the threephase contact line; however, this phenomenon cannot be seen in pure water droplets. While no effect of droplet diameter could be detected for diameters, ranging from 0.5 to 30 micrometers, the macroscopic contact angle of droplets is several degrees higher.

High-frequency shot-noise STM to study correlated electron systems — •MAIALEN ORTEGO LARRAZABAL¹, JIASEN NIU², KOEN M BASTIAANS³, JIAN-FENG GE², TJERK BENSCHOP², MILAN P ALLAN², and INGMAR SWART¹ — ¹Debye Institute for Nanomaterials Science, Utrecht University, PO Box 80000, 3508 TA Utrecht, The Netherlands — ²Leiden Institute of Physics, Leiden University, Niels Bohrweg 2, 2333 CA Leiden, The Netherlands — ³Kavli Institute of Nanoscience, Delft University of Technology, 2628 CJ Delft, Netherlands The fluctuations in time of a measured signal provide information that is not present in the time averaged value. For example, the discreteness of the electric charge leads to fluctuations in the tunneling current in an STM, known as shot-noise. Shot-noise measurements convey information about the correlations among the electrons in condensed matter systems, such as the effective charge of the carrier or their distribution in the tunneling process. However, other contributions to the measured noise, such as 1/f and thermal noise, make it difficult to isolate the shot-noise component. For this reason, we use custom-built electronics that allows us to read out the noise signal of the STM at high frequencies and cryogenic temperatures and that does not interfere with conventional STM measurements.

Access to hot electron dynamics in a nanotip via ultrafast THz-streaking — •DOMINIK WEBER, FELIX SOMMER, MORITZ HEINDL, and GEORG HERINK — Experimental Physics VIII - Ultrafast Dynamics, University of Bayreuth

Field enhancement and localization of single-cycle Terahertz radiation at metallic nanotips forms the basis for a broad range of emerging ultrafast interactions ranging from ultrafast nearfield and tunnelling microscopy, transient carrier dynamics to strong-field phenomena. We present an experimental access to ultrafast hot electron dynamics at the apex of a free-standing nanotip based on THznearfield streaking spectroscopy [1,2]. Using tunable fs-pulses, we induce nonequilibrium electron excitations and transient hot electron distributions. Access to local hot electron dynamics confined to the apex is provided via nonlinear sub-cycle field emission at the peak of the enhanced single-cycle THz-waveform. Based on experimental streaking waveforms, we discuss the impact of excitation conditions on hot electron relaxation and possibilities for external control of ultrafast carrier dynamics.

**Near-field optical investigation of bandgap effects in SnTe** — •CHRISTIAN JUS-TUS, KONSTANTIN G. WIRTH, DARIO SIEBENKOTTEN, LUKAS CONRADS, SOPHIA WAHL, MATTHIAS WUTTIG, and THOMAS TAUBNER — I. Institute of Physics (IA), RWTH Aachen University

Phase change materials (PCMs) are prime candidates for non-volatile memory solutions[1]. Storage mediums with high memory density require a method for determining material properties with nanometer precision. One such tool to investigate the optical properties of nano-structures is scattering-type scanning near-field optical microscopy (s-SNOM). Thus far, bandgap effects in semiconductors have eluded experimental observation in s-SNOM. Specifically metavalently bonded materials may exhibit a bandgap shift by over a factor of three in reduced dimensions, such as in the case of Tin Telluride (SnTe) with a shift from 0.2 to 0.7 eV[2]. The primary goal of this work is to use s-SNOM to spectoscopically characterize bandgap effects in SnTe thin films. We find good agreement between Fourier-transform infrared spectroscopy (FTIR) and s-SNOM measurements over a spectral range spanning 0.3 to 0.9 eV and are able to identify a bandgap contribution to the spectral s-SNOM data. Our results may help to get a deeper insight into confinement effects on the optical properties of nano-scale PCM structures, such as PCM memory cells, and may provide a valuable tool for the analysis and characterization of PCM memory devices with high storage density.

and Leonhard  ${\rm Grill}^1-{}^1{\rm Institute}$  for Chemistry, Department of Physical Chemistry, University of Graz, Austria $-{}^2{\rm Institute}$  for Ion Physics and Applied Physics, University of Innsbruck, Austria

A commercially available design of an electrospray deposition apparatus was optimized for cleaner and more controllable deposition in a high vacuum. The apparatus consists of a series of 5 differentially pumped chambers separated by skimmer cones or apertures. An angle-adjustable bellow was introduced between the second and third pumping chamber for better control over the alignment and, consequently, the ion beam flux reaching the final stage. Monitoring the flux/alignment was done by current measurements around the apertures and behind the last one with a conductive probe. Also, heating of the transfer capillary and enclosing the emitter-transfer capillary interface in a small transparent chamber (to allow different ambient gas environments) were introduced. The first depositions were done to test the performance of the improved design with some well-studied molecules.

Energy and momentum distribution of surface plasmon- induced hot carriers — •Christopher Weiss¹, Eva Prinz¹, Michael Hartelt¹, Benjamin Stadtmüller^{1,2}, and Martin Aeschlimann¹ — ¹Department of Physics and Research Center OPTIMAS, TU Kaiserslautern, Germany — ²Institute of Physics, Johannes Gutenberg University Mainz, Germany

Investigating the energy and momentum space signature of plasmon-induced hot electrons is essential for understanding novel plasmonic energy conversion schemes. The question remains, if plasmon-induced and photon-induced hot carriers are fundamentally different. For the bulk plasmon resonance, a fundamental difference is known, yet for the technologically important surface plasmons this is far from being settled. Just recently, we identified a similar characteristic signature in the surface plasmon polariton (SPP) emission that distinguishes them from photon-induced electrons [1].

To separate the energy and momentum distribution of the plasmon-induced hot electrons from those of the photoexcited electrons, we employ a twocolour femtosecond time-resolved 2-photon photoemission (2PPE) experiment. The spatial evolution of the photoemitted electrons was observed with energyresolved photoemission electron microscopy (PEEM) and momentum microscopy during the propagation of an SPP pulse along a gold surface. Building on these findings, we extend this concept to SPPs of single crystalline silver surfaces to investigate the influence of the band structure and material properties.

O 59.5 Wed 18:00 P4 Near-field optical investigation of few layer graphene — •LINA JÄCKERING, KONSTANTIN WIRTH, CHRISTIAN JUSTUS, and THOMAS TAUBNER — I. Institute of Physics (IA), RWTH Aachen University

Few layer graphene (FLG) samples usually consist of various stacking orders, which show different optical and electronical properties. Direct imaging and characterization of stacking domains in FLG samples can be done with scattering scanning near-field optical microscopy (s-SNOM) [1]. S-SNOM is outstanding for its nanoscale resolution of about 20 nm and its capability to image buried structures [2]. Thus, it allows to characterize encapsulated FLG samples as they are used in transport devices. Previous s-SNOM investigations focussed on the excitation of free charge carriers in FLG at about 0.1 eV [3,4]. Recently, FLG stackings have been identified by exciting interband transitions (0.27 - 0.56 eV) [1,5]. Interband resonances of FLG have only been measured at punctual energies or small energy regimes. Here, we investigate trilayer graphene and bilayer graphene in the spectral range of 0.27 - 0.9 eV, providing a deeper understanding of their near-field optical response, particularly of their interband resonance. Furthermore, we identify different stacking domains in FLG samples encapsulated in hexagonal boron nitride. Our findings provide a promising technique to select stacking domains for fabrication of transport devices.

Inelastic electron-photon scattering with broadband optical pulses •NIKLAS MÜLLER, RASMUS LAMPE, GERRIT VOSSE, CHRISTOPHER RATHJE, and SASCHA SCHÄFER - Institute of Physics, University of Oldenburg, 26129 Oldenburg, Germany

The inelastic scattering of fast electrons at spatially confined light fields has recently enabled new techniques in ultrafast transmission electron microscopy (UTEM) [1,2,3] but is typically performed with narrow bandwidth light pulses. Here, we study the interaction of fast electrons with broadband, strongly chirped light fields. Optical pulses are generated in a home-build noncollinear optical parametric amplifier (NOPA) [4] with a spectral width of up to 200 nm in the visible range. Light reflection at an aluminum coated silicon nitride membrane leads to an intense multicolor near-field at which we inelastically scatter femtosecond electron pulses forming photon sidebands in the electron energy spectrum. The spectral sideband position changes with the relative timing between electron and light pulse according to the instantaneous frequency of the driving laser field. Different parameter regimes of electron and light chirp and their impact on inelastic scattering patterns are discussed.

#### Probing Excitons-Photon interaction in WSe2 beyond the Non-Recoil Approximation — •FATEMEH CHAHSHOURI, MASOUD TALEB, and NAHID TALEBI - Institute of Experimental and Applied Physics, Kiel University, 24118 Kiel, Germany

Cherenkov radiation from electrons propagating in materials with a high refractive index have applications in particle-detection mechanisms. However, the theory of the Cherenkov radiation has been treated up to now using the nonrecoil approximation, which neglects the effect of electron deceleration in materials. Here, we report on the effect of the electron-beam deceleration on the radiated spectrum and exciton-photon interactions in nm-thick WSe2 crystals beyond the non-recoil approximation. The calculation of the Cherenkov radiation is performed by simulating the energy distribution of an electron beam propagating inside a thick WSe2 using the Monte Carlo method, and ascertaining the radiating power from electron beams with Liénard-Wiechert retarded potentials. Using this approach, we numerically demonstrate that in thick flakes the radiation due to the electron-beam deceleration is the dominating radiation mechanism. Our numerical findings agrees well with the experimental cathodoluminescence spectra. We further demonstrated that the captured CR in thick slabs could cause Fabry-Perot resonances that emerge as fine structures in the acquired CL spectra and demonstrate the fully coherent process of CR emission, happening due to its phase-matched excitation nature. Our findings pave the way for an accurate design of particle scintillators and detectors, based on the strong-coupling phenomenon.

Time: Thursday 9:30-10:15

**Invited Talk** O 60.1 Thu 9:30 S054 Exciting states in atomically thin layers — • THORSTEN DEILMANN — Institute of Solid State Theory, University of Münster, Germany

Monolayers of two-dimensional materials and its stacking unite the fascinating characteristics of the confined in-plane physics with novel features due to the interlayer interaction. Especially in semiconducting materials largely tunable band gaps and optical responses have been observed in various materials. Unraveling the corresponding excited states is a crucial challenge for basic research as well as for possible applications in opto-electronic devices. Several external stimuli, e.g. doping, electric, or magnetic fields, can be applied to probe the response of many-particle states like excitons or trions, and thus also of its fundamental properties. Applying first-principles methods allows to predict, e.g., the quantum mechanical nature when an exciton is doped and becomes a trion, or its *a* factor due to the Zeeman effect. These calculations facilitate a connection of the experimental observations with the physical properties of the excited states. In the talk, several features in mono- and multilayer transition metal dichalcogenides and similar materials will be demonstrated.

O 61.1 Thu 10:30 H2 Single Molecule Nonlinearity in a Plasmonic Waveguide — • MARKUS LIPPITZ - Experimental Physics III, University of Bayreuth

Plasmonic waveguides offer the unique possibility to confine light far below the diffraction limit. Past room temperature experiments focused on efficient generation of single waveguide plasmons by a quantum emitter. However, only the simultaneous interaction of the emitter with multiple plasmonic fields would lead to functionality in a plasmonic circuit. Here, we demonstrate the nonlinear optical interaction of a single molecule and propagating plasmons. An individual terrylene diimide (TDI) molecule is placed in the nanogap between two singlecrystalline silver nanowires. A visible wavelength pump pulse and a red-shifted depletion pulse travel along the waveguide, leading to stimulated emission depletion (STED) in the observed fluorescence. The efficiency increases by up to a factor of 50 compared to far-field excitation. Our study thus demonstrates remote nonlinear four-wave mixing at a single molecule with propagating plasmons. It paves the way toward functional quantum plasmonic circuits and improved nonlinear single-molecule spectroscopy.

O 61.2 Thu 11:00 H2 Excitation of coherent phonon modes in plasmonic gold nanoparticles •Dominik Höing^{1,2}, Robert Salzwedel⁴, Malte Selig⁴, Kartik Ayyer^{2,3}, Jochen Küpper^{2,3}, Andreas Knorr⁴, and Holger Lange^{1,2} — ¹Institute of ¹Institute of Physical Chemistry, Universität Hamburg, Hamburg, Germany — ²The Hamburg Centre for Ultrafast Imaging, Hamburg, Germany —  3 Center for Free-Electron Laser Science, Hamburg, Germany —  4 Institut für Theoretische Physik, Technische Universität Berlin, Berlin, Germany

The plasmonic properties of gold nanoparticles (AuNP) have been widely studied, because of their exhibition of strong light-matter coupling and hot carrier generation. The carrier dynamics that follow the optical excitation are presently understood as a series of events with increasing time-scales. Among them, the excitation of coherent acoustic phonon modes, also called breathing modes, is thought to result from the ultrafast heating of the lattice due to electron-phonon coupling. However, previous experimental studies were insufficient in detecting the onset of the breathing oscillation. Here, we use a combination of transient absorption spectroscopy, time-resolved X-ray scattering and a model combining quantum coherent and hydrodynamic theory to develop a different picture: We show that the gradient in electron density induced by the optical excitation instantaneously couples to coherent phonons, resulting in an immediate onset of the breathing oscillation with the optical excitation. Thus, the processes involved in the plasmon decay are more intertwined as previously assumed.

#### O 61.3 Thu 11:15 H2

**Probing a plasmon-polariton quantum wave packet** — SEBASTIAN PRES¹, Bernhard Huber¹, Daniel Fersch¹, Enno Schatz², Daniel Friedrich² Victor Lisinetskii¹, Ruben Pompe³, •Matthias Hensen¹, Bert Hecht² WALTER PFEIFFER³, and TOBIAS BRIXNER¹ - ¹Institut für Physikalische und Theoretische Chemie, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany — ²NanoOptics & Biophotonics Group, Experimental Physics 5, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany — ³Fakultät für Physik, Universität Bielefeld, Universitätsstr. 25, 33615 Bielefeld, Germany

Beyond the classical picture, plasmon-polariton modes are treated as quasiparticles in quantum physics and they are considered essential for the realization of future nanoscale quantum functionality. Implementing and demonstrating such functionality requires local access to the quasi-particle's quantum state to monitor its corresponding quantum wave-packet dynamics. Here, we report the local probing of such an eigenstate superposition, linked to a nanoslit resonator, using plasmon-polariton-assisted electron emission as signal in coherent two-dimensional nanoscopy¹. We observe a quantum coherence oscillating

Location: S054

Location: H2

at the third harmonic of the plasmon-polariton frequency and identify it, using quantum dynamical simulations, to arise from the superposition of energetically non-adjacent plasmon-polariton occupation number states. The simulations also contain an improved model for plasmon-polariton-assisted electron emission processes.

**Modelling Plasmon-Exciton Interaction using a Coupled-Oscillator Approach** – •SIMON DURST, CHRISTOPH SCHNUPFHAGN, and MARKUS LIPPITZ – Experimental Physics III, University of Bayreuth

Coupling effects between plasmonic and excitonic systems have attracted increasing interest in the last decade. In particular, Surface Lattice Resonances, diffractive modes supported by periodic arrays of metallic nanoparticles, allow for long-range coherent energy transfer and have been shown to strongly couple to interspersed excitonic emitters. Here, we will present experimental results showing strong coupling between Surface Lattice Resonances and the excitonic mode of a J-aggregate dye. The angle-resolved extinction spectra of this coupled system are modelled using a coupled oscillator model, which describes observed effects, such as a loss of contrast of the upper polariton branch or an asymptotic behaviour of the lower polariton branch well.

O 61.5 Thu 11:45 H2 Light emission from single self-decoupled molecules – •VIBHUTI RAI¹, LUKAS GERHARD¹, GABRIEL DERENBACH¹, NICO BALZER², MICHAL VALÁŠEK², MARCEL MAYOR², and WULF WULFHEKEL¹ – ¹Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology (KIT), D-76344 Eggenstein-Leopoldshafen, Germany – ²Institute of Nanotechnology, Karlsruhe Institute of Technology (KIT), D-76344 Eggenstein-Leopoldshafen, Germany

Realization of single molecules as electric light sources faces a dilemma: In order to emit light, they need to be decoupled from the metallic electrodes to prevent fluorescence quenching. To conduct, however, the molecular orbitals need to hybridize with the electrodes. This can be achieved by decoupling the molecular chromophore to a certain extent from the electrode via anchoring groups. In the past, such self-decoupled molecules often lacked reproducibility of the decoupling and energy of the emitted light. Here, we show reproducible and well defined electroluminescence of two different NDI chromophores linked to a gold substrate via a molecular tripod and via a vacuum barrier to the tip of a scanning tunnelling microscope [1]. The stability of the system allows to perform systematic experiments so far only possible for molecules decoupled via insulating layers.

O 61.6 Thu 12:00 H2

Investigation of chemical interface damping on electrochemically functionalized flat gold and nanoporous gold surfaces — •MAURICE PFEIFFER¹, XINYAN WU¹, ALEXANDER PETROV^{1,2}, and MANFRED EICH^{1,2} — ¹Institute of Optical and Electronic Materials, Hamburg University of Technology, Germany — ²Institute of Photoelectrochemistry, Helmholtz-Zentrum Hereon, Geesthacht, Germany The chemical interface damping (CID) effect occurs at metal surfaces when applying surface modifications, such as oxidation. It results in an increase of the electron collision frequency of the metal, thus altering its optical properties. Previous research showed that this effect may also enhance the efficiency of photocatalytic water splitting by visible light [1]. We investigate the CID effect on flat gold as well as nanoporous gold samples with the latter having the advantage of a very high surface to volume ratio, making surface effects (like CID) more pronounced. Our experimental setup consists of a spectroscopic ellipsometer to investigate the optical properties. This device is equipped with an electrochemical cell in which we can reversibly oxidize the sample surface, allowing an in-situ study of the CID effect. Previous research investigated the CID effect on gold nanoparticles and observed an increase of the damping rate at the plasmon resonance [2]. Our results on flat gold reveal a similar increase of the damping, but additionally enable the investigation of broadband properties from which we expect further insights on the nature of the damping mechanism.

Switching on the electroluminescence of single molecules adsorbed di**rectly on a metal surface** — VIBHUTI RA1¹, •LUKAS GERHARD¹, NICO BALZER², MICHAL VALÁŠEK², CHRISTOF HOLZER³, LIANG YANG², MARTIN WEGENER², CARSTEN ROCKSTUHL³, MARCEL MAYOR², and WULF WULFHEKEL¹ ¹Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology (KIT), D-76344 Eggenstein-Leopoldshafen, Germany -²Institute of Nanotechnology, Karlsruhe Institute of Technology (KIT), D-76344 Eggenstein-Leopoldshafen, Germany – ³Institute of Theoretical Solid State Physics, Karlsruhe Institute of Technology (KIT), D-76131 Karlsruhe, Germany Exciting single molecules to emit light into the far-field requires them to be electronically decoupled from the contacting metallic leads. In the scanning tunnelling microscope (STM) geometry, typically this has been achieved by inserting insulating layers between the molecules and the metal substrate [1]. Here, we report our finding that it is possible to activate the electroluminescence (EL) of individual 2,6- core-substituted naphthalene diimide derivatives (Tpd-sNDI), adsorbed directly on a metal surface with the help of the STM tip. We observe that to emit light, both orbitals involved in the optical transition need to be electronically decoupled. The STM measurements were performed with a home-built, low temperature, ultra-high vacuum scanning tunnelling micro-

scope (STM) with optical access [2].

First principles investigation of plasmonic hydrogen catalysis on metallic magnesium nanoparticles — •OSCAR A. DOUGLAS-GALLARDO, CONNOR L. BOX, and REINHARD J. MAURER — University of Warwick, Coventry, United Kingdom

Plasmon-induced hot-carrier photochemistry is currently a promising avenue to achieve highly selective and efficient chemical transformation on plasmonic metal surfaces. A new class of materials made up of Earth-abundant-elements has gained increasing interest in the plasmonic area, as an alternative to the oft studied late transition metals (Au, Ag and Cu).

Here, we will present our results on the optical and electronic properties of metallic magnesium nanoparticles and their potential use as plasmonic hydrogen catalysts. We explore the optical and electronic properties with time-dependent density functional tight-binding (TD-DFTB) and molecular dynamics with electronic friction (MDEF) simulations. Our results show that Mg nanoclusters can produce highly energetic hot-electrons and they energetically align with electronic states of physisorbed molecular hydrogen, the occupation of which by these hot electrons can promote hydrogen evolution on metallic Mg, may also be promoted by hot electrons, but following a different mechanism.

# O 62: Surface Reactions and Heterogeneous Catalysis 1

**Gaussian Approximation Potentials for Surface Catalysis** — •SINA STOCKER^{1,2}, GÁBOR CSÁNYI³, KARSTEN REUTER¹, and JOHANNES T. MARGRAF¹ — ¹Fritz Haber Institut der Max Planck Gesellschaft, Berlin, Germany — ²Technische Universität München, Germany — ³University of Cambridge, United Kingdom

Predictive-quality first-principles based microkinetic models are increasingly used to analyze (and subsequently optimize) reaction mechanisms in heterogeneous catalysis. In full rigor, such models require the knowledge of all possible elementary reaction steps and their corresponding reaction barriers. Unfortunately, for complex catalytic processes (such as the generation of ethanol from syngas) the number of possible steps is so large that an exhaustive first-principles calculation of all barriers becomes prohibitively expensive.

To overcome this limitation, we develop machine learned (ML) interatomic potentials to model syngas conversion on Rhodium. These ML potentials can be used to determine free energy reaction barriers for a large number of adsorbates nutational cost of the under

Location: H4

at various CO coverages and at a fraction of the computational cost of the underlying first-principles method. Specifically, we use here the Gaussian Approximation Potential (GAP) framework and explore iterative training in combination with umbrella sampling.

Hydrogen adsorption on Pd surfaces and its effect on CO₂ activation — •HERZAIN I. RIVERA-ARRIETA¹, IGOR KOWALEC², LUCAS FOPPA¹, ANDREW LOGSDAIL², DAVID WILLOCK², and MATTHIAS SCHEFFLER¹ — ¹The NO-MAD Laboratory at the Fritz Haber Institute of the Max Planck Society and the Humboldt-Universität zu Berlin, Germany — ²Cardiff Catalysis Institute, Cardiff University, UK

Understanding the reactivity of Pd-based catalysts in hydrogenation processes requires an accurate description of its surfaces at realistic temperature (*T*) and hydrogen pressure ( $p_{H_2}$ ). Herein, by modeling the surface phase diagram of Pd (111) and (100) as a function of *T*,  $p_{H_2}$  via *ab initio* atomistic thermodynamics

[1], we predict 1 monolayer (ML) coverage of H as the most stable configuration under common experimental reaction conditions [2]. Taking a particular interest in the activation of CO₂, we performed simulations concerning the interaction of the molecule with the surfaces as the H-coverage increases from 0 to 1ML. Our results show how 1 ML of H inhibits the formation of chemisorbed  $CO_2^{\delta^2}$ , the initial intermediate in the CO₂ hydrogenation reaction. The generated data will be combined with information from other metal surfaces, and the subgroup-discovery artificial-intelligence approach [3] will be applied to identify which basic materials parameters correlate with indicators of CO₂ activation, e.g. the adsorption energy or the C-O bond elongation.

Atomic steps as active sites in the Co-catalyzed Fischer-Tropsch synthesis: Evidence from an operando STM study on a stepped model catalyst — •KATHARINA GOLDER and JOOST WINTTERLIN — Ludwig-Maximilians-Universität München, Germany

Atomic steps are often assumed to represent the active sites on the surface of a heterogeneous catalyst. This assumption is based on turnover data that display a certain scaling of the activity with the particle sizes of the catalysts. However, this evidence is indirect and often controversial. We have recently shown that the activity of a Co(0001) single crystal surface in the Fischer-Tropsch synthesis of hydrocarbons is proportional to the density of atomic steps. This is a quite direct evidence for the activity of atomic steps, but it was obtained for a flat model system. Here we present results of investigations on a Co(10115) surface that has a similar step density as the Co particles of the industrial Fischer-Tropsch catalyst. The experiments were performed with a scanning tunneling microscope (STM) at a syngas (2H₂+CO) pressure of ~1 bar and a temperature of 503 K. Hydrocarbon products were detected by a special gas chromatograph (GC). The STM data show that the morphology of the stepped surface is stable under operando conditions. The activity measured by GC is considerably higher than that of the Co(0001) sample. It is close to the activities reported for supported Co catalysts, a result that bridges the materials gap between model systems and the industrial Fischer-Tropsch catalysts.

O 62.4 Thu 11:15 H4 **Predicting Binding Motifs of Complex Adsorbates Using Machine Learning** with a Physics-inspired Graph Representation — •WENBIN XU¹, KARSTEN REUTER¹, and MIE ANDERSEN² — ¹Fritz-Haber-Institut der MPG, Berlin, Germany — ²Aarhus Institute of Advanced Studies and Department of Physics and Astronomy, Aarhus University, Denmark

Complex adsorbates are involved in many surface catalytic reactions such as Fischer-Tropsch, methanol, or higher oxygenate synthesis. The modeling of these species at transition metal catalysts must account for their ability to exhibit a wide range of adsorption motifs, including mono- and multi-dentate adsorption modes. Given the combinatorial explosion of possible adsorption motifs and the computational cost of density functional theory, it is desirable to develop machine learning (ML) models for predicting the binding motifs and their associated adsorption enthalpies. Most ML models to date are only applicable to simple adsorbates. In this work, we overcome this limitation and propose a kernelized ML model with a physics-inspired graph representation for the prediction of complex species. The model is data-efficient and its good extrapolation ability makes it promising for comprehensively exploring complex reaction networks on novel catalysts. Furthermore, we show that the outliers with large prediction errors can be reliably captured from an ensemble uncertainty prediction approach.

#### O 62.5 Thu 11:30 H4

Machine-Learning Driven Global Optimization of Surface Adsorbate Geometries — •HYUNWOOK JUNG, SINA STOCKER, KARSTEN REUTER, and JO-HANNES T. MARGRAF — Fritz-Haber-Institut der MPG, Berlin, Germany The adsorption energy is an essential descriptor for predicting catalytic activity in theoretical models of heterogeneous catalysis. Although established scaling relations facilitate the prediction of adsorption energies for small adsorbates like OH, they are not applicable to larger adsorbates that are frequently encountered in syngas chemistry. Such systems often feature complex potential energy surfaces due to their flexibility and the possibility of multidentate binding to the surface. Consequently, computing adsorption energies for such adsorbates implies a complex global optimization to find the ground state geometry. This is prohibitively expensive at the density functional theory (DFT) level for routine applications. To tackle this issue, we present a global optimization protocol for adsorbate geometries which trains a surrogate Gaussian Approximation Potential on-the-fly. The approach is applicable to generic surface models (i.e. without defining surface sites) and minimizes both user intervention and the number of DFT calculations by iteratively updating the training set with configurations explored by the algorithm. We demonstrate this approach for diverse adsorbates on the Rh (111) and (211) surfaces.

#### O 62.6 Thu 11:45 H4

New catalysts for oxidative-coupling of methane: theoretical search and experimental validation — •Aliaksei Mazheika¹, Michael Geske¹, Matthias Mueller², Stephan Schunk², Frank Rosowski^{1,3}, and Ralph Kraehnert¹ — ¹Technische Universitaet, Berlin, DE — ²hte GmbH, Heidelberg, DE — ³BASF SE, Ludwigshafen, DE

Oxidative-coupling of methane (OCM) is a direct way for conversion of methane to higher hydrocarbons - ethane, ethylene. Despite many years spent for the search of an efficient catalyst, still a material which would satisfy industrial rentability has not been found. In our study we proceed from an experimentally observed volcano-like dependence of C2-yields on formation energies of carbonates on oxide catalysts [1]. We developed a new method which allows to calculate carbonates formation energies from CO₂ adsorption energies on the surfaces of corresponding oxides. In combination with artificial intelligence methods (data mining and symbolic regression) this was used in the high-throughput screening. The latter is done in a way of active-learning, and we demonstrate its advantages compared to traditional scheme. Several catalysts obtained from the screening have been synthesized and experimentally tested together with less promising materials. Obtained C2-yields follow the same volcano-type dependence that formed initial basis for the employed strategy. The best catalyst candidates reach maximum C2-yields comparable to the well-known OCM catalysts and outperform them at lower temperatures.

O 62.7 Thu 12:00 H4

Finding catalyst genes with subgroup discovery — •ALIAKSEI MAZHEIKA¹, YANGGANG WANG², ROSENDO VALERO³, FRANCESC VINES³, FRANCESC ILLAS³, LUCA M. GHIRINGHELLI⁴, SERGEY V. LEVCHENKO⁵, and MATTHIAS SCHEFFLER⁴ — ¹Technische Universitaet, Berlin, DE — ²University of Science and Technology, Shenzhen, CN — ³Universitat de Barcelona, Barcelona, ES — ⁴The NO-MAD Laboratory at the Fritz Haber Institute and Humboldt University, Berlin, DE — ⁵Moscow

Catalytic-materials design requires predictive modeling of the interaction between catalyst and reactants. This is challenging due to the complexity and diversity of structure-property relationships across the chemical space. Here, we report a strategy for a rational design of catalytic materials using the artificial intelligence approach (AI) subgroup discovery. We identify catalyst *genes* (features) that correlate with mechanisms that trigger, facilitate, or hinder the activation of carbon dioxide ( $CO_2$ ) towards a chemical conversion. The AI model is trained on first-principles data for a broad family of oxides. We demonstrate that surfaces of experimentally identified good catalysts consistently exhibit combinations of *genes* resulting in a strong elongation of a C-O bond. The same combinations of *genes* also minimize the OCO-angle, the previously proposed indicator of a cativation, albeit under the constraint that the Sabatier principle is satisfied. Based on these findings, we propose a set of new promising catalyst materials for  $CO_2$ conversion.—A. Mazheika *et. al.* Nature Comm. 2022, 13, 419.

#### O 62.8 Thu 12:15 H4

Selectivity in single-molecule reactions by tip-induced redox chemistry — •FLORIAN ALBRECHT¹, SHADI FATAYER^{1,2}, IAGO POZO³, IVANO TAVERNELLI¹, JASCHA REPP⁴, DIEGO PENA³, and LEO GROSS¹ — ¹IBM Research - Zurich, 8803 Rüschlikon (Switzerland) — ²Physical Science and Engineering Division, King Abdullah University of Science and Technology (KAUST), 23955-6900 Thuwal (Saudi Arabia) — ³Centro Singular de Investigación en Química Biolóxica e MateriaisMoleculares (CiQUS) and Departamento de Química Orgµnica, Universidade de Santiago de Compostela, 15782 Santiago de Compostela (Spain) — ⁴Institute of Experimental and Applied Physics, University of Regensburg, 93053 Regensburg (Germany)

Since the first experiments by S.-W. Hla in 2000 [1], tip-induced on-surface synthesis is an active field. Not only in on-surface chemistry, selective control over the outcome of a reaction is a major quest. Here, we activate a molecule adsorbed on ultrathin insulating films by dehalogenation and perform selective constitutional isomerization reactions in a low temperature UHV combined STM and AFM. The selectivity is controlled by the polarity and amplitude of applied voltage pulses. The insulating films stabilize the isomers in different charge states and allow for their characterization. The importance of molecular charge state on the reaction is supported by DFT-derived isomerization energy landscape. [1] S.-W. Hla et al., Phys. Rev. Lett. 85, 2777 (2000).

Abiotic Formation of an Amide Bond via Surface-Supported Direct Carboxyl-Amine Coupling — •BIAO YANG^{1,2}, KAIFENG NIU^{1,3}, FELIX HAAG², NAN CAO^{1,2}, JUNJIE ZHANG¹, HAIMING ZHANG¹, QING LI¹, FRANCESCO ALLEGRETTI², JONAS BJÖRK³, JOHANNES BARTH², and LIFENG CHI¹ — ¹Institute of Functional Nano and Soft Materials (FUNSOM), Soochow University, Suzhou 215123 (P. R. China) — ²Physics Department E20, Technical University of Munich, D-85748 Garching, (Germany) — ³Department of Physics, Chemistry and Biology, IFM, Linkçping University, 58183 Linköping (Sweden)

Amide bond formation is one of the most important reactions in biochemistry,

Thursday

notably being of crucial importance for the origin of life. Herein, we combine scanning tunneling microscopy and X-ray photoelectron spectroscopy studies to provide evidence for thermally activated abiotic formation of amide bonds between adsorbed precursors through direct carboxyl-amine coupling under ultrahigh-vacuum conditions by means of on-surface synthesis. Complementary insights from temperature-programmed desorption measurements and density functional theory calculations reveal the competition between cross-coupling amide formation and decarboxylation reactions on the Au(111) surface. Furthermore, we demonstrate the critical influence of the employed metal support: whereas on Au(111) the coupling readily occurs, different reaction scenarios prevail on Ag(111) and Cu(111).[1] [1] Biao Yang+*, Kaifeng Niu+, et al. Angew. Chem. Int. Ed. anie.202113590 (2021)

**Topical Talk** O 63.1 Thu 10:30 H6 Element and Structure Analysis of Surfaces Using Positrons - •CHRISTOPH HUGENSCHMIDT — Forschungs-Neutronenquelle Heinz Maier-Leibnitz (MLZ), Technische Universität München, Lichtenbergstr. 1, 85748 Garching, Germany With the advent of bright low-energy positron beams novel analysis tools have been developed exploiting the unique properties of positron matter interaction such as repulsive crystal potential or positron trapping in surface states [1]. Positron annihilation is established for defect spectroscopy and the characterization of the free volume in amorphous matter. By applying a slow positron beam, however, defects near the surface can be specifically addressed, e.g. for the determination of the oxygen vacancy concentration in YBa₂Cu₃O_{7-x} [2]. The positron counterparts of reflection high-energy electron diffraction (RHEED) and electron induced Auger-electron spectroscopy (AES) intrinsically exhibit superior surface sensitivity. In contrast to electrons, positrons show total reflection for small glancing angles. It was demonstrated that with reflection high-energy positron diffraction the structure of the topmost and the immediate subsurface atomic layer of surfaces are revealed with outstanding accuracy. The main advantages of positron annihilation induced AES are the missing secondary electron background and its topmost layer sensitivity for element analysis allowing, e.g. the in-situ observation of the Ni adatom migration from the Pd surface into the bulk [3]. [1] C. H.; Surf. Sci. Reports 71 (2016) 547; [2] M. Reiner et. al.; Phys. Rev. B 97 (2018) 144503; [3] S. Zimnik et. al.; Surf. Sci. 664 (2017) 61

Active sample manipulation with electrostatic beams: a different way of bridging the high-voltage gap — •FRANCESCO GUATIERI, KILIAN BRENNER, and CHRISTOPH HUGENSCHMIDT — Heinz Maier-Leibnitz Zentrum (MLZ), Technical University of Munich, Lichtenbergstr. 1, 85748 Garching, Germany

Most electrostatic positron beams used to perform surface studies are accelerated to the desired implantation energy by floating the target to a high electrostatic potential relative to ground. The presence of tens on kilovolts of electric potential makes the use of instrumentation attached directly to the sample inconvenient. The conventional solution to this hurdle consists in wiring insulated connections from the sample to a high-voltage galvanic decoupling placed outside of the experimental chamber far away from the sample holder. This solution carries limitations on the kind and amount of electrical connections employed. We will present, instead, a novel approach to in-operando sample manipulation that we have developed to be used at the Doppler broadening spectrometer installed on the NEPOMUC positron source, which implements the galvanic insulations.

#### O 63.3 Thu 11:15 H6

Advanced Kernel-Based NMR Cryoporometry Characterization of Mesoporous Solids — •HENRY R.N.B. ENNINFUL, DANIEL SCHNEIDER, RICHARD KOHNS, DIRK ENKE, and RUSTEM VALIULLIN — Leipzig University, Leipzig, Germany

NMR cryoporometry is a pore space characterization technique for industrial and natural materials such as catalysts, gas storage materials, cartilage, bones, rocks and many more. While gaining wide use, the fundamental phenomena underlying solid-liquid phase transitions in geometrically disordered porous materials is still not fully understood. This may lead to inaccurate pore size distributions from the NMR cryoporometry technique.

In this work, we have developed a new approach to NMR cryoporometry. Herein, it takes account of cooperativity effects in pores, the existence of a variable non-frozen layer (NFL) thickness between the frozen core and pore wall and the effect of curvature on thermal fluctuations in pores which hitherto are missing in the current approach. In the first place, we compile a family of transition curves characterizing the phase state in pores with different pore sizes, so called kernels. Thereafter, we apply a general framework for predicting phase equilibria in a collection of pores. Specifically, the proposed kernel-based approach is coupled with the serially-connected pore model (SCPM) to be able to predict phase behavior in independent pore systems as well as in pore networks. We demonstrate the new approach by applying it to ordered pores size distribution (PSD) is obtained.

Development of an electron spin resonance spectrometer in ultra-high vacuum for surface spins — •JUYOUNG PARK^{1,2}, FRANKLIN H. CHO^{1,2}, JISOO YU^{1,2}, LUCIANO COLAZZO^{1,2}, YEJIN JEONG^{1,2}, JUNJIE LIU³, ARZHANG ARDAVAN³, GIOVANNI BOERO⁴, ANDREAS HEINRICH^{1,2}, and FABIO DONATI^{1,2} — ¹Center for Quantum Nanoscience, Institute for Basic Science, Seoul, Republic of Korea — ²Ewha Womans University, Seoul, Republic of Korea — ³The Clarendon Laboratory, Department of Physics, University of Oxford, Oxford, UK — ⁴Ecole Polytechnique Fédérale de Lausanne, Laboratory for Microsystems, Lausanne, Switzerland

We present the development of an electron spin resonance (ESR) spectrometer operating in ultra-high vacuum (UHV) for studying surface-adsorbed molecular and atomic spin systems. Such surface spin systems are promising platforms for potential applications in quantum computing and information processing [Science 366, 509 (2019)]. Our spectrometer is capable of both continuous-wave and pulsed ESR measurement in the temperature range of 2.5 K to 300 K. The surface-sensitivity is attained using a surface-type microwave resonator with its resonance frequency in the X-band. The spectrometer is connected to a homebuilt in-situ preparation chamber which allows us to prepare and characterize surfaces with low-energy electron diffraction and Auger electron spectroscopy. We demonstrate that we are sensitive down to a monolayer of molecular film using organic radicals such as  $\alpha$ , $\gamma$ -Bisdiphenylene- $\beta$ -phenylallyl, and metal ph-thalocyanine complexes such as vanadyl phthalocyanine.

#### O 63.5 Thu 11:45 H6

Unsupervised machine learning-assisted analysis of multidimensional ARPES data — •STEINN YMIR AGUSTSSON¹, MOHAMMAD AHSANUL HAQUE², FATEMEH ZARDBANI², DAVIDE MOTTIN², PANAGIOTIS KARRAS², and PHILIP HOFMANN¹ — ¹Institute of Physics and Astronomy, Aarhus University, Denmark — ²Institute of Computer Science, Aarhus University, Denmark

In recent years, the size and complexity of experimental data sets has been dramatically growing in many fields of science. For photoemission spectroscopy, the development of novel detectors and multi-dimensional measurement modes (e.g., including a time dependence or spatial dependence), has lead to orders of magnitude more data being produced. Even after a necessary upgrade of the data management system, it remains highly challenging to visualize and superficially interpret the data fast enough to feed back into decisions about what to measure in an ongoing experimental run. A promising approach to address this is the application of machine learning tools. These have shown promising results when applied to data reduction and feature detection tasks in many fields of science. We have developed an unsupervised clustering method which is able to distinguish differences between ARPES spectra obtained from different spatial locations in nanoARPES measurements. This enables quick and automatic identification and classification of regions with different spectral features, allowing to invest more time in the collection of significant data.

O 63.6 Thu 12:00 H6

**ViPErLEED:** A modern all-in-one LEED I(V) package — •ALEXANDER M. IMRE¹, FLORIAN KRAUSHOFER^{1,2}, FLORIAN DOERR¹, TILMAN KISSLINGER³, MICHAEL SCHMID¹, ULRIKE DIEBOLD¹, LUTZ HAMMER³, and MICHELE RIVA¹ — ¹TU Wien, Vienna, Austria — ²TU Munich, Munich, Germany — ³FAU Erlangen-Nürnberg, Erlangen, Germany

Many surface science groups use Low-Energy Electron Diffraction (LEED) for quick, qualitative analysis of surface periodicity. Analysis of the beam intensities as a function of electron energy [LEED I(V)] is sensitive to surface atom positions at the picometer scale. Thus, comparison with calculated intensities can verify or reject structural models. Despite this, LEED I(V) is currently rather unpopular, largely because the available software solutions are not sufficiently user-friendly. To greatly lower the barrier of entry into the field, we present the Vienna Package for TensErLEED (ViPErLEED) which provides a truly allin-one package for LEED I(V). ViPErLEED includes a freely available design for electronics that enable upgrading existing LEED setups for LEED I(V) use. With sophisticated image acquisition and processing methods, as well as an automated spot-tracking tool for curve extraction, we greatly simplify the most tedious parts of the experiment. For the calculation of intensities, the package includes a user-friendly front-end and an extensive overhaul to the established TensErLEED package that only requires a few standardized input files. We further describe automated symmetry detection, improvements to the structure search algorithm, and a Python API.

**Gold-colored metallic water solution** — •TILLMANN BUTTERSACK¹, PHILIP MASON², CHRISTIAN SCHEWE², RYAN MCMULLEN³, FLORIAN TRINTER^{1,4}, DANIEL NEUMARK⁵, STEPHAN THÜRMER⁶, ROBERT SEIDEL⁷, BERND WINTER¹, STEPHEN BRADFORTH³, and PAVEL JUNGWIRTH² — ¹Fritz-Haber-Institute, Berlin, GER — ²Czech Academy of Sciences, Prague, CZ — ³U Southern California, Los Angeles, USA — ⁴DESY, Hamburg, GER — ⁵UC Berkeley, USA — ⁶Kyoto U, JP — ⁷BESSY, Berlin, GER

Whereas tap water and common aqueous solutions conduct some electricity, pure water is an almost perfect insulator. The required pressures to transform water into a metallic state will not be achievable on Earth. Liquid Ammonia undergoes a gradual phase transition from a blue electrolyte solution to a bronze-colored metallic solution if the concentration of solvated alkali metal is enhanced. Water and alkali metals react vigorous, as the valence electrons of the alkali metal are transferred to the aqueous solution almost instantly, leading to a Coulomb explosion. Here, we demonstrate, that water from the gas phase adsorbs onto the surface of sodium-potassium alloy droplet leading to the formation of a thin shiny and golden layer. Characterization of the liquid with photoelectron and UV/Vis spectroscopy revealed a plasmon energy of 2.7 eV and signatures of liquid water. These observations are spectroscopic evidence for an aqueous solution with metallic properties. Its plasmon frequency is in the visible region of the spectrum and thus is the reason for the fascinating golden color.

O 64.2 Thu 11:00 S051

**Standing molecules for quantum sensing** — •TANER ESAT — Peter Grünberg Institute (PGI 3), Forschungszentrum Jülich, 52425 Jülich, Germany — Jülich Aachen Research Alliance (JARA), Fundamentals of Future Information Technology, 52425 Jülich, Germany

Artificial nanostructures, fabricated by placing building blocks like atoms and molecules in well-defined positions, are an almost universal playground where quantum effects can be studied and exploited on the atomic scale. In my talk, I will show that the manipulation capabilities of a scanning tunneling microscope (STM) allow the fabrication of metastable structures which do not form spontaneously in nature and that these structures offer attractive functionalities for quantum information and sensing. Specifically, I will demonstrate that a large planar aromatic molecule can be lifted into an upright standing geometry on a pedestal of two metal adatoms using the STM tip. This atypical and surprisingly stable upright orientation of the single molecule enables the system to function as a quantum dot and a coherent single-electron field emitter. Utilizing a novel homebuilt STM that uses adiabatic demagnetization refrigeration (ADR) to reach millikelvin temperatures, I will show that the standing molecule is weakly coupled to the surface and that it exhibits spin-flip excitations corresponding to a spin-1/2 system. If the standing molecule is fabricated on the tip, it can be used for the measurement of surface potentials and magnetic fields on the atomic scale at the same time - possibly even as an electron spin resonance sensor on the tip.

#### O 64.3 Thu 11:30 S051

**On-surface synthesis and characterization of cyclo**[18]carbon — •KATHARINA KAISER¹, LOREL SCRIVEN², FABIAN SCHULZ¹, PRZEMYSLAW GAWEL², LEO GROSS¹, and HARRY ANDERSON² — ¹IBM Research - Zurich, Säumerstrasse 4, 8803 Rüschlikon, CH — ²Department of Chemistry, Oxford University, Chemistry Research Laboratory, Oxford, OX13TA, UK

Cyclo[n]carbons, purely sp-hybridized carbon allotropes with unique structural and electronic properties, have been predicted for decades to exist. Although a synthetic route was already elaborated in the 1980's, and glimpses of cyclocarbons were detected in gas phase, they could never be stabilized long enough for characterization. A distinctive feature of cyclo[n]carbons is their two conjuGNRs form crystallites, they cannot be brought onto the surface by direct contact printing and characterized using STM. Therefore, a new electrospray setup was developed for the deposition of GNR precursor molecules, large precursor polymers, and GNR from a solution. The instrument consists of a heatable stainless steel capillary to which a high voltage in the range -8 to 8 kV, with respect to the sample can be applied. The assembly is placed in a glovebox which ensures the cleanliness of the working process. The characterization of the depositis was done with STM under ultra high vacuum after sample transfer. The deposition of TPTP monomers from solution onto Au(111) brought comparable results as other, established approaches were cGNR were formed after direct contact printing in UHV. Larger polymers were also deposited and completely cyclized on the surface after deposition, forming promising GNRs that have not been studied anywhere before.

those synthesized on the surface and can be produced in large quantities. Since

gated  $\pi$ -systems that can lead to the formation of two orthogonal ring currents and so-called double-aromatic stabilization. However, distortions in the geometry can lead to a lowering in ground state energy, and theoretically predicted ground state structures were found to depend on the level of theory. Consequently, cyclo[n]carbon's structures remained unknown.

AFM and STM at low temperatures allow triggering certain on-surface chemical reactions by atom manipulation and can thus facilitate the controlled formation of highly reactive molecules on inert surfaces from more stable precursors. Using this approach, we formed cyclo[18]carbon on a thin layer of NaCl. By comparing high-resolution AFM images with a functionalized tip and AFM simulations of different predicted resonance structures, we identified two possible ground state structures of cyclo[18]carbon adsorbed on bilayer NaCl.

**Correlative in situ microscopy of hydrogen oxidation on rhodium: from the meso- to the nanoscale** — •JOHANNES ZEININGER — Institute of Materials Chemistry, TU Wien, Getreidemarkt 9, 1060 Vienna, Austria

Catalytic surface reactions, such as CO oxidation, may produce a variety of spatio-temporal effects on the catalyst surface. To reveal the mechanisms behind such spatio-temporal effects, it is advantageous to apply multiple techniques to the same samples, particularly at different length scales. In other research areas than catalysis this idea has led to the correlative microscopy approach. In catalysis, this approach is, if at all, used for sample characterization, often in two separate setups. In the present contribution, the correlative microscopy approach has been applied in situ to the catalytic hydrogen oxidation on rhodium to reveal the mechanism of multifrequential kinetic oscillations, a novel effect recently detected in this reaction. Such oscillations were first observed on a polycrystalline Rh foil, where the reaction oscillated in a self-sustained way between the states of high and low activity (a known behavior), but with different frequencies on adjacent domains (a new and unexpected behavior). Later on, such an effect was also observed on the nanofacets of a Rh tip modeling a single catalytic particle. Such behavior contradicts previous observations and expectations based on the known spatial coupling mechanisms and was never observed before, for any surface reaction.

Efficient electronic passivation schemes for surface calculations of semiconductors exhibiting spontaneous polarization: Thermodynamic and electronic properties of GaN surfaces - •Su-Hyun Yoo¹, Mira Todorova¹, LIVERIOS LYMPERAKIS¹, CHRIS VAN DE WALLE², and JÖRG NEUGEBAUER¹ -¹Department of Computational Materials Design, MPI für Eisenforschung, Germany — ²Computational Materials Group, Materials Department, UCSB, USA Semiconductor surfaces play a central role in modern technology related to catalysis, electronics, and energy applications. The most widespread approach to study surfaces with density-functional theory calculations is to use slab geometries with periodic boundary conditions. A common strategy employed to avoid artificial charge transfer from one side of the slab to another, is to passivate the dangling bonds at its backside. Using the examples of wurtzite polar and semipolar surfaces, we demonstrate that the conventional passivation scheme using pseudo-H atoms fails to describe the electronic structure of lowsymmetry semiconductors. We therefore developed an improved passivation method [npj Comp. Mater. 7, 58, 2021/PR Mater. 5, 044605, 2021] that takes the polarization effect and the concept of surface reconstructions into account. It accurately describes surface electronic properties and enables computationally efficient surface energy calculations. Using this novel approach we have studied the orientation-dependent thermodynamic stability and electronic properties of GaN surfaces. The resulting Wulff shape provides insight of how to avoid facetrelated defects such as V-pits hampering GaN-based electronics.

Segregation-enhanced epitaxy of borophene on Ir(111) by thermal decomposition of borazine — •KARIM OMAMBAC¹, MARKO KRIEGEL¹, MARIN PETROVIC^{1,2}, PANTELIS BAMPOULIS⁴, CHRISTIAN BRAND¹, PASCAL DREHER¹, DAVID JANOSCHKA¹, ULRICH HAGEMANN³, NILS HARTMANN³, PHILIPP VALERIUS⁴, THOMAS MICHELY⁴, FRANK-J. MEYER ZU HERINGDORF^{1,3}, and MICHAEL HORN-VON HOEGEN¹ — ¹Universität Duisburg-Essen, Germany — ²Institute of Physics, 10000 Zagreb, Croatia — ³Interdisciplinary Center for the Analytics on the Nanoscale, Germany — ⁴Universität zu Köln, Germany While borophene is typically prepared by molecular beam epitaxy [1], we report here on an alternative way of synthesizing large single-phase borophene domains by segregation enhanced epitaxy. X-ray photoelectron spectroscopy shows that borazine dosing at 1100°C onto Ir(111) yields a boron-rich surface without traces of nitrogen. At high temperatures the borazine thermally decomposes, nitrogen desorbs, and boron diffuses into the substrate. Using time-of-flight secondary ion mass spectroscopy we show that during cooldown the sub-surface boron segregates back to the surface where it forms borophene. In this case electron diffraction reveals a (6x2) reconstructed borophene  $\chi$ 6-polymorph [1], and

scanning tunneling spectroscopy suggests a Dirac-like behavior. Studying the kinetics of borophene formation in low energy electron microscopy shows elongated and extended borophene domains with exceptional structural order. [1] ACS Nano 13 (12), 14511-14518 (2019).

O 65.2 Thu 10:45 S052

**Investigation of sub-monolayer Sn phases on Au(111)** — •JULIAN ANDREAS HOCHHAUS^{1,2}, LUKAS KESPER^{1,2}, STEFANIE HILGERS¹, ULF BERGES^{1,2}, and CARSTEN WESTPHAL^{1,2} — ¹Technische Universität Dortmund, Fakultät Physik, Otto-Hahn-Str. 4, D-44227, Dortmund, Germany — ²DELTA, TU Dortmund, Maria-Goeppert-Mayer-Str. 2, D-44227, Dortmund, Germany

In this study we investigate the temperature and layer thickness dependence of sub-monolayer phases of Sn on Au(111).

Stanene, the two-dimensional graphene analog of tin, is predicted to exhibit similar exceptional electronic properties. Since tin is one of the heavier elements in the carbon group, stanene exhibits topological properties even at RT due to its strong spin-orbit coupling. Therefore, stanene is a promising material for application in future two-dimensional topological devices.

Since the surface and interface structure of low-dimensional materials often influences their electronic properties, we focus on the structural and chemical analysis of the Sn/Au interface.

Here, we report a structural and chemical investigation of different submonolayer Sn phases on Au(111) by means of low energy electron diffraction (LEED) and photoelectron spectroscopy (XPS). Tin layers of different thicknesses were deposited gradually on the Au(111) surface by physical vapor deposition and subsequently heated. A strong dependence of the structural and chemical configuration of the tin atoms on the layer thickness and the post-deposition annealing temperature was observed.

#### O 65.3 Thu 11:00 S052

**On the transition from MoS**₂ **single-layer to bilayer growth on the Au(111) surface** — •MORITZ EWERT¹, LARS BUSS¹, FRANCESCA GENUZIO³, TEVFIK ONUR MENTEŞ³, ANDREA LOCATELLI³, JENS FALTA², and JAN INGO FLEGE¹ — ¹Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology Cottbus-Senftenberg, Germany — ²Institute of Solid State Physics, University of Bremen, Germany — ³Elettra-Sincrotrone Trieste S.C.p.A., Basovizza, Trieste, Italy

 $MoS_2$  is well known for changing from an indirect to a direct band-gap semiconductor as a single layer. Here, for the model system  $MoS_2/Au(111)$ , we present in-situ studies of the continued growth of micron-size single-layer  $MoS_2$  islands including the first formation of bilayer patches.

We have used angle-resolved photoemission spectroscopy from micrometer sized regions to investigate the local band structure of the islands' rims and centers, showing a prevalence for bilayer and single-layer formation at the rims and centers, respectively. The bilayer patches can clearly be identified locally on the few nanometer scale employing intensity-voltage low-energy electron microscopy as a fingerprinting method. Astonishingly, micro-spot low-energy electron diffraction hints toward the nucleation of the second layer of the MoS₂ between the single layer MoS₂ and the Au(111) substrate when the step bunches formed by the single-terrace growth mechanism become sufficiently high.

#### O 65.4 Thu 11:15 S052

Structural and electronic investigations of CVD-grown TMDs on Au(111) – •JULIAN PICKER¹, MAXIMILIAN SCHAAL², ZIYANG GAN¹, MARCO GRUENEWALD², CHRISTOF NEUMANN¹, ANTONY GEORGE¹, FELIX OTTO², TORSTEN FRITZ², and ANDREY TURCHANIN¹ – ¹Institute of Physical Chemistry, Friedrich Schiller University Jena, Lessingstraße 10, 07743 Jena, Ger-

many —  2 Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany

Transition metal dichalcogenides (TMDs) are layered two-dimensional (2D) materials which have come into the focus of research in recent years. Especially, the exciting change of properties when going from bulk to monolayer make them interesting for novel electronic applications. Here, we demonstrate the *ex-situ* growth of  $MoS_2$  and  $MoSe_2$  monolayers on Au(111) by chemical vapor deposition (CVD) in a two-zone furnace. Afterwards, the samples were analyzed in ultra-high vacuum (UHV) with the help of surface sensitive methods, including (low-temperature) scanning tunneling microscopy and spectroscopy (STM/STS), low-energy electron diffraction (LEED) as well as X-ray and angle-resolved ultra-violet photoelectron spectroscopy (XPS/ARPES). While we could confirm the growth of high-quality single crystalline TMDs, we also accessed the structural and electronic properties of these samples down to the atomic scale. Finally, the impact of annealing on the structure and properties of the TMDs was studied.

#### O 65.5 Thu 11:30 S052

Spectroscopic and microscopic study of carborane based 2D materials — •MARTHA FREY¹, JULIAN PICKER¹, JAKUB VIŠŇÁK², CHRISTOF NEUMANN¹, TOMÁŠ BAŠE², and ANDREY TURCHANIN¹ — ¹Friedrich Schiller University Jena, Institute of Physical Chemistry, Lessingstraße 10, 07743 Jena, Germany — ²The Czech Academy of Sciences, Institute of Inorganic Chemistry, 250 68 Husinec-Rez, c.p. 1001, Czech Republic

Carboranes are electron-delocalized molecular clusters containing boron, carbon and hydrogen. Because of their high stability and structural variability, they are interesting for a wide range of applications including nanoscale engineering, catalysis and boron neutron capture therapy. Here, we present the fabrication of a novel boron-based two-dimensional (2D) material *via* electron irradiation induced cross-linking of carborane self-assembled monolayers (SAMs) on silver or gold substrates. The SAMs, the cross-linking process and the resulting 2D nanosheets have been characterized with different complementary surface sensitive techniques including X-ray photoelectron spectroscopy (XPS), low-energy electron diffraction (LEED), scanning tunneling microscopy (STM) and scanning electron microscopy (SEM).

#### O 65.6 Thu 11:45 S052

Growth and Structural Properties of 2D Blue Phosphorene on Au(111) and on Au(100) — •MAXIMILIAN SCHAAL¹, JULIAN PICKER², FELIX OTTO¹, MARCO GRUENEWALD¹, ROMAN FORKER¹, and TORSTEN FRITZ¹ — ¹Institute of Solid State Physics, Friedrich Schiller University Jena, Helmholtzweg 5, 07743 Jena, Germany — ²Institute of Physical Chemistry, Friedrich Schiller University Jena, Lessingstraße 10, 07743 Jena, Germany

Blue phosphorene (BlueP) is a novel two-dimensional material that shares properties with black phosphorene and is potentially even more interesting for optoelectronic applications because of its layer dependent band gap of approx. 2 to 3 eV and superior charge carrier mobility [1]. Despite these promising properties, the growth of quasi-freestanding BlueP is still challenging.

In our contribution we will report on the structural and electronic properties of epitaxial BlueP on Au(111) and on Au(100) by means of scanning tunneling [hydrogen] microscopy (ST[H]M), distortion-corrected low-energy electron diffraction (LEED) as well as X-ray photoelectron spectroscopy and diffraction (XPS and XPD). It is already known that on Au(111) a network consisting of BlueP islands, which are connected by Au linker atoms, is formed [2]. In contrast, we demonstrate that on Au(100) quasi-free standing BlueP domains grow [3].

How the supple Pt(110) surface paves the way to single-domain h-BN growth. — •MARCO THALER¹, DOMINIK STEINER¹, FLORIAN MITTENDORFER², and ER-MINALD BERTEL¹ — ¹Department of Physical Chemistry, University of Innsbruck, Austria — ²Institute of Applied Physics and Center for Computational Materials Science, Vienna University of Technology, Austria

Its structural flexibility renders Pt(110) an extraordinary substrate for hexagonal boron nitride (h-BN) growth. Borazine-exposure at high temperature yields either an extended film or empty terraces depending on dosage. Annealing preadsorbed Borazine, in contrast, yields nuclei with a structure differing from the extended film. DFT modelling of the latter was carried out by starting with a stretched film, which ruptured upon relaxation into smaller h-BN islands. The Pt surface layer below them is severely disordered. Only after high-T annealing the islands relaxe into the final h-BN/Pt(110)-(1xn) missing-row configuration. Thus, this non-classical, two-step nucleation proceeds via a metastable transition structure. Under the conditions of high-T exposure the metastable nuclei are continuously dissolved by desorption and H-induced etching. Stochastic formation of a critical island size with the more stable (1xn)m.r. structure requires a high supersaturation, but once formed, such an island grows explosively into an extended film. Hence, single-domain growth of h-BN on Pt(110) differs significantly from that on vicinal Cu(110), where (1-12) step edges act as nucleation sites giving rise to uniform nuclei capable of seamless coalescence.

O 65.8 Thu 12:15 S052

Development of strain- and gate-controllable STM sample holder -- •Jz-Yuan Juo¹, Bong Gyu Shin^{$\overline{1}$}, Soon Jung Jung¹, and Klaus Kern^{1,2} – ¹Max-Planck-Institut für Festkörperforschung, Heisenbergstraße 1, DE-70569 Stuttgart, Germany — ²Institut de Physique, École Polytechnique Fédérale de Lausanne, CH-1015 Lausanne, Switzerland

An atomic-scale understanding of strain effects on electronic properties is essential for implementing two-dimensional materials into flexible electronics. The

scanning tunneling microscopy (STM) is an ideal method to advance this understanding. However, the combination of STM and strain-controllable devices remains challenging due to the high demand for compatibilities with limited STM space, ultrahigh vacuum, and mechanical stability. We have developed an indentation-based sample holder for STM measurements. A gearbox and a piezo stack were used to control the distance between the indentor and 2D materials transferred on the suspended polyimide. The gearbox has a travel range of ~120  $\mu$ m and precision of ~1.4  $\mu$ m; the piezo stack has a travel range of ~1.8  $\mu$ m and precision of <1 nm. The combination of gearbox and piezo stack allowed us to tune the distance between indentor and sample continuously with nanometer precision, characterized by atomic force microscopy. Raman spectroscopy was used to measure strain distribution in monolayer MoS₂ at the indented area. The strain controllability is characterized by calculating graphene lattice constant changes in STM atomic-resolution images. Spectroscopic studies confirm the gate tunability by observing Dirac point shifts.

O 66.1 Thu 10:30 S053 Charge-ordered states on incipient ferroelectric polar surfaces - •CESARE FRANCHINI — University of Vienna — University of Bologna

The precise atomic-scale knowledge of surface properties is mandatory for interpreting experimental data, optimizing (photo)catalytic processes, or predicting novel electronic phases. This is particularly challenging for perovskite materials, which typically show a variety of surface structural reconstructions that prevent a generally valid and transferable understanding of surface properties. However, recent experiments have shown that a novel cleavage protocol based on controlled exploitation of ferroelectric instabilities can generate well-defined bulk-terminated (001) surfaces, paving the way for a precise characterization of the surface electronic structure. This talk shall report first principles electronic structure calculations on polar KTaO3(001), focusing on the dichotomy between charge localized/delocalized phases and their impact on surface reactivity. Our data, supported by experimental observations, show that polarityinduced uncompensated carriers in KTaO3(001) exhibit charged-order patterns rather than common 2DEGs, manifested by charge-density wave and (bi)polaron states. Eventually, the trapped charge suppresses ferroelectric surface distortions, resulting in a binary CO adsorption process.

O 66.2 Thu 11:00 S053 Surface phonons and their coupling to the 2D electron liquid at the CTO/STO surface — •M. DÖTTLING¹, E. B. GUEDES^{2,3}, T. P. VAN WAAS^{4,2}, S. PONCE^{4,5}, M. CAPUTO^{3,6}, N. C. PLUMB², N. MARZARI⁵, C. BERTHOD⁷, M. RADOVIĆ², J. H. DIL^{3,2}, and K. ZAKERI¹ — ¹PHI, Karlsruhe Institute of Technology — ²PSD, PSI - ³IPHYS, EPF Lausanne — ⁴IMCN, UC Louvain — ⁵THEOS, EPF Lausanne - ⁶Elettra, Trieste - ⁷DQMP, University of Geneva

Motivated by the recent discovery of a 2D electron liquid (2DEL) formed at the surface of CaTiO₃/SrTiO₃(001) heterostructure, we probed the phonon spectrum of the system by means of high-resolution electron energy-loss spectroscopy (HREELS). Our main aim was to address any possible interaction of 2DEL with phonons.

The HREELS measurements revealed the existence of the Fuchs-Kliewer (FK) phonon modes at the energies of 20, 60 and 93 meV. Interestingly, the Eliashbergfunction  $\alpha^2 F(\omega)$  constructed based on the quasiparticle band dispersion, probed by angle-resolved photoemission experiments, exhibits peaks at energies of 20, 60 and 80 meV.

The apparent redshift of the highest energy peak in  $\alpha^2 F(\omega)$ , compared to the 93 meV FK mode, can be attributed to the formation of band-gap states (BGS). Such states form upon photon irradiation at the same time as 2DEL is formed. This is shown by the simulated HREEL spectra including BGS. Our results demonstrate the importance of BGS and the necessity of their consideration in describing the properties of oxide heterostructures. Supported by DFG via Heisenberg Programme ZA 902/3-1, ZA 902/6-1 and ZA 902/5-1.

Reversible switching of the 2D electron gas of SrTiO₃(001) studied by HREELS — •HANNES HERRMANN, FLORIAN SCHUMANN, and WOLF WIDDRA · Martin-Luther-Universität Halle-Wittenberg, Institute of Physics, 06120 Halle, Germany

The formation of a 2D electron gas (2DEG) gained high interest in surface science as it became accessible under oxygen-poor conditions at the TiO2terminated SrTiO₃(001) surface [1]. In this work, we follow the 2DEG formation by studying the SrTiO₃ surface plasmon polaritions (SPP) by high-resolution electron energy loss spectroscopy (HREELS). The coupling of the SPP to the 2DEG leads to an asymmetric SPP line shape with extreme broadening. This strong electron-phonon coupling allows to quantify the 2DEG charge carrier density and is used to follow the reversible formation of the 2DEG by heating in UHV/O2 atmosphere or by adsorbing molecular oxygen at 100 K.

The dielectric response will be discussed in terms of a two-layer model with a surface 2DEG which is modelled using a Drude-like response with a strongly frequency-dependent electronic mobility.

Structure determination of a dodecagonal oxide quasicrystal — •SEBASTIAN SCHENK¹, OLIVER KRAHN¹, HOLGER L. MEYERHEIM², MARC DE BOISSIEU³, STEFAN FÖRSTER¹, and WOLF WIDDRA¹ — ¹Institute of Physics, Martin-Luther-Universität Halle-Wittenberg, 06120 Halle, Germany – ²Max-Planck-Institut für Mikrostrukturphysik, 06120 Halle, Germany — ³Universite Grenoble Alpes, CNRS, SIMaP, St Martin d Heres, France

The dodecagonal symmetry and the general tiling motive of oxide quasicrystals (OQC) have been proven by electron diffraction (LEED) and scanning tunneling microscopy (STM) from their first observations [1,2]. However, the detailed atomic structure, which includes the decoration of individual tiling elements with metal and oxygen atoms, has been under debate for more than eight years.

In this talk we solve the atomic structure by combination of STM and surface x-ray diffraction (SXRD) of a quasicrystal approximant, which is derived from an ultrathin layer of SrTiO₃ on Pt(111). The derived structure model can be generalized for all related ternary oxide quasicrystals and their approximants. The measured diffraction intensities will be compared with calculated ones by lifting the atomic structure of the OQC into its four-dimensional periodic superlattice. These intensities will be compared to SXRD data obtained in synchrotron measurements.

Structural analysis of complex 2D Sr-Ti-O/Pd(111) films. - •MARTIN HALLER, SEBASTIAN SCHENK, STEFAN FÖRSTER, and WOLF WIDDRA — Martin-Luther-Universität Halle-Wittenberg, Institute of Physics, Von-Danckelmann-Platz 3, 06120 Halle, Germany

In 2013 the first 2D oxide quasicrystal (OQC) in thin Ba-Ti-O/Pt(111) films with astonishing structural properties has been discovered [1]. It features a twelvefold rotational symmetry that is incompatible with lattice periodicity. Instead, it is described with a self-similar quasicrystalline structure that involves squares, triangles and rhombuses. In the wake of this discovery combinations of ternary oxide layers and different hexagonal substrates have been investigated to study the epitaxial preconditions for the formation of the OQC. In this contribution, we present a structural analysis for Sr-Ti-O on Pd(111). Globally, as seen from LEED, it forms a periodic structure with unit cell parameters a = 1.32 nm, b = 2.96 nm and  $\alpha = 93.43^{\circ}$ . However, locally a second phase has been identified in atomically-resolved STM data with twelvefold symmetric FFT and long range coherence in the 2D auto-correlation image. The analysis of the tiling statistics reveals a triangle:square:rhomb ratio of 2.84:1:0.39 which deviates slightly from the ideal OQC's ratio of 2.73:1:0.37 [2]. The given structure is discussed in terms of a disordered OQC which is further supported by a 4D hyperspace analyis.

**Transformation from honeycomb binary oxide to quasicrystalline ternary oxide** — •LOI V. TRAN, STEFAN FÖRSTER, and WOLF WIDDRA — Institute of Physics, Martin-Luther-University Halle-Wittenberg, Halle, Germany

Oxide quasicrystals (OQCs) are examples of aperiodically-ordered 2D materials. They have been found for 2D layers derived from BaTiO₃ on Pt(111) [1]. Their dodecagonal structure results from Ba decoration of a  $Ti_nO_n$  network where n = 4 (decorated with no Ba atom), 7 (decorated with one Ba atom) and 10 (decorated with two Ba and two addional O atoms). In contrast, periodic  $Ti_2O_3$  honeycomb structures with  $Ti_6O_6$  rings are well known in literature [2,3]. Here, we report on the transition of such honeycomb  $Ti_2O_3$  structures to dodecagonal OQCs by adsorption of Ba and subsequent annealing. The structural transition is monitored with LEED and workfunction measurements. Upon room temperature Ba deposition,  $Ti_2O_3$  honeycomb structure remains and  $Ti_6O_6$  rings are decorated with Ba, reducing the workfunction from 5.12 to 2.97 eV. Annealing to 873 K in oxygen converts the honeycomb structure into a dodecagonal OQC, for which the transformation will be discussed in context of the height differences of Ba ions above the surface and the resulting dipole strength.

#### O 66.7 Thu 12:15 S053

Barium decorated  $Ti_2O_3$  monolayers: a case study for Pd(111) substrates — •FRIEDERIKE WÜHRL, SEBASTIAN SCHENK, OLIVER KRAHN, STEFAN FÖRSTER, and WOLF WIDDRA — Institute of Physics, Martin-Luther-Universität Halle-Wittenberg, 06120 Halle, Germany

Oxides at the two-dimensional limit show a high flexibility in their structural properties ranging from hexagonal honeycomb structures to dodecagonal oxide quasicrystals (OQC) [1]. Recent work based on STM, surface x-ray diffraction (SXRD) and DFT calculations confirmed a structure model for oxide quasicrystals that explains this extraordinary structure as an aperiodically ordered Ti₂O₃ network with rings of different sizes on the metal support Pt(111), in which the largest rings are decorated with Ba ions [2]. The Ba ions form a self-similar tiling, which can be described through triangles, squares and rhombuses. In this contribution we report on a sequence of long-range ordered structures observed in Ba_xTi₂O_{3+y} on Pd(111) that are closely related to the OQC. We present a series of structures ranging from a Ba_{0.66}Ti₂O₃ to a BaTi₂O_{3.5} stoichometry. By varying the Ba content, we observe a transition from a triangle-square tiling via triangle-square tilings to one consisting of triangles and rhombuses only [3]. It will be discussed how the Ba density sets the ratio of four to seven to ten membered rings in the Ti₂O₃ backbone.

O 66.8 Thu 12:30 S053 The (2x1) reconstruction of calcite(104) — Jonas Heggemann¹, Yashasvi Ranawat², Ondřej Krejčí², Adam S. Foster², and •Philipp Rahe¹ — ¹Fachbereich Physik, Universität Osnabrück, Barbarastraße 7, Osnabrück, Germany — ²Department of Applied Physics, Aalto University, Helsinki, Finland

Calcite is an abundant material in the Earth's crust, a central constituent of biominerals in living organisms [1], and currently investigated as a capture material for CO2 [2]. Despite intensive studies, however, there is still serious ambiguity regarding the properties of this surface due to conflictive conclusions for the so-called row-pairing [3] and (2x1) reconstruction [4].

Here, we use a combination of non-contact atomic force microcopy (NC-AFM) with CO-functionalized tips at 5K, density functional theory with stateof-the-art dispersion corrections, and NC-AFM image simulations to clarify the microscopic geometry of calcite(104). A (2x1) reconstruction and a glide plane symmetry is consistently found in the NC-AFM data and DFT results. Most importantly, we identify two different adsorption positions for CO molecules within the (2x1) unit cell. These findings are most critical for future studies where processes on calcite(104)-(2x1) are influenced by the surface geometry.

O 66.9 Thu 12:45 S053

Growth of ultra thin  $Eu_x O_y$  films on Pt(001): A HREELS, XPS and LEED study — •ANNE OELSCHLÄGER, HANNES HERRMANN, STEFAN FÖRSTER, and WOLF WIDDRA — Martin-Luther-Universität Halle-Wittenberg, Institut of Physics, 06120 Halle, Germany

The gradually decreasing ionic radii along the series of lanthanides allow an exceptional fine tuning of lattice parameters, which makes this material class interesting for applications in epitaxial growth. In this contribution we report on the growth of thin  $Eu_xO_y$  films on Pt(001) and characterize the thin film oxidation upon annealing in various environments.

A 0.8 nm thin Eu layer has been deposited onto Pt(001) at room temperature in UHV conditions at a background pressure below  $3 \cdot 10^{-10}$  mbar. By monitoring the surface phonons with HREELS and the valence state of Eu with XPS a continuous oxidation of Eu at room temperature by water from the residual gas as well as by molecular oxygen is observed as a transition from metallic Eu to Eu₂O₃. The transition to Eu³⁺ can be followed by increasing (decreasing) intensities for the surface phonon polariton at 364 cm⁻¹ (525 cm⁻¹) in HREELS and the high binding energy component of the Eu3d core level at 1135 eV (1125 eV) in XPS. The long-range order starts to develop in the 0.8 nm thin layer upon annealing to 1000 K. LEED exhibits a complex twelve-fold diffraction pattern.

Quantile Random Forest Model for Extrapolation to the Complete Basis Set Limit in Density Functional Theory Calculations — •DANIEL SPECKHARD¹, CHRISTIAN CARBOGNO², SVEN LUBECK², LUCA GHIRINGHELLI², MATTHIAS SCHEFFLER^{2,1}, and CLAUDIA DRAXL^{1,2} — ¹Humboldt-Universität zu Berlin, Physics Department and IRIS Adlershof, Berlin, Germany — ²The NOMAD Laboratory at the FHI-MPG and HU, Berlin, Germany

The precision of density-functional theory (DFT) calculations depends on a variety of computational parameters, the most critical being the basis-set size. With an infinitely large basis set, i.e., in the limit of a complete basis set (CBS), the result of the calculation is as precise as possible for the chosen exchange-correlation functional. Our aim in this work is to find a model that can extrapolate the result of an imprecise DFT calculation to the CBS limit. As a starting point, we use a dataset of 63 binary solids investigated with various basis-set sizes [1] with two all-electron DFT codes, exciting and *FHI-aims*, which use very different types of basis sets. A quantile random forest model is used to estimate the deviation of the total energy with respect to fully converged calculations as a function of the basis set size. The non-linear random forest model outperforms a previous approach that used a linear model. The quantile random forest model presented also provides prediction intervals which give the user an idea of the model's uncertainty.

**Symmetry and completeness in machine-learning models for atomistic simulations** — •SERGEY POZDNYAKOV and MICHELE CERIOTTI — EPFL, Switzerland During the last decade, machine learning methods have drastically changed atomistic simulations. On the one hand, they scale linearly with the size of the Location: S054

system and thus, are significantly faster than the quantum mechanical calculations. On the other, they provide a functional form that is much more flexible than so-called classical force fields such as the Lennard Jones potential or embedded atom models. From one point of view, incorporating rotational symmetry is important for ML since it can make models more data-efficient and robust, but can also lead to incompleteness, limiting the ultimate accuracy of the model. I will discuss some examples of this and compare different types of models to show how one can find an optimal balance of the two effects.

O 67.3 Thu 11:00 S054

**Fast, robust, interpretable machine-learning potentials** — STEPHEN R. XIE^{1,2}, RICHARD G. HENNIG¹, and •MATTHIAS RUPP³ — ¹University of Florida, Gainsville, USA — ²KBR, NASA Ames Research Center, Mountain View, USA — ³University of Konstanz, Germany

Machine-learning potentials (MLPs) are increasingly successful in all-atom dynamics simulations where they act as surrogate models for ab-initio electronic structure methods. MLPs often result in two to three orders of magnitude improvements in the number of simulated atoms or duration of simulated time, enabling new insights and applications. Current limitations include data inefficiency, instabilities ("holes" in high-dimensional MLPs [2]), and lack of interpretability.

To address this challenge, we combine effective two- and three-body potentials in a cubic B-spline basis with second order-regularized linear regression. The resulting "ultra-fast potentials" are data-efficient, physically interpretable, sufficiently accurate for applications, can be parametrized automatically, and are as fast as the fastest traditional empirical potentials. [1] We demonstrate these qualities in retrospective benchmarks and present the prediction of thermal conductivities via the Green-Kubo formalism as a first application. [1] Stephen R. Xie, Matthias Rupp, Richard G. Hennig, Ultra-fast interpretable machine-learning potentials. arXiv:2110.00624, 2021 [2] Jeffrey Li, Chen Qu, Joel M. **Improving the transferability of high-dimensional neural network potentials by low-order terms** — •ALEA MIAKO TOKITA and JÖRG BEHLER — Georg-August-Universität Göttingen, Institut für Physikalische Chemie, Theoretische Chemie, Tammannstraße 6, 37077 Göttingen, Germany

High-dimensional neural network potentials (HDNNPs) are able to provide accurate potential energy surfaces suitable for atomistic simulations of large systems. The key to this accuracy is the high flexibility of the atomic neural networks allowing to reproduce energies and forces from reference electronic structure calculations with very small errors. At the same time, this flexibility is limiting the transferability of HDNNPs to atomic configurations that are very different from the reference geometries. Here, we investigate possible improvements in transferability of HDNNPs by the explicit inclusion of low-order terms in the functional form of the potential. The performance is demonstrated for a series of molecular model systems.

#### O 67.5 Thu 11:30 S054

**Predicting condensed-phase electron densities using machine learning** — •ALAN LEWIS¹, ANDREA GRISAFI², MICHELE CERIOTTI², and MARIANA ROSSI¹ —¹MPI for Structure and Dynamics of Materials, Hamburg, Germany — ²École Polytéchnique Fédèrale de Lausanne, Lausanne, Switzerland

The electron density is a fundamental quantity for understanding physical phenomena in materials, and is central to electronic structure theories such as density-functional theory. We present the SALTED machine learning method and demonstrate its ability to learn and predict the electronic densities of a range of materials from simple liquids and metals to hybrid organic-inorganic perovskites. This extends the framework presented in ACS Cent. Sci. 5, 57, 2019 to work with periodic boundary conditions and uses a resolution of the identity on a numeric atom-centered orbital basis to expand the all-electron periodic density. A Gaussian process regression model that makes use of local symmetryadapted representations of the atomic structure is employed, making our method both data-efficient and highly transferable.[1] We also compare various methods of dealing with the non-orthogonality of the basis, accounting for correlations between pairs of off-centered density components, finding that the best compromise between accuracy and computational efficiency comes from approximating the density expansion coefficients by directly minimizing the loss function. The total energies derived from the densities obtained in this way present errors with respect to DFT of just 0.1 meV/atom.

#### O 67.6 Thu 11:45 S054

**Equivariant N-center representations for machine learning molecular Hamiltonians** — •JIGYASA NIGAM, MICHAEL WILLATT, and MICHELE CERIOTTI — Laboratory of Computational Science and Modeling, Institute of Materials, Ecole Polytechnique Federale de Lausanne, 1015 Lausanne, Switzerland

Most of the widely used machine learning schemes that have been successful in predicting chemical and material properties rely on concise, symmetryadapted descriptions of the underlying atomic structure. A class of these structural descriptions is built on hierarchical correlations of atom-centered densities(ACDC)[1]. These are subsequently used to model corresponding atomic properties or atomic contributions to a global observable. However, many quantum mechanical quantities, such as the effective single-particle Hamiltonian written on an atomic-orbital basis, are associated with multiple atom-centers. This effectively renders ACDCs inadequate to describe the additional degrees of freedom of such multicenter properties. We recently proposed an N-centered representation[2] that extends the ACDC framework to the case of targets that are simultaneously indexed by N atoms. I will demonstrate how devising a family of N-center representations opens avenues for new classes of machine learning models that are fully equivariant and describe their role in assisting electronic structure calculations.

Similarity-of-materials analysis for reusability and interoperability of data in materials databases — •ŠIMON GABAJ, MARTIN KUBAN, SANTIAGO RIGAMONTI, and CLAUDIA DRAXL — Humboldt-Universität zu Berlin, Zum Großen Windkanal 2, 12489 Berlin, Germany

Large computational materials databases, such as NOMAD [1-2], make it possible to reuse already generated materials data. All these data typically come from different sources and have been created for a different purpose, be it geometry optimization, electronic structure, or alike. To support interoperability and thus reusability of such data, we devise a data-analysis workflow making use of similarity fingerprints. First, we encode the electronic density of states (DOS) in a vectorial representation [3] to obtain a descriptor. Then, we employ the Tanimoto coefficient to compute the similarity between all pairs of calculations. We demonstrate our workflow with selected materials, chosen from the NOMAD database. In the ideal case, all calculations of the same material in the same geometry should be identical. This is, however, not observed. Using our approach, we can uncover correlations between the DOS similarity and methodology as well as computational parameters. This way, we can also identify parameters that are relevant for the convergence of results.

Supervised and unsupervised deep Learning of topological phase transitions from entanglement aspect for one- and two-dimensional chiral p-wave superconductors — •MING-CHIANG CHUNG — Max-Planck-Institut für Physik komplexer Systeme, Dresden, Germany — National Chung-Hsing University, Taichung, Taiwan

The one-dimensional or two-dimensional chiral p-wave superconductor proposed by Kitaev has long become a classic example for understanding topological phase transitions through various methods, such as examining the Berry phase, edge states of open chains, and, in particular, aspects from quantum entanglement of ground states. In order to understand the amount of information carried in the entanglement-related quantities, here we study topological phase transitions of the model with emphasis of using the deep learning approach. Using both supervised or unsupervised ways, we feed different quantities, including Majorana correlation matrices (MCMs), entanglement spectra (ES) or entanglement eigenvectors (EE) originating from Block correlation matrices, into the deep neural networks for training, and investigate which one could be the most useful input format in this approach. We find that ES is information that is too compressed compared to MCM or EE. MCM and EE can provide us abundant information to recognize not only the topological phase transitions in the model but also phases of matter with different U(1) gauges, which is not reachable by using ES only. We also build a procedure for using unsupervised learning to find the phase transition points. We have used this method for other models.

#### O 67.9 Thu 12:30 S054

Machine Learning the Square-Lattice Ising Model — •BURAK ÇIVITCIOĞLU¹, ANDREAS HONECKER¹, and RUDOLF A. RÖMER² — ¹Laboratoire de Physique Theorique et Modelisation, CNRS UMR 8089, CY Cergy Paris Universit *e, Cergy-Pontoise, France — ²Department of Physics, University of Warwick, Coventry, CV4 7AL, United Kingdom

Recently, machine-learning methods have been shown to be successful in identifying and classifying different phases of the square-lattice Ising model. We study the performance and limits of classification and regression models. In particular, we investigate how accurately the correlation length, energy and magnetisation can be recovered from a given configuration. We find that a supervised learning study of a regression model yields good predictions for magnetisation and energy, and acceptable predictions for the correlation length.

# 0 68: Focus Session: Time-Resolved Momentum Microscopy

Time-resolved momentum microscopy is a new experimental technique to study electron dynamics in momentum space. In momentum microscopy, the reciprocal image plane of photoemitted electrons is mapped onto a positionsensitive detector. In addition, the kinetic energy is extracted by energy dispersive elements, such as Time-of-Flight drift tubes or hemispherical analysers. Hereby, the complete information about the electronic structure of twodimensional materials can be obtained (kx, ky, E). At the same time the signal can be restricted to micrometer-size spots, which is important for many types of quantum materials. By combining such electron spectrometers with pump-probe laser techniques, optical excitations, photo-induced phase transitions and charge transfer processes within the entire Brillouin zone can be imaged on ultrashort time scales. Several groups, with many of them in Germany, have established this technique during the last years in lab-based setups. In addition, first setups at large scale facilities, like ELI-ALPS or FLASH, are being commissioned or in operation. With higher photon energies available at free electron lasers, also structural dynamics will be observable through time-resolved electron diffraction.

Electron dynamics after a spin- and valley-polarized electronic excitation in  $WS_2 - \bullet Lasse Münster¹$ , Sarah Zajusch¹, Raul Perea-Causin¹, Samuel Brem¹, Katsumi Tanimura¹, Jens Güdde¹, Yaroslav Gerasimenko², Rupert Huber², Ermin Malic¹, Ulrich Höfer¹, and Robert Wallauer¹ - 1 Fachbereich Physik, Philipps-Universität Marburg, Germany —  2 Fachbereich Physik, Universität Regensburg, Germany

Atomically thin layers of TMDCs offer an ideal playground to study ultrafast electron dynamics. After optical excitation electrons scatter throughout the Brillouin zone to form a variety of excitonic states. We have shown that this formation process can be imaged by time-resolved momentum microscopy with tunable pump and high harmonic probe [1].

We recently incorporated a new pumping scheme, that allows us to excite the sample under an incident angle close to 0° with circularly polarized light. This results in an excitation, which is located purely within the K valley for one helicity and in the K' valley for the other helicity and provides access to all possible scattering processes. In the case of an excitation at K, electron scattering to K' and  $\Sigma$  is mediated by strong electron-phonon coupling with time constants of a few tens of femtoseconds. In additon, we observe the formation of spin-forbidden excitons in the K valley and electron scattering towards  $\Sigma$ '. Both of these processes involve a spin-flip and are significantly slower (50 - 100 fs). [1] R. Wallauer et al., Nano Lett. 21, 5867 (2021)

Coherent response of the electronic system driven by non-interfering laser **pulses** — •Tobias Eul¹, Eva Prinz¹, Michael Hartelt¹, Benjamin Frisch¹, Martin Aeschlimann¹, and Benjamin Stadtmüller^{1,2} — ¹Department of Physics and Research Center OPTIMAS, University of Kaiserslautern, Germany - ²Institute of Physics, Johannes Gutenberg University Mainz, Germany

The strength of light-matter interaction in condensed matter is fundamentally linked to the orientation and oscillation strength of the materials' optical transition dipoles. Structurally anisotropic materials, e.g. elongated molecules, exhibit optical transition dipoles with fixed orientations that govern the angulardependent light-matter interaction. Contrary, free electron like metals should exhibit isotropic light-matter interaction with the light fields dictating the orientation of the optical transition dipoles. Here, we demonstrate that an anisotropic direction of the optical transition dipoles even exists in highly free electron like noble metal surfaces. Our time- and phase-resolved photoemission experiment reveals coherent interference effects on the (110)-oriented silver surface after optical excitation with two non-interfering cross-polarized pulses. We explain this coherent material response within the density matrix formalism by an intrinsic coupling of the non-interfering light fields mediated by optical transition dipoles with fixed orientations in silver.

O 68.7 Thu 17:15 H3 Time-resolved photoemission orbital tomography of CuPc on Cu(001)-2O — •Alexa Adamkiewicz¹, Miriam Raths², Monja Stettner², Francois C. BOCQUET², CHRISTIAN KUMPF², ROBERT WALLAUER¹, F. STEFAN TAUTZ², and ULRICH HÖFER¹ — ¹Fachbereich Physik, Philipps Universität Marburg, Germany — ²Peter Grünberg Institute (PGI-3), Jülich Research Centre, Germany Charge transfer across molecular interfaces is reflected in the population of electronic orbitals. For ordered organic layers, time-resolved photoemission orbital tomography (tr-POT) is capable of spectroscopically identifying the involved orbitals and deducing their population from the measured angle-resolved photoemission intensity with high temporal resolution. In a first example, we found that for PTCDA/ Cu(001)-2O, two distinct excitation pathways could be observed with visible light [1]. The parallel component of the electric field induces a direct HOMO-LUMO transition, the perpendicular component transfers a substrate electron into the molecular LUMO. While in this case, a distinct excitonic signature was not observed, changes in the momentum pattern can in general serve as a measure of detecting excitonic processes. Here, we show such timedependent change of the pattern for CuPc/Cu(001)-2O. We demonstrate how the temporal evolution of the LUMO momentum distribution can be systematically disentangled from contributions of the projected HOMO. Moreover, we observe LUMO excitation of selected molecular orientation at normal incidence by aligning the pump polarization along the molecular axis. [1] R. Wallauer et al., Science 371, 1056 (2021).

# O 68.8 Thu 17:30 H3 Is there a perfect electron analyzer for time-resolved ARPES? - •LAURENZ

RETTIG — Fritz-Haber-Institut der Max-Planck-Gesellschaft Recent years have seen a huge popularity of time-of-flight based momentum microscopes (MMs), which based on advanced electrostatic optics have revolutionized angle-resolved photoemission spectroscopy (ARPES). Compared to conventional hemispherical analyzers (HAs) with angle-dispersing electron lenses, which access only a small fraction of the reciprocal space at a given configuration, MMs allow for the simultaneous detection of multiple Brillouin zones without the need to rearrange the sample geometry. However, one drawback of such instruments, in particular in time-resolved studies, arises from the large energy and momentum range covered simultaneously, which in combination with detection limitations of delay-line detectors and space charge restrictions can severely reduce the effective detection rate for selected energy-momentum regions compared to conventional HAs.

In my talk I will discuss the advantages and limitations of both types of instruments for several application scenarios in time-resolved ARPES, and present some recent highlights in charge-density wave materials, which take advantage of the combination of both types of instruments.

#### O 68.9 Thu 18:00 H3

Developing a fs-XUV source for time-resolved momentum microscopy on 2D **materials** — •Karl Schiller¹, Alan Omar², Lasse Sternemann¹, Matija STUPAR¹, CLARA SARACENO², and MIRKO CINCHETTI¹ – ¹Department of Physics, TU Dortmund University, Germany —  $^2\mathrm{Ruhr}\text{-Universit}\ddot{\mathrm{a}}$ Bochum, Germany

We introduce a newly developed setup for time-resolved momentum microscopy with femtosecond extreme ultraviolet (fs-XUV) radiation. The fs-XUV pulses with photon energy up to 30 eV are generated by high-harmonic generation in an Argon gas jet and are coupled to an energy-filtered momentum microscope (KREIOS MM, Specs GmbH). A commercial Ytterbium-based high-power laser system drives the generation with a variable high repetition rate between 100 kHz and 1 MHz (Carbide, Light Conversion). While this configuration allows for high energy resolution of 50 meV, a high temporal resolution can also be reached by coupling the laser to a tunable in-house build Herriot-type multipass cell compressor with peak powers up to 2 GW and pulse durations of ~ 45 fs [1]. In the talk, we will present the first characterization data of this setup and motivate its capability to examine few-layer 2D materials.

Why interlayer exchange is crucial for temperature programmed desorption – • TOBIAS DICKBREDER, RALF BECHSTEIN, and ANGELIKA KÜHNLE — Physical Chemistry I, Bielefeld University, Universitätstraße 25, 33615 Bielefeld

Understanding the desorption of molecules from surfaces is fundamental for both natural and application-oriented processes such as dewetting, weathering and catalysis. A powerful method to investigate desorption processes is temperature programmed desorption (TPD) as it offers the possibility to gain mechanistic insights into the desorption kinetics. In the past, several analysis methods have been developed for TPD data. These methods have in common that Location: H4

they rely on the Polanyi-Wigner equation, which requires proposing a desorption mechanism with a single (dominating) desorption path. For real systems, however, several coupled desorption paths can be easily envisioned. Here, we analyze the influence of exchange between the first and the second adsorbate layer on the desorption process. We show that considering this additional desorption pathway alters the desorption spectrum considerably. Thus, our study demonstrates that interlayer exchange can be crucial for the analysis of TPD data.

#### O 69.3 Thu 15:45 H4

CO oxidation on small size-selected Pt clusters supported on Fe₃O₄(001) -•Johanna Plansky¹, Sebastian Kaiser¹, Farahnaz Maleki², Ke Zhang³, Wolfgang Harbich⁴, Ueli Heiz¹, Sergio Tosoni², Barbara A.J. Lechner¹, Gianfranco Pacchioni², and Friedrich Esch¹ – ¹Technical University of Munich, Garching, Germany — ²University of Milano-Bicocca, Milano, Italy — ³Technical University of Denmark, Kgs. Lyngby, Denmark — ⁴École Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

Oxide-supported metal nanoparticles and clusters are common catalysts for heterogeneous reactions such as exhaust gas treatment. By studying supported sizeselected clusters, we disentangle the influence of cluster size and support on reaction mechanisms. In the Pt_n/Fe₃O₄(001) model system, we observe a complicated interplay between lattice oxygen reverse spillover, cluster encapsulation and gas phase pressure dependence. Sophisticated pulsed-valve reactor experiments (Sniffer-MS) combined with variable temperature scanning tunneling microscopy (STM) reveal the reaction of CO with lattice oxygen occurs on the cluster and not at the interface, but it is rapidly quenched by the strong metal-support interaction (SMSI). We will further demonstrate how UHV-based experiments can be quantified to provide turnover frequencies (TOFs) for comparison with real catalysts.

O 69.4 Thu 16:00 H4

A Model-Free Sparse Approximation Approach to Robust Formal Reaction Kinetics — •FREDERIC FELSEN, KARSTEN REUTER, and CHRISTOPH SCHEURER — Fritz-Haber-Institut der MPG, Berlin, Germany

Accurate and transferable models of reaction kinetics are of key importance for chemical reactors on both laboratory and industrial scale. Usually, setting up such models requires a detailed mechanistic understanding of the reaction process and its interplay with the reactor setup. We present a data-driven approach which analyzes the influence of process parameters on the reaction rate to identify effective rate laws without prior knowledge and assumptions. The algorithm we propose determines relevant model terms from a polynomial ansatz employing well established statistical methods. For the optimization of the model parameters special emphasis is put on the robustness of the results by taking not only the quality of the fit but also the distribution of errors [1] into account in a multi-objective optimization [2]. We demonstrate the flexibility of this approach based on synthetic kinetic data sets from microkinetic models. This way, we show that the kinetics of both the classical HBr reaction and a prototypical catalytic cycle are automatically reproduced. Further, combining our approach with experimental screening designs we illustrate how to efficiently explore kinetic regimes by using the example of the catalytic oxidation of CO.

Combining Planar Laser-Induced Fluorescence with Stagnation Point Flows for Small Single-Crystal Model Catalysts: CO Oxidation on a Pd(100) — JIAN-FENG ZHOU¹, •SEBASTIAN MATERA^{2,4}, SEBASTIAN PFAFF¹, SARA BLOMBERG^{1,3}, EDVIN LUNDGREN¹, and JOHAN ZETTERBERG¹ — ¹Lund University, SE-22100 Lund, Sweden — ²Freie Universität Berlin, D-14195 Berlin, Germany — ³Lawrence Berkeley National Laboratory, Berkeley, CA 94720-8229, USA — ⁴Fritz-Haber-Institut der MPG, D-14195 Berlin, Germany

Mass transfer limitations can have a tremendous impact on catalysts characterization and must be accounted for by an appropriate modelling and, if possible, reactor design. We present a stagnation flow reactor for reaction product imaging by planar laser-induced fluorescence (PLIF), which is amenable to efficient low order modeling. Using CO oxidation over a Pd(100) single crystal as a showcase, we discuss the peculiarities for the case of small single-crystal model catalysts. While the ideal stagnation flow equations are not valid in this limit, a slightly modified theory can be derived, which exploits the information encoded in the PLIF signal. This combination of PLIF and half-theory/half-data driven modelling allows to efficiently analyze the experimental data and to estimate the turnover frequency and the CO₂, CO and O₂ concentrations at the surface from solely the CO₂ profile at some distance of the surface.

O 69.6 Thu 16:30 H4

**On-surface collision reactions** — •MATTHEW J. TIMM, KELVIN ANGGARA, LY-DIE LEUNG, ZHIXIN HU, and JOHN C. POLANYI — Lash Miller Chemical Laboratories, Department of Chemistry, University of Toronto, 80 St. George Street, Toronto, Ontario M5S 3H6, Canada

Collisions between atoms and molecules are required for forming chemical bonds, thus they are central to any chemical reaction. The outcome of these collisions depends on the collision energy, geometry, and miss-distance between centers of the colliding reagents (called the impact parameter). As the incoming species - in general - randomly misses the target's center of mass, measurement of the impact parameter is a long-standing problem. Recently, a 'surface-molecular-beam' approach has been demonstrated that can allow for selection of impact parameter in a surface-reaction [1-3]. Energetic, oppositely-recoiling CF2 or F-atom "projectiles" are formed on a Cu(110) surface by dissociation of chemisorbed CF3 molecules with the tip of a Scanning Tunneling Microscope (STM). The inherent corrugation of Cu(110) leads to collimated trajectories of these projectiles, allowing them be aimed to collide with nearby molecular "targets" at chosen impact parameters. The pattern of reactive and non-reactive scattering was then determined by STM with the dynamics of the collision elucidated by density functional theory calculations.

O 69.7 Thu 16:45 H4 Faster oxygen adatom diffusion in a more densely packed CO adlayer on Ru(0001): A high-speed STM and DFT study — •HANNAH ILLNER¹, SUNG SAKONG², AXEL GROSS², and JOOST WINTTERLIN¹ — ¹Ludwig-Maximilians-Universität München, Germany — ²Universität Ulm, Germany

Oxygen atoms on a Ru(0001) surface covered with 0.33 monolayers (ML) of coadsorbed CO travel through the CO layer by the so-called door opening mechanism. It is facilitated by structural fluctuations in the CO layer and leads to an enhanced diffusion constant [Henß et al., Science 363, 715 (2019)]. Expecting a lower diffusion constant on a more densely CO-covered surface we have investigated how this mechanism changes when the CO coverage is enhanced. The experiments were performed by means of a variable-temperature, high-speed STM. In the analyzed temperature range between 239 and 280 K the CO layer is disordered at a coverage of 0.47 ML. The obtained trajectories of the O atoms show that jumps occur in six equivalent directions with the same probability, in contrast to 0.33 ML, where three directions are preferred. Surprisingly, the Arrhenius plot of the hopping rates suggests a lower activation energy for the diffusion at the higher CO coverage than at 0.33 ML of CO. Density functional theory calculations suggest that at  $\theta$ (CO) > 0.33 ML clusters form at which the CO density is locally enhanced, and that the configurations of the O atoms with respect to CO molecules are modified. However, the door opening mechanism is still efficient. A weaker binding of the O atoms in the dense CO layer effectively leads to a lower diffusion barrier.

Machine-learning Gaussian Approximation Potentials to solve a longstanding puzzle about RuO₂ surfaces — •YONGHYUK LEE, JAKOB TIMMERMANN, CHRISTOPH SCHEURER, and KARSTEN REUTER — Fritz-Haber-Institut der MPG, Berlin, Germany

Machine-learning Gaussian Approximation Potentials (GAPs) have recently evolved as a powerful class of surrogate models to computationally demanding first-principles calculations. Along with structure exploration techniques, they enable us to examine the potential energy surface of interest with a hitherto unforeseen combination of physical accuracy and computational efficiency and to achieve global surface structure determination (SSD) for increasingly complex systems. This can be leveraged e.g. to discover novel surface motifs which are critical in understanding the "living" state of heterogeneous catalysts and their degradation under dynamic operating conditions. In our preceding study, this versatility could be leveraged by a general and data-efficient iterative training protocol that allows for the on-the-fly generation of GAPs via the actual surface exploration process. The iterative refinement of GAPs identifies plenty of unknown low energy terminations of RuO₂ even within the restricted sub-space of  $(1 \times 1)$  surface unit-cells. Moreover, by extending the protocol to larger surface unit-cells, we discovered new surface structures, which provide solutions to longstanding questions in heterogeneous catalysis.

O 69.9 Thu 17:15 H4

**Hydrogen cleaning induced surface changes of GaAs(110)** — •DOROTHEE S. ROSENZWEIG¹, MORITZ N.L. HANSEMANN¹, PHILIPP EBERT², MICHAEL SCHNEDLER², HOLGER EISELE¹, and MARIO DÄHNE¹ — ¹Institut für Festkörperphysik, Technische Universität Berlin, 10623 Berlin, Germany — ²Forschungszentrum Jülich GmbH, Peter Grünberg Institut, 52425 Jülich, Germany

For the nanoscopic analysis of III/V nanowire (110) surfaces, hydrogen cleaning is a commonly used procedure. While hydrogen cleaning is reported to be destruction free [1] and to achieve clean, atomically flat surfaces—as they are present directly after growth—the actual processes and dynamics during cleaning are rarely examined. However, a detailed understanding of these issues is crucial for the interpretation of electronic surface properties, of the growth of Nanaowires, as well as of built-in and distribution of dopands.

Here, we investigate the modifications of GaAs(110) as model system upon atomic hydrogen exposure at room temperature and under commonly used cleaning conditions at the atomic level. For depiction and measurement at the atomic scale, we used scanning tunneling microscopy and spectroscopy under UHV conditions. Using these methods we study the geometric arrangement of the adsorbed atoms as well as adsorbation induced additional electronic states, band bending, defect states, and Fermi level pinning.

O 69.10 Thu 17:30 H4

In-situ characterization of cyclic reduction and reoxidation of CeOx(111) and CeOx(100) islands on Cu(111) —  $\bullet$ LINUS PLEINES¹, LARS BUSS², TEVFIK ONUR MENTEŞ³, FRANCESCA GENUZIO³, ANDREA LOCATELLI³, JENS FALTA^{1,4}, and JAN INGO FLEGE² — ¹Institute of Solid State Physics, University of Bremen, Germany — ²Applied Physics and Semiconductor Spectroscopy, Brandenburg University of Technology Cottbus-Senftenberg, Germany — ³Elettra-Sincrotrone Trieste S.C.p.A., Basovizza Trieste, Italy — ⁴MAPEX Center for Materials and Processes, Bremen, Germany

Cerium oxide  $(CeO_x)$  is of special interest due to its catalytic activity and various other electronic and optical applications. The inverse model catalyst  $CeO_x$  on Cu(111) has a high activity for methanol synthesis from H₂ and CO₂. For the activation of CO₂, Ce³⁺ sites have to be present at the surface, which means that

the CeO_x has to be reduced to some extent. This may be achieved by exposure to H₂ at elevated temperatures. We studied the interaction of H₂ and CO₂ with CeO_x islands on Cu(111) with low-energy electron microscopy (LEEM) and X-ray absorption spectroscopy (XAS). From earlier studies, the orientation of the CeO_x is known to be decisive for its catalytic activity. In our experiments (100)

and (111)  $\text{CeO}_x$  islands are grown side by side on the metal substrate, so that identical reaction conditions prevail during the experiment. At a high temperature of 550 °C, exposure to H₂ leads to partial reduction, and exposure to CO₂ leads to reoxidation of the CeO_x. The differences observed for the two island orientations regarding structure and composition will be discussed.

### O 70: Supported nanoclusters: Structure, Reactions, Catalysis

Time: Thursday 15:00-17:45

#### **Topical Talk**

O 70.1 Thu 15:00 H6

Stability and dynamics of cluster catalysts and their supports — SEBASTIAN KAISER, JOHANNA PLANSKY, FABIAN KNOLLER, ALEXANDER BOURGUND, KE ZHANG, UELI HEIZ, FRIEDRICH ESCH, and •BARBARA A. J. LECHNER — Department of Chemistry & Catalysis Research Center, Technical University of Munich, Germany

The intrinsic metastability of supported clusters can induce a vast range of dynamics that strongly influence their physical and chemical properties, while being experimentally highly challenging to investigate. Here, I will present a range of surface dynamics that occur in supported cluster dynamics, ranging from confined cluster diffusion, cluster encapsulation, support mobility and reactant spillover to lateral diffusion linked to reactivity. Our experimental approach is to combine static, statistically sound, and dynamic, time-resolved scanning tunneling microscopy (STM) to investigate the diffusion, sintering, and restructuring of size-selected clusters on weakly and strongly interacting supports.

#### O 70.2 Thu 15:30 H6

The role of water in oxidation of the Pt/Co3O4 interface — •YAROSLAVA LYKHACH¹, LUKÁŠ FUSEK^{1,2}, MAXIMILIAN KASTENMEIER¹, TOMÁŠ SKÁLA², NATALIYA TSUD², VIKTOR JOHÁNEK², SASCHA MEHL³, JOSEF MYSLIVEČEK², OLAF BRUMMEL¹, and JÖRG LIBUDA¹ — ¹Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — ²Charles University, Prague, Czech Republic — ³Elettra-Sincrotrone Trieste SCpA, Basovizza-Trieste, Italy

Electronic metal-oxide interactions (EMSI) play a major role in the design of advanced functional materials for applications in catalysis. We investigated the influence of the EMSI on the oxidation state of ultra-small Pt particles supported on a well-ordered Co3O4(111) substrate in the presence of co-adsorbates, i.e. hydroxyl groups and molecularly adsorbed water, by means of synchrotron radiation photoelectron spectroscopy and scanning tunnelling microscopy. The EMSI gives rise to charge transfer across the metal-oxide interface and results in partial oxidation of Pt deposits coupled with partial reduction of Co3O4(111). We detected ultra-small Pt $\delta$ + aggregates in combination with atomically dispersed Pt2+/4+ species. While the oxidation degree of Pt deposits is not influenced by the presence of co-adsorbates, the magnitude of the charge transfer is enhanced in the presence of molecularly adsorbed water. Subsequent annealing in UHV leads to re-oxidation of Co3O4(111) accompanied by an increase in the amount of Pt4+ species. This observation suggests the re-dispersion of Pt $\delta$ + aggregates to Pt4+ species triggered by the dissociation of water.

#### O 70.3 Thu 15:45 H6

Ripening mechanism changes with cluster size: In situ observation of Pt cluster diffusion on  $Fe_3O_4(001)$  — •SEBASTIAN KAISER, JOHANNA PLANSKY, UELI HEIZ, BARBARA A. J. LECHNER, and FRIEDRICH ESCH — Technical University of Munich, Garching, Germany

Ripening of small oxide-supported metal clusters is a common deactivation mechanism in heterogeneous catalysis. We use scanning tunneling microscopy (STM) to follow the diffusion and ripening of size-selected Pt clusters on an  $Fe_3O_4(001)$  support. Thanks to a strong cluster-support bonding, ripening and coalescence only set in at elevated temperatures. Particle size analysis of our STM images reveals that Pt19 exhibits Ostwald ripening at temperatures above 800 K, i.e. with cluster growth by atom diffusion. In contrast, the smaller  $Pt_5$  and  $Pt_{10}$ clusters show Smoluchowski ripening, i.e. the diffusion of entire clusters, already in the temperature range of 600 to 800 K and Ostwald ripening >800 K. We not only observe the ripened clusters in STM, but could successfully follow the diffusion process in situ by STM movies. Surprisingly, temperature programmed desorption (TPD) measurements of CO molecules show that in this temperature range the clusters get concomitantly encapsulated by iron oxide via strong metal support interaction (SMSI). Cluster diffusion thus occurs despite a strong interaction with the magnetite support and the diffusing species is most likely a cluster with Fe and O atoms on top.

#### O 70.4 Thu 16:00 H6

Tuning SMSI Kinetics on Pt-loaded TiO₂(110) by Choosing the Pressure — •PHILIP PETZOLDT¹, MORITZ EDER¹, SONIA MACKEWICZ¹, MONIKA BLUM^{2,3}, TIM KRATKY⁴, SEBASTIAN GÜNTHER⁴, MARTIN TSCHURL¹, UELI HEIZ¹, and BARBARA LECHNER⁵ — ¹Physical Chemistry, Department of Chemistry and Catalysis Research Center, Technical University of Munich — ²Advanced Light

Location: H6  $a^{3}$  Chemical Sciences Division.

Source, Lawrence Berkeley National Laboratory — ³Chemical Sciences Division, Lawrence Berkeley National Laboratory — ⁴Physical Chemistry with Focus on Catalysis, Department of Chemistry and Catalysis Research Center, Technical University of Munich — ⁵Functional Nanomaterials, Department of Chemistry and Catalysis Research Center, Technical University of Munich

The encapsulation of noble metal particles on reducible supports due to a strong metal-support interaction (SMSI) has already been extensively studied. However, there is still an ongoing debate on important aspects such as the influence of oxygen or hydrogen treatments on the encapsulating overlayer. We have utilized synchrotron-based NAP-XPS in order to investigate the SMSI for Pt-loaded TiO₂(110) single crystals under the influence of H₂ and O₂ at different pressures. In an O₂ atmosphere two different, pressure-dependent phenomena, namely, an oxidation of Pt particles and a loss of Pt signal intensity, are observed at 800 K. While the oxidation is partially reversed in vacuum, the intensity of the platinum signal cannot be recovered. H₂ annealing has no significant additional effect compared to vacuum annealing. In the presentation, we discuss possible origins of these observations.

O 70.5 Thu 16:15 H6 Deposition and annealing of FeNi nanoparticles on surfaces — •Mahboobeh Ravankhah¹, Mathias Getzlaff¹, Gerhard Dehm², and Philipp Watermeyer² — ¹Institut für Angewandte Physik, Universität Düsseldorf — ²Max-Planck-Institut für Eisenforschung GmbH, Düsseldorf

3d bimetallic nanoparticles have received lots of attention due to their technological applications in ultrahigh density information storage, catalysis and biomedicine. The thermal stability and the magnetic properties of the invacuo prepared bimetallic nanoparticles are shown to depend on the composition and their structure. Here we report on new findings of structure and composition of Fe-Ni nanoparticles, synthesized via a magnetron sputtering source and deposited on a Tungsten crystal surface. The elemental distribution of nanoparticles is determined by high resolution transmission electron microscopy (HRTEM) and electron energy loss spectroscopy (EELS). It is found that the nanoparticles have a shell formed by Fe atoms and a core composed of Fe and Ni with the gradient of composition from core to the surface. The melting behavior of nanoparticles was studied under UHV conditions by scanning tunneling microscopy (STM) as a function of heating temperature. The unrolling carpet, surface diffusion and anisotropy spreading are driving processes to form monolayer high islands above the melting point. The relevant result could be helpful for the design and preparation of stable and controllable bimetallic nanoparticles for technological applications.

#### O 70.6 Thu 16:30 H6

**Reaction Pathways in Alcohol Photoreforming on Cluster Co-Catalyst Loaded TiO₂(110)** — •SONIA MACKEWICZ, MORITZ EDER, PHILIP PETZOLDT, MARTIN TSCHURL, and UELI HEIZ — Physical Chemistry, Department of Chemistry and Catalysis Research Center, Technical University of Munich

Heterogeneous photocatalysis offers the prospect of utilizing solar energy for the environmentally benign production of chemical fuels such as hydrogen. State-of-the-art materials often comprise co-catalyst loaded semiconductors, but these systems are still limited in efficiency. In order to systematically optimize photocatalysts, a profound knowledge of reaction mechanisms is crucial, whose details are so far little understood. Alcohols are an ideal model system to investigate reaction mechanisms in photocatalysis. Furthermore, they may serve as renewable sources for hydrogen in the future. In this talk, we give insights into the mechanistics of the alcohol photoreforming reaction on co-catalyst loaded TiO₂(110). It is shown that semiconductor photocatalysis selectively enables new reaction pathways, which are not accessible by thermal or conventional chemical methods.

O 70.7 Thu 16:45 H6

Electron transfer reaction by time resolved (TRS) and core level spectroscopy (XPS) and STM on Au/TiO2(110) single crystal systems. — •HICHAM IDRISS — Institute of functional Interfaces, KIT, Karlsruhe

Charge transfer from or to a metal deposited on an oxide semiconductor are central to photocatalysis. In order to probe into this phenomenon, the effect of gold coverage on the chemical state of Ti cations, upon photoexcitation of rutile TiO2(110) single crystal, was investigated by X-ray photoelectron spec-

troscopy (XPS). Photocatalytic reaction of gas phase ethanol (a hole scavenger) on TiO2(110) and Aux/TiO2(110) resulted in the formation of Ti3+ cations. Increasing the Au coverage resulted in the gradual decrease of these Ti3+ cations. The "quasi" total consumption of these reduced states was found at a ratio Au atoms to reacted Ti3+ close to one; this corresponded to about 0.50 at. % of Au. The relationship suggests that electron transfer occurs from the excited semiconductor to Au atoms during the catalytic reaction. In order to complement the work H2 production rates of an electron donor, such as ethanol, over Au clusters with different sizes and coverage deposited on single crystal rutile TiO2(110) were studied by scanning tunneling microscopy, online mass spectrometry and complemented by femto second pump probe spectroscopy. It was also found that there is a non-linear increase of the H2 production rate with increasing gold coverage. The key determining factor appears to be the Au inter-particle distance. Increasing this distance resulted in an increase in the normalized reaction rate.

O 70.8 Thu 17:00 H6

Surface Ligand Infrared Spectroscopy: In-Situ Characterization of Noble Metal Clusters and Metal Oxides at Work — •ERIC SAUTER¹, DARIA Gashnikova², Florian Maurer², Alexei Nefedov¹, Stefan Heissler¹, YUEMIN WANG¹, JAN-DIRK GRUNWALD², and CHRISTOF WÖLL¹ — ¹Intitute of Functional Interfaces, KIT, Eggenstein-Leopoldshafen, Germany —  $^2 {\rm Institute}~{\rm of}$ Chemical Technology and Polymer Chemistry, KIT, Karlsruhe, Germany

To achieve a full understanding of chemical processes at exposed surfaces insitu and operando investigations are required. For studies of catalytic processes under real conditions, IR spectroscopy offers a number of advantages. In the present study, surface ligand infrared spectroscopy was used to perform an insitu investigation of the surface characteristics of cerium oxide single crystals as well as catalytic active NM-clusters on cerium oxide nanoparticles. Low temperature adsorption of carbon monoxide was used to identify the surface structure and morphology, visible through distinctive adsorption bands blue shifted in respect to the gas phase, which can be used as reference for the interpretation of more complicated spectra like powders or nanoparticles. Additionally, noblemetal clusters were investigated in pristine condition as well as in the reduced state. Upon heating, desorption of the probe molecule occurred and at higher temperatures deformation and sintering of the clusters was observed. The investigation shows the power of infrared spectroscopy as a tool for in-situ investigations and characterization of NM-clusters and metal oxides at work.

AI with Experimental and Theoretical Data toward the Understanding  $\mathrm{CO}_2$  Hydrogenation Catalysis: The Role of the Support Materials •RAY MIYAZAKI¹, KENDRA BELTHLE², HARUN TÜYSÜZ², LUCAS FOPPA¹, and MATTHIAS SCHEFFLER¹ -¹The NOMAD Laboratory at the Fritz Haber Institute of the Max Planck Society, Germany - ²Max-Planck-Institut für Kohlenforschung, Germany

The genesis of organic molecules from CO₂ at a hydrothermal vent, which is a fissure on the seafloor, is one of the theories for the origin of life [1]. We focus on CO₂ hydrogenation catalyzed by cobalt nanoparticles supported on SiO₂, which mimic the environment of a hydrothermal vent. In particular, we investigate the role of support materials by using several amorphous  $SiO_2$  supports incorporating different elements (e.g., Ti, Zr). In this study, the experimental selectivity toward organic molecules (e.g., methanol, formic acid) is modeled by the sure-independence screening and sparsifying operator (SISSO) AI approach [2]. Both experimental and theoretical data are adopted as the input features for SISSO, such as atomic-scale features calculated by density functional theory and experimental characterization data. Our approach identifies the key descriptive parameters correlated to the selectivity, which lead to a better understanding of the origin of life and to design of novel  $\text{CO}_2$  hydrogenation catalysts. O 70.10 Thu 17:30 H6

Near-ambient pressure studies of size selected clusters on ultrathin silica films — •Matthias Krinninger, Florian Kraushofer, Friedrich Esch, and BARBARA A.J. LECHNER - Department of Chemistry, Technical University of Munich, 85748 Garching, Germany

Silicon oxide is a widely used catalyst support material for clusters and nanoparticles. Understanding the relationship between these clusters and the support is challenging, however, because SiO₂ is insulating, and in most applications not crystalline, which limits the use of diffraction-based experimental techniques. Some progress has been made by growing ultrathin, quasi-2D silica bilayer films on a variety of metal supports [1], which can then be measured by scanning tunneling microscopy (STM). Here, we show first results for ultrathin silica films grown on Pt(111) and their interaction with deposited metal clusters, examined by near-ambient pressure (NAP) XPS and NAP-STM. We investigate the stability of the films, their ability to stabilize small clusters without sintering, and the dependence of this stability on the crystallinity of the film.

O 71.1 Thu 15:00 S051 Theory for Electron Spin Resonance based on electron transport - •NICOLAS LORENTE¹, JOSÉ REINA², and CHRISTOPH WOLF² — ¹Centro de Física de Materiales & DIPC, Donostia, Spain — ²Center for Quantum Nano Science, Seoul, Korea

Recent progress in electron spin resonance with the scanning tunneling microscope (ESR-STM) [1] is greatly advancing the experimental possibilities of manipulating atomic spins by all-electrical means. Two-qubit operations have been made possible using a pulse-mode in the ESR-STM [2], and addressing remote qubits has been rendered possible by creating a new muti-frequency operational mode [3]. We aim at developing a computational tool that permits us to interpret and predict the outcome of experiments in ESR. The first results of such a simulation tool have addressed one and two spins under an STM current [4,5]. We use a non-equilibrium Green's function approach with Hubbard operators that allows us to write quantum adiabatic Markovian master equations in the presence of an electron current and under the driving of an external electric field. The results are enticing and the modelling is flexible enough to treat many different physical situations. References: [1] S. Baumann et al, Science 350, 417 (2015). [2] K. Yang et al, Science 366, 509 (2019). [3] S.-H. Phark et al, ArXiv:2108.09880. [4] J. Reina et al, Phys. Rev. B 100, 035411 (2019). [5] J. Reina et al, Phys, Rev. B 104, 245435 (2021).

O 71.2 Thu 15:30 S051

Modeling the Electron Spin Resonance Spectrum in Scanning Tunneling **Microscopy** – •Christian R. Ast¹, Piot Kot¹, Maneesha Ismail¹, and Juan Carlos Cuevas² – ¹MPI for Solid State Research, 70569 Stuttgart – ²Universidad Autónoma de Madrid, 28049 Madrid, Spain

The theory of electron spin resonance (ESR) spectroscopy in scanning tunneling microscopy (STM) has been debated for some time now with a number of different proposals having different origin, but essentially leading to very similar results. While the focus so far has been on the ESR signal itself, the measured DC tunneling spectrum offers more details that allow for a more precise verification of the underlying theory. Here, we discuss the ESR signal from a theory point of view by allowing the tunneling electrons to interact with both the driven spin system and the incident microwave during the tunneling process. We find a more complete description of the whole tunneling current also going beyond the typical approximation of a constant density of states.

#### O 71.3 Thu 15:45 S051

A new view on the origin of zero-bias anomalies of Co atoms atop noble metal surfaces — JUBA BOUAZIZ¹, FILIPE S. M. GUIMARAES¹, and •SAMIR LOUNIS^{1,2} — ¹Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich & JARA, Jülich 52425, Germany — ²Faculty of Physics & CENIDE, University of Duisburg-Essen, 47057, Duisburg, Germany

Many-body phenomena are paramount in physics. In condensed matter, their hallmark is considerable on a wide range of material characteristics spanning electronic, magnetic, thermodynamic and transport properties. In this talk, we address systematically zero-bias anomalies detected by scanning tunneling spectroscopy on Co atoms deposited on Cu, Ag and Au(111) substrates, which remarkably are almost identical to those obtained from first-principles [1]. These features originate from gaped spin-excitations induced by a finite magnetic anisotropy energy, in contrast to the usual widespread interpretation relating them to Kondo resonances. Resting on relativistic time-dependent density functional and many-body perturbation theories, we furthermore unveil a new many-body feature, the spinaron, resulting from the interaction of electrons and spin-excitations localizing electronic states. Besides Co, we will show examples of anomalous spin-excitations characterising adatoms on Nb(110) surface [2,3].

Location: S051

#### O 71.4 Thu 16:00 S051

**Real-space observation of the Kondo effect in MoS**₂ **mirror twin boundaries** — CAMIEL VAN EFFEREN¹, JEISON FISCHER¹, ACHIM ROSCH², THOMAS MICHELX¹, and •WOUTER JOLIE¹ — ¹II. Physikalisches Institut, Universität zu Köln — ²Institut für Theoretische Physik, Universität zu Köln

Finite mirror twin boundaries in monolayer  $MoS_2$  on graphene confine strongly correlated one-dimensional electronic states [1]. Using scanning tunneling microscopy and spectroscopy, we observe a resonance at the Fermi energy when the highest occupied confined state is filled with one electron. Magnetic field and temperature-dependence of the resonance unambiguously point to the Kondo effect, i.e., screening of the spin- $\frac{1}{2}$  confined state within the mirror twin boundary. Theoretical models for both Kondo resonance and spin- $\frac{1}{2}$  state are used to extract the Kondo coupling strength. Real-space mapping gives access to the correlated beating of both confined state and Kondo resonance along the boundary. Hence, our experiments reveal the behavior of the Kondo effect for a delocalized electronic state on the atomic scale.

#### O 71.5 Thu 16:15 S051

Moiré tuning of spin excitations: individual Fe atoms on  $MoS_2/Au(111) - CHRISTIAN LOTZE¹, SERGEY TRISHIN¹, NILS BOGDANOFF¹, FELIX VON OPPEN², and KATHARINA J. FRANKE¹ - ¹Fachbereich Physik, Freie Universität Berlin, 14195 Berlin, Germany - ²Dahlem Center for Complex Quantum Systems and Fachbereich Physik, Freie Universität Berlin, 14195 Berlin, Germany$ 

Magnetic adatoms have been investigated on various surfaces in regard to stabilizing, controlling and manipulating single quantum spins. Here, we study individual iron atoms adsorbed on a single layer of molybdenum disulfide ( $MoS_2$ ) on a Au(111) crystal.  $MoS_2$  has been recently reported as a well-suited system for decoupling molecules. We show that the Fe atoms are largely decoupled from the Au(111) substrate with the remaining coupling strength varying along the moiré structure. As a consequence, the spectroscopic fingerprints range from pure inelastic excitations to Kondo resonances. Moreover, we see spatial variations of those excitations over one atom, which result from the formation of Fe-S hybrid states and interference effects. In conclusion, our work establishes  $MoS_2$  on Au(111) as a tuning layer for quantum spin properties. This tuning can be realized continuously.

#### O 71.6 Thu 16:30 S051

**Spin excitations on hexagonal zinc oxide** — •LUKAS ARNHOLD, HENRIK LICHTL, LEON RULLKÖTTER, NICOLAJ BETZ, SUSANNE BAUMANN, and SEBAS-TIAN LOTH — University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany

Few-layer materials are widely used to tailor different electronic properties, down to the atomic level. We use a double layer of ZnO, a hexagonal wide bandgap semiconductor [1], to mitigate electron scattering between the Ag (111) substrate and Co atoms deposited on the ZnO surface. With low-temperature scanning tunneling microscopy we observe spin excitations and the ability to manipulate transition metal atoms on the surface into hexagonal arrangements. These findings make ZnO a viable candidate for resonant spin spectroscopy methods [2,3] and construction of geometrically frustrated magnetic structures.

#### Topical Talk

#### O 71.7 Thu 16:45 S051

Stochastic resonance as a new tool to investigate spin dynamics — •SUSANNE BAUMANN¹, NICOLAJ BETZ¹, MAX HÄNZE¹, GREGORY MCMURTRIE¹, SUSAN COPPERSMITH², and SEBASTIAN LOTH¹ — ¹University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany — ²School of Physics, University of New South Wales, Sydney, Australia

Stochastic resonance is an unusual phenomenon in which noise can be used as a resource to synchronize stochastic dynamics to a control signal [1,2]. In this talk, I will show how stochastic resonance can be induced in the spin switching of magnetic nanostructures on surfaces [3], and, more importantly, how we can use this as a tool to investigate the magnetization dynamics of these spin systems.

With this tool, one can get insight into the interaction of these structures with their environment. This also enables the observation of ultrafast dynamics of excited spin states that are not easily accessible to other scanning probe techniques. The new frequency resolved spectroscopy method allows for the broadband observation of spin dynamics with previously inaccessible bandwidth ranging from milliseconds to picoseconds.

References: [1] R. Benzi, J. Phys. A: Math. Gen 14, L453 (1981). [2] R. Löfstedt, S. N. Coppersmith, Phys Rev. Lett. 72, 1947 (1994). [3] M. Hänze*, G. McMurtrie* et al. Science Adv. 7 eabg2616 (2021).

O 71.8 Thu 17:15 S051

**Path-resolved measurement of ultrafast spin dynamics** — •NICOLAJ BETZ¹, MAX HÄNZE^{1,2}, GREGORY MCMURTRIE¹, SUSANNE BAUMANN¹, and SEBASTIAN LOTH^{1,2} — ¹University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany — ²Max Planck Institute for Solid State Research, Stuttgart, Germany

Transitions between quantum mechanical states are fundamentally random processes. While it is possible to directly observe individual quantum jumps [1] in a time resolved measurement [2], the dynamics of many systems exceed the resolution of real time measurements. This requires the use of time-averaged measurements such as pump probe experiments. These methods typically measure state occupation times and contain little information about the relaxation process itself. Here, we introduce a dynamic response measurement that is sensitive to the switching path between spin states and can be applied in scanning tunneling microscopy. By using stochastic resonance [3], this method resolves spin- switching dynamics of magnetic atoms and nanostructures ranging from milliseconds to picoseconds. Crucially, in more complex spin structures the measurement can distinguish multiple switching paths between higher excited states. This provides deeper insight into ultrafast spin dynamics than possible with relaxometry.

Growth and magnetic characterization of thermally robust cobalt islands on Cu3Au(111) — •Aleš Cahlík, Danyang Liu, Berk Zengin, and Fabian Natterer — Institute of Physics, UZH, Zurich, Switzerland

Due to a larger tunability of the effective lattice parameter, bimetallic alloys can be an appealing choice as an alternative substrate for the growth of thin films and nanostructures. In this respect, we investigate  $Cu_3Au(111)$  as a platform for the growth of cobalt nano-islands. Using STM, we demonstrate unique thermal stability of  $Co/Cu_3Au(111)$  up to ~  $340^{\circ}C$ , compared to the fast intermixing of Co/Cu(111) at room temperature. We explore the structural and magnetic properties of the Co islands with spin-polarized and nickelocene functionalized tips. Finally, we find an effective method to produce spin-polarized tips by deliberately lifting off an entire island from the substrate and transferring it to the STM tip.

O 71.10 Thu 17:45 S051

Transport in the Rashba-split surface state of  $(\sqrt{3} \times \sqrt{3})$ Bi/Ag(111)R30° revealed by MONA — •MARKUS LEISEGANG, PATRICK HÄRTL, and MATTHIAS BODE — Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany

Transport measurements that are sensitive to the band structure of a material require techniques that operate on the length scale of the charge carrier's mean free path. A novel method that fulfills this requirement is the molecular nanoprobe (MONA), which uses a single molecule to detect charge carriers [1].

In this study, we investigate the rotation and tautomerization of phthalocyanine molecules on the  $(\sqrt{3} \times \sqrt{3})$ Bi/Ag(111)R30° surface and utilize these excitations to investigate transport in the Rashba-split surface state characteristic for this surface [2]. We find that both excitation processes are driven by the N-H stretching mode and can be triggered by a single electron [3]. Our transport measurements proof the sensitivity to hot charge carriers which preferably propagate in the Rashba-split surface state of the BiAg₂ alloy. The expected impact of the spin-momentum-locking of this Rashba-split surface state on the surface transport is discussed and first experimental results obtained with spin-polarized tips will be presented.

The transition metal oxide CoO2 forms bulk layered structures that exhibit complex correlated electronic states. However, little has been known about the electronic properties of the isolated single layer. We have now [1] studied CoO2/Au(111), using angle-resolved photoemission spectroscopy, x-ray photoelectron diffraction, and density functional theory. The results of our study show single-layer CoO2 to be metallic, with electronic correlations. They emphasize the interest of oxides as a new subject within two-dimensional materials research. O 72.2 Thu 15:15 S052 Unified Treatment of Magnons and Excitons in Monolayer CrI3 from Many-Body Perturbation Theory — • THOMAS OLSEN — Technical University of Den-

mark We present first principles calculations of the two-particle excitation spectrum of CrI3 using many-body perturbation theory including spin-orbit coupling. Specifically, we solve the Bethe-Salpeter equation, which is equivalent to summing up all ladder diagrams with static screening, and it is shown that excitons as well as magnons can be extracted seamlessly from the calculations. The resulting optical absorption spectrum as well as the magnon dispersion agree very well with recent measurements, and we extract the amplitude for optical excitation of magnons resulting from spin-orbit interactions. Importantly, the results do not rely on any assumptions of the microscopic magnetic interactions such as Dzyaloshinskii-Moriya (DM), Kitaev, or biquadratic interactions, and we obtain a model independent estimate of the gap between acoustic and optical magnons of 0.3 meV. In addition, we resolve the magnon wave function in terms of band transitions and show that the magnon carries a spin that is significantly smaller than  $\hbar$ . This highlights the importance of terms that do not commute with  $S_{\tau}$  in any Heisenberg model description.

Excitons in two-dimensional magnetic semiconductors — •MARIE-CHRISTIN HEISSENBÜTTEL, THORSTEN DEILMANN, PETER KRÜGER, and MICHAEL ROHLF-ING — Institute of Solid State Theory, University of Münster, Germany

Semiconducting two-dimensional magnets exhibit peculiar interrelation between magnetic properties and light-matter interaction. We will present and discuss ab-initio GW/Bethe-Salpeter equation calculations to examine excitonic states in different magnetic systems.

Due to the hexagonal crystal structure the out-of-plane ferromagnetic monolayer CrI3 came to the fore for the construction of heterobilayers with transitionmetal dichalcogenides [1]. Due to coupling effects the magnetic properties are transferred and can be observed in a splitting and a modified Zeeman effect of the excitons. On the other hand, CrSBr shows in-plane magnetization in combination with a large crystal anisotropy. This is reflected in the quasi-1D behavior of different opto-electronic properties [2].

### O 72.4 Thu 15:45 S052

Nanoscale view of massive Dirac quasiparticles in lithographic superstruc**tures** — •Alfred Jones¹, Lene Gammelgaard², Deepnaryan Biswas¹, Mikkel Sauer³, Roland Koch⁴, Chris Jozwiak⁴, Eli Rotenberg⁴, Aaron Bostwick⁴, Kenji Watanabe⁵, Takashi Taniguchi⁵, Cory Dean⁶, Thomas Pedersen³, Antti-Pekka Jauho², Peter Bøggild², Bjarke Jessen⁶, and Søren Ulstrup¹ – ¹Aarhus University, Denmark – ²Technical University of Denmark, Denmark — ³Aalborg University, Denmark — ⁴Advanced Light Source, USA — ⁵National Institute for Materials Science, Japan — ⁶Columbia University, USA

Massive Dirac quasiparticles play a central role in a number of emerging physical phenomena such as topological phase transitions and anomalous Hall effects. Single-layer graphene appears to be an ideal platform to explore such properties, however engineering the transition from massless to massive Dirac quasiparticles in a controllable fashion remains a significant challenge. Here, we employ angle-resolved photoemission with a nanoscale light spot (nanoARPES) to directly measure the electronic structure modifications induced by lithographic patterning of an antidot superlattice onto a graphene device. We observe a transition from massless Dirac fermions in the pristine graphene to a massive character in patterned regions, and determine that the mass scales linearly with antidot diameter, consistent with theory. Gate-induced electron-doping of the patterned graphene produces an enhancement of the mass, highlighting the versatility of nanopatterned graphene as a platform for engineering such quasiparticles.

O 72.5 Thu 16:00 S052 Tuning lower dimensional superconductivity with hybridization at a superconducting-semiconducting interface — •ANAND KAMLAPURE¹, MANUEL SIMONATO¹, EMIL SIERDA¹, MANUEL STEINBRECHER¹, UMUT Kamber¹, Elze J. Knol¹, Peter Krogstrup², Mikhail I. Katsnelson¹, Malte Rösner¹, and Alexander A. Khajetoorians¹ – ¹Institute for Molecules and Materials, Radboud University, 6525 AJ Nijmegen, the Netherlands —  2 Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, 2100 Copenhagen, Denmark

Study of influence of interface electronic structure on the superconductivity (SC) in lower dimensions is important to tune SC in view of its applications to gated superconducting electronics, and superconducting layered heterostructures. Here, using ultra-low temperature scanning tunneling microscopy and spectroscopy, we demonstrate the formation of hybrid electronic structure at the interface between a lead film and black phosphorus. We show that interfacial hybridization weakly modifies the confinement potential and leads to a renormalization of the superconducting gap and a strong modification of the observed vortex structure. Using ab initio methods combined with analytical modeling, we link the renormalized gap to a weighting of the superconducting order parameter in reciprocal space. These results illustrate that interfacial hybridization can be used to tune SC in quantum technologies based on lower dimensional superconducting electronics. Reference: arXiv:2109.08498 (2021).

Diversity of defect-related excitons in hBN from ab initio calculations - •Alexander Kirchhoff, Thorsten Deilmann, Peter Krüger, and MICHAEL ROHLFING — Westfälische Wilhelms-Universität Münster, Institut für Festkörpertheorie, Wilhelm-Klemm-Straße 10, 48149 Münster

While pristine hexagonal boron nitride (hBN) is an insulator with an optical gap of ~5 eV, point defects in this material are discussed as single-photon emitters in the visible optical spectrum. In this study, we examine different defects consisting of carbon or oxygen substitutions and vacancies in an hBN monolayer from an ab initio approach, via the GW/BSE approximation. Our results show deep defect states and defect-related excitations with energies in the visible regime. We present a detailed analysis of their structure and energetic composition and furthermore discuss the dependence of the excitonic spectrum on the geometry. Finally, we present a defect of two carbon substitutions adjacent to a divacancy, which shows an antiferromagnetic ground state.

#### O 72.7 Thu 16:30 S052

Engineering magnetic interactions in magnetic thin films with two-dimensional materials — •HANGYU ZHOU^{1,2}, MANUEL DOS SANTOS DIAS^{1,3,4}, WEISHENG ZHAO², and SAMIR LOUNIS^{1,3} — ¹Peter Grünberg Institut and Institute for Advanced Simulations, Forschungszentrum Jülich & JARA, 52425 Jülich, Germany — ²School of Integrated Circuit Science and Engineering, MIIT Key Laboratory of Spintronics, Beihang University, Beijing 100191, China -³Faculty of Physics, University of Duisburg-Essen and CENIDE, 47053 Duisburg, Germany — ⁴Scientific Computing Department, STFC Daresbury Laboratory, Warrington WA4 4AD, United Kingdom

Two-dimensional (2D) materials have received great attention due to their unique physical and chemical properties and ease of integration in heterostructures, which can lead to improved magnetic properties. Here, we explore with density functional theory calculations the impact of monolayers of graphene and hexagonal boron nitride (h-BN) on the magnetism and structural properties of a Co monolayer placed on Pt(111) and Au(111) surfaces. In particular, we investigate how the magnetic interactions, such as the Heisenberg exchange interaction and the Dzyaloshinskii-Moriya interaction (DMI), are influenced by the 2D monolayer and by structural reconstructions, which in turn can be utilized to ignite complex spin-textures. These results may contribute to an enhanced tunability of skyrmion formation in such composite magnetic heterostructures.

O 73.1 Thu 15:00 S053 Rashba-split image-potential state at Re(0001) — •FABIAN SCHÖTTKE, SVEN

SCHEMMELMANN, PETER KRÜGER, and MARKUS DONATH — Westfälische-Wilhelms-Universität Münster, Germany

Since image states are located mainly in the vacuum in front of the surface, the influence of spin-dependent interactions on these states is a topic of ongoing debate in the literature. In particular, calculations predict Rashba-type spin splittings for image states [1], but experimental results of small spin splittings are controversial [2,3]. In addition, these two-photon-photoemission results using circular dichroism provide only indirect information about the spin polarization of states.

We measured the unoccupied surface electronic structure of Re(0001) with spin- and angle-resolved inverse photoemission. This method allows to investigate the spin orientations directly. We identified the n = 1 image state at a binding energy of  $E_V - E = 0.68 \pm 0.04 \text{ eV}$  and with an effective mass of  $m^*/m_e = 1.2 \pm 0.1$ . Careful spin-resolved measurements for several angles of electron incidence allowed us to detect Rashba-type spin-dependent energy splittings of this state with a Rashba parameter of  $\alpha_R = 105 \pm 33 \text{ meV} \text{ Å}$  [4].

Rashba-split surface state and spin-dependent photon emission from Re(0001) at  $\overline{\Gamma}$  – •Sven Schemmelmann¹, Fabian Schöttke¹, Peter Krüger², and Markus Donath¹ – ¹Physikalisches Institut, Westfälische Wilhelms-Universität, Münster – ²Institut für Ferstkörpertheorie, Westfälische Wilhelms-Universität, Münster

The unoccupied electronic structure of the Re(0001) surface around the center of the surface Brillouin zone was investigated by spin- and angle-resolved inverse photoemission [1]. The detected states were studied with respect to intrinsic and extrinsic spin-polarization effects. A surface state with Rashba-type spin splitting is detected close to the Fermi level, that disperses downward below the Fermi energy. Furthermore, for normal electron incidence, we observed spin-dependent photon emission from unpolarized bulk and surface states. The sign of the observed spin asymmetry varies for different states and depends on experimental parameters such as electron spin-polarization direction and photon-detection angle. Maximum spin asymmetry is observed if the electron spin polarization and the plane of photon emission are perpendicular. The asymmetry is zero if both are parallel [2]. The effect is traced back to the spin-orbit-induced hybridization of the involved states.

O 73.3 Thu 15:30 S053

Distinct Tamm and Shockley surface states on Re(0001) - mixed by spin-orbit interaction — •MARCEL HOLTMANN¹, PETER KRÜGER¹, KOJI MIYAMOTO², TAICHI OKUDA², PASCAL J. GRENZ¹, SHIV KUMAR², and MARKUS DONATH¹ — ¹Physikalisches Institut, Westfälische Wilhelms-Universität Münster, Wilhelm-Klemm-Straße 10, 48149 Münster, Germany — ²Hiroshima Synchrotron Radiation Center, Hiroshima University, 2-313 Kagamiyama, Higashi-Hiroshima 739-0046, Japan

Tamm and Shockley states - two paradigmatic concepts are used to describe surface states not only in electronic systems but also in photonic and phononic crystals. The Re(0001) surface hosts both types of electronic surface states in neighboring but qualitatively different energy gaps. Interestingly, spin-orbit interaction generates a double "W"-shaped energy vs.  $\mathbf{k}_{\parallel}$  dispersion by mixing both types of states and lifting their spin degeneracy. By combining spin- and angle-resolved photoemission, tight-binding model calculations as well as density functional theory including the photoemission process, we develop verifiable criteria to distinguish between the two types of surface states and arrive at a consistent picture of the role of spin-orbit interaction in such a scenario.

process for ions close to the displacement energy, that is the minimum ion energy needed to displace the target atom. The dominating influence of the chemical interaction of projectile and target atoms and its effect on the displacement energy are adressed in this work. For that, we carried out ab-initio molecular dynamics (MD) simulations for a broad range of projectiles (elements Hydrogen to Argon) impacting on graphene and h-BN, and determined the energies needed to displace C, N and B atoms, respectively. We further present and validate a scheme to incorporate the effect of spin-polarization on the displacement process - as spin-polarized ab-initio MD runs tend to fail at bond-breaking.

O 73.4 Thu 15:45 S053

Electronic structure of a square Te adlayer on Au(100) surface — •BEGMUHAMMET GELDIYEV¹, TILMAN KISSLINGER², PHILIPP ECK³, MAXIMILLAN ÜNZELMANN¹, TIM FIGGEMEIER¹, JAKUB SCHUSSER¹, NIKOLAI TEZAK¹, LUTZ HAMMER², M. ALEXANDER SCHNEIDER², DOMENICO DI SANTE³, GIORGIO SANGIOVANNI³, HENDRIK BENTMANN¹, and FRIEDRICH REINERT¹ — ¹Experimentelle Physik 7 and Cluster of Excellence ct.qmat, Universität Würzburg — ³Institut für Theoretische Physik und Astrophysik and Cluster of Excellence ct.qmat, Universität Würzburg

In light of several theoretical predictions regarding the so-called square tellurene [1, 2], the growth and the electronic structure of Te deposited on a Au(100) surface is reported. At a coverage of 1/4 monolayer, Te forms a  $p(2 \times 2)$  square lattice of adatoms on Au(100) as determined by a thorough LEED-IV characterization ( $R_{\rm p} = 0.085$ ) and STM. Utilizing angle-resolved photoemission spectroscopy and density functional theory an interface-like state with mixed Te  $p_{x,y}$  and Au d orbital character is identified in addition to a complex multitude of backfolded bands of the substrate. Vastly differing Rashba parameters along the  $\overline{\rm XG}$  and  $\overline{\rm XM}$  lines cannot be explained within an (anisotropic) Rashba picture. The spin splitting rather depends on the momentum space texture of the atomic orbitals. Our work may stimulate further experimental explorations of symmetry and topology effects in 2D square-lattice systems. [1] Xian et al., 2D Mater. **4**, 041003, (2017)

O 73.5 Thu 16:00 S053

Interplay of exchange and spin-orbit interaction in ultrathin Ni films on  $W(110) - \cdot PASCAL JONA GRENZ¹$ , PETER KRÜGER², and MARKUS DONATH¹ - ¹Physikalisches Institut, Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany - ²Institut für Festkörpertheorie, Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany

Ferromagnetic adsorbates on high-Z substrates are prototypical systems for studying the combined influence of spin-orbit and exchange interaction on electronic states [1,2]. The unoccupied electronic states of ultrathin Ni films on W(110) were investigated with spin- and angle-resolved inverse photoemission. Measurements were performed along  $\overline{\Gamma N}$  ( $\overline{\Gamma M}$  with respect to the Ni(111) surface Brillouin zone), where the quantization axis of the Rashba-spin component is collinear to the easy magnetization axis. Remarkably, the observed unoccupied Ni-derived exchange-split states change their energy-momentum dispersion upon magnetization reversal. Density functional theory calculations show that this phenomenon is a consequence of substrate-induced spin-orbit coupling within the Ni adlavers.

O 73.6 Thu 16:15 S053

ARPES studies of Hf(0001) monocrystal: experiment and theory — •SALEEM AYAZ KHAN¹, LAURENT NICOLAI¹, JEAN ZARAKET^{2,3}, MARIA CHRISTINE RICHTER^{2,3}, OLIVIER HECKMANN^{2,3}, LAXMAN NAGI REDDY^{2,3}, WALY NDIAYE^{2,3}, MAURO FANCIULLI^{2,3}, KAROL HRICOVINI^{2,3}, and JAN MINAR¹ — ¹NTC, Univiversity of West Bohemia, Plzeň, Czech Republic — ²LPMS, CY Cergy Paris University, France — ³DRF, IRAMIS, LIDYL, CEA Saclay, France

We present first ARPES studies of the electronic structure of the Hf(0001) surface. High-Z materials have attracted much interest, because the strong spinorbit coupling in combination with the broken inversion symmetry and an important effective electric field at the surface results in a spin-momentum locking. Spin-polarized electrons at the surface are of interest in physics and novel applications in electronics and data processing. Extra sharp peaks observed in experiment are identified thanks to *ab-initio* calculations performed within the SPR-KKR package. These extra states come from oxygen contamination of the highly reactive surface of Hf(0001). Further comparison is done on the ARPES level, thanks to the one-step model which include all matrix elements effect, resulting in an excellent agreement.

#### O 73.7 Thu 16:30 S053

Establishing fundamentals of ARPES spin textures with model material  $PtTe_2 - \bullet$ Mohammed Qahosh, Honey Boban, Xiao Hou, Claus-Michael Schneider, and Lukasz Plucinski — Electronic Properties-Peter Grünberg Institute (PGI-6).

A novel quantum material  $PtTe_2$  is used to establish the connection between ARPES spin textures and initial state spin textures.  $PtTe_2$  is predicted to host Dirac type-II fermions and a number of application-relevant properties. The crystal structure of the most stable 1T-PtTe₂ polytype is trigonal, belongs to the space group 164 ( $P\bar{3}m1$ ), and exhibits 3-fold mirror planes and inversion symmetry. Since bulk 1T-PtTe₂ is both inversion-symmetric and non-magnetic, no bulk spin-polarized bands are allowed due to the Kramers degeneracy. At the surface, spin polarization is expected due to the broken inversion symmetry, however, it must obey the mirror and time-reversal symmetries.

We measured the dependence of spin-polarization on the symmetries of the ARPES experiment. This is performed in two geometries, with the reaction plane parallel to K- $\Gamma$ -K and M- $\Gamma$ -M reciprocal directions, i.e. either along or orthogonal to the crystal mirror plane. The measured spin texture is symmetric when the reaction plane is parallel to K- $\Gamma$ -K. However, we could see asymmetries in the spin texture when the reaction plane is parallel to M- $\Gamma$ -M. Such asymmetries are not allowed in the initial state and illustrate the mechanism of geometry-induced spin filtering in ARPES.

#### O 73.8 Thu 16:45 S053

Surface doping of the  $MnBi_2Te_4$  family by rubidium deposition — •KLARA VOLCKAERT¹, PAULINA MAJCHRZAK¹, RAPHAËL DUBOURG¹, ZHIHAO JIANG¹, XING-CHEN PAN², YONG CHEN¹, and SØREN ULSTRUP¹ — ¹Department of Physics and Astronomy, Aarhus University, Denmark — ²Advanced Institute for Materials Research, Tohoku University, Japan

Intrinsic magnetic topological insulators, in the form of MnBi₂Te₄, have recently been realised as a remarkable platform to study quantised magnetoelectric phenomena. Here we look into the surface electronic structure during rubidium deposition in a combined angle-resolved photoemission and core level study. We find that for MnBi₂Te₄, the initial electron doping effect from the adsorbed rubidium atoms is small. However, deposition on the higher stoicheometry compound MnBi₄Te₇ leads to a dramatic modification of the electronic structure, which is different for the surface terminated by a Bi₂Te₃ quintuple layer compared to a MnBi₂Te₄ septuple layer. Additionally, high rubidium deposition rates lead to a change of the electronic structure including a shift of the valence bands towards the Fermi level for both compounds, presumably due to Rb-Te-Bi alloying. A distinct quantization of the valence states is simultaneously observed. These results are the first to explore the tunability of electronic states the surface terminations of MnBi₄Te₇ with in situ alkali doping and substitution, which could modify the surface magnetic ordering.

O 73.9 Thu 17:00 S053 Theoretical and experimental HARPES study of Weyl-semimetal TaAs: The application of machine-learning —  $\bullet$ TRUNG-PHUC VO¹, ARIAN ARAB², SUNIL WILFRED D'SOUZA¹, LAURENT NICOLAÏ¹, TIEN-LIN LEE³, NITESH KUMAR⁴, CLAUDIA FELSER⁴, ALEXANDER GRAY², and JÁN MINÁR¹ — ¹New Technologies - Research Centre, University of West Bohemia, 301 00 Pilsen, Czech Republic — ²Department of Physics, Temple University, Philadelphia, Pennsylvania 19122, USA — ³Diamond Light Source Ltd., Didcot, Oxfordshire OX11 0DE, United Kingdom — ⁴Max Planck Institute for Chemical Physics of Solids, Nöthnitzer Str. 40, 01187 Dresden, Germany

The electronic structure properties of tantalum arsenide (TaAs), a Weyl semimetal, have been studied by soft and hard X-ray angle-resolved photoemis-

sion spectroscopy (ARPES) at energies of 440 eV and 2150 eV, respectively. For the first time, TaAs is experimentally investigated by the bulk sensitive photoemission in the hard X-ray regime. In order to interpret experimental data we performed one-step model of photoemission calculation which includes all matrix elements and final state effects. Due to the strong photon momentum effects and uncertainty in the tilt of experimental geometry we used a so-called machine learning algorithm combined with a free-electron final-state model to find best possible experimental parameters. Our findings re-emphasize the overwhelming accuracy of hard X-ray ARPES compared to the traditional ultraviolet and soft X-ray one in case of bulk electronic structure, motivating further material discoveries.

#### O 73.10 Thu 17:15 S053

Electron correlation in SrTiO3 studied by double photoemission spec**troscopy with a MHz high-order harmonics laser source** – •ROBIN KAMRLA¹, CHENG-TIEN CHIANG^{1,2}, FRANK OLIVER SCHUMANN³, and WOLF WIDDRA¹ – ¹Institute of Physics, Martin-Luther-Universität Halle-Wittenberg, Halle (Saale), Germany — ²Academica Sinica, Institute of Atomic and Molecular Sciences, Taiwan — ³Max Planck Institute of Microstructure Physics, Halle (Saale), Germany Photoelectron spectroscopy (PES) has provided deep insights into the electronic structure of solids. However, correlation effects can only be addressed indirectly. To observe such phenomena directly, double photoemission (DPE) spectroscopy is able to detect pairs of correlated photoelectrons that are emitted upon absorption of a single photon. Upon surface near doping, SrTiO3 (001) with a bandgap of 3.4 eV forms a two-dimensional electron gas (2DEG). In this contribution we present PES and DPE data for SrTiO3 (001) with and without 2DEG states at the surface, obtained by a high-order harmonic (HHG) light source at 25.2 and 30.0 eV. PES reveals a change in spectral weight of the O2p states and a surface band bending of 250 meV upon flipping SrTiO3 (001) into the 2DEG state and oxygen vacancy derived states emerging within the bandgap. In DPE, a bandbending induced shift of 500 meV, changes in the intensity of the O2p derived two hole states as well as emission from vacancy-valence pairs are identified via the two-electron sum energy spectrum. In addition, the role of Auger decays for the shallow Sr4p and O2s core level will be discussed.

#### O 73.11 Thu 17:30 S053

Doping of 1D topologically protected edge states on the (001) surface of the topological crystalline insulator (Pb,Sn)Se — •FLORIAN KELLER, ARTEM ODOBESKO, and MATTHIAS BODE — Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany Topological crystalline insulators (TCI) are a class of materials with topological

protected surface states protected by crystalline symmetry. A particularly popular representative of this material class is (Pb,Sn)Se which exhibits four Dirac cones per Brillouin zone. It has been shown that surface step edges with a height equivalent to an odd number of atomic layers results in a topologically protected one-dimensional edge state which is characterized by a peak at the Dirac energy [1]. Theoretical analysis suggests that this state is caused by the broken translation-invariance at the step edge and originates from flat-dispersing bands which connect pairs of surface Dirac nodes [1]. Due to intrinsic doping, the energy of the edge modes of as-grown crystals is usually well separated from the Fermi level. Here we investigate the behavior of these one-dimensional edge modes during Fe surface doping. Since Fe donates charge to p-doped PbSnSe, it results in a downwards-bending of the surface band structure. We observe a peak splitting as the Dirac energy gets close to the Fermi level. We discuss the potential origins of this observation in terms of electron correlations. [1] Sessi, Paolo, Science 354, 6317 (2016)

### 0 74: Organic Molecules at Surfaces 5: Molecular Switches

Time: Thursday 15:00-18:00

O 74.1 Thu 15:00 S054

**Reprogrammable molecular memory array based on chemical switching** – •TOBIAS BIRK¹, ANJA BAUER¹, FABIAN PASCHKE¹, RAINER WINTER², and MIKHAIL FONIN¹ – ¹Fachbereich Physik, Universität Konstanz, 78457 Konstanz, Germany – ²Fachbereich Chemie, Universität Konstanz, 78457 Konstanz, Germany

Technology on a molecular base promises highly interesting innovations for ultra-dense information storage devices and molecular electronics. Recently, a molecular three-state switch based on triazatruxene (TAT) on Ag(111) has been shown to have a great potential as data storage unit [1].

Here, we demonstrate the precise manipulation of the switching characteristics of individual TAT molecules within a 2D array using a low temperature scanning tunneling microscope (STM). By using the tip of the STM and the field applied within the contact, a successive pinning of the molecule via alkyl groups is achieved, leading to a gradual suppression of the current induced molecular switching. The possibility to reversibly switch between differently pinned molecules in combination with the three-level switching of the unpinned molecule offers the possibility to realize 9 states on a single molecule. We also demonstrate that the intermolecular interaction between the switches within the 2D array leads to a strong increase of the number of states, which can be detected on a single TAT unit, yielding up to 24 distinguishable states. Uni-directional rotation of molecular motors on Cu(111) — •MONIKA SCHIED^{1,2}, DEBORAH PREZZI³, DONGDONG LIU⁴, PETER JACOBSON^{1,5}, ELISA MOLINARI³, JAMES M. TOUR⁴, and LEONHARD GRILL¹ — ¹University of Graz, Austria — ²Elettra Sincrotrone Trieste, Italy — ³Nanoscience Institute of CNR, Italy — ⁴Rice University, USA — ⁵The University of Queensland, Australia Artificial molecular motors that convert external energy into controlled motion have seen great developments in the last decades [1]. While many studies exist

in solution, little is known how such functional molecules behave on a surface. However, such a solid support can be advantageous as it offers fixed points of reference as well as confinement in two dimensions, making it easier to study the directionality of their motion.

We have used low-temperature scanning tunnelling microscopy (STM) to study single molecules with a so-called Feringa motor [2,3] on a Cu(111) surface. It was found that rotations of individual molecules can be induced over rather long distances by voltage pulses with the STM tip. Importantly, these rotations show high directionality (clockwise or anticlockwise), which will be discussed in view of their specific chemical structure and adsorption.

**Precise control of single-molecule motion on Ag(111)** — •DONATO CIVITA, GRANT SIMPSON, and LEONHARD GRILL — Department of Physical Chemistry, University of Graz, Austria

The motion of molecules adsorbed on metal single crystal surfaces is of fundamental importance in various fields such as heterogeneous catalysis, and onsurface polymerization. During diffusion, however, the motion of adsorbed molecules is characterised by random direction changes and thus control is limited. Moreover, adsorbates in the surroundings as well as substrate defects can strongly influence molecular motion.

With the use of a scanning tunnelling microscope (STM) at low temperature, we can control the motion of single di-bromo-ter-fluorene (DBTF) molecules on a Ag(111) surface over distances of more than 100 nm with picometric precision [1]. We find that a single molecule can move strictly along one atomic row across the surface. The molecule can be repelled or attracted by the STM tip, driven by an interplay of van der Waals and electrostatic interactions. The large spatial extension of the motion, and its unidimensional confinement allow the direct measurement of the molecular velocity. Ultimately, this system demonstrates the possibility of studying the influence of surrounding adsorbates, crystal defects, and STM tip on the molecular motion and velocity.

**Dynamics of a chiral molecular rotor under a scanning-tunneling microscope** — •RICHARD KORYTÁR¹ and FERDINAND EVERS² — ¹Charles University, Prague — ²Universität Regensburg

Motivated by an experimentally realized chiral molecular switch, we devise a classical theory of the switching process, relevant for molecular electronics. The system of interest is a chiral molecular rotor in a scanning-tunneling setup, i.e. the switching occurs under the electric current. The molecule is modeled by a path in three dimensions. The path is massive and can rotate around a fixed axis. The incident electron traverses the path, inducing a torque on the path. We represent this two-body dynamics in a Lagrangian formalism. Switching mechanism and switching rates are discussed.

O 74.5 Thu 16:00 S054

**Bipolar single-molecule electrofluorochromism** — •TZU-CHAO HUNG¹, ROBERTO ROBLES², BRIAN KIRALY¹, JULIAN H. STRIK¹, BRAM A. RUTTEN¹, ALEXANDER A. KHAJETOORIANS¹, NICOLAS LORENTE², and DANIEL WEGNER¹ — ¹Institute for Molecules and Materials, Radboud University, Nijmegen, The Netherlands — ²Centro de Fisica de Materiales, CFM/MPC (CSIC-UPV/EHU), Paseo de Manuel de Lardizabal 5, 20018 Donostia-San Sebastián, Spain

The interplay between the charge state and the fluorescence of a molecule is not only important for the spectroscopic analysis of chemical reactions, but electrofluorochromic molecules can also be utilized in displays, sensors, and switches. To understand the fundamental mechanisms on the single-molecule level, we studied the transient charged state of zinc phthalocyanine (ZnPc) adsorbed on ultrathin NaCl films on Ag(111) by combining scanning tunneling microscopy (STM) and spectroscopy (STS) with STM-induced luminescence (STML). We found evidence for both cationic ([ZnPc]⁺) and anionic ([ZnPc]⁻) fluorescence, depending on the polarity of the tip-sample bias. By carefully mapping the molecular frontier orbitals over a wide energy range, correlating them with onset energies for light emission and comparing with results from DFT calculations, we propose an alternative charging and electroluminescence mechanism. Our study provides new insights into the tunability of molecular optical response, as well as novel aspects toward utilization of bipolar electrofluorochromism in devices.

#### O 74.6 Thu 16:15 S054

Electronic Motor Based on Single Tripodal Chiral Molecule — •JULIAN SKOLAUT¹, LUKAS GERHARD¹, NICO BALZER², MICHAL VALASEK², JAN WILHELM⁴, PHILIPP MARKUS⁵, MARCEL MAYOR^{2,3}, FERDINAND EVERS⁴, and WULF WULFHEKEL^{1,5} — ¹Institute for Quantum Materials and Technologies,

Karlsruhe Institute of Technology, Eggenstein- Leopoldshafen, Germany — ²Institute of Nanotechnology, KIT, Eggenstein-Leopoldshafen, Germany — ³Department of Chemistry, University Basel, Basel, Switzerland — ⁴Institute of Theoretical Physics, University of Regensburg, Regensburg, Germany — ⁵Physikalisches Institut, KIT, Karlsruhe, Germany

We present our results concerning a single molecular motor driven by the current in an STM. Three anchoring groups fix the molecules to a Au(111) surface. In specific ordered structures, the molecules adsorb such, that the protruding head group is free to rotate. This chiral group is supposed to perform a rotation in a preferred direction, proposed to be driven based on the chiral-induced spin selectivity (CISS) effect. At fixed tip positions above the molecules, three distinguishable current levels can be observed. These are interpreted as metastable rotational states. That way, two rotation directions can be defined. Via binomial tests, we verify that the surplus of rotational switches in one direction compared to the other is statistically significant. In voltage and current dependent measurements, two interesting trends are observed. Firstly, the rate of events decreases with increasing current. Secondly, the asymmetry in the switching events shows non-monotonic behavior, depending on the voltage.

**Proton Transfer in Single Asymmetric Porphycene Molecules** — •SIMON JAEKEL^{1,2}, JACEK WALUK³, and LEONHARD GRILL¹ — ¹Department of Physical Chemistry, University of Graz, Austria — ²Chair of Physical Chemistry II, University of Erlangen-Nürnberg (FAU), Germany — ³Polish Academy of Science, Warsaw, Poland

Studying single molecular switches is of interest for a better understanding of fundamental physical and chemical processes, but also in view of their possible use in smart materials and nanoscale applications. It has been shown that switches based on tautomerization, i.e. hydrogen transfer, are especially suited for scanning tunneling microscopy (STM) studies, because the electronic states near the Fermi level are very sensitive to the position of the hydrogen atoms. Experiments on symmetric molecules such as naphthalocyanine [1], tetraphenylporphyrin [2], and porphycene [3] showed that the energies of the tautomers are degenerate, barring environmental modulation. Thus, if one is interested in switching processes with preferential switching directions between multiple states, structurally asymmetric molecules are of particular interest.

Here, we report STM results of the tautomerization properties of 22-Oxahemiporphycene, a derivative of porphycene with an asymmetric macrocycle, on a metal surface.

Tuning the chirality change of a single molecule by van der Waals interactions — •YUNJUN CAO and KARINA MORGENSTERN — Physical Chemistry I, Ruhr-Universität Bochum, Bochum, Germany

The chiral induction and control of molecules by non-covalent intermolecular interactions, like hydrogen bonding and van der Waals interactions, is crucial to understand the origin of homochirality in nature. However, it remains challenging to address these subtle intermolecular interactions at a single-molecular level, especially the weakest of them, the van der Waals interactions. Here, by adsorbing a specifically designed carbene molecule on a copper surface, we examine the influence of the van der Waals interactions on the chirality induction by scanning tunneling microscopy. While the strongly binding carbene center of this molecule suppresses any side-reactions upon excitation, its two low-interacting phenyl rings facilitate a chirality change induced by inelastically tunneling electrons. The potential energy of the chirality change is modified by the van der Waals interactions in the presence of a tip. A marginal change induces an asymmetric distribution of the carbene molecule between its two enantiomers during this chirality change. Our study shows how the weak van der Waals interactions alter the dynamics of chirality changes at the molecular level, enabling an in-depth understanding of the origin of homochirality in nature and providing new insights into the construction of homochiral supramolecular assemblies in solutions and on solid surfaces.

O 74.9 Thu 17:00 S054

Lateral Force Microscopy Reveals the Energy Barrier of a Molecular Switch — Alfred John Weymouth, Elisabeth Riegel, •Bianca Simmet, Oliver Gretz, and Franz Josef Giessibl — Universität Regensburg, Regensburg, Germany

Copper phthalocyanine (CuPc) is a small molecule often used in organic light emitting diodes where it is deposited on a conducting electrode. Previous scanning tunneling microscopy (STM) studies of CuPc on Cu(111) have shown that inelastic tunneling events can cause CuPc to switch between a ground state and two symmetrically equivalent metastable states in which the molecule is rotated. We investigated CuPc on Cu(111) and Ag(111) with STM and lateral force microscopy (LFM). Even without inelastic events, the presence of the tip can induce rotations and upon closer approach, causes the rotated states to be favored. Combining STM measurements at various temperatures and LFM measurements, we show that the long-range attraction of the tip changes the potential energy landscape of this molecular switch. We can also determine the geometry of the rotated and ground states. We compare our observations of CuPc on Cu(111) to CuPc on Ag(111). On Ag(111), CuPc appears flat and does not rotate. Stronger bonding typically involves shorter bond lengths, larger shifts of energy levels, and structural stability. Although the binding of CuPc to Cu(111) is stronger than that on Ag(111), the nonplanar geometry of CuPc on Cu(111) surface.

**Evidence of trion-libron coupling in chirally adsorbed single molecules** — •JIŘÍ DOLEŽAL^{1,2}, SOFIA CANOLA¹, PROKOP HAPALA¹, RODRIGO FERREIRA¹, PABLO MERINO³, and MARTIN ŠVEC¹ — ¹Institute of Physics, Czech Academy of Sciences; Cukrovarnická 10/112, CZ16200 Praha 6, Czech Republic — ²Faculty of Mathematics and Physics, Charles University; Ke Karlovu 3, CZ12116 Praha 2, Czech Republic — ³Instituto de Ciencia de Materiales de Madrid; CSIC, Sor Juana Inés de la Cruz 3, E28049 Madrid, Spain

Interplay between the motion of nuclei and excited electrons in molecules plays a key role both in biological and artificial nanomachines. Here we provide a detailed analysis of coupling between quantized librational modes (librons) and charged excited states (trions) on single phthalocyanine dyes adsorbed on a surface. By means of tunnelling electron-induced electroluminescence, we identify libronic progressions on a  $\mu$ eV energy range in spectra of chirally adsorbed phthalocyanines, which are otherwise absent from spectra of symmetrically adsorbed species. Experimentally measured libronic spectra match very well the theoretically calculated libron eigenenergies and peak intensities (Franck-Condon factors) and reveal an unexpected depopulation channel for the zero libron of the excited state that can be effectively controlled by tuning the size of the nanocavity. Our results showcase the possibility of characterizing the dynamics of molecules by their low-energy molecular modes using  $\mu$ eV-resolved tip-enhanced spectroscopy.

O 74.11 Thu 17:30 S054 Design Principles for Metastable Standing Molecules — HADI H. AREFI¹, MARVIN KNOL¹, DANIEL CORKEN², JAMES GARDNER², F. STEFAN TAUTZ¹, REIN-HARD J. MAURER², and •CHRISTIAN WAGNER¹ — ¹Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, Germany — ²Department of Chemistry, University of Warwick, Coventry, UK Molecular nanofabrication with a scanning probe microscope is a promising route towards the prototyping of metastable functional molecular structures and devices which do not form spontaneously. The aspect of mechanical stability is crucial for such structures especially if they extend into the third dimension vertical to the surface. A prominent example are freestanding molecules on a metal which can function as field emitters or electric field sensors[1,2]. Improving the stability of such molecular configurations is an optimization task involving many degrees of freedom. Here, we present a combination of scanning probe experiments with ab initio potential energy calculations to investigate the stability of a prototypical standing molecule. We cast our results into a simple set of universal design principles for such metastable structures, the validity of which we demonstrate in two computational case studies. This offers the intuition needed to fabricate new devices without tedious trial and error.

O 74.12 Thu 17:45 S054 Improving the Switching Efficiency in Azobenzene Derivative Film on Graphite-Air Interface — •THIRUVANCHERIL G. GOPAKUMAR¹, KHUSHBOO YADAV¹, HARIOM BIRLA¹, SHOWKAT H. MIR^{1,2}, THOMAS HALBRITTER², ALEXANDER HECKEL², and JAYANT K. SINGH³ — ¹Department of Chemistry, Indian Institute of Technology Kanpur, Kanpur 208016, India — ²Institute for Organic Chemistry and Chemical Biology, Goethe-University Frankfurt, Maxvon-Laue-Str. 9, 60438 Frankfurt, Germany — ³Department of Chemical Engineering, Indian Institute of Technology Kanpur, Kanpur 208016, India

The trans isomer of azobenzene (AB) and its derivatives is the most abundant under equilibrium-thermodynamical conditions and is known to switch between its trans and cis states when triggered by light and electrons/holes on graphite.[1] In this work, we show that AB derivatives are switching between two cis states (cis, cis') when electrons/holes induced switching is performed on a cis dominant non-equilibrium initial condition at HOPG-air interface. The switching efficiency in the cis adlayer is several folds higher than that in the trans adlayer. This is related to the low switching barrier for cis-cis' switching compared to that of trans-cis switching as revealed by density functional theory (DFT) calculations.

Reconfiguring magnetic resonances with the plasmonic phase-change material  $In_3SbTe_2$  — •LUKAS CONRADS, ANDREAS HESSLER, KONSTANTIN WIRTH, MATTHIAS WUTTIG, and THOMAS TAUBNER — I. Institute of Physics (IA), RWTH Aachen University

For miniaturized active nanophotonic components, resonance tuning of nanoantennas is a key ingredient. Phase-change materials (PCMs) have been established as prime candidates for non-volatile resonance tuning based on a change in refractive index [1]. Currently, a novel material class of switchable infrared plasmonic PCMs, like In₃SbTe₂ (IST), is emerging. Since IST can be locally optically switched between dielectric (amorphous phase) and metallic (crystalline phase) states in the whole infrared range, it becomes possible to directly change the geometry and size of nanoantennas to tune their infrared resonances [2]. Here, crystalline IST split-ring resonators (SRRs) are directly optically written and reconfigured in their arm size to continuously tune their magnetic dipole resonances over a range of 2.4  $\mu m$  without changing their electric dipole resonances. The SRRs are further modified into crescents and J-antennas, which feature more complex resonance modes dependent on the polarization of the incident light [3]. Our concepts are well-suited for rapid prototyping, speeding up workflows for engineering ultrathin, tunable, plasmonic devices for infrared nanophotonics, telecommunications, or (bio)sensing.

#### O 78.2 Fri 10:45 H3

Impact of atomistic structure and dynamics on inelastic light scattering in a plasmonic picocavity — •FRANCO BONAFÉ¹, SHUYI LIU², HEIKO APPEL¹, MARTIN WOLF², TAKASHI KUMAGAI^{2,3}, and ANGEL RUBIO¹ — ¹MPI for Structure and Dynamics of Matter, Hamburg, Germany — ²Dpmt. of Physical Chemistry, Fritz-Haber Institute, Berlin, Germany — ³Center for Mesoscopic Sciences, Institute for Molecular Science, Okazaki, Japan

Atomically sharp metallic tips can focus an electromagnetic field down to the sub-nanometer scale, leading to strong light-matter interactions in plasmonic "picocavities". This atomic-scale field can be used in plasmon-enhanced spectroscopy, such as tip-enhanced Raman spectroscopy (TERS), which has enabled the visualization of optical properties at sub-molecular resolution. However, a full microscopic understanding of the interplay of structural relaxation, bonding, near-fields and vibrations has not been achieved.

In this work, we combine experimental observations of inelastic light scattering from a single silver adatom in a plasmonic picocavity controlled by a low-temperature scanning tunneling microscope (STM), with ab initio real-time electron dynamics simulations. The experiment demonstrates a dramatic enhancement of Raman scattering that occurs upon the formation of a quantum point contact. We model possible geometries for the plasmonic tips and compute the vibrational modes, electronic current and near-fields localized in the vicinity of the single adatom. These simulations reveal a crucial role of the atomistic structural relaxation in the optical response in a plasmonic nanocavity.

Non-linear photoemission microscopy has been established as an excellent tool to investigate nano-optical fields at surfaces, in particular the fields of surface plasmon polaritons (SPPs). In a pump-probe experiment with femtosecond laser pulses we excite SPPs at grooves that are ion-milled into a Au platelet. The electric field of the probe-laser pulse interferes coherently with the electric field of the SPP and electrons are liberated through a nonlinear process by the combined field at the surface. The contrast depends on the alignment of the probe polarization and the orientation of the in-plane component of the SPP's electric field. Using a set of different polarizations for the probe laser pulse while keeping the same excitation conditions, one can reconstruct the in-plane component of the electric field of the SPP. The out-of-plane field component is calculated by Maxwell's equations to reconstruct the full electric vector field. Here, we measure and image complex electric vector fields of SPPs and analyze their topology.

**Mode-selective imaging and control of nano-plasmonic near-fields** — •MURAT SIVIS^{1,2}, HUGO LOURENÇO-MARTINS^{1,2}, ANDRE GEESE², TYLER R. HARVEY², THOMAS DANZ^{1,2}, RADWAN M. SARHAN³, MATIAS BARGHEER³, ARMIN FEIST^{1,2}, and CLAUS ROPERS^{1,2} — ¹Max Plank Institute for Multidisciplinary Sciences, Göttingen, Germany — ²4th Physical Institute - Solids and Nanostructures, University of Göttingen, Germany — ³Institut für Physik und Astronomie, Universitä Potsdam, Potsdam, Germany

Electron energy-loss spectroscopy (EELS) in a transmission electron microscope allows for the study of optical excitations in plasmonic nanostructures with subnanometer spatial resolution. While EELS is a powerful tool, it can only provide information about the spontaneous losses in a system with limited spectral resolution (10-100 meV in the most advanced microscopes). Recent developments in ultrafast transmission electron microscopy overcome these limitations and enable the probing of laser-excited modes by using photon-induced near-field electron microscopy (PINEM). Here, we demonstrate how PINEM can be used to measure the modal structure of the optical response of individual plasmonic systems (metal nano-triangle-resonators) at the nanoscale. Using our boundary element method (BEM)-based data analysis, we extract the magnitude and relative phase of each plasmonic mode from optical near-field maps. This approach opens a route to study the influence of the laser polarization, wavelength and incidence angle on the population of each mode, as well as the control of complex mode patterns created by multicolor fields.

**Tailoring of nonlinear metasurfaces using sampling-based optimization** — •DAVID HÄHNEL, JENS FÖRSTNER, and VIKTOR MYROSHNYCHENKO — Paderborn University, Theoretical Electrical Engineering, Warburger Str. 100, 33098 Paderborn, Germany

Various efficient methods for the design and optimization of linear metasurfaces have already been developed in the past [1]. Nowadays, attempts are being made to use these methods also for the design and optimization of nonlinear metasurfaces, which is a quite complex task due to the nonlinear processes involved. Here we present the design and optimization of all-dielectric nonlinear metasurfaces using a simple sampling method combined with Monte Carlo simulation, demonstrating that the use of sophisticated optimization methods is not necessarily required. Furthermore, this combination provides an effective approach in the optimization of nonlinear metasurfaces with a dynamic problem, such as a varying number of optimization parameters that are unknown in advance. We apply this method combination in the optimization of a nonlinear beam deflector metasurface for the third harmonic, which consist of an array of elliptical silicon disks and obtained an significant improvement in the radiated intensity compared to literature results [2]. [1] Chen, S. et al., Advanced Optical Materials 2018, 6, 1800104. [2] Lei Wang et al., Nano Lett. 2018, 18, 6, 3978-3984.

#### O 78.7 Fri 12:00 H3

Polarization selective investigation of plasmonic Bloch modes with dark-field spectroscopy — •MAXIMILIAN JOHANNES BLACK and NAHID TALEBI — Institute for Experimental and Applied Physics, Kiel University, 24118 Kiel, Germany Plasmonic and photonic crystals are widely used to mold the flow of light. Owing to its symmetry even the seemingly simple structure of a periodic square lattice of holes within a thin gold film shows a broad variety of plasmonic Bloch modes that are distinguished by the momenta and polarization. Therefore, the response of the system to the excitation is formed by a superposition of these modes. In this work we use polarization-selective optical dark-field microscopy

549

to decompose these modes. Dark-field microspectroscopy is used to enhance the resolution and to suppress the background illumination, whereas linear polarizers both in the illumination and the detection path enable the selection of Bloch modes by polarization. We find that the dominating signal is formed by the selective excitation and detection of radiating magnetic moments. These and a variety of other modes are visualized by hyperspectral imaging. In the far-field reciprocal space interference fringes are resolved, indicating the propagation of the observed modes along the surface of the plasmonic crystal. Our results prove the possibility to thoroughly investigate plasmonic Bloch modes using dark-field microscopy, adding its versatility to the range of methods for measuring lightmatter interactions.

O 78.8 Fri 12:15 H3

A Ginzburg Landau model for femtosecond charge-density wave dynamics at the atomic scale — •KURT LICHTENBERG¹, MOHAMAD ABDO^{1,2}, SHAOXI-ANG SHENG¹, LUIGI MALAVOLTI^{1,2}, and SEBASTIAN LOTH^{1,2} — ¹University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany — ²Max Planck Institute for Solid State Research, Stuttgart, Germany Charge-density waves (CDWs) feature collective excitations that can be observed as an oscillatory response of the electron system of a material to a fast optical stimulus [1]. At the same time, scanning tunneling microscopy (STM) measurements reveal highly localized interactions with atomic defects [2]. THz pumpprobe spectroscopy in the STM reveals highly heterogeneous dynamics with spatial variations down one unit cell of the CDW. To improve the understanding of such local CDW dynamics, we developed an empirical model that is motivated by former approaches [3,4] and based on time-dependent Ginzburg Landau Theory. The combination of this theory with THz-STM measurements establishes a possibility to study the interplay between collective CDW dynamics with atomic pinning sites.

Exploitation of Heterocycles for N-doped Graphene Nanomaterials — RÉMY PAWLAK¹, ULRICH ASCHAUER², SILVIO DECURTINS², JASCHA REPP³, PAVEL JELINEK⁴, ERNST MEYER¹, LAERTE L. PATERA⁵, and •SHI-XIA LIU² — ¹Department of Physics, University of Basel, Klingelbergstrasse 82, 4056 Basel, Switzerland — ²Department of Chemistry, Biochemistry and Pharmaceutical Sciences, University of Bern, 3012 Bern, Switzerland — ³Institute of Experimental and Applied Physics, University of Regensburg, 93053 Regensburg, Germany — ⁴Institute of Physics of Czech Academy of Sciences, 16200 Prague, Czech Republic — ⁵Department of Chemistry and Catalysis Research Center, Technical University of Munich, 85748 Garching, Germany

On-surface chemical reactions have been intensively investigated in order to obtain carbon-based functional nanomaterials which very often cannot be synthesized by wet chemistry. Thus, tailored heterocyclic precursors are becoming increasingly important for the development of highly symmetric 2D-conjugated porous architectures and 1D N-doped graphene nanoribbons (GNRs) with desired functions due to their intrinsic electronic properties. This presentation will focus on our collaborative work on C-C coupling reactions on various surfaces leading to the formation of a range of nanostructures, including molecular wires, fully fused porphyrin-GNR hybrids, as well as 1D- and 2D-conjugated porous networks. All of these atomically precise nanostructures can be directly visualized by STM and AFM. The fine-tuned electronic properties by chemical modification are discussed.

O 79.2 Fri 11:00 H4 On-surface cyclomerization of oxygen heterocycles: Controlling the ring size by tuning the molecule-surface interaction — •ANDREAS DÖRR¹, NE-MANJA KOCIC¹, LUKAS FROMM², VLADIMIR AKHMETOV³, KONSTANTIN Y. AMSHAROV³, ANDREAS GÖRLING², and SABINE MAIER¹ — ¹Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen (Germany) — ²Department of Chemistry and Pharmacy, Chair of Theoretical Chemistry, Friedrich-Alexander-Universität Erlangen-Nürnberg, 91058 Erlangen (Germany) — ³Institute for Chemistry, Martin-Luther-University Halle-Wittenberg, 06099 Halle (Germany)

Heterocycles with nitrogen, oxygen, or sulfur atoms are the basic units that incorporate chemical functionalization into carbon scaffolds. For oxygen-doped nanographenes, furan and pyran, having five- and six-membered rings, respectively, are the most common ones. However, their on-surface synthesis via cyclomerization reactions has so far been elusive. Here, we present a lowtemperature scanning tunneling microscopy study combined with density functional theory calculations to understand the on-surface synthesis of furan and pyran derivatives from ketone-functionalized precursors on metal surfaces. We first discuss the self-assemblies of the precursors, which are strongly influenced by molecule-surface interactions. Upon annealing, the different intermolecular binding motifs resulted in selective cyclomerization reactions toward furan and pyran moieties.

University of Bern, Freiestrasse 3, CH-3012 Bern — ³Physikalisches Institut, Karlsruhe Institute of Technology, Wolfgang-Gaede-Str. 1, D-76131 Karlsruhe

Atomically precise nanographenes (NGs) can be efficiently synthesized through on-surface reactions. On such designed NGs, topological superconductivity could be fostered via proximity to a s-wave superconductor. However, on-surface synthesis of NGs is still missing on superconducting surfaces [1-3]. To fill the gap, we first fabricate a Ag buffer layer on the Nb(110) superconductor [4], and grow atomically precise NGs on the Ag/Nb substrate using DBBA as the precursor. Through the investigation of low temperature STM/AFM, we demonstrate successful synthesis of polymeric chains and NGs on the superconducting Ag/Nb(110) substrate. We believe our method provides a promising platform for studying the role of topology in the interaction between carbon magnetism and superconductivity [5]. #### O 79.4 Fri 11:30 H4

Real-space Imaging of Unprecedented Phenyl Group Migration Reaction on Metal Surfaces — •ZILIN RUAN^{1,2}, BAIJIN LI², SHIJIE SUN², YONG ZHANG², LEI GAO³, JIANCHEN LU², MICHAEL GOTTFRIED¹, and JINMING CAI² — ¹Department of Chemistry, Philipps University Marburg, Hans-Meerwein-Straße 4, 35037 Marburg (Germany) — ²Faculty of Materials Science and Engineering, Kunming University of Science and Technology, Kunming, Yunnan 650093 (China) — ³Department of Chemistry, Philipps University Marburg, Hans-Meerwein-Straße 4, 35037 Marburg (Germany)

We report on-surface identification and visualization of an unprecedented and universal phenyl group migration reaction of 1,4-dimethyl-2,3,5,6-tetraphenyl benzene (DMTPB)a precursor on Au(111), Cu(111) and Ag(110) substrates by a combination of bond-resolved scanning tunneling microscopy (BR-STM) and density functional theory (DFT) calculations. The phenyl group migration reaction of DMTPB precursor results in formations of variously unprecedented polycyclic aromatic hydrocarbons on the substrates. DFT calculations reveal that the multiple-steps phenyl group migration reactions are facilitated by the radical attack and rearomatization of the DMTPB precursor. Our study provides unprecedented insights into complex surface reaction mechanisms at the single molecule level, which may guide the design of chemical species.

#### O 79.5 Fri 11:45 H4

Deciphering the intramolecular C-C coupling mechanism of a model aryl radical via bond-level AFM imaging — •QIGANG ZHONG¹, JANNIS JUNG², DANIEL KOHRS³, DANIEL EBELING¹, DOREEN MOLLENHAUER², HERMANN A. WEGNER³, and ANDRÉ SCHIRMEISEN¹ — ¹Institute of Applied Physics, Justus-Liebig University Giessen (JLU), Germany — ²Institute of Physical Chemistry, JLU, Germany — ³Institute of Organic Chemistry, JLU, Germany

Although on-surface dehalogenative and dehydrogenative C-C coupling has proved to be a versatile and prevailing approach to constructing atomically precise carbon-based nanostructures, understanding of the reaction mechanisms remains limited by the elusive intermediates. Here, we studied the intramolecular cyclodehydrobromination of 1-bromo-8-phenylnaphthalene on Cu(111) and Ag(111) using bond-level atomic force microscopy (BL-AFM). The reaction occurs at room temperature on both metal surfaces, while the reaction rate on Cu(111) is much higher than that on Ag(111) presumably due to the higher catalytic activity of copper. Surface-bound radicals, cyclized intermediates and dehydrogenated product were captured by BL-AFM imaging and verified by DFT calculations, suggesting a multi-step reaction process, i.e. debromination, radical cyclization and dehydrogenation. The large proportion (up to 65 percent) of cyclized intermediates on Cu(111) indicates that dehydrogenation is the ratedetermining step, which is corroborated by DFT calculations of activation barriers. To achieve a reasonable activation barrier for dehydrogenation, multiple pathways were theoretically evaluated.

#### O 79.6 Fri 12:00 H4

Interplay between  $\pi$ -conjugation and exchange magnetism in onedimensional porphyrinoid polymers — •KALYAN BISWAS¹, MAXENCE URBANI¹, ANA SÁNCHEZ-GRANDE¹, DIEGO SOLER², KOEN LAUWAET¹, ADAM MATĚJ², PINGO MUTOMBO², JOSÉ M. GALLEGO¹, RODOLFO MIRANDA¹, DAVID ÉCIJA¹, PAVEL JELÍNEK², TOMÁS TORRES¹, and JOSÉ I. URGEL¹ — ¹IMDEA Nanoscience, Madrid, Spain — ²CATRIN, Olomouc, Czech Republic

The field of carbon magnetism has gained an increased attention in view of the recent progress made in the synthesis and characterization of open-shell polycyclic aromatic hydrocarbons following a bottom-up synthetic approach. In this work, we introduce an exemplary approach toward the bottom-up fabrication of unprecedented magnetic porphyrinoid-based polymers homocoupled via surface-catalyzed [3 + 3] cycloaromatization of isopropyl substituents studied on Au(111) under ultra-high vacuum conditions. The chemical structure of the polymer, formed by thermal-activated intra- and intermolecular oxidative ring closure reactions followed by controlled tip-induced hydrogen dissociation from the porphyrinoid units, have been clearly elucidated by scanning tunneling microscopy and non-contact atomic force microscopy. Scanning tunneling spectroscopy, complemented by computational investigations reveals the antiferromagnetic singlet ground state (S=0), which display singlet-triplet inelastic excitations observed between spins of adjacent porphyrinoid units only along a specific  $\pi$ -conjugation pathway. We envision that our approach can be a highly relevant in nanoscale spintronic devices.

O 79.7 Fri 12:15 H4

Photoactivation of Azide in SURMOFs — •JIMIN SONG, XIAOJUAN YU, MANUEL TSOTSALAS, ALEXANDER KNEBEL, ALEXEI NEFEDOV, STEFAN HEISSLER, YUEMIN WANG, and CHRISTOF WÖLL — Institute of Functional Interfaces, Karlsruhe Institute of Technology,76344, Eggenstein-Leopoldshafen, Germany

The ability to turn the surface activation of metal-organic frameworks (MOFs) is essential for developing advanced MOF applications. Here, we have successfully synthesized a surface-mounted MOF (SURMOF) model system with azide side groups in order to investigate the photoactivation of phenyl azide and its reaction pathways. In situ UHV infrared reflection absorption spectroscopy (IRRAS) was applied to precisely monitor the chemical changes taken place on the surface of highly oriented and crystalline SURMOFs under UV irradiation at different temperatures. Combining with in situ XRD, MS and XPS, a two-step mechanism is proposed including the activation and subsequent reaction of azide with adjacent C=C bonds yielding pyrrole species.

O 79.8 Fri 12:30 H4

Differences in the Intermolecular Interaction of Electron-rich Phosphines on a Metal and a Salt Surface — •VLADIMIR LYKOV¹, FLORENZ BUSS², MIL-ICA FELDT³, KARINA MORGENSTERN¹, and FABIAN DIELMANN⁴ — ¹Chair of Physical Chemistry I, Ruhr Universität Bochum, Germany — ²Institute for Inorganic and Analytical Chemistry, Westphalian Wilhelms University of Münster, Germany — ³Leibniz-Institut für Katalyse e.V. (LIKAT), Rostock, Germany — ⁴Department of General, Inorganic and Theoretical Chemistry, University of Innsbruck, Austria

Electron-rich phosphines are attractive as capture molecules, for instance, for carbon dioxide ( $CO_2$ ) and sulfur dioxide ( $SO_2$ ) by forming zwitterionic Lewis base adducts with them [1]. The main focus of this project is understanding the interaction behind this capturing in real space. For this purpose, we use a low-temperature (7 K) scanning tunneling microscope (STM). To understand the influence of the metal surface on this capture process, we compare the molecules adsorbed on Ag(100) to those on NaBr(100). As a first step, the different interaction of phosphines with the salt multilayers and with the metal was investigated by step-wise heating from 43 K to 135 K. The difference in intermolecular interaction on these surfaces will be discussed in this presentation.

By means of scanning tunneling microscopy (STM) and spectroscopy (STS) the precise spin states of such carbon-based nanostructures have been studied. Such experimental findings, are supported by calculations from density functional theory (DFT), mean-field Hubbard model (MFH), and Heisenberg model.

Both nanostuctures are achieved thanks to on-surface synthesis. TNS hosts antiferromagnetically coupled spin-1 showing a complex many-body inelastic excitation spectrum. A5T ground state has a spin larger than one. Here the presence of the N heteroatom substitution plays an important role in the spin state on surface.

### O 80.2 Fri 10:45 S051

Local access to the Ln-Ln bonding orbital in dimetallofullerene molecular magnets — •FABIAN PASCHKE¹, TOBIAS BIRK¹, FUPIN LIU², STANISLAV M. AVDOSHENKO², ALEXEY A. POPOV², and MIKHAIL FONIN¹ — ¹Department of Physics, Universität Konstanz, 78457 Konstanz — ²Leibniz Institute for Solid State and Materials Research (IFW Dresden), 01069 Dresden

One of the key players in the single-molecule magnet community are members of the lanthanide (Ln) dimetallofullerene family that combine air-stable chemical robustness, easy functionalization, a large magnetic moment and slow magnetic relaxation up to 28 K [1]. Two  $\text{Ln}^{3+}$  ions are ferromagnetically coupled by a singly occupied Ln – Ln bonding orbital in the void of a C₈₀ fullerene cage.

In this talk I will first demonstrate the robust on-surface magnetism of  $\{Ln_2\}$  complexes that show outstanding magnetic blocking temperatures [2,3], an important prerequisite to address its molecular magnetism on a local scale. Subsequently, scanning tunneling spectroscopy unambiguously identifies the unoccupied component of the single-electron Ln – Ln bonding orbital in the spectrum of  $\{Dy_2\}$  on a graphene/Ir(111) surface [4]. This finding outlines a new route how to access the molecular spin dynamics of single  $\{Ln_2\}$  complexes and provides a working point for spin manipulation using chemical doping.

indirect spin-readout of rare-earth-based single-molecule magnet with STM — •HONGYAN CHEN¹, TIMO FRAUHAMMER¹, TIMOFEY BALASHOV², GABRIEL DERENBACH^{1,3}, SVETLANA KLYATSKAYA⁴, EUFEMIO MORENO-PINEDA⁵, MARIO RUBEN^{3,4,6}, and WULF WULFHEKEL^{1,3} — ¹Physikalisches Institut, Karlsruhe Institute of Technology (KIT), 76131 Karlsruhe, Germany — ²Physikalisches Institut, RWTH Aachen, 52074 Aachen, Germany — ³Institute for Quantum Materials and Technologies, KIT, 76021 Karlsruhe, Germany — ⁴Institute of Nanotechnology, KIT, 76021 Karlsruhe, Germany — ⁴Institute of Nanotechnology, KIT, 76021 Karlsruhe, Germany — ⁵Departamento de Química-Física, Escuela de Química, Facultad de Ciencias Naturales, Exactas y Tecnología, Universidad de Panamá 0824, Panama — ⁶Centre Européen de Sciences Quantiques (CESQ) in the Institut de Science et d'Ingénierie Supramoléculaires (ISIS), 8 allée Gaspard Monge BP 70028, 67083 Strasbourg Cedex, France

Rare-earth based SMMs are promising candidates for magnetic information storage as their large magnetic moments are carried by localized 4f electrons. However, this in turn hampers a direct readout of the moment. Here, we present the indirect readout of the Dy moment in  $DyPc_2$  molecules on Au(111) using mK-STM. Because of an unpaired electron on the Pc ligand, the molecules show a Kondo resonance that is, however, split by the ferromagnetic exchange interaction between the unpaired electron and the Dy spin. Using spin-polarized STS, we read out the Dy spin as a function of the applied magnetic field, exploiting the spin polarization of the exchange-split Kondo state.

Location: S051

**Yu-Shiba-Rusinov states of Fe dimers on NbSe**₂ — •LISA M. RÜTTEN¹, EVA LIEBHABER¹, HARALD SCHMID¹, GAËL REECHT¹, KAI ROSSNAGEL^{2,3}, FELIX VON OPPEN¹, and KATHARINA J. FRANKE¹ — ¹Fachbereich Physik, Freie Universität Berlin, 14195 Berlin, Germany — ²Institut für Experimentelle und Angewandte Physik, Christian-Albrechts-Universität zu Kiel, 24118 Kiel, Germany — ³Ruprecht Haensel Laboratory, Deutsches Elektronen-Synchrotron DESY, 22607 Hamburg, Germany

Unpaired adatom spins on superconductors interact with the Cooper pairs of the substrate and induce Yu-Shiba-Rusinov (YSR) states inside the superconducting gap. These can be probed by scanning tunneling spectroscopy at the single-atom scale. 2H-NbSe₂ is a superconducting, layered van der Waals material, where the YSR wave functions of magnetic impurities extend over several nanometers. This provides a wide range of adatom spacings over which their interaction is sufficiently strong to be potentially observed as a splitting in the tunneling spectra. In addition to superconductivity, 2H-NbSe₂ hosts an incommensurate charge-density wave (CDW). The imposed variation of the local density of states leads to shifts in the energy of the YSR states and alters the spatial symmetry of YSR wave functions. Here, we arrange Fe atoms on 2H-NbSe₂ using the tip of a scanning tunneling microscope and realize dimers with different spacings and symmetries. We investigate the influence of spacing and position with respect to the CDW on the interaction between the YSR states.

#### O 80.5 Fri 11:30 S051

Atomic manipulation of spin structures on the  $\beta$ -Bi₂Pd Superconductor — CRISTINA MIER¹, DIVYA JYOTI^{1,2}, JIYOON HWANG³, JINKYUNG KIM³, YUJEONG BAE³, ANDREAS HEINRICH³, NICOLAS LORENTE^{1,2}, and •DEUNG-JANG CHOI^{1,2,4} — ¹Centro de Fisica de Materiales, CFM/MPC (CSIC-UPV/EHU), Paseo Manuel de Lardizabal 5, 20018 Donostia-San Sebastian, Spain — ²Donostia International Physics Center (DIPC), Paseo Manuel de Lardizabal 4, 20018 Donostia-San Sebastian, Spain — ³Center for Quantum Nanoscience (QNS), Institute for Basic Science (IBS), Seoul 03760, South Korea — ⁴Ikerbasque, Basque Foundation for Science, 48013 Bilbao, Spain

Recently, the introduction of impurity states in the superconducting gap has received a lot of attention. Indeed, the search of a new superconducting state called topological superconductivity is strongly based in the combination of doping classical (s-wave) superconductors with magnetic impurities that arrange spins in a chiral fashion. We present the first results of controlled single-atom manipulation to assemble a chain of Cr atoms on a  $\beta$ -Bi₂Pd superconductor [1,2]. Such magnetic impurities on different substrates allow us to explore many-body effects and exotic phenomena in different experimental spin systems giving an understanding on the parameters on each system.

Organic-inorganic hybrid two dimensional (2D) Ruddlesden-Popper perovskites (RPPs), made of soft insulating organic layers sandwiched between conducting inorganic frameworks, have recently gained a great deal of attention as candidates for the next generation of optoelectronic devices. To gain an understanding of the cooperative lattice relaxation governing the optoelectronic properties of 2D RPPs, we present sub-angstrom resolution imaging of both soft organic layers and inorganic framework in a prototypical 2D lead-halide RPP crystal using a tip-functionalized Scanning Tunneling Microscopy (STM), noncontact Atomic Force Microscope (ncAFM) and Kelvin Probe Force Microscopy (KPFM) corroborated by theoretical simulations, namely Density Functional Theory (DFT)[1]. We unveil the overall twin-domain composition of the RPP crystal, with alternating quasi-one-dimensional electron and hole-channels at neighboring twin-boundaries, possibly responsible for the long-distance exciton transport in RPPs. Reference: [1] https://arxiv.org/abs/2109.05878

#### O 80.6 Fri 11:45 S051

Theory of transport between superconducting states bound to magnetic impurities — •CIPRIAN PADURARIU¹, HAONAN HUANG², BJÖRN KUBALA^{1,3}, CHRISTIAN R. AST², and JOACHIM ANKERHOLD¹ — ¹Institute for Complex Quantum Systems and IQST, Ulm University, Ulm, Germany — ²Max-Planck-Institut für Festkörperforschung, Stuttgart, Germany — ³Institute of Quantum Technologies, German Aerospace Center (DLR), Ulm, Germany

The realization of the Majorana chain [1], a 1D-chain of superconducting states bound to magnetic impurities, suggests that Majorana edge states can be probed using the superconducting tunneling microscope (STM). Recently, we have developed an ideal tool to probe and manipulate the edge states of a Majorana chain. It consists of a mK-STM with its own in-gap Yu-Shiba-Rusinov (YSR) state created by a magnetic impurity on the tip. With this device we have studied the sharp resonant transport between the YSR state on the tip and another YSR on the sample, and have developed the theory [2].

Here, we summarize and expand the theory of YSR-YSR tunneling to phenomena that occur when one YSR state is close to zero energy, near its quantum phase transition. If the zero-energy state sits at the edge of a Majorana impurity chain, theory predicts that the topological edge state will transfer from the chain to the tip.

**Many-body Excitations of a Quantum Spin on a Proximitized Superconductor** — STEFANO TRIVINI¹, •JON ORTUZAR¹, KATERINA VAXEVANI¹, JINGCHEN LI², ANE GARRO¹, F. SEBASTIAN BERGERET³, MIGUEL.A CAZALILLA^{4,5}, and JOSÉ IGNACIO PASCUAL^{1,5} — ¹CICnanoGUNE, San Sebastian,Spain — ²School of Physics, Sun Yat-sen University, Guangzhou 510275, China — ³Centro de Fisica de Materiales (CFM-MPC), 20018 San Sebastian, Spain — ⁴Donostia International Physics Center (DIPC), 20018 San Sebastian, Spain — ⁵Ikerbasque, Basque Foundation for Science, 48013 Bilbao, Spain

In magnetic molecules intrinsic magnetic anisotropy breaks spin degeneracy, allowing inelastic spin excitations that can be protected by a superconducting gap. The coupling of the spin to the superconductor induces Yu-Shiba-Rusinov (YSR) states, detected by scanning tunnelling microscopy (STM) as long-lived quasiparticles excitations inside the superconducting gap.

Here, we observe the signature of both described excitations in an Feporphyrin adsorbed on a Au/V(100) proximitized superconducting surface. We found that the STM tip affects in a similar way both in-gap and out-gap states, hint that they are correlated. Solving an effective Hamiltonian of the system, we describe the observed signals as multiple excitations of entangled states formed by the molecular spin and superconductor.

Quantum spin Hall edge states and interlayer coupling in twisted bilayer  $WTe_2 - \bullet FELIX LÜPKE^1$ , DACEN WATERS², ANH PHAM³, JIAQIANG YAN⁴, DAVID G. MANDRUS⁵, PANCHAPAKESAN GANESH³, and BENJAMIN M. HUNT⁶ - ¹Peter Grünberg Institut (PGI-3), Forschungszentrum Jülich, 52425 Jülich, Germany - ²Physics, University of Washington - ³Center for Nanophase Materials Sciences, Oak Ridge National Lab - ⁴Materials Science and Technology Division, Oak Ridge National Lab - ⁵Department of Materials Science and Engineering, University of Tennessee - ⁶Physics, Carnegie Mellon University

The quantum spin Hall (QSH) effect, characterized by topologically protected spin-polarized edge states, was recently demonstrated in monolayers of the transition metal dichalcogenide (TMD) WTe₂. However, the robustness of this topological protection remains largely unexplored in van der Waals heterostructures containing one or more layers of a QSH insulator. In this work, we use scanning tunneling microscopy and spectroscopy (STM/STS), to study twisted bilayer (tBL) WTe₂ and compare it to topologically trivial natural bilayer. By comparing our experimental observations to first principles calculations, we conclude that the twisted bilayers are weakly coupled, preserving the QSH states and preventing back scattering.

While gating and doping in two-dimensional (2D) materials is well-known, the physics of photosensitizing and advanced optical properties have not been fully investigated, especially in the context of molecular vdW heterostructures (MVHs), that is, regular monolayer stacks on 2D materials. In a recent work [1], we employed an adapted Gersten-Nitzan (two point dipoles) model and real time time-dependent density functional tight-binding to study the optoelectronics of self-assembled monolayers on graphene nanoribbons. We found Fano resonances that cause electromagnetic induced opacity and transparency and reveal an additional incoherent process leading to interlayer exciton formation with a characteristic charge transfer rate. These results showcase hybrid van der Waals heterostructures as paradigmatic 2D optoelectronic stacks, featuring tunable Fano optics and unconventional charge transfer channels. Our findings open a path for improved design of modular multilayer organic photovoltaic devices.

High-throughput stacking reveals emergent and switchable properties of 2D van der Waals bilayers — •SAHAR PAKDEL, ASBJØRN RASMUSSEN, MADS KRUSE, ALIREZA TAGHIZADEH, THOMAS OLSEN, and KRISTIAN SOMMER THYGESEN — CAMD, Computational Atomic-Scale Materials Design, Department of Physics, Technical University of Denmark, 2800 Kgs. Lyngby Denmark

Stacking atomically thin two-dimensional monolayers into van der Waals (vdW) heterostuctures offer new opportunities to tune physical properties of 2D materials. Here we provide a systematic ab initio-based study of homo-bilayers created by stacking several hundreds of stable monolayers containing up to 10 atoms per unit cell. We investigate all configurations commensurate with the primitive cell and verify our approach by comparing our stacking orders with available bulk compounds. For the stable bilayers within a 3 meV/Å² binding energy distance from the most stable configuration, we calculate a range of electronic and magnetic properties. We explore switchable properties in bilayer pairs related with a slide vector. Our work is a step towards rational design of layered vdW materials and contributes to the systematisation of 2D materials. Our results will be available online and integrated with the Computational 2D Materials Database (C2DB) which allows for comparison between mono- and bilayer properties.

TURCHANIN¹ — ¹Friedrich Schiller University Jena, Institute of Physical Chemistry, Germany — ²Ulm University, Central Facility of Materials Science Electron Microscopy, Germany — ³Friedrich Schiller University Jena, Institute of Applied Physics, Germany — ⁴Leibniz Institute of Photonic Technology (IPHT), Germany

Lateral heterostructures (LH) of dissimilar monolayer transition metal dichalcogenides provide great opportunities to build 1D in-plane p-n junctions for subnanometer thin low-power electronic, optoelectronic, optical, and sensing devices. Electronic and optoelectronic applications of such p-n junction devices fabricated using a scalable chemical vapor deposition process yielding MoSe₂-WSe₂ LHs are reported here. Their growth is achieved by in situ controlling the partial pressures of the oxide precursors by a two-step heating protocol. The grown LHs are characterized structurally and optically using optical microscopy, Raman spectroscopy, and photoluminescence spectroscopy. High-resolution transmission electron microscopy further confirms the high-quality 1D boundary between MoSe₂ and WSe₂ in the LH. p-n junction devices are fabricated from these LH and their applicability solar cells, photodetectors, and electroluminescent emitters are demonstrated.

#### O 82.1 Fri 10:30 S053

**Electron- and Hole-Like Transport in Shockley Type Surface States Detected by MONA** — •ANDREAS CHRIST, MARKUS LEISEGANG, PATRICK HÄRTL, and MATTHIAS BODE — Physikalisches Institut, Experimentelle Physik II, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany

In recent years, we have established the STM-based molecular nanoprobe (MONA) technique to detect the transport of hot charge carriers over distances of a few nanometers [1,2]. In short, MONA uses a charge carrier-driven molecular switching events, such as a tautomerization or rotation, to detect currents injected a few nanometers away. Earlier experiments performed on Ag(111) showed that the surface state characteristic for fcc(111) surfaces facilitates effective charge transport between the charge injection point at the tip position and a single phthalocyanine (HPc) detector molecule [3]. Since, however, the energy threshold for tautomerization of HPc exceeds the energy onset of the Ag(111) surface state (E = -63 meV), hole transport remained inaccessible. In order to investigate the influence of the band structure on the propagation of hot charge carriers we compare results of MONA experiments performed on Ag(111) with the isoelectronic Cu(111) surface. Our results reveal that due to the lower surface state onset in Cu(111) at E = -440 meV hole-like charge transport can also be detected.

Exploring polaron stability and defect structures at the Li₄Ti₅O₁₂ (LTO) surface: A combined theoretical and experimental approach - •Yu-TE CHAN¹, MATTHIAS KICK², CRISTINA GROSU^{2,3}, CHRISTOPH SCHEURER¹, and HARALD OBERHOFER² — ¹Fritz-Haber-Institut — ²TU München — ³IEK-9, FZ Jülich Spinel Li₄Ti₅O₁₂ (LTO) is a promising anode material for next-generation allsolid-state Li-ion batteries (ASSB) due to its "zero strain" charge/discharge behavior. Pristine, white LTO possesses poor ionic and electronic conductivity. Through tailoring the sintering protocol, one can produce oxygen vacancies, resulting in a performant, blue LTO material. Polarons induced by oxygen vacancies have been proposed as one of the origins of the higher electronic conductivity. However, detailed knowledge about polaron stability, distribution, and dynamics in LTO bulk and surface has been lacking. By performing Hubbard corrected density functional theory (DFT+U) calculations we are able to show that in fact polaron formation and a possible polaron hopping mechanism can not only play a significant role in enhancing electronic conductivity but boost Li⁺ diffusion nearby through lowering the hopping barrier, in line with the experimentally observed improved conductivities.[1,2] In combination with positron lifetime spectroscopy data and theoretical positron lifetimes, we arrive at a rather complete picture of the bulk vs. surface defect chemistry in LTO particles and the resulting mixed ionic electronic conductivity.

Spin-polarized VLEED from Au(111): Surface sensitivity of the scattering process — •Christoph Angrick¹, Jürgen Braun², and Markus Donath¹ — ¹Westfälische Wilhelms-Universität Münster — ²Ludwig-Maximilians Universität München

Low-energy electron diffraction from Au(111) shows the well-known threefold symmetry of the diffracted electron beams despite the sixfold symmetry of the surface layer. This is due to the influence of the second and deeper layers and the probing depth of the electrons. In this work, we investigated Au(111) with spin-polarized very-low-energy electron diffraction (VLEED) [1,2] experimentally and theoretically. We monitor the reflected specular beam at a fixed polar angle of incidence of  $\Theta = 45^{\circ}$  while the azimuthal orientation of the crystal is varied. This puts the surface sensitivity of the VLEED scattering process to a test.

Our results show that the electron reflection and the spin-orbit-induced reflection asymmetry along  $\overline{\Gamma} \overline{M}$  and  $\overline{\Gamma} \overline{M}'$  are equivalent. The observed sixfold symmetry suggests a sensitivity to one atomic layer only. At azimuth angles deviating from the high-symmetry directions  $\overline{\Gamma} \overline{M}$  and  $\overline{\Gamma} \overline{M}'$ , however, the VLEED signal from Au(111) shows a threefold symmetry. To reveal the origin of this effect, we varied the parameters in the calculation. The results indicate a nonnegligible influence of the second atomic layer in the VLEED scattering process.

O 82.4 Fri 11:15 S053

The quantum corral: Pertubation by adatoms and bonding description by LCAO — •ANDREAS BERECZUK¹, MARTIN STEINAU¹, FABIAN STILP², FRANZ JOSEF GIESSBIL², and KLAUS RICHTER¹ — ¹Institut of Theoretical Physics, University of Regensburg, Germany — ²Institute of Experimental and Applied Physics, University of Regensburg, Germany

The quantum corral, first investigated in 1993 [1] consists of a circle of 48 iron atoms placed on a copper surface and gives rise to a standing wave pattern of the local charge density (LDOS). Afterwards a plurality of different confinement shapes have been investigated [2,3]. We revisited this structure in [4] using atomic force microscope (AFM) and scanning tunneling microscopy (STM). A tight-binding model [5] provides a LDOS in consistency with STM measurements for the original and the perturbed quantum corral. We further consider weak bonds between the AFM tip and the artifical atom, indicated by a widely spread LDOS, by using linear combinations of atomic orbitals (LCAO).

O 82.5 Fri 11:30 S053

Single-Molecule Ultrafast Fluorescence-Detected Pump-Probe Microscopy — •DANIEL FERSCH¹, PAVEL MALÝ^{1,2}, JESSICA RÜHE³, VICTOR LISINETSKII¹, MATTHIAS HENSEN¹, FRANK WÜRTHNER^{3,4}, and TOBIAS BRIXNER^{1,4} — ¹Institut für Physikalische und Theoretische Chemie, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany — ²Faculty of Mathematics and Physics, Charles University, Ke Karlovu 5, 121 16 Prague, Czech Republic — ³Institut für Organische Chemie, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany — ⁴Center for Nanosystems Chemistry (CNC), Universität Würzburg, Theodor-Boveri-Weg, 97074 Würzburg, Germany

The spectroscopic signatures of bulk samples can differ vastly from those of the respective single molecules. In particular, access to the femtosecond dynamics of single molecules remains a large experimental challenge. Here, we present

a novel setup consisting of a spectrally tunable femtosecond laser source and a scanning confocal fluorescence microscope with fully reflective excitation geometry and single-molecule sensitivity. Using a phase-stable interferometer we create a pulse pair with variable time delay to measure the molecular fluorescence excitation spectrum by means of Fourier-transform spectroscopy. By exciting the molecule with an additional prior pump pulse, we gain access to the dynamics of the excited state as a function of the pump-probe delay, resulting in a fluorescence-detected pump-probe spectrum. We have obtained first results on single terrylene bisimide molecules and compare them to a spincoated thin film.

O 82.6 Fri 11:45 S053

Anomalies at the Dirac point in doped graphene (B, N, BN) — •SANGEETA THAKUR^{1,2}, ARINDAM PRAMANIK³, BAHADUR SINGH³, PHILIP WILLKE⁴, MARTIN WENDEROTH⁴, HANS HOFSÄSS⁵, GIOVANNI DI SANTO¹, LUCA PETACCIA¹, and KALOBARAN MAITI³ — ¹Elettra Sincrotrone Trieste, Strada Statale 14 km 163.5, 34149 Trieste, Italy — ²Freie Universität Berlin, Institut für Experimentalphysik Arnimallee 14, 14195 Berlin, Germany — ³Department of Condensed Matter Physics and Materials Science, Tata Institute of Fundamental Research,Homi Bhabha Road, Colaba, Mumbai 400005, India — ⁴IV. Physikalisches Institut, Georg-August-Universität Göttingen, 37077 Göttingen, Germany — ⁵II. Physikalisches Institut, Georg-August-Universität Göttingen, 37077 Göttingen, Germany

The changes in the electronic properties of graphene on SiC, induced by different atomic species, B, N and BN, substituted, via low energy (25eV) ion bombardment were investigated via angle-resolved photoemission spectroscopy. The anomalies at the Dirac point for B, N, and BN doped graphene are attributed to the spectral width arising from the lifetime and momentum broadening in the experiments. An energy gap at the Dirac point of graphene is not observed even after 5 % of B and N substitution [1]. These results will provide new insight to tune the carrier properties of graphene while keeping the Dirac fermionic properties protected, which is important for exploring its technological applications. Interplay of intrinsic and extrinsic states in pinning and passivation of mplane facets of GaN n-p-n junctions — •LARS FRETER^{1,2}, YUHAN WANG^{1,2}, MICHAEL SCHNEDLER¹, JEAN-FRANÇOIS CARLIN³, RAPHAËL BUTTÉ³, NICO-LAS GRANDJEAN³, HOLGER EISELE⁴, RAFAL EDWARD DUNIN-BORKOWSKI^{1,5}, and PHILIPP EBERT¹ — ¹Peter Grünberg Institut, Forschungszentrum Jülich GmbH, 52425 Jülich, Germany — ²Lehrstuhl für Experimentalphysik IV E, RWTH Aachen University, 52056 Aachen, Germany — ³Institute of Physics, Ecole Polytechnique Fédérale de Lausanne (EPFL), 1015 Lausanne, Switzerland — ⁴Technische Universität Berlin, Institut für Festkörperphysik, Hardenbergstr. 36, 10623 Berlin, Germany — ⁵Ernst Ruska-Centrum, Forschungszentrum Jülich GmbH, 52425 Jülich, Germany

Intrinsic and extrinsic pinning and passivation of *m*-plane cleavage facets of GaN *n*-*p*-*n* junctions were investigated by cross-sectional scanning tunneling microscopy and spectroscopy. On freshly cleaved and clean *p*-type GaN( $10\overline{10}$ ) surfaces, the Fermi level is found to be extrinsically pinned by defect states, whereas *n*-type surfaces are intrinsically pinned by the empty surface state. For both types of doping, air exposure reduces the density of pinning states and shifts the pinning levels toward the band edges. These effects are assigned to water adsorption and dissociation, passivating intrinsic and extrinsic gap states. The revealed delicate interplay of intrinsic and extrinsic surface states at GaN( $10\overline{10}$ ) surfaces is a critical factor for realizing flatband conditions at sidewall facets of nanowires exhibiting complex doping structures.

Alchemical machine learning for high entropy alloys — •NATALIYA LOPAN-ITSYNA, GUILLAUME FRAUX, and MICHELE CERIOTTI — École Polytechnique Fédérale de Lausanne, Switzerland

High entropy alloys (HEAs) are a class of metallic materials composed of five or more principal elements. Interest in HEAs has grown over the last decades due to their exceptional structural and mechanical properties. HEAs are particularly challenging for atomistic modeling. Machine-learning (ML) models have emerged as a promising alternative to inaccurate empirical forcefields and very demanding first-principles simulations, with the ability to deliver the accuracy of first principle methods with lower computational resources. However, the complexity of ML models grows exponentially with the number of different elements due to the unfavourable scaling of their associated feature space sizes, limiting the chemical diversity of the systems tackled thus far. To address the problems arising from the high feature space dimensionality, first, we propose a chemical embedding compression scheme to reduce the dimensionality of the feature space required for multi-component systems, based on the framework of Willatt et al [ Phys. Chem. Chem. Phys., 2018 ], and implemented in PyTorch. Second, we generate a dataset of several thousands configurations, assembled from 25 d-block elements, which aims to represent cross-elemental interactions, evaluating their energies and forces at the DFT level. We demonstrate the effectiveness dataset, and provide showcase calculations of the properties of some realistic HEA compositions.

#### O 83.2 Fri 10:45 S054

Stacking the odds: Distribution-biased generative deep learning for molecular design — •JOE GILKES^{1,2}, JULIA WESTERMAYR¹, RHYAN BARRETT³, and REINHARD J. MAURER¹ — ¹Department of Chemistry, University of Warwick, UK — ²HetSys CDT, University of Warwick, UK — ³Warwick Mathematics Institute, UK

Organic electronics applications pose a number of often competing requirements on molecular design that are hard to satisfy by conventional synthesis. Devices such as organic light-emitting diodes (OLEDs) must exhibit closely aligned optoelectronic properties, yet their component molecules must be easily synthesisable and stable. The odds of finding suitable molecules when drawing random samples from chemical space are still too low for targeted design of candidate systems for OLED devices. We develop an automated molecular design approach based on iterative biasing of a generative deep learning model. In successive iterations, the output of this model is filtered with a deep learning surrogate model of electronic structure and then used to retrain the generative model with a bias. This enables us to create models that are progressively biased towards, e.g., higher ionisation potentials, or smaller fundamental gaps. We also demonstrate how we can bias towards multiple properties simultaneously by filtering our results with the SCScore model for synthetic complexity. This creates more synthetically viable molecules while still meeting optoelectronic requirements. Our approach efficiently creates novel molecules with tuned optoelectronic properties. Clustering analysis reveals trends in bonding patterns which can be utilised in molecular design.

#### O 83.3 Fri 11:00 S054

Machine learning TCP phases with domain knowledge of the interatomic bond — •MARIANO FORTI, ALESYA BURAKOVSKAYA, RALF DRAUTZ, and THOMAS HAMMERSCHMIDT — ICAMS, Ruhr-Universität Bochum, Universitätsstr. 150, 44801 Bochum, Germany.

The understanding of the precipitation of topological close packed (TCP) phases in single-crystal superalloys is of central importance for the design of these materials for high-temperature applications. However, the structural complexity of these intermetallic compounds and the chemical complexity of the superalloys with typically N=5-10 elements hampers the exhaustive sampling of chemical space by density-functional theory (DFT) calculations. For example, the computation of the convex hull of the R phase with 11 inequivalent lattice sites would require N¹¹ DFT calculations in an N-component system. We overcome this computational limitation by combining machine learning (ML) techniques with descriptors of the local atomic environment of the TCP phases. We present descriptors that are derived from bond order potential (BOP) theory which retain domain knowledge of the interatomic interaction from tight-binding Hamiltonians. We demonstrate that these descriptors enable us to predict the structural stability of TCP phases with simple regression algorithms. We apply this methodology to several systems with experimental evidence of R phase formation.

#### O 83.4 Fri 11:15 S054

Ab initio random structure search of organic molecules at substrates — •DMITRII MAKSIMOV^{1,2} and MARIANA ROSS1^{1,2} — ¹Fritz Haber Institute of the Max Planck Society, Berlin, Germany — ²Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, Germany

Finding stable structures of molecular adsorbates (in isolation or forming layers) from calculations is challenging, exacerbated when the adsorbates are flexible. To make matters more complicated, in these situations, it is often difficult to find good and cheap potentials of such complex interfaces that allow a thorough and reliable global search of the structural space. To make this problem tractable with ab initio potentials, we present a random global geometry optimization package that can explicitly take into account the internal degrees of freedom of molecules, their position and orientation with respect to fixed surroundings, as well as periodic boundary conditions [1]. Electronic structure calculations and local geometry optimizations are performed through a connection to the ASE software [2], making it possible to interface this algorithm with various codes. To increase the efficiency of geometry optimizations, we introduce a framework to construct initial approximate Hessians for BFGS algorithms that are specially tailored to accelerate the relaxation of van der Waals bonded structures and handle large structural changes. We showcase the algorithm for the adsorption of di-L-alanine at Cu(110). [1] https://github.com/sabia-group/gensec [2] Larsen et. al., J. Phys.: Condens. Matter 29, 273002 (2017).

#### O 83.5 Fri 11:30 S054

Active learning and element-embedding approach in neural networks for infinite-layer versus perovskite oxides — Armin Sahinovic and •Benjamin Geisler — Fakultät für Physik, Universität Duisburg-Essen

The observation of superconductivity in NdNiO₂ films on SrTiO₃(001) by Li *et al.* [1] has sparked considerable interest in the materials class of infinite-layer oxides. Here we combine first-principles simulations and active learning of neural networks to explore formation energies of oxygen vacancy layers, lattice parameters, and their statistical correlations in infinite-layer versus perovskite oxides across the periodic table, and place the superconducting nickelate and cuprate

families in a comprehensive context. Neural networks accurately predict these observables, which act as a fingerprint of the complex reduction reaction, using only a fraction of the data for training. Unbiased by external knowledge, element embedding autonomously identifies chemical similarities between the individual elements in line with human knowledge. Active learning renders the training highly efficient, based on the physical concepts of entropy and information, and provides systematic accuracy control [2]. We recently applied this concept also to nitrides and fluorides [3]. This exemplifies how AI may assist on the quantum scale in discovering novel materials with optimized properties.

**Indirect learning interatomic potential models for accelerated materials simulations** — •JOE D. MORROW and VOLKER L. DERINGER — Department of Chemistry, Inorganic Chemistry Laboratory, University of Oxford, Oxford OX1 3QR, United Kingdom

Machine learning (ML) based interatomic potentials are emerging tools for materials simulations but require a trade-off between accuracy and speed. We show how one ML potential can be used to train another: we use an existing, accurate, but more computationally expensive model to generate reference data (labels and locations) for a series of much faster "indirectly-learned" potentials. Extensive reference datasets can be easily generated without the need for quantummechanical reference computations at the indirect learning stage, and we find that the additional data significantly improve the predictions of fast potentials with less flexible functional forms.

We apply the technique to disordered silicon, including a simulation of vitrification and polycrystalline grain formation under pressure with a system size of a million atoms. When comparing indirectly learned potentials to models learned directly from a DFT-labelled database, the latter make unphysical predictions for large systems ( $10^5$  atoms) that are not apparent in smaller simulations ( $\leq 10^4$  atoms). This emphasises the importance of carefully validating ML potentials *chemically*, not only via numerical error measures. Our work provides conceptual insight into the machine learning of interatomic potential models, and it suggests a route toward accelerated simulations of nanostructured materials.

O 83.7 Fri 12:00 S054

**Predicting hot electrons free energies from ground-state data** — •CHIHEB BEN MAHMOUD, FEDERICO GRASSELLI, and MICHELE CERIOTTI — EPFL, Lausanne, Switzerland

Machine-learning potentials, while extremely successful in describing the stability of condensed phases, are usually trained on ground-state electronic-structure calculations depending exclusively on the atomic positions and ignoring the electronic temperature. Hence, they are limited in their ability to describe hot electrons. We introduce a rigorous framework to calculate the finite-temperature electron free energy based exclusively on ground-state total energy and electronic density of states, while allowing to sample on-the-fly the electronic free energy at any temperature [1]. Our physically-motivated approach facilitates modeling material properties in extreme conditions with a fraction of the usual cost. We demonstrate it by computing the equation of state and heat capacity of hydrogen in planetary conditions. This approach demonstrates the impact of a universal model describing structural and electronic properties inexpensively and its ability to enable more accurate and predictive materials modeling and design.

O 83.8 Fri 12:15 S054

Machine Learning the RPA density-density response function — •MARIO ZA-UCHNER, JOHANNES LISCHNER, and ANDREW HORSFIELD — Imperial College London, London, United Kingdom

Clusters and nanoparticles are used in a variety of scientific and industrial applications, including optoelectronics, photocatalysis, single electron transistors and medical imaging, among others. Electronic excitations often play a key role in these applications, but theoretical techniques for calculating excited-state properties of materials, such as the first-principles GW/Bethe-Salpeter method, are typically limited to very small systems. A key bottleneck of such excited-state calculations of clusters and nanoparticles is the determination of the static density-density response function, which is often calculated using a sum-overstates technique. In this talk, we present a technique to decompose the density-density response function into atomic contributions. This can be achieved by exploiting the locality of the density-density response function in non-metallic systems. These atomic contributions can then be used to train a machine-learning model using a set of structural features with the same rotational symmetry as the atomic response functions, thus allowing direct prediction of the density-density response functions and the same rotational symmetry.

#### O 83.9 Fri 12:30 S054

**MD-based Raman Spectra using Machine Learning** — •MANUEL GRUMET¹, KARIN S. THALMANN¹, TOMÁŠ BUČKO^{2,3}, and DAVID A. EGGER¹ — ¹Department of Physics, Technical University of Munich, Garching, Germany — ²Comenius University in Bratislava, Slovakia — ³Slovak Academy of Sciences, Slovakia Theoretical calculations of Raman spectra based on molecular dynamics (MD) trajectories allow to directly incorporate both anharmonic and temperaturedependent effects and thus yield more realistic spectra compared to a phononbased approach [1]. The spectra can be calculated from the Fourier-transformed velocity correlation function of the polarizability tensor  $\alpha$ . However, this requires evaluating  $\alpha$  for a large number of MD configurations along each trajectory, which has high computational cost if done by ab-initio methods.

We therefore use kernel-based machine learning (ML) methods with densitybased descriptors [2, 3] to predict  $\alpha$  based on atomic positions. Ab-initio calculations are then only needed for obtaining a training data set, reducing the computational cost significantly. We use a number of test systems, including both solids and small molecules, to test and optimize several different variants of this approach and compare the achieved prediction performances. We also test transferability of the trained models to trajectories at different temperatures. [1] M. Thomas et al., Phys. Chem. Chem. Phys. **15**, 6608 (2013)

[2] A. P. Bartók et al., Phys. Rev. B 87, 184115 (2013)

[3] A. Grisafi et al., Phys. Rev. Lett. 120, 036002 (2018)

O 83.10 Fri 12:45 S054 Thermal Transport via Green-Kubo Method and Message-Passing Neural-Network Potentials — MARCEL F. LANGER^{1,2}, FLORIAN KNOOP^{2,3}, CHRISTIAN CARBOGNO², MATTHIAS SCHEFFLER², and •MATTHIAS RUPP^{2,4} — ¹TU Berlin, Germany — ²The NOMAD Laboratory, FHI-MPG & HU Berlin, Germany — ³Theoretical Physics Division, Linköping U, Sweden — ⁴Konstanz U, Germany Accurate, precise, and efficient computational access to thermal conductivities of materials is relevant for scientific understanding and industrial applications. The Green-Kubo method with first-principles calculations enables the determination of thermal conductivities, even for strongly anharmonic materials [1]. However, the high computational cost of long dynamics simulations of large supercells required for convergence limits applicability for large-scale, high-throughput materials discovery. Machine-learning potentials can reduce this cost [2].

Message passing neural networks (MPNNs) are a promising, but for this task yet untested, class of models due to their relational inductive bias, implicit longrange nature, and ability to incorporate directional information. We adapt the heat flux definition for MPNNs, investigate the impact of equivariance, present a systematic account of their convergence behavior and performance, and compare them to a simpler baseline model.

### O 84: Overview Talk Claus M. Schneider (joint session O/CPP)

Time: Friday 13:15-14:00

Invited Talk O 84.1 Fri 13:15 S054 Exploring the Mysteries of Topology in Quantum Materials — •CLAUS M. SCHNEIDER — Peter Grünberg Institut PGI-6, Forschungszentrum Jülich, 52425 Jülich

A characteristic feature of emergent or quantum materials is the competition of various spin-dependent interactions, such as spin-orbit coupling and exchange interaction. In addition, depending on the material system, there may be a breaking of time-reversal and/or inversion symmetries at play. As a consequence, topological materials may range from metals to insulators. In the vicinity of the Fermi level, this situation leads to peculiar electronic dispersions associated with Dirac and Weyl points, eventually also resulting in complex spin textures

in momen- tum space. The interplay of competing mechanisms often results in unusual charge and spin transport phenomena in such materials. In order to understand the physical properties of quantum materials on a fundamental level, we need to explore these electronic states in detail and disentangle the role of the various interactions. For this purpose, we employ electron spectroscopic approaches, which explicitly take the electron spin as an experimental quantity into account. In this contribution we discuss an avenue starting from simple single-crystalline systems (e.g. W(011), Fe(100) and Co(100)) to more complex 2D and 3D quantum materials and detail the role of the individual interactions and symmetry-breaking mechanisms by experimental examples.

### Sessions

- Invited Talks, Tutorials, Contributed Talks, and Posters -

### SOE 1: Tutorial: Stochastic Processes from Financial Risk to Genetics (joint session SOE/TUT/BP/DY)

Macroscopic and microscopic models from Economy to Biology must account for stochasticity on various levels. While classical physics strives for deterministic descriptions through differential equations from fundamental level to thermodynamics, many physics-based models on higher level explicitely include stochasticity from various sources. Discrete and continuous stochastic processes then become the mathematical foundation of these models. This tutorial highlights classical as well as current methods and approaches of probabilistic models and stochastic processes in physics, biology as well as socio-economic systems, thereby bridging the risk to extinction in genetics with its economic counterpart. (Session organized by Jens Christian Claussen.)

Time: Sunday 16:00-18:30

#### Tutorial

SOE 1.1 Sun 16:00 H4 Diffusion approximations for particles in turbulence - •BERNHARD MEHLIG - University of Gothenburg, Gothenburg, Sweden

The subject of this tutorial is the dynamics of particles in turbulence, such as micron-sized water droplets in the turbulent air of a cumulus cloud. The particles respond in intricate ways to the turbulent fluctuations. Non-interacting particles may cluster together to form spatial patterns - even though the turbulent fluid is incompressible [1]. In this tutorial I explain how to understand spatial clustering using diffusion approximations, highlighting an analogy with Kramers' escape problem [2]. I introduce/review the necessary elements of diffusion theory. My goal is to give a pedagogical introduction to diffusion approximations in non-equilibrium statistical physics, using particles in turbulence as an example.

[1] K. Gustavsson and B. Mehlig, Statistical models for spatial patterns of heavy particles in turbulence, Adv. Phys. 65 (2016) 57 (read Sections 1, 3.1, and 6.1).

[2] H. A. Kramers, Brownian motion in a field of force and the diffusion model of chemical reactions, Physica 7 (1940) 284 (read up to eq. (17)).

SOE 1.2 Sun 16:50 H4 Tutorial Probabilities in physics, paradoxes and populations - • TOBIAS GALLA - Instituto de Física Interdisciplinary Sistemas Complejos, IFISC (CSIC-UIB), Campus Universitat Illes Balears, E-07122 Palma de Mallorca, Spain

It is notoriously hard for humans to develop a good intuition for probabilities and stochastic processes. Our brains are not able to do this naturally, and there

are numerous mistakes which are easy to make. These mistakes are in fact made regularly in the press (sometimes perhaps deliberately). More worrisome, decision makers such as judges, doctors or politicians are also prone to mishandling probabilities. In this tutorial I will outline a few of these traps, and how to avoid them. I will also discuss the nature of probabilistic models of physical processes - is there genuine randomness in the world around us? I will then present a number of instances in which physics approaches combined with stochastic modelling can make a difference. As one example, I will outline experimental and theoretical results which highlight the importance of stochastic processes in population dynamics. Other examples will include stochastic processes in genetics, the evolution of cancer and in game theory.

#### SOE 1.3 Sun 17:40 H4 Tutorial Risk Revealed: Cautionary Tales, Understanding and Communication -•PAUL EMBRECHTS — Department of Mathematics, ETH Zürich

The title of the tutorial refers to a forthcoming book, to be published by Cambridge University Press, co-authored with Valérie Chavez-Demoulin (Lausanne) and Marius Hofert (Waterloo). Extreme Value Theory (EVT) offers a mathematical tool for the modeling of so-called What-If events, or stress scenarios. I will present several examples of risk-based decision-making and show how EVT can be used as part of the solution. The current pandemic has clearly shown that the communication of scientific evidence has a difficult stand in the ubiquitous environment of social media. I will discuss some examples of this struggle.

### SOE 2: Invited Talk Rainer Hegselmann: Opinion Formation

Time: Monday 9:30-10:15

#### **Invited Talk** SOE 2.1 Mon 9:30 H11 Two-armed bandits versus Carnapian truth seekers and epistemic free riders with bounded confidence — • RAINER HEGSELMANN — Frankfurt School of Finance & Management, Adickesallee 32-34, 60322 Frankfurt

In its original version, the so-called bounded confidence model only knows the exchange of opinions among individuals. The individuals may have formed their opinions beforehand through systematic experience (observation, experimentation), but no signal from the external world enters the modeled social exchange process. Later, Ulrich Krause and I extended the model to include a signal from the external world acting on the social exchange process. However, we put all details of this influence process into a black box.

In my talk I will present how this black box can be opened: The social exchange process of the bounded confidence model is linked to an explicitly modeled experimentation and evaluation of experimentally obtained data. The starting point is a community that has a choice between n strategies (n = 2), each leading to success with a constant but unknown probability. Such problems are known as n-armed-bandit-problems. It is further assumed that the community consists only partly of truth-seekers who 'conscientiously', following certain rules from Carnap's inductive logic, evaluate their experiences. Another part of the community consists of epistemic free riders, who do no statistics at all, but opportunistically follow their close-by neighbors. The talk will show that such a setting allows to answer questions about the efficiency of different epistemic policies.

### **SOE 3: Economic Models**

Time: Monday 10:15-11:45

SOE 3.1 Mon 10:15 H11 Generic catastrophic poverty when selfish investors exploit a degradable common resource — •CLAUDIUS GROS — Institute for Theoretical Physics, Goethe University Frankfurt a.M.

The productivity of a common pool of resources may degrade when overly exploited by a number of selfish investors, a situation known as the tragedy of the commons. We examine the case that degradation is functionally dependent on total investments. The payoffs, which are independently optimized by each

agent, are given by the balance between the return from investing in the common resource and the investment costs, which are a function of the agent-specific per-unit costs. The payoffs of most agents are shown rigorously not to scale as 1/N, the result for cooperating agents, but as 1/(N*N), where N is the number of agents. This scaling in the stationary state is denoted catastrophic poverty. A finite number of oligarchs may be present in addition, with the payoffs of the oligarchs remaining finite even in the large-N limit. The results hold under very general conditions for a wide class of models.

#### SOE 3.2 Mon 10:45 H11

**Games in rigged economies** — •LUIS F SEOANE — Systems Biology Department, Spanish National Center for Biotechnology (CNB-CSIC), C/ Darwin 3, Madrid, Spain.

Modern economies evolved from simpler material exchanges into very convoluted systems. Today, a multitude of aspects can be regulated, tampered with, or left to chance; these are economic degrees of freedom (DOF) which shape the flow of wealth. Economic actors can exploit them, at a cost, and bend that flow in their favor. If intervention becomes widespread, microeconomic strategies can collide or resonate, building into macroeconomic effects. How viable is a *rigged* economy? How do growing economic complexity and wealth affect it? We capture essential elements of rigged economies with a simple model. Nash equilibria in tractable cases show how increased intervention turns economic DOF from minority into majority games through a dynamical phase. This is reproduced by agent-based simulations of our model, which allow us to explore scenarios out of reach for payoff matrices. Increasing economic complexity appears as a mechanism to defuse cartels or consensus situations. But excessive complexity enters abruptly into a regime of large fluctuations (resulting from non-competitive intervention efforts coupled across DOF) that threaten the system's viability. Thus high economic complexity can result in negative spillover from non-competitive actions. Simulations suggest that wealth must grow faster than linearly with complexity to avoid this large fluctuations regime. Our model provides testable conclusions and phenomenological charts to guide policing of rigged economies.

SOE 3.3 Mon 11:00 H11

**Risk Preferences in Time Lotteries** — YONATAN BERMAN¹ and •MARK KIRSTEIN² — ¹King's College London — ²Max Planck Institute for Mathematics in the Sciences, Leipzig

An important but understudied question in economics is how people choose when facing uncertainty in the timing of events. Here we study preferences over time lotteries, in which the payment amount is certain but the payment time is uncertain. Expected discounted utility theory (EDUT) predicts decision makers to be risk-seeking over time lotteries. We explore a normative model of growthoptimality, in which decision makers maximise the long-term growth rate of their wealth as suggested by the framework of ergodicity economics. Revisiting experimental evidence on time lotteries, we find that growth-optimality accords better with the evidence than EDUT. We outline future experiments to scrutinise further the plausibility of growth-optimality.

#### SOE 3.4 Mon 11:15 H11

**Macroscopic approximation for an agent based socio-economic model** – •SÖREN NAGEL¹, ECKEHARD SCHÖLL^{1,2}, and JOBST HEITZIG¹ – ¹Potsdam Institute for Climate Impact Research – ²Institut für Theoretische Physik, TU Berlin We investigate an agent-based model for economic growth that contains an underlying social network in order to incorporate bounded rationality. To further extend the results presented in [1] we combine a moment closure approach for the economy and a stochastic differential equation approximation for the social choice. With this approach we can reproduce some characteristics of the original model like economic inequality, and we are able to link the business cycle oscillations to noise-induced excitation oscillations and coherence resonance.

[1] Yuki M Asano, Jakob J Kolb, Jobst Heitzig, and J Doyne Farmer. Emergent inequality and business cycles in a simple behavioral macroeconomic model. PNAS 118, e2025721118 (2021).

#### SOE 3.5 Mon 11:30 H11

Location: H11

Location: H11

Socioeconomic modeling of a fossil-fuel and renewable-energy based twosector economy — •PHILIPPE LEHMANN¹, ECKEHARD SCHÖLL^{1,2}, and JOBST HEITZIG¹ — ¹Potsdam Institute for Climate Impact Research — ²Institut für Theoretische Physik, TU Berlin

We study a stylized economic model to capture the influence of social dynamics on investment decisions in a fossil-fuel and renewable energy based two-sector production economy. For this purpose the socioeconomic model in [1] is extended to two sectors. Although this model is based on simple assumptions, it shows extensive complex dynamics which we illustrate graphically to reveal the underlying mechanism. This empirical approach allows us to draw several analogies to patterns of our real economy that challenge current econometric models.

### **SOE 4: Financial Risk**

Time: Monday 12:00-12:30

SOE 4.1 Mon 12:00 H11

From many-body physics to financial markets: sparse modeling for inverse problems — •DANIEL GUTERDING — Fachbereich Mathematik, Naturwissenschaften und Datenverarbeitung, Technische Hochschule Mittelhessen, Wilhelm-Leuschner-Straße 13, 61169 Friedberg, Germany

The accurate valuation of plain-vanilla derivatives is one of the fundamental tasks of mathematical finance. In particular, arbitrage-free interpolations of marketquoted option prices or implied volatilities are needed for the pricing of most options. For this purpose, various standard interpolation techniques have been modified to accommodate the no-arbitrage conditions required by quantitative finance.

Despite this problem being so important for option pricing, the available approaches are quite involved and largely not stable against the noisy inputs that are often encountered in practical applications. Making use of recent progress on inverse problems in many-body physics [1], our method [2] is based on the relation between the terminal density of the underlying asset and plain-vanilla option prices.

We construct a few-parameter model for this relation using the singular value decomposition, which obviates the need to explicitly choose expansion or regression basis functions, such as they are encountered in many other methods. Furthermore, we show that our method by construction delivers arbitrage-free models even for inputs containing noise or severe arbitrage.

SOE 4.2 Mon 12:15 H11 An ABM Marketmodel Study: Dynamics, Stochastics and Rule based Decisions — •MAGDA SCHIEGL — University of Applied Sciences Landshut, Am Lurzenhof 1, D-84036 Landshut

Riskmanagement is a main topic in insurance business with a variety of traditional methods. In recent years more and more methods of the field of complex systems as complex networks or ABMs play an important role. One of the first in the insurance mathematical literature published ABMs is by Ingram et al. [1]. The paper describes a model of a competitive (insurance and not only insurance) market that shows cyclical behavior.

We reformulate the above cited model in a form that makes it accessible for analytical as well as numerical treatment and discussion. We find three, interacting components of the model: the dynamics, the stochastics and the rule based decisions. The agents, insurance companies, play a rule based strategic game, competing with each other. The actions of the agents depend on both, the statistics of the single agent and the statistics of the market as a whole. We analyze the dynamics of the model being responsible for a parameter dependent, periodic behavior and investigate its stochastic and rule-based components. We implemented the model as a Monte Carlo simulation and examine the interactions of the model's different components.

### **SOE 5: Social Systems, Opinion and Group Dynamics**

Time: Monday 12:30-13:30

SOE 5.1 Mon 12:30 H11 Bounded rational agents playing a public goods game — •PRAKHAR GODARA, TILMAN DIEGO ALEMAN, and STEPHAN HERMINGHAUS — Max Planck Institute for Dynamics and Self-Organization (MPIDS), 37077 Goettingen, Germany An agent-based model for human behavior in the well-known public goods game (PGG) is developed making use of bounded rationality, but without invoking mechanisms of learning. The underlying Markov decision process is driven by a path integral formulation of reward maximization. The parameters of the model

can be related to human preferences accessible to measurement. Fitting simulated game trajectories to available experimental data, we demonstrate that our agents are capable of modeling human behavior in PGG quite well, including aspects of cooperation emerging from the game. We find that only two fitting parameters are relevant to account for the variations in playing behavior observed in 16 cities from all over the world. We thereby find that learning is not a necessary ingredient to account for empirical data.

SOE 5.2 Mon 12:45 H11

**Social nucleation:** Group formation as a phase transition — FRANK SCHWEITZER and •GEORGES ANDRES — ETH Zürich, Chair of Systems Design, Switzerland

The spontaneous formation and subsequent growth, dissolution, merger, and competition of social groups bear similarities to physical phase transitions in metastable finite systems. In this talk, I will examine three different scenarios, percolation, spinodal decomposition, and nucleation, to describe the formation of social groups of varying size and density. In an agent-based model, I will present a feedback between the opinions of agents and their ability to establish links. Groups can restrict further link formation, but agents can also leave if costs exceed the group benefits. I will show how to identify the critical parameters for costs and benefits and social influence to obtain either one large group or the stable coexistence of several groups with different opinions. Analytic investigations then allow to derive different critical densities that control the formation and coexistence of groups. This approach sheds light on the much-neglected early stage of network growth and the emergence of large connected components.

SOE 5.3 Mon 13:00 H11

**Multiscale Causal Structure in Armed Conflict** — •NIRAJ KUSHWAHA and ED-WARD LEE — Complexity Science Hub Vienna, Josefstädter Straße 39, 1080 Vienna, Austria

Armed conflict is a major and ongoing problem around the world today. The very features of conflict that makes it important, its multiscale and multidimensional impact, render it difficult to understand quantitatively. Here, we introduce a first principles approach to conflict by clustering sequences of conflict events into causal conflict avalanches. We rely on armed conflict data from the ACLED

project, occurring from the years 1996-2021 in Africa. We investigate different spatial and temporal scales with a systematic coarse-graining procedure. For space, we tile the region with semi-regular bins that constitute our level of resolution, and for time we group days into discrete intervals. This formalism bridges the gap between microscopic and macroscopic descriptions of armed conflict. To infer causal relationships between different spatial bins we use a standard non-linear measure of statistical dependency called transfer entropy. Using transfer entropy, we extract a directed causal network that links adjacent geographic locations. We then leverage this causal structure to join two conflict events if they are adjacent in time and belong to adjacent and causally connected spatial bins. We call the resulting sequences of conflict events, conflict avalanches. Further statistical and dynamical analysis reveal that many conflict avalanche features follow power-law distributions. Our work paves way for future investigation on classes of models which can explain the emergence of scaling in conflict across different scales.

#### SOE 5.4 Mon 13:15 H11

**Ordering dynamics and path to consensus in multi-state voter models** — LUCÍA RAMIREZ, MAXI SAN MIGUEL, and •TOBIAS GALLA — Instituto de Física Interdisciplinary Sistemas Complejos, IFISC (CSIC-UIB), Campus Universitat Illes Balears, E-07122 Palma de Mallorca, Spain

We investigate the time evolution of the density of active interfaces and of the entropy of the distribution of agents among opinions in multi-state voter models. Individual realisations undergo a sequence of extinctions until consensus is reached. After each elimination the population remains in a meta-stable state. The density of active interfaces and the entropy in these states varies from realisation to realisation. Making some simple assumptions we are able to analytically calculate the average density of active interfaces and the average entropy in each of these states. We also show that, averaged over realisations, the density of active interfaces decays exponentially, with a time scale set by the size and geometry of the interaction graph, but independent of the initial number of opinion states. The decay of the average entropy is exponential only at long times when there are at most two opinions left in the network. Finally, we show how meta-stable states comprised of only a subset of opinions can be engineered as genuinely stationary states by introducing precisely one zealot in each of the prevailing opinions.

### SOE 6: Data Analytics for Complex Systems (joint session DY/SOE)

Time: Monday 15:00-17:45

#### SOE 6.1 Mon 15:00 H18

**Estimating covariant Lyapunov vectors from data** — •NAHAL SHARAFI, CHRI-STOPH MARTIN und SARAH HALLERBERG — Hamburg University of Applied Sciences, Hamburg, Germany

Covariant Lyapunov vectors characterize the directions along which perturbations in dynamical systems grow. They have also been studied as predictors of critical transitions and extreme events. For many applications, it is necessary to estimate these vectors from data since model equations are unknown for many interesting phenomena. We propose a novel approach for estimating covariant Lyapunov vectors based on data records without knowing the underlying equations of the system. In contrast to previous approaches, our approach can be applied to high-dimensional datasets. We demonstrate that this purely data-driven approach can accurately estimate covariant Lyapunpov vectors from data records generated by low and high-dimensional dynamical systems. Additionally we test for the robustness against noise in a low-dimensional dynamical system.

#### SOE 6.2 Mon 15:15 H18

Extending the limits of Electrochemical Impedance Spectroscopy with Machine Learning and Digital Twins — •LIMEI JIN^{1,2}, FRANZ P. BERECK², CHRISTIAN H. BARTSCH², JOSEF GRANWEHR², RÜDIGER-A. EICHEL², KARSTEN REUTER¹, and CHRISTOPH SCHEURER¹ — ¹Fritz-Haber-Institut der MPG, Berlin, Germany — ²IEK-9, Forschungszentrum Jülich, Jülich, Germany Electrochemical impedance spectroscopy (EIS) is widely used to characterize electrochemical energy conversion systems. The traditional analysis with equivalent circuit models (ECM) has recently been augmented by a transform based distribution of relaxation times (DRT) analysis which allows one to reduce the ambiguity in the construction of ECMs and thus overfitting. Yet, DRT, just like most traditional analyses, is firmly based in the linear response regime as well as based on frequency sweeps on a logarithmic scale. The latter makes these approaches time-consuming, the first limits their scope severely. To develop novel

experimental spectroscopic excitation schemes that address these limitations, a model space of sufficiently realistic systems is required that substitutes for timeconsuming measurements in terms of a digital twin. We present a joint experimental and theoretical approach for the construction of such a target space for the case of battery cell performance and ageing behaviour. SOE 6.3 Mon 15:30 H18

Bayesian approach to anticipate critical transitions in complex systems – •MARTIN HESSLER^{1,2} and OLIVER KAMPS² – ¹Westfälische Wilhelms-Universität Münster, 48149 Münster – ²Center for Nonlinear Science, Westfälische Wilhelms-Universität Münster, 48149 Münster

Complex systems in nature, technology and society can undergo sudden transitions between system states with very different behaviour. In order to avoid undesired consequences of these tipping events, statistical measures as variance, autocorrelation, skewness and kurtosis have been proposed as leading indicators based on time series analysis. Under favourable conditions they can give a hint of an ongoing bifurcation-induced destabilization process. However, they suffer from their loose connection to complex system dynamics, sensitivity to noise and sometimes misleading trends. Therefore, we want to present an alternative approach assuming the dynamical system being described by a Langevin equation. Starting from this stochastic description, we combine MCMC sampling, rolling window methods and Bayesian reasoning to derive the drift slope as an alternative early warning sign. The Bayesian approach enables us to define credibility bands which make it easier to distinguish random fluctuations from real trends that imply a less resilient system. Our investigations suggest that the estimation procedure is rather robust even under strong noise. Besides, the noise level of the system is computed to get insights into the probability of a noise induced transition. We want to present some of the results and discuss possible limitations and tasks of future research.

#### SOE 6.4 Mon 15:45 H18

Stochastic Interpolation of Sparsely Sampled Time Series by a Superstatistical Random Process and its Synthesis in Fourier and Wavelet Space — •JEREMIAH LÜBKE¹, JAN FRIEDRICH², and RAINER GRAUER¹ — ¹Institute for Theoretical Physics I, Ruhr-University Bochum, Universitätsstr. 150, 44801 Bochum, Germany — ²ForWind, Institute of Physics, University of Oldenburg, Küpkersweg 70, 26129 Oldenburg, Germany

A novel method is presented for stochastic interpolation of a sparsely sampled time signal based on a superstatistical random process generated from a Gaussian scale mixture. In comparison to other stochastic interpolation methods such as kriging, this method possesses strong non-Gaussian properties and is thus applicable to a broad range of real-world time series. A precise sampling algorithm is provided in terms of a mixing procedure that consists of generating a field  $u(\xi, t)$ , where each component  $u_{\xi}(t)$  is synthesized with identical underlying noise but covariance  $C_{\xi}(t, s)$  parameterized by a log-normally distributed parameter  $\xi$ . Due to the Gaussianity of each component  $u_{\xi}(t)$ , standard sampling algorithms and methods to constrain the process on the sparse measurement points can be exploited. The scale mixture u(t) is then obtained by assigning each point in time t a  $\xi(t)$  and therefore a specific value from  $u(\xi, t)$ , where  $\log \xi(t)$  is itself a realization of a Gaussian process with a correlation time large compared to the correlation time of  $u(\xi, t)$ . Finally, a wavelet-based hierarchical representation of the interpolating paths is introduced, which is shown to provide an adequate method to locally interpolate large datasets.

#### SOE 6.5 Mon 16:00 H18

**Global sensitivity analysis of Monte Carlo models using Cramer-von Mises distance** – •SINA DORTAJ^{1,2} and SEBASTIAN MATERA^{1,2} – ¹Fritz-Haber-Institut der Max-Planck-Gesellschaft, Faradayweg 4-6, 14195 Berlin, Germany – ²Institute for Mathematics, Freie Universität Berlin, Arnimallee 6, 14195 Berlin, Germany

Typically, the parameters entering a physical simulation model carry some kind of uncertainty, e.g. due to the intrinsic approximations in a higher fidelity theory from which they have been obtained. Global sensitivity analysis (GSA) targets quantifying which parameters uncertainties impact the accuracy of the simulation results, e.g. to identify which parameters need to be determined more accurately.

We present a GSA approach on basis of the Cramers-von Mises distance. Unlike prevalent approaches it combines the following properties: i) it is equally suited for deterministic as well as stochastic model outputs, ii) it is free of gradients, and iii) it can be estimated from any suitable numerical quadrature (NQ) without further numerical tricks. Using Quasi-Monte Carlo for NQ and prototypical first-principles kinetic Monte Carlo models (kMC), we examine the performance of the approach. We find that the approach typically converges in a modest number of NQ points. Furthermore, it is robust against even extreme relative noise. All these properties make the method particularly suited for expensive (kinetic) Monte Carlo models, because we can reduce the number of simulations as well as the target variance of each of these.

#### 15 min. break

SOE 6.6 Mon 16:30 H18

Reproducible and transparent research software pipelines using semantic research data management and common workflow language — •ALEXANDER SCHLEMMER^{1,2,5}, INGA KOTTLARZ^{1,3}, BALTASAR RÜCHARDT^{1,5}, ULRICH PARLITZ^{1,3,5}, and STEFAN LUTHER^{1,4,5} — ¹Max Planck Institute for Dynamics and Self-Organization, Göttingen — ²IndiScale GmbH, Göttingen — ³Institute for the Dynamics of Complex Systems, Georg-August-Universität Göttingen — ⁴Institute of Pharmacology and Toxicology, University Medical Center Göttingen — ⁵German Center for Cardiovascular Research (DZHK), Partner Site Göttingen

Sustainable and well-documented scientific software is essential for effectiveness and reproducibility in data-intensive research. In practice, incompletely documented software hinders in many cases replicability, reproducibility and method comparison. In our terminology, documentation includes method and algorithm descriptions as well as human- and machine-readable representations of parameters, initial conditions and data, versions and dependencies and a welldefined software execution environment. We present an approach combining semantic data management with CaosDB and processing pipelines with Common Workflow Language (CWL), showing use cases from dynamical systems research. The CWL-based environment provides a transparent description of the process and includes metadata that can be searched within CaosDB. Input-/output-data and parameters can be directly linked to algorithms and software snapshots. The employment of containers simplifies reproducibility and interoperability.

#### SOE 6.7 Mon 16:45 H18

**MDSuite:** A post-processing engine for particle simulations — •FABIAN ZILLS¹, SAMUEL TOVEY¹, FRANCISCO TORRES-HERRADOR², CHRISTOPH LOHRMANN¹, and CHRISTIAN HOLM¹ — ¹Institute for Computational Physics, University of Stuttgart, Stuttgart, Germany — ²von Karman Institute for Fluid Dynamics, Rhode-St-Genese, Belgium

Particle-based simulations are experiencing a rapid growth wherein system sizes in the hundreds of thousands or even millions are becoming commonplace. With

this growth in system size comes the additional challenge of post-processing the simulation data.

In this talk, we introduce the Python package MDSuite. MDSuite is designed for the post-processing of particle-based simulation in an efficient manner and on modern hardware. Built on top of TensorFlow, MDSuite calculators are fully parallelised, gpu-enabled, and, due to the use of modern data pipe-lining methods, completely memory safe. Furthermore, the use of HDF5 and SQL database structures enables effective tracking of calcualtion parameters as well as a compressed trajectory storage medium. We present MDSuite as a standalone package for the storage, analysis, and comparison of large-scale simulation studies.

Distinguishing noise from high-dimensional chaos — •INGA KOTTLARZ^{1,2} and ULRICH PARLITZ^{1,2} — ¹Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — ²Institute for Dynamics of Complex Systems, Georg-August-Universität Göttingen, Göttingen, Germany

The ordinal pattern-based Complexity-Entropy Plane is a popular tool in nonlinear dynamics for distinguishing noise from chaos. While successful attempts to do so have been documented for low-dimensional maps and continuous-time systems, high-dimensional systems have been somewhat neglected so far. To address the question in which way time series from highdimensional chaotic attractors can be characterized by their location in the Complexity-Entropy Plane we analyze data from the high-dimensional continuous-time Lorenz-96 system, the discrete generalized Hénon map and the Mackey-Glass equation as a delay system and discuss the crucial role of the lag and the pattern length or the ordinal pattern, and the length of the available time series.

#### SOE 6.9 Mon 17:15 H18

The impact of the UEFA European Football Championship on the spread of COVID-19 — •JONAS DEHNING¹, SEBASTIAN B. MOHR¹, SEBASTIAN CONTRERAS¹, PHILIPP DÖNGES¹, EMIL IFTEKHAR¹, OLIVER SCHULZ², PHILIP BECHTLE³, and VIOLA PRIESEMANN^{1,4} — ¹MPI for Dynamics and Self-Organization, 37077 Göttingen — ²MPI for Physics, 80805 München — ³Physikalisches Institut, University of Bonn — ⁴Institute for the Dynamics of Complex Systems, University of Göttingen

Large-scale international events like the UEFA Euro 2020 football championship offer a unique opportunity to quantify the impact of match-related social gatherings on COVID-19, as the number of matches played by participating countries resembles a randomized trial. Moreover, soccer-related activities have a marked gender-imbalance that we can exploit for inference. In our work, we build a differentiable Bayesian SEIR-like model. Its parameters are inferred with Hamiltonian Monte-Carlo using the PyMC3 package. Our model simulates COVID-19 spread in each country using a discrete renewal process and gender-resolved case numbers. On average, 3.2% (95% CI: [1.3%, 5.2%]) of new cases in the 12 analyzed countries can be associated with the match-related social gatherings throughout our analysis period. Individually, England, the Czech Republic and Scotland showed a significant effect. Besides these insights on the spread of COVID-19 during large-scale events, our approach is an example of how modern Bayesian tools can be leveraged to gain insights on a complex dynamic process.

#### SOE 6.10 Mon 17:30 H18

Recurrence-based analysis of instantaneous fractal characteristics of geomagnetic variability — •REIK V. DONNER^{1,2}, TOMMASO ALBERTI³, and DAVIDE FARANDA⁴ — ¹Hochschule Magdeburg-Stendal, Magdeburg, Germany — ²Potsdam Institute for Climate Impact Research, Potsdam, Germany — ³National Institute for Astrophysics, Rome, Italy — ⁴LSCE, Université Paris-Saclay, Gif-sur-Yvette, France

We employ two complementary approaches based on the concept of recurrences in phase space to quantify the local (instantaneous) and global fractal dimensions of the temporal variations of a suite of low (SYM-H, ASY-H) and high latitude (AE, AL, AU) geomagnetic indices and discuss similarities and dissimilarities of the obtained patterns for one year of observations during a solar activity maximum. Subsequently, we introduce bivariate extensions of both approaches, and demonstrate their capability of tracing different levels of interdependency between low and high latitude geomagnetic variability during periods of magnetic storms and magnetospheric substorms, respectively. Our results open new perspectives on the nonlinear dynamics and intermittent mutual entanglement of different parts of the geospace electromagnetic environment, including the equatorial and westward auroral electrojets, in dependence of the overall state of the geospace system affected by temporary variations of the solar wind forcing.

Revealing interactions between HVDC cross-area flows and frequency stability with explainable AI — •SEBASTIAN PÜTZ^{1,2}, BENJAMIN SCHÄFER³, DIRK WITTHAUT^{1,2}, and JOHANNES KRUSE^{1,2} — ¹Forschungszentrum Jülich, Institute for Energy and Climate Research - Systems Analysis and Technology Evaluation (IEK-STE), 52428 Jülich, Germany — ²Institute for Theoretical Physics, University of Cologne, 50937 Köln, Germany — ³Karlsruhe Institute of Technology, Institute for Automation and Applied Informatics (IAI), 76344 Eggenstein-Leopoldshafen, Germany

The energy transition introduces more volatile energy sources into the power grids. In this context, power transfer between different synchronous areas through High Voltage Direct Current (HVDC) links becomes increasingly important. Such links can balance volatile generation by enabling long-distance transport or by leveraging their fast control behavior. Here, we investigate the interaction of power imbalances - represented through the power grid frequency - and power flows on HVDC links between synchronous areas in Europe. We use explainable machine learning to identify key dependencies and disentangle the interaction of critical features. Our results show that market-based HVDC flows introduce deterministic frequency deviations, which however can be mitigated through strict ramping limits. Moreover, varying HVDC operation modes strongly affect the interaction with the grid. In particular, we show that load-frequency control via HVDC links can both have control-like or disturbance-like impacts on frequency stability.

From sample management to workflow integration: Semantic research data management in glaciology. — •FLORIAN SPRECKELSEN¹, DANIEL HORNUNG¹, and JOHANNES FREITAG² — ¹IndiScale Gmbh, Göttingen — ²Alfred Wegener

Institute, Helmholtz Centre for Polar and Marine Research, Bremerhaven Organizing data from a diversity of sources, from acquisition to publication, can be a tough challenge. We present implementations with the flexible open-source research data management toolkit CaosDB in the glaciology department at the Alfred Wegener Institute (AWI) in Bremerhaven. CaosDB is used in a diversity of fields such as turbulence physics, legal research, animal behavior and glaciology. CaosDB links research data, makes it findable and retrievable, and keeps data consistent, even if the data model changes.

At AWI, CaosDB keeps track of ice core samples and to whom samples are loaned for analyses. It made possible additional features such as: A revision system to track all changes to the data and the sample state at the time of analysis. Automated gathering of information for the publication in FAIR-DO meta-data repositories, e.g. Pangaea. Tools for storing, displaying and querying geospatial information and graphical summaries of all analyses performed on each ice core. Automatic data extraction and refinement into data records in CaosDB to minimize manual users interaction. A state machine which guarantees certain workflows, simplifies development and can be extended to trigger additional actions upon transitions.

We demonstrate how CaosDB simplifies semantic data in science.

### SOE 8: Invited Talk Theo Geisel: Human Synchronization in Music Performance

Time: Tuesday 9:30-10:15

Invited TalkSOE 8.1Tue 9:30H11Musicians' Synchronization and the Enigma of Swing — •THEO GEISEL —<br/>Max Planck Institute for Dynamics and Self-Organization & Bernstein Center<br/>for Computational Neuroscience Göttingen, Germany

It is a widespread opinion that musicians who are interacting together in a performance should perfectly synchronize their timing. This view was challenged for the swing feel, a salient feature of jazz, which has eluded scientific clarification for a century. For much of this period it was considered arcane, arguing that swing can be felt but not explained, until the theory of 'participatory discrepancies' raised the controversial claim that swing is caused by microtiming deviations between different participating musicians [1]. Location: H11

In several projects we have clarified the controversy on the central role of microtiming deviations for the swing feel using time series analysis and experiments with temporally manipulated MIDI-recordings, whose swing feel was measured through ratings of professional jazz musicians. We thereby showed that involuntary random microtiming deviations are irrelevant for swing, whereas a particular systematic microtiming deviation between musicians enhances the swing feel and is a key component of swing in jazz [2]. It consists in slightly delaying downbeats but not offbeats of soloists with respect to a rhythm section. This effect was unknown to professional jazz musicians, who are using it unconsciously but were unable to determine its nature.

### SOE 9: Physics of Contagion Processes

Time: Tuesday 10:15-11:15

SOE 9.1 Tue 10:15 H11

**Emergence of synergistic and competitive pathogens in a coevolutionary spreading model** — •PHILIPP HÖVEL¹, ALESSIO CARDILLO², KAI SEEGERS³, and FAKHTEH GHANBARNEJAD⁴ — ¹University College Cork, Ireland — ²Universitat Rovira i Virgili, Tarragona, Spain — ³Technische Universität Berlin, Germany — ⁴Sharif University of Technology, Iran

Cooperation and competition between pathogens can alter the amount of individuals affected by a coinfection giving rise to phenomena like comorbidity and cross-immunity. However, the evolution of the pathogens' behavior has been underexplored. We present a coevolutionary model where the simultaneous spreading is described by a two-pathogen susceptible-infected-recovered model in an either synergistic or competitive manner. At the end of each epidemic season, the pathogens species reproduce according to their fitness following a replicator equation. The fitness depends on the payoff accumulated during the spreading season in a hawk-and-dove game. We demonstrate that the proposed coevolutionary model displays a rich set of features and emergent behavior. For example, the evolution of the pathogens' strategy induces abrupt transitions in the epidemic prevalence. Furthermore, we observe that the long-term dynamics results in a single, surviving pathogen species, and that the cooperative behavior of pathogens can emerge even under unfavorable conditions.

SOE 9.2 Tue 10:45 H11 Assessing the effectiveness of COVID intervention measures in small communities using agent-based simulations — •JANA LASSER — Graz University of Technology, Graz, Austria — Complexity Science Hub Vienna, Vienna, Austria Location: H11

The necessity of intervention measures like the wearing of masks, preventive testing and vaccinations to prevent the spread of COVID-19 have been vigorously in our societies. At the centre of these discussions is the effectiveness of these measures in suppressing large outbreaks. With our research, we contribute the necessary facts to the discussion by simulating the spread of COVID-19 using agent-based simulations that are calibrated to empirical outbreak data. Here we present three application cases of our simulations: (i) the development of a preventive testing strategy in nursing homes in a situation where no vaccinations are available yet, (ii) the assessment of the effectiveness of different combinations of measures in schools and (iii) an evaluation of the feasibility of preventing large outbreaks while requiring in-presence teaching in universities under the condition of community spreading of the Omicron variant.

SOE 9.3 Tue 11:00 H11

**Epidemic processes on self-propelled particles** — •JORGE P. RODRIGUEZ¹, MATTEO PAOLUZZI², DEMIAN LEVIS², and MICHELE STARNINI³ — ¹IMEDEA, CSIC-UIB, Esporles, Spain — ²Departament de Física de la Matèria Condensada,Universitat de Barcelona, Barcelona, Spain — ³ISI Foundation, Torino, Italy Most spreading processes require spatial proximity between agents. The stationary state of spreading dynamics in a population of mobile agents thus depends on the interplay between the time and length scales involved in the epidemic process and their motion in space. We analyze the steady properties resulting from such interplay in a simple model describing epidemic spreading on self-propelled particles. The epidemic dynamics is described by a Susceptible-Infected-Susceptible model, while the movement of each particle is ruled by Run-and-Tumble motion. The interactions are given by the proximity between particles, with the particles'

563

movement modifying the relative distances between themselves. We analyze this problem from a continuum description of the system, and validate those results by numerical simulations of an agent-based model. Focusing our attention on the diffusive long-time regime, we find that the agents' motion changes qualitatively the nature of the epidemic transition characterized by the emergence of a macroscopic fraction of infected agents. Indeed, the transition becomes of the mean-field type for agents diffusing in one, two and three dimensions, while, in the absence of motion, the epidemic outbreak depends on the dimension of the underlying static network determined by the agents' fixed locations.

Stable Poisson chimeras in networks of two subpopulations — •SEUNGJAE LEE and KATHARINA KRISCHER — Technical University of Munich, Garching, Germany

In this talk, we introduce recent results on dynamical and spectral properties of chimeras in two-population network based on Kuramoto order parameter and Lyapunov stability analysis. In particular, we address two qualitatively different dynamics of incoherent oscillator populations according to the given initial conditions, and which led to the classification of Poisson and non-Poisson chimera states. We numerically calculate the Lyapunov exponents and covariant Lyapunov vectors to determine the spectral properties of the chimera states, and then expound the classification of the Lyapunov exponents. Our stability analysis also confirms that the chimera states of Kuramoto-Sakaguchi phase oscillators in two-population networks are neutrally stable in many directions. Furthermore, we demonstrate that two *perturbations* of the phase model that reflect more realistic situations render Poisson chimeras stable. These models consider a nonlocal intra-population network and Stuart-Landau planar oscillators with amplitude degrees of freedom, respectively. Both these 'perturbations' might be considered a heterogeneity of the phase model and give rise to an asymptotically attracting Poisson chimera in two-population networks.

#### SOE 10.2 Tue 11:30 H19 On rational reactions - and other ones - of overloaded magnetic gears — •INGO REHBERG and STEFAN HARTUNG — Universität Bayreuth

Experiments exploring the coupling of two rotating spherical magnets reveal a cogging-free coupling for two specific angles between the input and output rotation axes. The striking difference between these two phase-locked modes of operation is the reversed sense of rotation of the driven magnet. For other angles, the cogging leads to a more complex dynamical behaviour. The experimental results can be understood by a mathematical model based on pure dipole-dipole interaction, with the addition of adequate friction terms [1].

Like all magnetic couplings, the setup contains intrinsic overload protection. The dynamic answer of the gear with cogging to an overload shows a plethora of modes of the driven magnet.

Heteroclinic units acting as pacemakers: Entrained dynamics for cognitive processes — •BHUMIKA THAKUR and HILDEGARD MEYER-ORTMANNS — School of Science, Jacobs University Bremen, Campus Ring 1, 28759 Bremen, Germany Heteroclinic dynamics is a suitable framework for describing transient and reproducible dynamics such as cognitive processes in the brain. We demonstrate how heteroclinic units can act as pacemakers to entrain larger sets of units from a resting state to hierarchical heteroclinic motion that is able to describe fast oscillations modulated by slow oscillations, features which are observed in brain dynamics. The entrainment range depends on the type of coupling, the spatial location of the pacemaker and the individual bifurcation parameters of the pacemaker and the driven units. Noise as well as a small back-coupling to the pacemaker facilitate synchronization. Units can be synchronously entrained to different temporal patterns, depending on the selected path in the hierarchical heteroclinic network. These locally generated temporal sequences of information items can be transferred over a spatial grid by entrainment to the pacemaker dynamics. Such spatiotemporal patterns are believed to code informaLocation: H19

Tuesday

tion in brain dynamics. Depending on the number and location of pacemakers on two-dimensional grids, synchronization can be maintained in the presence of a large number of resting state units and mediated via target waves when the pacemakers are concentrated to a small area of such grids. In view of brain dynamics, our results indicate a possibly ample repertoire for coding information in temporal patterns.

#### SOE 10.4 Tue 12:00 H19

Suppression of quasiperiodicity in circle maps with quenched disorder —
 DAVID MÜLLER-BENDER¹, JOHANN LUCA KASTNER¹, and GÜNTER RADONS^{1,2}
 ⁻¹Institute of Physics, Chemnitz University of Technology, 09107 Chemnitz, Germany — ²Institute of Mechatronics, 09126 Chemnitz, Germany

We show that introducing quenched disorder into a circle map leads to the suppression of quasiperiodic behavior in the limit of large system sizes. Specifically, for most parameters the fraction of disorder realizations showing quasiperiodicity decreases with the system size and eventually vanishes in the limit of infinite size, where almost all realizations show mode-locking. Consequently, in this limit, and in strong contrast to standard circle maps, almost the whole parameter space corresponding to invertible dynamics consists of Arnold tongues.

Details can be found in the preprint D. Müller-Bender, J. L. Kastner, and G. Radons, Suppression of quasiperiodicity in circle maps with quenched disorder, arXiv:2204.09392 [nlin.cd] (2022).

**Reservoir Computing and Nonlinear Dynamics** — •ULRICH PARLITZ — Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — Institute for the Dynamics of Complex Systems, Georg-August-Universität Göttingen, Göttingen, Germany

We discuss the interrelation between reservoir computing (RC) and nonlinear dynamics (NLD). On the one hand, the performance of RC can be characterized and improved by concepts from NLD such as generalized synchronization and delay embedding. On the other hand, RC can be used to predict and control dynamical systems, including hybrid architectures that employ physically informed machine learning. Various aspects of this mutual relationship between RC and NLD are illustrated using low-dimensional and spatially extended chaotic dynamical systems.

Chameleon attractors in deterministic and stochastic Lorenz-63 systems •Reik V. DONNER^{1,2}, TOMMASO ALBERTI³, and DAVIDE FARANDA⁴ ¹Hochschule Magdeburg-Stendal, Magdeburg, Germany — ²Potsdam Institute for Climate Impact Research, Potsdam, Germany – ³National Institute for Astrophysics, Rome, Italy – ⁴LSCE, Université Paris-Saclay, Gif-sur-Yvette, France The dynamical chaacteristics of a trajectory on a chaotic or stochastic attractor undergo marked changes when successively eliminating the low-frequency variability components and focusing on the fast fluctuations only, motivating the new concept of Chameleon attractors. Here, we study the time scale dependent instantaneous and average fractal characteristics of partial sums of dynamical modes identified by means of empirical mode decomposition for the Lorenz-63 system and two stochastic versions thereof with additive and multiplicative noise as obtained by exploiting recurrences in phase space using extreme value theory. While the average fractal dimensions converge to the expected values as more and more low-frequency modes are included, we find an excess dimension larger than 3 for higher frequency modes below the Lyapunov time scale resulting from the stochastic components.

Modeling tumor disease and sepsis by networks of adaptively coupled phase oscillators — •ECKEHARD SCHÖLL^{1,2,3}, JAKUB SAWICKI², RICO BERNER^{1,4}, and THOMAS LÖSER⁵ — ¹Institut für Theoretische Physik, TU Berlin, Germany — ²Potsdam Institute for Climate Impact Research — ³Bernstein Center for Computational Neuroscience Berlin — ⁴Institut für Physik, HU Berlin — ⁵Institut LOESER, Wettiner Straße 6, 04105 Leipzig

In this study, we provide a dynamical systems perspective to the modelling of pathological states induced by tumors or infection. A unified disease model is established using the innate immune system as the reference point. We propose a two-layer network model for carcinogenesis and sepsis based upon the interaction of parenchymal cells (organ tissue) and immune cells via cytokines, and the co-evolutionary dynamics of parenchymal, immune cells, and cytokines [1]. Our aim is to show that the complex cellular cooperation between parenchyma and stroma (immune layer) in the physiological and pathological case can be functionally described by a simple paradigmatic model of phase oscillators. By this, we explain carcinogenesis, tumor progression, and sepsis by destabilization of the healthy state (frequency synchronized), and emergence of a pathological state (multifrequency cluster). The coupled dynamics of parenchymal cells (metabolism) and nonspecific immune cells (reaction of innate immune system) are represented by nodes of a duplex layer. The cytokine interaction is modeled by adaptive coupling weights. [1] Sawicki, J., Berner, R., Löser, T., and Schöll, E., Frontiers Netw. Physiology 1,730385 (2022), arXiv:2106.13325v2.

#### SOE 12.2 Wed 10:45 H11 twork — • TOBIAS WAND — WWU

Football clubs buy and sell players for millions of Euros and until Covid, their combined transfer values were growing steadily at an impressive rate. Instead of analysing their aggregated transfer activities, one can take a look at the topology of the network of player transfers: complex networks have already been used in various sciences [1] including research on sports [2] and provide a novel approach to investigate the football transfer market network and in particular the impact of Covid on football clubs.

Variability in mesoscale structure inference using stochastic blockmodels — •LENA MANGOLD and CAMILLE ROTH — CNRS (Paris) / Centre Marc Bloch (Berlin)

Characterising the mesoscale structure of networks, in terms of patterns variously called communities, blocks, or clusters, has represented both a central issue and a key instrument in the study of complex systems. Clearly, distinct methods designed to detect different types of patterns may provide a variety of answers to the mesoscale structure. Yet, even multiple runs of a given method can sometimes yield diverse and conflicting results, posing challenges of model and partition selection. As an alternative to forcing a global consensus from a distribution of partitions (i.e. choosing one among many by maximising some objective), recent work has emphasised the importance of exploring the variability of partitions. Here we examine how a specific type of mesoscale structure (e.g. assortative communities or core-periphery) may be linked with more or less inconsistency in resulting partitions. We focus on Stochastic blockmodels (SBMs), initially proposed in mathematical sociology and increasingly used to infer mesoscale structure with a relatively general definition of similarity between nodes in the same group, and whose stochastic nature lends itself to the exploration of disagreement within populations of partitions. In particular, we generate families of synthetic networks in which we plant different types

Location: H11

of mesoscale structures and explore the transitions between consensus and dissensus in the landscape of partitions over multiple SBM runs.

#### SOE 12.4 Wed 11:15 H11

**Extracting signed relations from interaction data** — •Georges Andres, GIONA CASIRAGHI, GIACOMO VACCARIO, and FRANK SCHWEITZER — ETH Zürich, Chair of Systems Design, Switzerland

Social relations influence human interactions and hence, help to explain individual behaviours. Moreover, humans perceive patterns of signed relations, either positive (e.g., friendship) or negative (e.g., enmity), and adapt to them. Data about signed relations are rare, despite their importance for understanding phenomena at the community level. Interaction data is, however, more abundantly available, for example, about proximity or communication events. Interactions and relations change on different time scales; interactions are more volatile and evolve faster than relations. Using this, I will present an ensemble-based approach to infer pair-wise signed relations from interaction data and consequently construct a signed network from them. By studying different datasets on interactions and relations, e.g. between students, I will further evaluate the quality of the inferred networks. Subsequently, I will study the presence of structural balance in the studied communities, describing the cognitive dissonance ensuing from particular triadic constellations of signed relations. Bearing similarities to frustrations in spin systems, structural balance can now be analysed solely from interaction data thanks to the presented method, a task which was previously out of reach.

#### SOE 12.5 Wed 11:45 H11

Disentangling homophily, community structure and triadic closure in networks — •TIAGO PEIXOTO — Central European University, Vienna, Austria

Network homophily, the tendency of similar nodes to be connected, and transitivity, the tendency of two nodes being connected if they share a common neighbor, are conflated properties in network analysis, since one mechanism can drive the other. Here we present a generative model and corresponding inference procedure that is capable of distinguishing between both mechanisms. Our approach is based on a variation of the stochastic block model (SBM) with the addition of a triadic closure dynamics, and its inference can identify the most plausible mechanism responsible for the existence of every edge in the network, in addition to the underlying community structure itself, based only on the final observation of the network. We show how the method can evade the detection of spurious communities caused solely by the formation of triangles in the network, and how it can improve the performance of link prediction when compared to the pure version of the SBM without triadic closure.

#### SOE 12.6 Wed 12:15 H11

**Evolving networks towards complexity: an evolutionary optimization approach** — ARCHAN MUKHOPADHYAY and •JENS CHRISTIAN CLAUSSEN — University of Birmingham, UK

Complexity measures for graphs have been proposed and compared [1,2] widely, but the question how to mathematically define complexity is less clear as for text strings where Lempel-Ziv and Kolmogorov complexity provide clear approaches. In complexity science, the notion of complexity implies distinction from regular structures (lattices) as well as from random structures (here: random graphs). This however has not lead to any constructive definition. Complexity measures therefore typically assess artefacts of complexity (in some cases quite successfully). Here we present a complementary computational approach: we utilize each complexity measure as a fitness function of an evolutionary algorithm, and investigate the properties of the resulting networks. The goal is a better understanding of the existing complexity measures, and to shed some light on (artificial) network evolution: what evolutionary goals lead to complexity?

### SOE 13: Energy Networks (joint session SOE/DY)

Time: Wednesday 12:45-13:15

SOE 13.1 Wed 12:45 H11

**Revealing drivers and risks for power grid frequency stability with explainable AI** — •BENJAMIN SCHÄFER¹, JOHANNES KRUSE^{2,3}, and DIRK WITTHAUT^{2,3} — ¹Institute for Automation and Applied Informatics, Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany — ²Forschungszentrum Jülich, Institute for Energy and Climate Research-Systems Analysis and Technology Evaluation (IEK-STE), Jülich, Germany — ³Institute for Theoretical Physics, University of Cologne, Köln, Germany

The transition to a sustainable energy system is challenging for the operation and stability of electric power systems as power generation becomes increasingly uncertain, grid loads increase, and their dynamical properties fundamentally change. At the same time, operational data are available at an unprecedented level of detail, enabling new methods of monitoring and control. To fully harness these data, advanced methods from machine learning must be used.

Here, we present explainable artificial intelligence (XAI) as a tool to quantify, predict, and explain essential aspects of power system operation and stability in three major European synchronous areas. We focus on the power grid frequency, which measures the balance of generation and load and thus provides the central observable for control and balancing. Combining XAI with domain knowledge, we identify the main drivers and stability risks, while our model and open dataset may enable further XAI research on power systems.

SOE 13.2 Wed 13:00 H11

**Cascading Failures and Critical Infrastructures in Future Renewable Power Systems** — FRANZ KAISER^{1,2}, JOHANNES KRUSE^{1,2}, •PHILIPP C. BÖTTCHER¹, MARTHA MARIA FRYSZTACKI³, TOM BROWN^{3,4}, and DIRK WITTHAUT^{1,2} — ¹IEK-STE Forschungszentrum Jülich, Jülich, Germany — ²THP Uni Köln, Köln, Germany — ³KIT-IAI, Karlsruhe, Germany — ⁴Institut für Energietechnik TU Berlin, Germany

The world's power systems are undergoing a rapid transformation, shifting away from carbon-intensive power generation to renewable power sources. As a result, there is a growing importance of long-distance power transmission, while the intrinsic system inertia provided by thermal power plants decreases. This poses several challenges to the system such as accelerated dynamics and thus a higher control effort for transmission system operators. These developments make power grids more vulnerable to cascading failures, which may result in a splitting of the grid and eventually in a large-scale blackout. While large blackouts are rare but devastating events, several smaller splits were observed in recent years.

In this work, we use the state of the art open energy system model PyPSA to generate future energy systems and assess the risk of cascading failures and systems splits in the European power grid for different carbon reduction targets. We determine the likelihood of dangerous splits and discuss mitigation strategies.

Issue bundles: Understanding ideological patterns of polarization in political spaces. — •ECKEHARD OLBRICH¹ and SVEN BANISCH² — ¹Max Planck Institut for Matematics in the Sciences, Leipzig, Germany — ²Institute of Technology Futures, Karlsruhe Institute of Technology, Germany

Many scholars of politics discuss the rise of the new populism in Western Europe and the US with respect to a new political cleavage related to globalization. In this contribution we empirically address this reconfiguration of the political space by comparing political spaces for Germany built using topic modeling with the spaces based on the content analysis of the Manifesto project and the corresponding categories of political goals. We find that both spaces have a similar structure and that the right-wing populist AfD appears on a new dimension. In order to characterize this new dimension we employ a novel technique to identify clusters of political goals, issue bundles, by maximizing the coherence of inter-issue consistency networks (IICN). These issue bundles allow to analyze the evolution of the correlations between the political positions on different issues over several elections. We find that the new dimension introduced by the AfD can be related to the split off of a new "culturally right" issue bundle from the previously existing center-right bundle.

E. Olbrich, and S. Banisch, The rise of populism and the reconfiguration of the German political space, Frontiers in Big Data 4, 731349 (2021).

**Idea engines: Innovation & obsolescence in markets, genetic evolution, science** – •Edward Lee¹, CHRISTOPHER KEMPES², and GEOFFREY WEST² – ¹Complexity Science Hub Vienna, Vienna, Austria – ²Santa Fe Institute, Santa Fe. USA

Innovation and obsolescence describe dynamics of ever-churning and adapting systems from the development of economic markets and scientific progress to biological evolution. The shared aspect is that agents destroy and extend the "idea lattice" in which they live, finding new possibilities and rendering old solutions irrelevant. We focus on this aspect with a simple model to study the central relationship between the rates at which replicating agents discover new ideas and at which old ideas are rendered obsolete. When the rates match, the space of the possible (e.g. ideas, markets, technologies, mutations) is static. A positive or negative difference distinguishes flourishing, ever-expanding idea lattices from Schumpeterian dystopias in which the system collapses. We map the phase space in terms of rates at which agents enter, replicate, and die. With higher dimensions, cooperative agents, or obsolescence-driven innovation, we find that the essential features of the model are preserved. In all cases, we predict a density profile of agents that drops close to new and old frontiers. With data, we reveal that the density signals a follow-the-leader dynamic in firm cost efficiency and biological evolution, whereas scientific progress reflects consensus that waits on old ideas to go obsolete. We show how the fundamental forces of innovation and obsolescence provide a unifying perspective on complex systems.

Loss of sustainability in scientific work — •NIKLAS REISZ¹, VITO DOMENICO PIETRO SERVEDIO¹, VITTORIO LORETO^{1,2,3}, WILLIAM SCHUELLER², MÁRCIA FERREIRA¹, and STEFAN THURNER^{1,4,5} — ¹Complexity Science Hub Vienna, Vienna, Austria — ²Sony Computer Science Lab, Paris, France — ³Sapienza University, Rome, Italy — ⁴Medical University of Vienna, Vienna, Austria — ⁵Santa Fe Institute, Santa Fe, USA

For decades the number of scientific publications has been rapidly increasing, effectively out-dating knowledge at a tremendous rate. Only few scientific milestones remain relevant and continuously attract citations. Here we quantify how long scientific work remains being utilized, how long it takes before today's work is forgotten, and how milestone papers differ from those forgotten. To answer these questions, we study the complete temporal citation network of all APS journals. We quantify the probability of attracting citations for individual publications. We capture both aspects, the forgetting and the tendency to cite already popular works, in a microscopic generative model. We find that the probability of citing a specific paper declines with age as a power law with an exponent of a=-1.4. Whenever a paper in its early years can be characterized by a scaling exponent above a critical value, ac, the paper is likely to become "ever-lasting". We validate the model with out-of-sample predictions. The model also allows us to predict that 95% of papers cited in 2050 have yet to be published. Our findings suggest a worrying tendency toward information overload and raises concerns about scientific publishing's long-term sustainability.

SOE 14.5 Wed 16:30 H11 On the empirical distribution functions of examination performance in beginning semesters in mathematics and physics — •MAGDA SCHIEGL — University of Applied Sciences Landshut, Am Lurzenhof 1, D-84036 Landshut With increasing heterogeneity of student groups, the measurement and interpretation of individual study performance becomes more and more important,

both in terms of classification in group performance and under developmental aspects. We investigate the empirical distribution of study performance in the 1st and 2nd semesters of industrial engineering over several years. The basis of the study is the exam performance of large groups (approx. 100 students and more per year). We compare the subjects mathematics and physics. Characteristics of the empirical CDFs of the respective cohorts (year groups) are examined. The results are compared, summarised and interpreted.

Gravity Model in Estimating Park Visitation Pre and during COVID-**19 Pandemic** — ZAHRA GHADIRI¹, AFRA MASHHADI², and •FAKHTEH GHANBARNEJAD^{1,3} — ¹Department of Physics, Sharif University of Technology, Tehran, Iran — ²Computing and Software Systems, University of Washington, Bothell, WA, USA – ³Chair for Network Dynamics, Institute for Theoretical Physics and Center for Advancing Electronics Dresden (cfaed), Technical University of Dresden, 01062 Dresden, Germany

The COVID-19 pandemic and the resulting economic recession have negatively affected many people's social, and psychological health. Parks may have ameliorated the negative effects of the pandemic by creating opportunities for outdoor recreation. At the same time, other public activities were restricted due to the risk of disease transmissions. In our study, we seek to improve our understanding of how the COVID-19 pandemic impacts park visitations by performing a longitudinal study based on the aggregated telecommunication data. To do so, we introduce a novel approach based on the Gravity Model to understand, quantify and model the relationship between distance and the visitation patterns. Particularly, we aim to find out how the park visitation behavior changes post-pandemic and how this change of visitation varies for different socio-economic groups of visitors. Our results show that the park visitation pattern in Washington state (U.S.A) obeys the gravity law. Moreover, we show that, although parameters of the model may vary, the gravity model can still accurately estimate the visitation after applying socio-economic and spatial filters.

CaosDB - a scientific research data management toolkit — •FLORIAN Spreckelsen¹, Daniel Hornung¹, and Johannes Freitag² – ¹IndiScale Gmbh, Göttingen — ²Alfred Wegener Institute, Helmholtz Centre for Polar and Marine Research, Bremerhaven

Processing interconnected, multi-modal data poses a challenge in many fields, especially when the data model, i.e. the way how data is organized, changes over time or when its structure is poorly documented. The open-source software CaosDB is a toolkit for research data management which was originally developed at the Max Planck Institute for Dynamics and Self-Organization (Göttingen) because existing software could not fulfill the needs of the scientists.

We present examples where CaosDB helped make data FAIR (Findable, Accessible, Interoperable, Retrievable) and how it can simplify the workflows for researchers: Automated data collection and integration, export to data repositories, API libraries for third-party programs, integrated revisioning and workflow is convenient, in a sense, due to door-to-door service, but is inefficient since it usually serves one customer only. Demand-responsive ridepooling (DRRP) with minibuses is more efficient, but leads to undue competition with line services (LS), which provide even better pooling but are less convenient due to fixed routes and stops. A combination of both modes, DRRP and LS, may provide an ideal solution but is challenging to organize. Here we introduce a model for such bimodal on-demand transportation based on a square-grid geometry. Our model quantifies under what circumstances bimodal public transportation is feasible, both in terms of convenience and ecological footprint. Moreover, the model yields estimates for how to operate (LS frequency, modal split) a bimodal transportation system optimally. Perhaps surprisingly, we find that operating LS at maximum capacity is not necessarily optimal. We also consider the intricate interplay between LS operations and DRRP performance, i.e., detours, waiting times, and occupancy, via simulations.

separately, none of them is both, sustainable and convenient. A taxi service

Urban road networks: Geometric characteristics and generative models -•REIK DONNER — Hochschule Magdeburg-Stendal, Magdeburg, Germany — Potsdam Institute for Climate Impact Research, Potsdam, Germany

Urban road networks provide the spatial backbone of the development of cities. As planar networks, they possess characteristic size, shape and orientation distributions of their basic constituting elements (road segments and cellular structures). Comparisons with simple benchmark planar graph models show that the latter commonly fail to mimic those characteristic features of the real-world networks, including heavy-tailed object size distributions, specific shapes of node and cell degree distributions, and the predominant orthogonality of street patterns. In order to account for these discrepancies, I introduce a hierarchy of planar network models combining the successive evolution of the network with a perpendicular splitting of road segments controlled by a spatial potential function. The resulting model networks can be used as benchmarks for generating *surrogate cities* for further testing dynamical models of urban traffic.

Location: P2

state machines. If the data model needs to change, existing data can remain asis and future search queries will return matching results containing "old" and "new" data. We demonstrate how raw and processed data, analysis settings and results, and even labnotebooks and publications can be linked against each other, to improve long-term usability of data and reproducibility of results.

We show how CaosDB can make semantic data AI ready in science.

SOE 17.2 Thu 15:00 P2 contagion dynamics of self-proppeled particles in porous media - EHSAN IRANI¹, ABBAS SHOJAKANI², MOHADDESE SADAT ASGARI², and •FAKHTEH GHANBARNEJAD^{2,3} — ¹Max Delbrück Center for Molecular Medicine in the Helmholtz Association (MDC), The Berlin Institute for Medical Systems Biology (BIMSB), 10115 Berlin, Germany -²Department of Physics, Sharif University of Technology, Tehran, Iran -³Chair for Network Dynamics, Institute for Theoretical Physics and Center for Advancing Electronics Dresden (cfaed), Technical University of Dresden, 01062 Dresden, Germany

SOE 15.3 Wed 17:45 H11

We investigate the effect of heterogeneous environment on the spread of disease in systems of active agents. Here we couple susceptible-infected-recovered (S-I-R) contagion dynamics to a system of self-propelled active particles with polar alignment, in the presence of randomly distributed obstacles. The heterogeneity of the environment is controlled by the density of obstacles. The temporal-spatial dynamics of the system is determined by the alignment strength and Peclet number as well as the density of the obstacles. We analyze how the heterogeneity of the environment results in rich set of spatial structures which significantly affect the epidemic dynamics of the disease. We further show that increasing the heterogeneity of the environment could change the outbreaks statistics in a nonmonotonic way.

**Modelling discussion dynamics across Reddit communities** — •RICCARDO CARLUCCI and JOÃO PINHEIRO NETO — Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, 37077 Göttingen, Germany

Understanding the dynamics of online discussions is an important research challenge, not only in its own right but also in relation to e.g. the study of political polarization. With more than 20 million contributing monthly users, Reddit is one of the largest and most influential social media platforms in the world. Here we analyse the distribution of the number of comments-per-discussion within the largest 500 Reddit communities from an almost fully-sampled dataset, focusing on content created between 2019 and 2021. We find that about 60% of these communities exhibit a distribution which is well-approximated by a power-law with an upper exponential cut-off. However, the width and the exponent of the power-law regime are specific to each particular community. In order to explain this variability we develop a preferential attachment model where the ability of a discussion to attract comments is affected by its age and also by an intrinsic fitness value. After estimating aging and fitness from data, we find that the model is able to reproduce both non-power-law and power-law behaviour. In particular, the width and the exponent of the power-law regime are correlated with the average number of comments and discussion created per day in a community.

Population dynamics and Nash equilibria in optimizing complexity measures — •ARCHAN MUKHOPADHYAY and JENS CHRISTIAN CLAUSSEN — University of Birmingham, UK

Do natural networks evolve towards complexity? In a related project (Mukhopadhyay and Claussen, to be submitted) we utilize graph complexity measures as fitness function for an evolutionary algorithm. This effectively leads to an evolutionary dynamics between complexity measures as "species" or "strategies". Here we rephrase each complexity measure value from the numerical simulations (when optimizing towards annother complexity measure as co-evolutionary fitness value of one species within a population where annother species is highly abundant). We analyze the resulting payoff matrix with respect

to their Nash equilibria and evolutionarily stable strategies, if interpreted within the context of evolutionary game theory.

#### SOE 17.5 Thu 15:00 P2

Die Nützlichkeit der mathematischen Begriffstheorie von E.K. Wojschwillo zur Kulturwissenschaft und Gender-Studies — •MARINA ZAKHARCHUK — Moskau, Russland

In der mathematischen Logik gibt es eine Begriffstheorie von E.K. Vojschvillo, die heute von D.V. Zaitsev und A.A. Iljin entwickelt wird, die, die Begriffen als Mengen analysiert. Dieses Begriffsverständnis kann mit einem Venn-Diagramm dargestellt werden. Diese Theorie kann man auch in der Kunstforschung benutzen. Wir zeigen, wie das beschriebene Schema konkret zur Klassifizierung von Drag-Künstlern angewendet werden kann. Als Parameter nehmen wir das biologische Geschlecht einer Person und das Geschlecht ihrer Spielfigur. Wir unterteilen jeden der Parameter dichtomisch: biologisch ein Mann, biologisch kein Mann; Spielfigur ist ein Mann, Spielfigur ist kein Mann. Dieses Schema umfasst Bioqueen, Bioking, Drag Queen, Drag King sowie Künstler, die sich keiner dieser Klassen zuordnen. Darüber hinaus kann das Schema erweitert werden, indem eine Unterteilung nach der Modifikation der Grundlage eingeführt wird, wobei die Geschlechtsidentität des Künstlers als Grundlage genommen wird. Zum Beispiel: biologisch männlich -> Spielfigur ist nicht männlich -> Transgender. Diese Klassifikation ist innovativ und fortschrittlich im Bereich der Kulturwissenschaft und Gender-Studies: es ist übersichtlich und macht es einfacher zu definieren. wer welcher Drag-Künstler ist.

## Organisation der soziotechnischen Systeme mit dem industriellen Internet der Dinge (IIOT) — •Dміткії Авизнек — Moscow, Russia

Das Verwenden der Konzepte von Internet der Dinge kann helfen Kosten für Produktion und Entsorgung senken. Zum Beispiel, die Lösungen des Russischen Unternehmens "Strizh" als ein von mehreren. Auf Basis dieser Technologie können wir intelligente Gas-, Wasser- und Stromzähler erstellen. Die Erfassung und Analyse von Ressourcenverbrauchsdaten hilft uns, sie besser zu verwalten und Unfälle und Lecks zu erkennen. Die Grundlage der Plattform "Strizh" modifiziert die LPWAN Technologie. Dank der Energieeinsparung kann die Heizung der Wohnhäuser billiger werden, besonders in Systemen, in denen grüne Energie verwendet wird. Die Strizh-Plattform besteht aus Sensoren, Daten, und Auswertungsprogrammen unter XNB Protocol mit DBPSK Modulation. Sie kommunizieren miteinander und helfen Lösungen der unvermeidlichen zu machen. Die Einführung von IIOT bei Volvo ist zudem interessant. Das System von Volvo ermöglicht die Kommunikation zwischen Wagen, Volvo-Ingenieure, und Reparaturwerkstatt. Das ist möglich dank IIOT. Es verbessert die Qualität von Kundenservice. Aufgrund des kommerziellen Erfolges von IIOT kann man sagen dass diese Technologie eine große Zukunft hat.

Thermodynamic uncertainty relations for many-body systems with fast jump rates and large occupancies — •OHAD SHPIELBERG¹ and ARNAB  $PAL^2$  — ¹University of Haifa, Haifa, Israel. — ²Department of Physics, Indian Institute of Technology, Kanpur, India

The thermodynamic uncertainty relations constitute an important inequality, bounding the entropy production through current fluctuations. The results have been successfully applied, in particular for single body dynamics. Here we present uncertainty relations and other useful inequalities for the many body systems, in the limit of highly occupied systems. The resulting coarse grained theory also accounts for tighter inequalities than the single body case. SOE 20.2 Fri 11:45 H19 Effects of measures on phase transitions in two cooperative susceptibleinfectious-recovered dynamics — ADIB KHAZAEE¹ and •FAKHTEH GHANBARNEJAD^{1,2} — ¹Sharif University of Technology, Tehran, Iran — ²Chair for Network Dynamics, Institute for Theoretical Physics and Center for Advancing Electronics Dresden (cfaed), Technical University of Dresden, 01062 Dresden, Germany

In recent studies, it has been shown that a cooperative interaction in a coinfection spread can lead to a discontinuous transition at a decreased threshold. Here, we investigate effects of immunization with a rate proportional to the extent of the infection on phase transitions of a cooperative co-infection. We use the mean-field approximation to illustrate how measures that remove a portion of the susceptible compartment, like vaccination, with high enough rates can change discontinuous transitions in two coupled susceptible-infectiousrecovered dynamics into continuous ones while increasing the threshold of transitions. First, we introduce vaccination with a fixed rate into a symmetric spread of two diseases and investigate the numerical results. Second, we set the rate of measures proportional to the size of the infectious compartment and scrutinize the dynamics. We solve the equations numerically and analytically and probe the transitions for a wide range of parameters. We also determine transition points from the analytical solutions. Third, we adopt a heterogeneous mean-field approach to include heterogeneity and asymmetry in the dynamics and see if the results corresponding to homogeneous symmetric case stand. (Physical Review E 105 (3), 034311)

#### SOE 20.3 Fri 12:00 H19

ANDOR and beyond: Dynamically switchable logic gates as modules for flexible information processing in biochemical regulatory networks — •MOHAMMADREZA BAHADORIAN^{1,2} and CARL D. MODES^{1,2,3} — ¹Max Planck Institut for Molecular Cell Biology and Genetics (MPI-CBG), 01307 Dresden, Germany — ²Center for Systems Biology Dresden (CSBD), 01307 Dresden, Germany — ³Cluster of Excellence Physics of Life, TU Dresden, 01069 Dresden, Germany

Understanding how complex (bio-)chemical regulatory networks may be capable of processing information in flexible, yet robust ways is a key question with implications in biology and dynamical systems theory. Considerable effort has been focused on identification and characterization of structural and dynamical motifs of biological information processing, but a framework for studying flexibility and robustness of the motifs is lacking. We here propose a small set of effective modules capable of performing different logical operations based on the basin of attraction in which the system resides. These dynamically switchable logic gates require fewer components than their traditional analogs where static, separate gates are used for each desired function. We demonstrate the applicability and limits of these circuits by determining a robust range of parameters over which they correctly operate and then characterize their resilience against intrinsic noise of the constituent reactions using the theory of large deviations. Trade-offs between multi-functionality and robustness against various types of noise are shown.

#### SOE 20.4 Fri 12:15 H19

**Memory formation in adaptive networks** — •KOMAL BHATTACHARYYA¹, DAVID ZWICKER¹, and KAREN ALIM^{1,2} — ¹Max Planck Institute for Dynamics and Self-Organization, 37077 Göttingen, Germany — ²Physik-Department, Technische Universität München, Garching, Germany

Continuous adaptation of networks like our vasculature ensures optimal network performance when challenged with changing loads. Here, we show that adaptation dynamics allow a network to memorize the position of an applied load within its network morphology. We identify that the irreversible dynamics of vanishing network links encode memory. Our analytical theory successfully predicts the role of all system parameters during memory formation, including parameter values which which prvent memory formation. We thus provide an analytically tractable theory of memory formation in disordered systems.

#### SOE 20.5 Fri 12:30 H19

Inference of fractional nonlinear models from temperature time series and application to predictions —  $\bullet$ JOHANNES A. KASSEL and HOLGER KANTZ — MPI for the Physics of Complex Systems, Dresden, Germany

We introduce a method to reconstruct macroscopic models of one-dimensional nonlinear stochastic processes with long-range correlations from sparsely sampled time series by combining fractional calculus and discrete-time Langevin equations. We reconstruct a model for daily mean temperature data recorded at Potsdam (Germany) and use it to predict the first frost date. Including the Arctic Oscillation Index as an external driver into our model, we predict extreme temperatures for several European weather stations, illustrating the potential of long-memory models for predictions in the subseasonal-to-seasonal range.

- Invited Talks, Contributed Talks, and Posters -

### TT 1: Topology: Majorana Physics

Time: Monday 9:30-13:15

#### Invited Talk

TT 1.1 Mon 9:30 H10

**Stability of Floquet Majorana box qubits** — •ANNE MATTHIES — Institute for Theoretical Physics, University of Cologne, Germany

A topological superconductor in one dimension can host Majorana zero modes at its edge. By driving the system periodically, so-called  $\pi$  modes (also named Floquet-Majoranas) can arise. These are topologically protected modes with the quasi-energy  $\pi/T$ , where T is the period of the drive. We consider the role of  $\pi$ modes in the presence of long-range Coulomb interactions and therefore study a Cooper pair box made of two Josephson coupled superconducting topological quantum wires. Time-dependent gate voltages periodically drive the system and can induce  $\pi$  modes. The presence of four Majoranas and four  $\pi$  Majoranas in our setup allows us to define three topological qubits in a fixed fermion parity sector within one single box. We investigate how to obtain and control the  $\pi$  modes and study their stability in the presence of interactions. The stability of the Floquet-Majorana box qubit depends crucially on the initialization of the Floquet state. If the system is prepared by adiabatically increasing the amplitude of the oscillating gate voltage, the topological Floquet phase is always inherently unstable. The instability arises due to resonant quasi-particle creation mediated by interactions. However, a stable Floquet phase can be reached by using a two-step protocol. First, the amplitude of the oscillating gate voltage is adiabatically increased, while the frequency of the oscillation is small. Then, the oscillation frequency is increased slowly. With this frequency-sweep protocol, we can achieve a stable Floquet device despite interactions. [1] PRL 128, 127702

TT 1.2 Mon 10:00 H10

Quantized phase-coherent heat transport of counterpropagating Majorana modes — Alexander G. Bauer¹, Benedikt Scharf², Laurens W. Molenkamp³, Ewelina M. Hankiewicz², and •Björn Sothmann¹ — ¹Theoretische Physik, Universität Duisburg-Essen and CENIDE, D-47048 Duisburg, Germany - ²Institute of Theoretical Physics and Astrophysics and Würzburg-Dresden Cluster of Excellence ct.qmat, University of Würzburg, Am Hubland, 97074 Würzburg, Germany — ³Experimentelle Physik III, Physikalisches Institut, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany We demonstrate that phase-coherent heat transport constitutes a powerful tool to probe Majorana physics in topological Josephson junctions. We predict that the thermal conductance transverse to the direction of the superconducting phase bias is universally quantized by half the thermal conductance quantum at phase difference  $\phi = \pi$ . This is a direct consequence of the parity-protected counterpropagating Majorana modes which are hosted at the superconducting interfaces. Away from  $\phi = \pi$ , we find a strong suppression of the thermal conductance due to the opening of a gap in the Andreev spectrum. This behavior is very robust with respect to the presence of magnetic fields. It is in direct contrast to the thermal conductance of a trivial Josephson junction which is suppressed at any phase difference  $\phi$ .

#### TT 1.3 Mon 10:15 H10

**Cookbook for perfect topological Majorana fermions** — •PRATHYUSH P. PODUVAL^{1,2}, THOMAS L. SCHMIDT¹, and ANDREAS HALLER¹ — ¹University of Luxembourg, Luxembourg, Luxembourg — ²Indian Institute of Science, Bangalore, India

It has been demonstrated that Majorana corner modes of higher order topological insulators (HOTI) can be rotated by magnetic and superconducting pairing fields which pump the corner modes through the edges, and effectively realise a two-fold particle exchange [1]. These results are based on exact diagonalization of quadratic Hamiltonians that predict extended corner Majorana modes. Here, we show analytically that the topological phase of the 2D Majorana HOTI model can be adiabatically deformed to a scenario we dub "sweet spot limit", with perfectly localized Majorana corner modes. The existence of sweet spot limits are important for obtaining analytical solutions and also for possible experimental realizations with constraints on the total number of lattice nodes. Our findings are based on a systematic corner mode construction, which we apply to known lattice models in one and two spatial dimensions. The key idea is to obtain the typical lattice dimerization picture of the Hamiltonian matrix elements in a simultaneous eigenbasis of Majorana fermions and the symmetry operator which protects the corner modes. Based on our findings, we propose a novel 3D model featuring perfectly localized Majorana corner modes which avoids the dimensional obstruction encountered in 2D and may pave the way towards braiding. [1] Phys. Rev. Res. 2, 032068

 $\label{eq:transformation} \begin{array}{c} TT \ 1.4 & Mon \ 10:30 & H10 \\ \mbox{Edge $\mathbb{Z}_3$ parafermions in fermionic lattices.} & - \bullet \mbox{Raphael L R C TEIXEIRA}^{1,2} \\ \mbox{and LUIS G G V DIAS DA SILVA}^1 & - ^1 \mbox{Instituto de Fisica - Universidade de Sao} \\ \mbox{Paulo, Sao Paulo Brazil} & - ^2 \mbox{Department of Physics and Materials Science Université du Luxembourg, Luxembourg, Luxembourg} \end{array}$ 

Parafermions modes are non-Abelian anyons which were introduced as  $\mathbb{Z}_N$  generalizations of  $\mathbb{Z}_2$  Majorana states. In particular,  $\mathbb{Z}_3$  parafermions can be used to produce Fibonacci anyons, laying a path towards universal topological quantum computation. Due to their fractional nature, much of theoretical work on  $\mathbb{Z}_3$  parafermions has relied on bosonization methods or parafermionic operators. In this work, we introduce a representation of  $\mathbb{Z}_3$  parafermions in terms of purely fermionic models operators in the single-occupancy basis (t - J regime). We establish the equivalency of a family of 1D-lattice fermionic models written in the t - J model basis supporting free  $\mathbb{Z}_3$  parafermionic modes at its ends. By using density matrix renormalization group calculations, we are able to characterize the topological phase transition and study the effect of local operators (doping and magnetic fields) on the spatial localization of the parafermionic modes and their stability. Moreover, we discuss the necessary ingredients towards realizing  $\mathbb{Z}_3$  parafermions in strongly interacting electronic systems.

TT 1.5 Mon 10:45 H10

 $2\pi$  domain walls for tunable Majorana devices — •DANIEL HAUCK¹, STEFAN Rex^{2,3}, and MARKUS GARST¹ — ¹Karlsruhe Institute of Technology, Institute for Theoretical Solid State Physics, Wolfgang-Gaede-Str. 1, 76131 Karlsruhe — ²Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, 76021 Karlsruhe, Germany — ³Institute for Theoretical Condensed Matter Physics, Karlsruhe Institute of Technology, 76131 Karlsruhe

Superconductor-magnet hybrid structures provide a platform for investigating topological phases with localized Majorana states. Such states have previously been predicted for elongated Skyrmions in the magnetic layer. Here we consider  $2\pi$  domain walls which are easier to realize and tweak experimentally. We show that localized Majorana states can be found in these systems and investigate possible ranges of parameters. This establishes  $2\pi$  domain walls as tunable elements for the realization of Majorana devices.

TT 1.6 Mon 11:00 H10 **Fraunhofer pattern in the presence of Majorana modes** — •FERNANDO DOMINGUEZ¹, ELENA G. NOVIK², and PATRIK RECHER^{1,3} — ¹Institute for Mathematical Physics, TU Braunschweig, Germany — ²Institute of Theoretical Physics, Technische Universität Dresden, Germany — ³Laboratory for Emerging Nanometrology, Braunschweig, Germany

We investigate signatures of the presence of Majorana bound states that can arise in the Fraunhofer pattern of Josephson junctions made of Top.Sc/Qu.Spin Hall /Top.Sc. In this setup,the presence of Majorana bound states at the NS interfaces introduces electron-hole reflections with parallel spin, which due to spinmomentum locking, are forced to take place between opposite edges. In contrast to local electron-hole reflections (with opposite spin), the presence of such nonlocal processes do not accumulate a geometrical phase and therefore, they can change drastically or partially the periodicity of the Fraunhofer pattern. In order to observe such a change in the Fraunhofer pattern, the quantum spin-Hall edges have to be coupled either directly or through the bulk. Here, we propose two different scenarios where this can occur and provide numerical results from a scattering and tight-binding models.

TT 1.7 Mon 11:30 H10

**Photonic noise as a probe of Majorana bound states** — •LENA BITTERMANN¹, FERNANDO DOMINGUEZ¹, and PATRIK RECHER^{1,2} — ¹Institut für Mathematische Physik, Technische Universität Braunschweig, D-38106 Braunschweig, Germany — ²Laboratory for Emerging Nanometrology Braunschweig, D-38106 Braunschweig, Germany

We propose a route to detect Majorana bound states (MBSs) by coupling a topological superconductor to a quantum dot (QD) in a pn-junction. Here, two MBSs are coherently coupled to electrons on the QD, which recombine with holes in situ to photons. Importantly, the polarization of the emitted photons provides

Location: H10

direct information on the spin structure [1,2] and nonlocality [2,3] of the MBSs. Here, we focus on the shot noise of the emitted photons which allows to clearly distinguish the cases of well separated MBSs at zero energy from overlapping MBSs. In addition, we show that quasiparticle poisoning changes the shot noise from super-Poissonian to sub-Poissonian. Furthermore, this setup can be extended by coupling a second QD close to the second MBS which gives rise to more resonances in the shot noise leading to additional signatures of the MBSs. [1] D. Sticlet, C. Bena, P. Simon, PRL 108, 096802 (2012)

#### TT 1.8 Mon 11:45 H10

Zero energy modes of artificial spin chains from ab initio calculations — •BENDEGÚZ NYÁRI¹, ANDRÁS LÁSZLÓFFY², LÁSZLÓ SZUNYOGH¹, and BALÁZS ÚJFALUSSY² — ¹Department of Theoretical Physics, Budapest University of Technology and Economics, Hungary — ²Wigner Research Centre for Physics, Institute for Solid State Physics and Optics, Hungary

The conditions under which Majorana zero modes (MZM) appear and their physical properties in realistic materials have been of high interest over the past few years triggered by their possible applications as fault tolerant quantum bits. The MZMs are topological states corresponding to triplet pairing at zero energy emerging in an inner gap inside the superconducting gap. However, experimentally it is very challenging to identify MZMs based solely on the spectral properties. Ab inito calculations are able to reproduce the measured spectral quantities and provide additional information on the nature of the in-gap states reported in corresponding experiments.

In this work we present ab initio calculations in the superconducting state of the in-gap density of states and the singlet and triplet order parameters for Fe chains on Nb(110) surface covered by one monolayer of Au. The Fe chains are also assumed to be in various artificial spin-spiral states. In a wide range of the spin-spiral wavelength we find an inner gap with states at zero-energy and large triplet pairing order parameter. A similar behavior to previous studies based on tight-binding models further supports the conjecture that there are MZMs in this system.

#### TT 1.9 Mon 12:00 H10

Quantitative theory of of Yu-Shiba-Rusinov states of magnetic adatoms on Nb(110) surface and various overlayers — •BALAZS UJFALUSSY¹, ANDRAS LASZLOFFY¹, BENDEGUZ NYARI², KYUNGWHA PARK³, and LASZLO SZUNYOGH² — ¹Wigner Research Centre for Physics, Budapest, Hungary — ²Budapest University of Technology, Budapest, Hungary — ³Department of Physics, Virginia Tech, Blacksburg, Virginia, USA

We present a fully relativistic first-principles-based theoretical approach for the calculation of the spectral properties of Fe, Co, Cr and Mn adatoms on the surface of Nb(110) substrate in the superconducting state, providing a material-specific framework for the investigation of the Yu-Shiba-Rusinov (YSR) states. We study the effect of spin-orbit coupling, the strength of the exchange field and induced moments. Furthermore, we attempt to explain certain features of the STM experiments, and to link some properties to the normal state density of states. In order to study the effect of the substrate, we provide results for the YSR states in the case of impurities on various Nb(110)/overlayer systems as well. We also study the formation of a zero-bias peak for single adatoms and dimers.

#### TT 1.10 Mon 12:15 H10

Matrix modelling of potential disorder effects on in-gap spectra of a vortex on a proximitized topological insulator surface — •ALEXANDER ZIESEN and FABIAN HASSLER — RWTH Aachen University, Aachen, Germany

We study a heterostructure of a three-dimensional topological insulator and an *s*-wave superconductor. If a single superconducting flux quantum is trapped on the proximitized surface of the topological insulator, it is theoretically predicted that a Majorana zero mode is hosted in this vortex core. To enable the usage of this non-Abelian anyon for quantum computation, it is essential to maximize the spectral gap between the Majorana zero mode and the first excited in-gap state. For clean systems tuned close to the charge neutrality point of the topological insulator and vortex radii close to the superconducting coherence length, this excitation gap is predicted to be comparable to the superconducting gap. On the other hand, for strongly disordered topological insulators, supersymmetric

 $\sigma$ -models of symmetry class BD predict a finite, but experimentally barely resolvable excitation gap. In this work, we build the bridge between both limits with a matrix description of an effective two-dimensional surface model for strong proximization and potential disorder. With it, we quantify the amount of disorder tolerable in the system to allow for experimental resolution.

TT 1.11 Mon 12:30 H10

Steering Majorana braiding via skyrmion-vortex pairs: a scalable platform — JONAS NOTHHELFER¹, •SEBASTIÁN A. DÍAZ¹, STEPHAN KESSLER², TOBIAS MENG³, MATTEO RIZZI^{4,5}, KJETIL M. D. HALS⁶, and KARIN EVERSCHOR-SITTE¹ — ¹University of Duisburg-Essen, Duisburg, Germany — ²Johannes Gutenberg University of Mainz, Mainz, Germany — ³Technische Universität Dresden, Dresden, Germany — ⁴Forschungszentrum Jülich, Jülich, Germany — ⁵University of Cologne, Cologne, Germany — ⁶University of Agder, Grimstad, Norway

Majorana zero modes are quasiparticles that hold promise as building blocks for topological quantum computing. However, the litmus test for their detection, the observation of exotic non-abelian statistics revealed by braiding, has so far eluded experimental efforts. Here we take advantage of the fact that skyrmionvortex pairs in superconductor-ferromagnet heterostructures harboring Majorana zero modes can be easily manipulated in two spatial dimensions. We adiabatically braid the hybrid topological structures and explicitly confirm the nonabelian statistics of the Majorana zero modes numerically using a self-consistent calculation of the superconducting order parameter. Our proposal of controlling skyrmion-vortex pairs provides the necessary leeway toward a scalable topological quantum computing platform.

#### TT 1.12 Mon 12:45 H10

Sachdev-Ye-Kitaev circuits for braiding and charging Majorana zero modes — •JAN BEHRENDS¹ and BENJAMIN BÉRI^{1,2} — ¹TCM Group, Cavendish Laboratory, University of Cambridge, J.J. Thomson Avenue, Cambridge CB3 0HE, United Kingdom — ²DAMTP, University of Cambridge, Wilberforce Road, Cambridge CB3 0WA, United Kingdom

The Sachdev-Ye-Kitaev (SYK) model is an all-to-all interacting Majorana fermion model for many-body quantum chaos and the holographic correspondence. Here we construct fermionic all-to-all Floquet quantum circuits of random four-body gates designed to capture key features of SYK dynamics. Our circuits can be built using local ingredients in Majorana devices, namely, charging-mediated interactions and braiding Majorana zero modes. This offers an analog-digital route to SYK quantum simulations that reconciles all-to-all interactions with the topological protection of Majorana zero modes, a key feature missing in existing proposals for analog SYK simulation. We also describe how dynamical, including out-of-time-ordered, correlation functions can be measured in such analog-digital implementations by employing foreseen capabilities in Majorana devices.

TT 1.13 Mon 13:00 H10

Location: H22

Symplectic topological Kondo effect — •ELIO KOENIG¹, JUKKA VAYRYNEN², and GUANGJIE LI² — ¹Max-Planck-Institute for Solid State Research, Heisenbergstr. 1, 70569 Stuttgart, Germany — ²Purdue University, West Lafayette, IN 47907-2036, USA

The topological Kondo effect describes the stable, strongly coupled, non-Fermi liquid state obtained by screening a topological quantum dot, a so-called Majorana Cooper pair box, by means of external metallic leads. The symmetry group describing this exotic Kondo effect is the orthogonal group of rotations of real Majorana fermions. In this talk, I am going to present a symplectic topological Kondo effect, which, crucially, does not rely on the presence of Majorana modes. As I present in detail, this system can be implemented by coupling leads to a quantum dot consisting of a floating conventional s-wave superconductor coupled to spinful fermionic zero modes, as obtained e.g., in arrays of 1D topological insulators. Combining the solution of this problem at strong coupling with known results from Bethe Ansatz and conformal field theory demonstrates that this model harbors emergent anyonic excitations, including Fibonacci anyons, depending on the number of external leads. Importantly, the non-trivial physics is stable to anisotropies in the coupling to different leads.

### TT 2: Nanotubes, Nanoribbons and Graphene

Time: Monday 9:30-13:15

TT 2.1 Mon 9:30 H22

The longitudinal vibration of a suspended carbon nanotube has been observed many times in low temperature transport spectra via distinct harmonic Franck-Condon sidebands. Typically, strong Franck-Condon coupling has been attributed to disorder-induced or deliberately targetted charge localization. Here, we present the observation of a strong, tunable coupling in an ultra-clean carbon nanotube with N = 1 or N = 2 electrons in the conduction band. The clean transport spectrum allows a tentative identification of the electronic base quantum states according to their valley quantum number. Interestingly, the Franck-Condon coupling strength g, as extracted from our data, both depends on the magnetic field and on the precise electronic quantum states participating in transport. While spin-dependent Franck-Condon phenomena have already been observed, our results clearly point towards a valley-dependent origin. As possible cause of this phenomenon, re-shaping of the electronic wavefunction envelope by the magnetic field is discussed. A simple calculation demonstrates that variations of g as observed in the experiment can be reproduced by the theory, paving the way towards more realistic and detailed quantum-mechanical modelling.

#### TT 2.2 Mon 9:45 H22

**Transparent low-temperature contacts to MOS_2 microtubes** — •ROBIN T. K. SCHOCK¹, JONATHAN NEUWALD¹, MATTHIAS KRONSEDER¹, SIMON REINHARDT¹, LUKA PIRKER², MAJA REMŠKAR², and ANDREAS K. HÜTTEL¹ — ¹Institute for Experimental and Applied Physics, University of Regensburg, 93040 Regensburg, Germany — ²Solid State Physics Department, Institute Jožef Stefan,1000 Ljubljana, Slovenia

Even though synthesis procedures of transition metal dichalcogenide (TMDC) based nanotubes have been established for many years, the quantum transport properties remain largely unexplored to date. First low-temperature transort spectroscopy results clearly show Coulomb blockage at 300 mK [1]. However, the contact material still remains a limiting factor due to the Fermi level pinning near the conduction band. Recently, for planar MoS₂ materials [2], the use of bismuth improved room-temperature contact resistances drastically. Here we present first transport measurements on  $MoS_2$  microtubes with bismuth contacts at millikelvin temperatures. Our  $MoS_2$  tubes are grown via a chemical transport reaction, yielding diameters down to 7 nm and lengths up to several millimeters. After transfering the tubes onto a Si/SiO₂ substrate, contacts are deposited using electron beam lithography. The resulting devices show Coulomb blockade, with in many cases, a transition from transparent conduction into a band gap. Disorder, compared with previous scandium-based devices, is significantly reduced. [1] S. Reinhardt *et al.*, Phys. Stat. Sol. RRL **13**, 1900251 (2019)

[2] P. C. Shen et al., Nature 593, 211 (2021).

#### TT 2.3 Mon 10:00 H22

**Topological transitions in dc+ac-driven superconductor nanotubes** — •VLADIMIR M. FOMIN¹ and OLEKSANDR V. DOBROVOLSKIY² — ¹Institute for Integrative Nanosciences, Leibniz IFW Dresden, 01069 Dresden — ²Superconductivity and Spintronics Laboratory, Nanomagnetism and Magnonics, Faculty of Physics, University of Vienna, 1090 Vienna

A complex interplay of the patterns of superconducting screening currents with the 3D geometry unveils a plethora of emerging effects in the dynamics of topological defects in curved 3D superconductor nanoarchitectures [1]. We discuss topological transitions in the dynamics of vortices and slips of the phase of the order parameter in open superconductor nanotubes under a modulated dc+ac transport current [2]. Relying upon the time-dependent Ginzburg-Landau equation, we reveal two voltage dynamics regimes. The first regime with a pronounced first harmonic in the FFT spectrum of the induced voltage occurs when the dominant area of the open tube is in the superconducting or normal state. The second regime entails a rich FFT spectrum of the induced voltage because of the complex interplay between the dynamics of vortices/phase slips and the screening currents. Our findings represent novel dynamical states in superconductor open nanotubes, in particular, paraxial and azimuthal phase-slip regions, their branching and coexistence with vortices, and allow for their control by superimposed dc+ac current stimuli.

#### TT 2.4 Mon 10:15 H22

**Graphene nanomembranes as valleytronic devices** — •NIKODEM SZPAK¹, WALTER ORTIZ^{2,3}, and THOMAS STEGMANN³ — ¹Fakultät für Physik, Universität Duibsurg-Essen, Duisburg, Germany — ²Instituto de Investigacion en Ciencias Basicas y Aplicadas, Universidad Autonoma del Estado de Morelos, Cuernavaca, Mexico — ³Instituto de Ciencias Fisicas, Universidad Nacional Autonoma de Mexico, Cuernavaca, Mexico

We investigate the electronic transport in graphene nanoelectromechanical resonators (GrNEMS), known also as graphene nanodrums or nanomembranes. We demonstrate that these devices, despite small values of strain, between 0.1 and 1%, can be used as efficient and robust valley polarizers and filters. Their working principle is based on the pseudomagnetic field generated by the strain of the graphene membrane. They work for ballistic electron beams as well as for strongly dispersed ones and can be also used as electron beam collimators due to the focusing effect of the pseudomagnetic field. We show additionally that the current flow can be estimated by semiclassical trajectories which represent a computationally efficient tool for predicting the functionality of the devices. [1] W. Ortiz, N. Szpak, T. Stegmann, arXiv:2202.01739 (2022), submitted

#### TT 2.5 Mon 10:30 H22

Quantum interference in graphene by dynamic strain — •CHRISTIAN GLASE-NAPP, PAI ZHAO, MARTA PRADA, LARS TIEMANN, and ROBERT H. BLICK — Center for Hybrid Nanostructures, Universität Hamburg, Luruper Chaussee 149, 22761 Hamburg, Germany

We exploit surface acoustic waves (SAW) as a time-dependent strain wave that propagates through graphene [1] and study its influence on the weak localization (WL) phenomenon at 4 Kelvin. WL is a quantum interference effect that occurs due to the wave nature of charge carriers. In the case of graphene, it can be characterized by inelastic scattering and elastic inter- and intravalley scattering [2]. We fabricated interdigital transducers (IDTs) on a piezoelectric LiNbO₃ substrate, which can be actuated by a radiofrequency (RF) signal to generate a SAW. A large sheet of CVD-grown monolayer graphene was transferred onto the substrate and a Hall bar was patterned in the path of the SAW. In low-field magnetotransport measurements without SAW we observe a well-defined WL effect. When we launch a SAW that strains the graphene layer, WL becomes progressively suppressed with increasing SAW intensity. In this presentation we will show how SAW-induced dynamic strain affects the scattering mechanisms of WL.

TT 2.6 Mon 10:45 H22

**Tunable geometric phase in graphene quantum dots with spin-orbit coupling** — •DARIO BERCIOUX^{1,2}, DIEGO FRUSTAGLIA³, and ALESSANDRO DE MARTINO⁴ — ¹Donostia International Physics Center (DIPC), Manuel de Lardizbal 4, E-20018 San Sebastián, Spain — ²IKERBASQUE, Basque Foundation for Science, Euskadi Plaza, 5, 48009 Bilbao, Spain — ³Departamento de Física Aplicada II, Universidad de Sevilla, E-41012 Sevilla, Spain — ⁴Department of Mathematics, City, University of London, London EC1V 0HB, United Kingdom

We show how chiral states in circular graphene pn junctions subject to normal magnetic fields and strong proximitized spin-orbit coupling can mimic those of propagating spin carriers in semiconducting quantum rings. We derive the effective one-dimensional Hamiltonian governing the spin dynamics of the zero-mode and calculate the associated geometric phase. We find that for a given polarity of the junction, it exists a special point in parameter space where the spin is fully polarized along the radial direction in the graphene plane. We further propose a quantum-Hall interferometer where these features can be readily identified.

#### TT 2.7 Mon 11:00 H22

Effective short distance interacting Hamiltonians for higher Landau levels in graphene — •NIKOLAOS STEFANIDIS¹ and INTI SODEMANN^{2,1} — ¹Max-Planck Institute for the Physics of Complex Systems, D-01187 Dresden, Germany — ²Institut für Theoretische Physik, Universität Leipzig, D-04103 Leipzig, Germany

We study the many body problem in graphene in the quantum Hall regime. Although dominated by Coulomb interactions, short range corrections can select among the degenerate ground states. For the N = 0 Landau level (LL) their importance has been demonstrated [1,2] and recent work[3] suggests that this remains true in the N = 1 LL . In this talk, we will present results on effective Hamiltonians with  $N \neq 0$ . We analyse the point group symmetries of graphene and find the Hamiltonians dictated by those.

Massless Dirac fermions with time-dependent magnetic barriers — •NICO LEUMER¹ and WOLFGANG HÄUSLER² — ¹IPCMS, CNRS, University of Strasbourg, France — ²University of Augsburg, Germany

Potential barriers controlled by gate electrodes, as common for 2D-electron gases, are inefficient to guide graphene carriers, due to the Klein tunneling phenomenon. One well known way out consists in using inhomogeneous magnetic fields [1]. However, when considering temporal variations, fundamental differences arise between electric and magnetic fields. While to good approximation the former can be treated on its own, time dependent magnetic fields always will induce electric fields of comparable strengths, according to Maxwell's equations. Following Ref. [2] we report on the complete analytical solution for transmission through a weakly,  $\omega$ -periodically modulated magnetic fields generalize the scattering problem to two dimensions. We find that sideband transport requires the static barrier to be permeable, while momentum conservation imposes new, independent conditions for complete reflection.

**Measuring correlated phases in encapsulated bilayer graphene via graphite contacts** — •ISABELL WEIMER, ANNA SEILER, and THOMAS WEITZ — 1st Physical Institute, Faculty of Physics, University of Göttingen, Friedrich-Hund-Platz 1, Göttingen 37077, Germany

Encapsulation of graphene in hexagonal Boron Nitride (hBN) as well as the addition of graphite top and bottom gates to the sample have been central to a lot of the research done on graphene in the recent years. This has allowed the observation of multiple new correlated phases including Stoner metals [1-3], correlated insulators [1] and superconductivity [2] at large electric fields in trigonal warped bilayer graphene.

The extent to which the phase space of Bernal bilayer graphene can be even further explored is amongst other parameters limited by the maximum electric field and thus by the maximum values of gate voltages that can be applied to the sample without breaking through the dielectric. With the aim of increasing these maximum voltages, we have explored the method of using graphite contacts to contact bilayer graphene flakes within van-der-Waals heterostructures [1]. Using graphite contacts instead of commonly used 1D edge contacts [4] removes the necessity to etch into the hBN flakes, which had previously been a limiting factor for the applied electric fields.

TT 2.10 Mon 12:00 H22

Mapping electrostatically tunable bands in twisted double bilayer graphene in magnetic fields — •Yulia Maximenko^{1,2}, Marlou Slot^{1,3}, Sungmin Kim^{1,2}, Daniel Walkup¹, Evgheni Strelcov¹, En-Min Shih^{1,3}, Dilek Yildiz^{1,2}, Steven Blankenship¹, Kenji Watanabe⁴, Takashi Taniguchi⁴, Yafis Barlas⁵, Paul Haney¹, Nikolai Zhitenev¹, Fereshte Ghahari⁶, and Joseph Stroscio¹ — ¹NIST MD USA — ²U of Maryland USA — ³Georgetown U DC USA — ⁴NIMS Tsukuba Japan — ⁵U of Nevada-Reno NV USA — ⁶George Mason U VA USA

After the first demonstration of superconductivity in magic-angle twisted bilayer graphene (MATBG), 2D moiré superlattices proved to be valuable systems for band engineering and studying correlated quantum phases. An imposed periodic potential can drive a crystal into a flat-band phase facilitating strong electron-electron interactions. In MATBG, flat bands appear only at a few precise values of the twist angle. In contrast, small-angle twisted double bilayer graphene (TDBG) can be tuned in and out of the correlated regime using electrostatic fields in a continuous range of twist angles. Local probe studies are key to avoid the common complication of angle disorder. Here we employ scanning tunneling microscopy and electrostatic gating to study TDBG with atomic spatial and high energy resolution in magnetic fields up to 15 T. We observe Landau quantization and map out the TDBG band structure in response to the applied electric field. We use theoretical modeling of the effects of displacement fields, Berry curvature, and magnetic fields to support our experimental findings.

#### TT 2.11 Mon 12:15 H22

Novel correlated phases near the van Hove singularity in Bernal bilayer graphene — •ANNA SEILER¹, FAN ZHANG², and THOMAS WEITZ¹ — ¹1st Physical Institute, Faculty of Physics, University of Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen, Germany — ²Department of Physics, University of Texas at Dallas, Richardson, TX, 75080, USA

Diverging density of states offers a unique opportunity to explore a wide variety of correlated phases in low dimensional systems. Graphene few-layers can host electric-field controlled Lifshitz transitions and concomitant van-Hovesingularities in the density of states. Here, we present the observation of experimental signatures consistent with various interaction-driven phases in trigonally warped Bernal bilayer graphene including the fractional metals of Stoner type (1-3). More prominently, we have found a Chern-insulating phase that emerges at finite densities in between two Lifshitz transitions and even survives at zero magnetic field (1). This phase is consistent with a topologically nontrivial Wigner-Hall crystalline phase, i.e., an electron crystal with a quantized Hall conductance as originally proposed at finite magnetic fields in 1989 (4). Evidently, our discovery shows that the reproducible, tunable, and simple Bernal bilayer graphene is a fertile ground for exploring new, rich, and intricating many-body physics.

**Towards quantum transport mesaurements on encapsulated rhombohedrally stacked multilayer graphene** — •MONICA KOLEK MARTINEZ DE AZAGRA and THOMAS WEITZ — 1. Physikalische Institut, Georg August Universität Göttingen In the recent past flat band multilayer graphene systems have become an experimental playground to explore a plethora of highly correlated many body phenomena such as superconductivity, topological insulators and ferromagnetic phases. However, so far the broad range of phenomena across the different systems, i.e., bilayer, twisted bilayer and rhombohedral trilayer graphene, still hold open questions to the origins and physical limitations of these phenomena. To further investigate these phenomena, we prepare high quality encapsulated multilayer graphene samples, using a variety of techniques such as Raman spectroscopy, scanning near field microscopy, atomic force microscopy and the dry transfer method with the goal to study these samples through magneto quantum transport measurements in the milli Kelvin regime.

TT 2.13 Mon 12:45 H22

Effective mass measurements near electric field controlled Lifshitz transitions in trigonally warped bilayer graphene — •MARTIN STATZ¹, ANNA SEILER¹, FRANCESCA FALORSI¹, JONAS PÖHLS¹, KENJI WATANABE², TAKASHI TANIGUCHI³, and R. THOMAS WEITZ¹ — ¹Univ. of Göttingen, Göttingen, Germany — ²Research Cent. for Funct. Mater., Tsukuba, Japan — ³Int. Cent. for Mater. Nanoarchitectonics, Tsukuba, Japan

Various spontaneous symmetry broken phases such as Stoner ferromagnetism, spin-polarized superconductivity, a quantum anomalous Hall octet and a topologically non-trivial Wigner-Hall crystal phase have recently been reported in bilayer graphene (BLG). Since these interaction-driven phenomena are dictated by the ratio of the Coulomb and kinetic energy of carriers, they can be promoted by the formation of flat bands and a divergent density of states (DoS) near Lifshitz transitions (LT). Trigonally warped BLG at low vertical displacement fields (D-field) and carrier densities ( $\sim 10^{11}~{\rm cm}^{-2}$ ) displays one centre and three off-centre Dirac cones in each valley and therefore offers a rich playground for correlated phases (CP) by inducing charge density and D-field driven LT. Insights on the renormalized bandstr. and eff. masses of carriers near such LT will foster a deeper understanding of the formation of these CP. Here, we report on our status on eff. mass measurements via T-dep. (1.9-25 K) Shubnikov-de Haas osc. in the vicinity of charge density and D-field driven LT in trigonally warped BLG. To minimize effects from pot. disorder, we encapsulate BLG in hex. boron-nitride and employ graphite contacts and graphite gates.

**Ising superconductivity induced from valley symmetry breaking in twisted trilayer graphene** – •TOBIAS STAUBER¹ and JOSE GONZALEZ² – ¹Instituto de Ciencia de Materiales de Madrid, CSIC – ²Instituto de Estructura de la Materia, CSIC

We show that the e-e interaction induces a strong breakdown of valley symmetry in twisted trilayer graphene, just before the superconducting instability develops in the hole-doped material. We analyze this effect by means of an atomistic selfconsistent Hartree-Fock approximation, which is a sensible approach as the Fock part becomes crucial to capture the breakdown of symmetry. This effect allows us to reproduce the experimental observation of the Hall density, including the reset at 2-hole doping. Moreover, the breakdown of valley symmetry has important consequences for the superconductivity, as it implies a reduction of symmetry down to the C3 group. This leads to spin-splitting with respect to the two different valleys, suggesting Ising superconductivity and leading to a Paul-violation with a factor 2-3 as seen in experiments [1]. We also find spin-layer locking which might explain the strong-coupling limit of superconductivity seen in general moiré-samples. We stress that the breakdown of symmetry down to C3 and subsequent spin-valley and spin-layer locking may be shared by other materials with valley symmetry breaking.

#### TT 3.1 Mon 9:30 H23

Is lead really a prototypical type I superconductor? New results on the phase diagram at ultra-low temperatures — Thomas Gozlinski, Qili Li, Rolf Heid, Jörg Schmalian, and •Wulf Wulfhekel — Karlsruhe Institute of Technology

Superconductors are classified by their behavior in a magnetic field into type I, which transitions from a superconducting Meissner to a normal state at the critical field and type II, which have an additional Shubnikov phase consisting of magnetic vortices with one magnetic flux quantum, each. For type I superconductors of finite lateral dimensions, the transition to the normal state is, however,

known to occur locally in form of domains in the so-called intermediate Landau state. Basis for this classification are thermodynamic considerations near the critical temperature and a single band description of superconductivity. Although bulk lead (Pb) is classified as a prototypical type I superconductor, we surprisingly observe single and multi-flux quanta vortices in the intermediate state at temperatures far below the critical temperature using a 25 mK scanning tunneling microscope hand in hand with a complex superconducting behaviour of the two distinct Fermi surfaces of Pb. By probing the quasiparticle local density of states (LDOS) inside the vortices and comparison with quasiclassical simulations based on DFT band-structure calculations, we identify the Caroli-de-Gennes-Matricon states of the two superconducting bands of Pb and are consequently able to determine their winding number.

 $\label{eq:transition} TT 3.2 \ Mon 9:45 \ H23$  High-precision impedance measurements near the Berezinski-Kosterlitz-Thouless transition in strongly disordered superconductors — •LEA PFAFFINGER¹, ALEXANDER WEITZEL¹, THOMAS HUBER¹, KLAUS KRONFELDNER¹, LORENZ FUCHS¹, SVEN LINZEN², EVGENI IL'ICHEV², NICOLA PARADISO¹, and CHRISTOPH STRUNK¹ — ¹University of Regensburg, Germany — ²Leibniz Institute of Photonic Technology, Jena, Germany

We investigate the Berezinskii-Kosterlitz-Thouless (BKT) transition - a vortex induced topological phase transition - in 3 nm thin atomically layer deposited NbN films. The samples are placed inside a RLC-resonator, whose design enables us to perform AC measurements of the superfluid stiffness  $J_s$  and four-probe current-voltage (IV) characteristics in the same cooling cycle. In contrast to earlier experiments, we observe a sharp discontinuous jump of  $J_s$  at the BKT transition temperature  $T_{BKT}$ . Comparison of the  $J_s$  and the DC resistance measurements reveal quantitative agreement of both  $T_{BKT}$  and  $T_{c0}$ . Powerlaw exponents extracted of IV characteristics agree quantitatively with  $J_s$  and calculations based on renormalization group. Surprisingly, if a DC current is added to the rf-drive,  $J_s(I)$  reaches a pronounced maximum before dropping sharply to zero at a current much smaller than the pair breaking critical current. This behaviour may be tentatively explained as a cut-off of the BKT renormalisation flow by the current.

TT 3.3 Mon 10:00 H23

**Prediction of ambient-pressure superconductivity in ternary hydride PdCuH**_x — •RICCARDO VOCATURO¹, CESARE TRESCA², GIACOMO GHIRINGHELLI³, and GIANNI PROFETA^{2,4} — ¹IFW-ITF, Dresden, Germany — ²Università degli studi dell'Aquila, L'Aquila, Italy — ³Politecnico di Milano, Milano, Italy — ⁴CNR-SPIN, L'Aquila, Italy

We present an ab initio study of the ternary hydride PdCuH_x, a parent compound of the superconducting PdH, at different hydrogen content (x=1,2). We investigate its structural, electronic, dynamical, and superconducting properties, demonstrating that, at low hydrogen content, the system is not a superconductor above 1K; however, the highly hydrogenated structure is a strongly coupled superconductor. We give a solid rationale for the unusual increase of the superconducting critical temperature in hydrogenated palladium when alloyed with noble metals (Cu, Ag, and Au), as observed in Stritzker's experiments in 1972 but never investigated with modern experimental and theoretical techniques. We highlight the important role played by H-derived phonon modes at intermediate frequencies, dynamically stabilized by anharmonic effects, as they strongly couple with states at the Fermi level. We hope that the present results will stimulate additional experimental investigations of structural, electronic, and superconducting properties of hydrogenated palladium-noble metal alloys. Indeed, if confirmed, these compounds could be considered a novel class of superconducting hydrides, showing different coupling mechanisms, which can be exploited to engineer new ambient-pressure superconductors.

## TT 3.4 Mon 10:15 H23

Theory of spin-excitation anisotropy in the nematic phase of FeSe obtained from RIXS measurements — •ANDREAS KREISEL¹, PETER HIRSCHFELD², and BRIAN M. ANDERSEN³ — ¹Institut für Theoretische Physik, Universität Leipzig — ²Department of Physics, University of Florida, Gainesville — ³Niels Bohr Institute, University of Copenhagen

Recent resonant inelastic x-ray scattering (RIXS) experiments have detected a significant high-energy spin-excitation anisotropy in the nematic phase of the enigmatic iron-based superconductor FeSe [1], whose origin remains controversial. We apply an itinerant model previously used to describe the spin-excitation anisotropy as measured by neutron scattering measurements [2], with magnetic fluctuations included within the RPA approximation. The calculated RIXS cross section exhibits overall agreement with the RIXS data [3], including the high energy spin-excitation anisotropy such that the picture of a localized Heisenberg model does not need to be evoked in order to explain the experimental data. ## TT 3.5 Mon 10:30 H23

Local measurements of (super-)conducting microstructure in  $Rb_xFe_{2-y}Se_2$ — •DONALD M EVANS¹, STEPHAN KROHNS¹, DORINA CROITORI², VLADIMIR TSURKAN^{1,2}, and ISTVÁN KÉZSMÁRKI¹ — ¹Experimental Physics V, University of Augsburg, 86135 Germany — ²Institute of Applied Physics, MD 2028 Chisinau, Moldova.

There are many reports on the bulk coexistence of competing orders in ironbased superconductors. In some of these systems, such as RbFe₂Se₂, this is because even single crystals spontaneously phase separate into a superconducting phase made up of micron scale islands, within an antiferromagnetic host matrix. Such phase coexistence makes any bulk data challenging to interpret and, rather, requires local measurement techniques.

In this work, we use low-temperature conducting atomic force microscopy (cAFM) to map the local current response of the superconducting islands in RbFe₂Se₂. Below T_c (~ 32K) these islands show large current values, as expected for a superconductor. Unexpectedly, there is no distinct change in these current values when heating through Tc: rather, the high currents persist within the islands until they becoming as insulating as the bulk matrix at ~ 150K. This enhanced conductivity vanishes in response to external magnetic fields. This implies that the reported bulk Tc is the temperature at which the superconductivity is strong enough to connect the islands, i.e. the percolation limit, while the superconductivity within individual islands persists to higher temperatures. This work shows the strength of cAFM to understand the local properties of inhomogeneous superconductors.

## TT 3.6 Mon 10:45 H23

**Cascade of collapsed phases in SrNi**₂**P**₂ and **CaKFe**₂**As**₂ under various strain conditions — •ADRIAN VALADKHANI¹, SHUYANG XIAO², IGOR MAZIN³, SEOK-WOO LEE², PAUL CANFIELD⁴, and ROSER VALENTI¹ — ¹Goethe University, Frankfurt am Main, Germany — ²University of Connecticut, Connecticut, United States — ³George Mason University, Fairfax, USA — ⁴Iowa State University, Ames, United States

Most of crystalline solids have a maximum recoverable strain of less than 1%. Further strain will cause plastic deformation or fractures. In the current work we present  $SrNi_2P_2$ , whose maximum recoverable compressive strain is ~ 14% and tensile is ~ 6%. These widespread values of strain are realizable due to a double lattice collapse-expansion mechanism. The ab initio density functional theory calculations are in very good agreement with the experiment[1,2]. Instead of the usual uncollapsed to collapsed tetragonal transition for the generic tetragonal 122s, a second transition to an orthorhombic superstructure is observed. By a detailed investigation of the Sr, Ni, (and /) or P from first principles, we are able to give a deeper insight in the theory description of this doubly lattice collapse-expansion mechanism. Within this framework we will also discuss structural phases in CaKFe₂As₂ under varios strain conditions.

This work is support by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) for funding through TRR 288.

**3DSC** - A new dataset of superconductors including crystal structures — •TIMO SOMMER, ROLAND WILLA, JÖRG SCHMALIAN, and PASCAL FRIEDERICH — Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany

More than 100 years after the discovery of superconductivity in mercury, the search for new superconducting materials still remains challenging. In contrast to most other phenomena, making theoretical predictions about the superconductivity of a certain material is extremely difficult, due to the need to model the comparably tiny energy gain of the superconducting phase, compared to the other energy scales of the problem. Data-driven methods, in particular machine learning, are well-known for finding complex patterns in existing datasets. In the case of superconductors, the use of data science tools is to date slowed down by a lack of accessible data. Here we present a new and publicly available superconductivity dataset ("3DSC"), featuring the critical temperature  $T_c$  of superconducting materials additionally to tested non-superconductors. In contrast to existing databases such as the SuperCon database, the 3DSC contains not only the chemical composition, but also the approximate three-dimensional crystal structure of each material. We perform machine learning experiments which show that access to this structural information improves the prediction of the critical temperature  $T_{\rm c}$ . Additionally, we provide ideas for further research to improve the 3DSC in multiple ways. We argue that expanding and developing the 3DSC is a promising direction towards the reliable prediction of new superconductors using machine learning.

Control of the critical temperature of a superconductor/chiral magnet heterostructure — •JULIUS GREFE¹, JANNIS WILLWATER¹, RODRIGO DE VAS-CONCELLOS LOURENÇO², MARKUS ETZKORN^{2,3}, STEFAN SÜLLOW¹, and DIRK MENZEL^{1,3} — ¹IPKM, TU Braunschweig, Germany — ²IAP, TU Braunschweig, Germany — ³LENA, TU Braunschweig, Germany

Recently, theory has predicted that spin valves consisting of a superconducting film and a magnetic substrate exhibiting a non-collinear spin structure can be controlled via the proximity effect by changing the spin orientation of the magnet. The critical temperature  $T_c$  of a thin superconducting Nb film on top of a magnetic MnSi substrate is supposed to be altered when the spin helix vector switches from the in-plane to the out-of-plane direction [1]. We have prepared substrates for molecular beam epitaxy from MnSi single crystals. After preparation the surface roughness has been investigated by AFM and TEM and is in the order of 1 nm. Afterwards, a 20 nm superconducting Nb thin film has been deposited on top of the MnSi substrate. In dependence of the orientation of the external magnetic field and, thus, the direction of the spin helix vector in the MnSi substrate, we observe a change of  $T_c$  in the Nb film. To distinguish between the influence of the helix on  $T_c$  and pure geometry effects, we compare the result with observations on a Nb film deposited on an isostructural but non-magnetic CoSi substrate.

Gate controlled switching in A15 and non-centrosymmetric superconducting devices — •JENNIFER KOCH, LEON RUF, SIMON HAUS, ROMAN HARTMANN, ELKE SCHEER, and ANGELO DI BERNARDO — Universität Konstanz, Konstanz, Germany

Gate-controlled superconducting devices have become of great interest for the development of energy-efficient hybrid superconductor/semiconductor computing architectures. The idea behind this technology stems from the recent discovery that superconducting devices can be controlled electrically with the application of a gate voltage [1-3]. We investigate gate-controlled subticing devices made of A15 and non-centrosymmetric superconductors like Nb₃Ge (A15) and Nb_{0.18}Re_{0.82} (non-centrosymmetric). These materials promise a low switching voltage due to their disordered structure and high spin-orbit coupling and should therefore be more suitable for the realization of devices working at voltages comparable to those used for the control of CMOS transistors.

Fano interference of the Higgs response and CDW fluctuations in cuprate high- $T_c$  superconductors — •LIWEN FENG^{1,2,3}, HAO CHU^{1,2,4}, SERGEY KOVALEV⁵, LUKAS SCHWARZ¹, TAO DONG⁶, MIN-JAE KIM^{1,2,3}, GIDEOK KIM¹, GENNADY LOGVENOV¹, BERNHARD KEIMER¹, DIRK MANSKE¹, NANLIN WANG⁶, JAN-CHRISTOPH DEINERT⁵, and STEFAN KAISER^{1,2,3} — ¹Max Planck Institute for Solid State Research, Stuttgart, Germany — ²4th Physics Institute, University of Stuttgart, Germany — ³Institute of Solid State and Materials Physics, Technical University Dresden, Dresden, Germany — ⁴Quantum Matter Institute, University of British Columbia, Vancouver, Canada — ⁵Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — ⁶International Center for Quantum Materials, Peking University, Beijing, China

Cuprate high- $T_c$  superconductors exhibit a rich phase diagram due to the presence of multiple orders. The interplay of these orders is difficult to access directly by experimental probes. Here, we introduce phase-resolved Higgs spectroscopy, i.e. THz driven amplitude oscillations of the superconducting order parameter. We find a Fano interference of the driven Higgs mode with charge density fluctuations in superconducting  $La_{2-x}Sr_xCuO_2$  ( $0.05 \le x \le 0.25$ ). The interference manifests itself as a distinct jump in the phase of the driven Higgs oscillation, which we characterize in an extensive doping- and magnetic field-dependent study. As such, Higgs spectroscopy provides a novel and direct view

on the intriguing interplay of charge density fluctuations and superconductivity in high- $T_c$  cuprates.

## TT 3.11 Mon 12:15 H23

Clarifying the origin of CDW and finding the routes to superconductivity in Ti-Se systems. — •ANDRII KUIBAROV, YULIA SHEMERLIUK, ALEXANDER FEDOROV, and SERGEY BORISENKO — IFW Dresden, Deutschland

Two-dimensional chalcogenides have gained renewed attention mainly because of the novel topological properties observed in single crystals and thin films. Although  $TiSe_2$  has been intensively researched over the last 20 years, the true nature of its charge density waves (CDW) state remains controversial. Several different theories have been proposed during these years to explain CDW formation: Fermi surface nesting, Jahn-Teller effect and excitonic insulator.

We try to answer this question using high-resolution ARPES measurements and DFT calculations for different Ti-Se systems:  $TiSe_2$ ,  $Cu_xTiSe_2$ , TiSeS. We show that the CDW state does disappear at various Cu-doping in  $Cu_xTiSe_2$  as it was thought before.

Superconductivity in the type-I Weyl semimetal trigonal-PtBi₂ — •Arthur Veyrat¹, Valentin Labracherie¹, Federico Caglieris^{1,2}, Jorge I. Facio¹, Grigory Shipunov¹, Jeroen van der Brink^{1,3}, Bernd Büchner^{1,3}, Saicharan Aswartham¹, and Joseph Dufouleur^{1,4} — ¹Leibniz Institute for Solid State and Materials Research (IFW Dresden), Dresden, Germany — ²CNR-SPIN, Genova, Italy — ³Department of Physics, TU Dresden, Dresden, Germany — ⁴Center for Transport and Devices, TU Dresden, Dresden, Germany

Symmetry breaking in topological matter became a key concept in condensed matter physics to unveil novel electronic states. In particular, the interplay between topology and superconductivity in topologically non-trivial materials is of great interest for the study of unconventional superconducting states. In this talk, I present DFT calculations showing a type-I Weyl semimetal band structure in trigonal PtBi₂. We also evidenced, via transport measurements, that single crystals of trigonal PtBi₂ are superconducting ( $T_c ~ 600mK$ ), which represents the first unambiguous report of bulk superconductivity in exfoliated thin flakes of trigonal PtBi₂ to be 2-dimensional, up to 126 nm, and we evidence a Berezinskii-Kosterlitz-Thouless transition in flakes up to 60nm thick, with  $T_{BKT} ~ 310mK$ . This discovery makes trigonal PtBi₂ a very interesting platform to study the interplay between low dimensional superconductivity and topology, into relatively thick and easily fabricated samples.

## TT 3.13 Mon 12:45 H23

Vortex inductance as a directional probe of Lifshitz invariants in synthetic Rashba-superconductors — LORENZ FUCHS¹, DENIS KOCHAN¹, CHRIS-TIAN BAUMGARTNER¹, SIMON REINHARDT¹, SERGEI GRONIN², GEOFFREY C. GARDNER², TYLER LINDEMANN², MICHAEL J. MANFRA², CHRISTOPH STRUNK¹, and •NICOLA PARADISO¹ - ¹University of Regensburg - ²Purdue University In type II superconductors, the magnetic field penetrates the sample in quantized units of flux, which correspond to vortices in the superfluid. To save condensation energy, vortices tend to be pinned to defects. If these are sharp, the pinning potential  $U(\vec{r})$  is harmonic near the vortex core, where it mirrors the superfluid density  $|\Psi(\vec{r})|^2$ . In this work, we show that in 2D Rashba superconductors the combination of spin orbit interaction and in-plane magnetic field leads to an anisotropic squeezing of the vortex core. This, in turn, produces a strong enhancement of the pinning strength, which can be measured by vortex inductance measurements. To this end, we developed a technique to measure small inductances which is compatible with the application of both DC bias and strong magnetic fields. Vortex inductance is sensitive to the curvature of the pinning potential along the direction perpendicular to the supercurrent. Thus, our method enables a full tomography of the vortex core, obtained by measuring inductance as a function of the angle between current and field. Our results can be interpreted as the effect of the spin orbit-induced Lifshitz invariant term in the Ginzburg-Landau free energy.

**Dynamics of visons and thermal Hall effect in perturbed Kitaev models** — •APREM JOY and ACHIM ROSCH — Institute for Theoretical Physics, University of Cologne, Cologne, Germany

A vison is an excitation of the Kitaev spin liquid which carries a  $\mathbb{Z}_2$  gauge flux. While immobile in the pure Kitaev model, it becomes a dynamical degree of freedom in the presence of perturbations. We study an isolated vison in the isotropic Kitaev model perturbed by a small external magnetic field h, an offdiagonal exchange interactions  $\Gamma$  and a Heisenberg coupling J. In the ferromagnetic Kitaev model, the dressed vison obtains a dispersion linear in  $\Gamma$  and h and a fully universal low-T mobility,  $\mu = 6v_m^2/T^2$ , where  $v_m$  is the velocity of Majorana fermions. In contrast, in the antiferromagnetic Kitaev model interference effects preclude coherent mobility. The motion of a single vison due to Heisenberg interactions is strongly suppressed for both signs of the Kitaev coupling. Vison bands induced by h in the AFM Kitaev model are topological and contribute to the thermal Hall effect.

Microscopic modeling of the Kitaev spin liquid candidates  $Li_3Co_2SbO_6$  and  $Na_3Co_2SbO_6$  under uniaxial strain — •WILLI ROSCHER, HUIMEI LIU, JEROEN VAN DEN BRINK, and OLEG JANSON — Leibniz Institute for Solid State and Materials Research IFW Dresden, 01069 Dresden, Germany

We have studied the magnetic properties of two Kitaev spin liquid candidates  $Li_3Co_2SbO_6$  [1] and  $Na_3Co_2SbO_6$  [2] under strain effect by using a microscopic density functional theory (DFT)-based analysis. Previous theoretical work [3] suggested that honeycomb cobaltates are promising candidates to realize the Kitaev spin liquid phase and can be driven there by lattice engineering. Following this conjecture, we simulate the effect of uniaxial strain along the *c*-axis. Low-energy tight-binding Hamiltonians were first obtained using DFT calculations and Wannier projections. Using the DFT-estimated parameters, we calculate the exchange parameters of the extended Kitaev-Heisenberg model. In this way, we get insights into the magnetic behavior of these materials under uniaxial strain. A small reduction of the trigonal splitting is found for tensile strain. Even though the strain is insufficient to drive the compounds into the spin liquid phase, the non-Kitaev terms are greatly suppressed in the investigated strain range. Our quantitative calculations shed light for the materialization of the Kitaev model. [1] M. Stratan *et al.*, New J. Chem. **43**, 13545 (2019)

## TT 5.3 Mon 15:45 H10

Thermal conductivity of a new quantum Kagome antiferromagnet  $YCu_3(OH)_{6.5}Br_{2.5} - \bullet XIAOCHEN HONG^{1,2}$ , MAHDI BEHNAMI², LONG YUAN³, BOQIANG LI³, WOLFRAM BRENIG⁴, BERND BÜCHNER², YUESHENG LI³, and CHRISTIAN HESS^{1,2} - ¹Bergische Universität Wuppertal - ²IFW-Dresden - ³Huazhong University of Sci. and Tech., Wuhan, China - ⁴TU Braunschweig Herbertsmithite ZnCu₃(OH)₆Cl₂ has long been studied as the archetypal quantum Kagome antiferromagnet whose ground state is anticipated to be a spin liquid. However, there is no consensus on the ground state properties of Herbertsmithite, in particular whether a spin gap exist or not, due to its Cu/Zn site mixing effect that distorts the Kagome plane.

Here we report low temperature thermal conductivity measurements of a newly synthesized quantum Kagome antiferromagnet YCu₃(OH)_{6.5}Br_{2.5}. We observe a downwards deviation of its thermal conductivity  $\kappa$  from a standard phononical power-law temperature dependence beyond a characteristic temperature  $T^*$  and a systematic enhancement of this deviation upon application of a magnetic field. Furthermore, up to 16 T no residual  $\kappa/T$  occurs. Our findings imply that the thermal conductivity is dominated by phonons in the mK range, excluding itinerant gapless excitations contributing to it. We interpret the suppression of  $\kappa$  in magnetic field as a consequence of enhanced scattering of the phonons off magnetic fluctuations beyond  $T^*$ . Our analysis favors a small gap in the magnetic field.

## TT 5.4 Mon 16:00 H10

Spinless fermions in a  $\mathbb{Z}_2$  gauge theory on a triangular ladder — •WOLFRAM BRENIG — Institute for Theoretical Physics, Technical University Braunschweig, D-38106 Braunschweig, Germany A study of spinless matter fermions coupled to a constrained  $\mathbb{Z}_2$  lattice gauge theory on a triangular ladder is presented. The triangular unit cell and the ladder geometry lead to a physics different from that on the square lattice. In the static case, even and odd gauge theories are identical. The gauge field dynamics is strongly influenced by the absence of periodic boundary conditions, rendering the deconfinement-confinement process a crossover in general and a quantum phase transition only for decorated electric coupling. At finite doping and in the static case, distinct flux phases can be identified versus magnetic energy. As for the square lattice, a single transition into a confined fermionic phase is found versus electric coupling, however dimer resonances in the confined phase are second order processes only. Global scans of the quantum phases in the intermediate coupling regime are provided.

#### TT 5.5 Mon 16:15 H10

Nesting instability of gapless U(1) spin liquids with spinon Fermi pockets in two dimensions — •WILHELM KRÜGER and LUKAS JANSSEN — Institut für Theoretische Physik and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, 01062 Dresden, Germany

Quantum spin liquids are exotic states of matter that may be realized in frustrated quantum magnets and feature fractionalized excitations and emergent gauge fields. Here, we consider a gapless U(1) spin liquid with spinon Fermi pockets in two spatial dimensions. Such a state appears to be the most promising candidate to describe the exotic field-induced behavior observed in numerical simulations of the antiferromagnetic Kitaev honeycomb model. We consider the regime close to a Lifshitz transition, at which the spinon Fermi pockets shrink to small circles around high-symmetry points in the Brillouin zone. By employing renormalization group and mean-field arguments, we demonstrate that interactions lead to a gap opening in the spinon spectrum at low temperatures, which can be understood as a nesting instability of the spinon Fermi surface. This leads to proliferation of monopole operators of the emergent U(1) gauge field and confinement of spinons. While signatures of fractionalization may be observable at finite temperatures, the gapless U(1) spin liquid state with nested spinon Fermi pockets is ultimately unstable at low temperatures towards a conventional longrange-ordered ground state, such as a valence bond solid.

Frustrated magnetism in pyrochlore rare earth materials: a pseudofermion-FRG study — •BERNHARD WORTMANN — Universität zu Köln — Köln — Deutschland

The family of rare earth pyrochlore materials is intensely scrutinized in the search for quantum spin-ice and quantum spin liquid phases. On the theoretical side, an initial focus has been to explore frustration phenomena in Heisenberg models in order to model the low temperature physics of these materials. It has, however, become increasingly clear that one has to also consider the sometime dominating effect of anisotropic exchange interactions, such as bond-directional Kitaev or Gamma couplings. In this talk, I will discuss the phase diagram of the Heisenberg-Kitaev-Gamma model on the pyrochlore lattice, calculated for S=1/2 quantum spins using the pseudofermion functional renormalization group. The rich phase diagram obtained when considering the competition of antiferromagnetic exchanges allows us to identify coupling regimes where we find agreement with recent neutron scattering experiments.

## TT 5.7 Mon 16:45 H10

**Competition between X-Cube and Toric Code in three dimensions** — •MATTHIAS MÜHLHAUSER¹, KAI PHILLIP SCHMIDT¹, JULIEN VIDAL², and MATTHIAS REIMUND WALTHER¹ — ¹Institute for Theoretical Physics I, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — ²Sorbonne Université, CNRS, Laboratoire de Physique Théorique de la Matière Condensée, LPTMC, F-75005 Paris, France

We investigate the competition of the X-Cube model with the 3D Toric Code using high-order series expansions. We determine the complete phase diagram, which interestingly consists of four regions, i.e. apart from the topologically ordered Toric-Code phase and the X-Cube fracton phase we find two regions which are adiabatically connected to classical spin-liquid phases.

# TT 6: Kondo Physics, f-Electron Systems and Heavy Fermions

Time: Monday 15:00-18:15

# TT 6.1 Mon 15:00 H22

**Zooming in on heavy fermions in Kondo lattice models** — BIMLA DANU¹, ZIHONG LIU¹, FAKHER ASSAAD¹, and •MARCIN RACZKOWSKI² — ¹Institut für Theoretische Physik und Astrophysik and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, 97074 Würzburg, Germany — ²Institut für Theoretische Physik und Astrophysik, Universität Würzburg, 97074 Würzburg, Germany

Resolving the heavy fermion band in the conduction electron momentum resolved spectral function of the Kondo lattice model (KLM) is challenging since, in the weak coupling limit, its spectral weight is exponentially small. To alleviate this limitation we consider a composite fermion operator, consisting of a conduction electron dressed by spin fluctuations that shares the same quantum numbers as the electron. Using auxiliary field quantum Monte Carlo simulations we show that for the SU(2) spin-symmetric model on the square lattice at half filling, the quasiparticle residue of the composite fermion tracks the Kondo coupling  $J_k$ . This result holds down to  $J_k/W = 0.05$ , with W the bandwidth, and confirms that magnetic ordering, present below  $J_k/W = 0.18$ , does not destroy the heavy quasiparticle. We also study the spectral function of the composite fermion in the ground state and at finite temperatures, for SU(N) generalizations of the KLM, as well as for ferromagnetic Kondo couplings, and compare our results to analytical calculations in the limit of high temperatures, large-N, large-S and large  $J_k$ .

TT 6.2 Mon 15:15 H22

**Two-channel Kondo effect in locally non-centrosymmetric systems** – •DANIEL HAFNER – Max Planck Institute for Chemical Physics of Solids, Dresden, Germany

A scalable model is presented, which shows that two-channel Kondo (2CK) physics is possible in centrosymmetric crystals, in which the spin-orbit (SO) energy splitting  $\alpha$  of conduction electron states is stronger than the hopping parameter t between an inversion symmetric pair of them. The potential difference introduced by the SO coupling effectively suppresses the hopping and disentangles the conduction states into two channels, allowing them to independently couple to impurity spins. If the impurity sites are located on inversion centers, the identical Kondo coupling strengths lead to a symmetrical 2CK effect below the Kondo temperature  $T_{2CK}$ . Since the coupling between sectors is still present, the impurity spin is eventually fully quenched by the entangled part of the conduction electrons in a single-channel Kondo effect below  $T_{1CK}$ . For  $\alpha/t > \sqrt{2}$ , a temperature region  $T_{2CK} > T > T_{1CK}$  with dominant 2CK physics is found. If the impurities are not located on inversion centers, the resulting channel-asymmetric 2CK model introduces a third temperature scale. Below this, each of two inversion-symmetric impurity sites is screened by one of the two channels, creating a Fermi liquid made up of two types of Kondo singlets linked by inversion symmetry. The similarity of the presented 2CK model to the well established 2CK effect in quantum dots is discussed as well as possible candidate materials like the locally non-centrosymmetric heavy-fermion superconductor CeRh₂As₂.

Spin chain on a metallic surface: Dissipation-induced order vs. Kondo entanglement — •Віміа Danu¹, MATTHIAS VOJTA², TARUN GROVER³, and FAKHER F. ASSAAD¹ — ¹Institut für Theoretische Physik und Astrophysik and Würzburg. Dresden Cluster of Excellence ct.qmat, Universität Würzburg, 97074 Würzburg, Germany — ²Institut für Theoretische Physik and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, 01062 Dresden, Germany — ³Department of Physics, University of California at San Diego, La Jolla, CA 92093, USA

We study the physics of an antiferromagnetic spin-1/2 chain Kondo coupled to a two dimensional metal as realized, for example, by depositing an array of magnetic adatoms on a metallic surface with scanning tunneling microscopy (STM) methods. Based on a field theoretical perturbative approach we show that at weak Kondo coupling this system maps onto a spin-1/2 chain coupled to a dissipative Ohmic bath. We argue that in this limit the dissipation induces long-range antiferromagnetic order along the spin chain. Using auxiliary field quantum Monte-Carlo simulations we show that the spin chain as a function of the Kondo coupling exhibits a quantum phase transition from an antiferromagnetic phase to a paramagnetic heavy fermi liquid phase. Since the heavy quasiparticle is not destroyed in the magnetic phase and at the critical point, this quantum phase transition falls in a Hertz-Millis-Moriya type quantum criticality. We discuss the relevance of our results in the context of STM experiments of magnetic adatom chains on metallic surfaces.

TT 6.4 Mon 15:45 H22

**Quasiparticle critical slowing down in a heavy-fermion system** — •CHIA-JUNG YANG¹, KRISTIN KLIEMT², CORNELIUS KRELLNER², JOHANN KROHA³, MANFRED FIEBIG¹, and SHOVON PAL^{1,4} — ¹Department of Materials, ETH Zurich, 8093 Zurich, Switzerland — ²Physikalisches Institut, Goethe-Universität Frankfurt, 60438 Frankfurt, Germany — ³Physikalisches Institut and Bethe Center for Theoretical Physics, Universität Bonn, 53115 Bonn, Germany — ⁴School of Physical Sciences, National Institute of Science Education and Research, HBNI, Jatni, 752 050 Odisha, India

Critical slowing down (CSD) is a universal phenomenon in phase transitions. A system, after suffering an initial perturbation, takes a very long time to return to its equilibrium state. While CSD is universally observed in the dynamics of bosonic excitations, it is not observed to occur for fermionic excitations. This is because of the half-integer nature of the fermionic spin. In this contribution, we show a fermionic CSD in the heavy-fermion (HF) compound YbRh₂Si₂ (YRS) by using phase-sensitive terahertz time-domain spectroscopy (THz-TDS). THz-TDS has recently been introduced as a novel tool to investigate the quasiparticle dynamics across quantum phase transition (QPT) in HF compounds [1–3]. We see that near the QPT in YRS, the build-up of spectral weight towards the Kondo temperature  $T_K^* = 25$  K is followed by a logarithmic rise of the quasiparticle excitation rate on the heavy-Fermi-liquid side below 10 K. A critical two-band HF liquid theory shows that this is indicative of fermionic CSD, the softening of the HF quasiparticle dispersion.

TT 6.5 Mon 16:00 H22 **Pressure tuning of the low-temperature states of CeRh₂As₂** – •MEIKE PFEIFFER¹, KONSTANTIN SEMENIUK², and ELENA HASSINGER^{1,2} – ¹Technische Universität München, 85748 Garching, Germany – ²Max Planck Institut für chemische Physik fester Stoffe, 01187 Dresden, Germany

CeRh₂As₂ is a heavy-fermion superconductor with a centrosymmetric tetragonal crystal structure lacking local inversion symmetry at the Ce sites. It presents two-phase superconductivity with an exceptionally high ratio of critical field (> 15 T) to critical temperature ( $T_c = 0.3$  K). An additional phase can be observed below 0.4 K, believed to be a quadrupole-density wave (QDW) order. We conducted an electrical resistivity study of CeRh₂As₂ down to 30 mK applying hydrostatic pressure up to 3 GPa. We find that under pressure the Kondo coherence peak shifts linearly to higher temperature at a rate of 10 K/GPa. The QDW order is highly sensitive to lattice compression and gets fully suppressed at about 0.7 GPa. The superconducting  $T_c$  decreases with a significantly lower rate suggesting no influence of QDW on superconductivity. The upper critical fields show an anisotropic behaviour: for  $H \parallel c$  it decreases. We relate our observations to the change of the relevant energy scales, such as Kondo temperature, Rashba spin-orbit coupling, and interlayer hopping.

TT 6.6 Mon 16:15 H22

The quadrupole density wave and its interplay with supercon- ductivity in CeRh₂As₂: A thermodynamic study — •Pavlo Khanenko^{1,2}, Daniel HAFNER¹, ROBERT KÜCHLER¹, JACINTHA BANDA¹, THOMAS LÜHMANN¹, JAVIER F. LANDAETA¹, FLORIAN BÄRTL³, TOMMY KOTTE³, JOACHIM WOSNITZA^{2,3}, CHRISTOPH GEIBEL¹, SEUNGHYUN KHIM¹, ELENA HASSINGER^{1,4}, and MANUEL BRANDO¹ — ¹Max Planck Institute for Chemical Physics of Solids, Germany — ²Institut für Festkörper- und Materialphysik, Technische Universität Dresden, Germany — ³Hochfeld-Magnetlabor Dresden (HLD-EMFL) and Würzburg-Dresden Cluster of Excellence, Germany — ⁴Technical University Munich, Germany

The heavy-fermion CeRh₂As₂ is a rare case of multi-phase superconductor ( $T_c = 0.26$  K) located in the vicinity of a quantum critical point. Two different superconducting (SC) phases are observed for a magnetic field applied along the *c*-axis of the tetragonal locally-non-centrosymmetric crystalline structure. The upper critical field along *c*-axis ( $B \parallel c$ ) is huge,  $B_{c2} = 14$  T, but with field within the basal *ab*-plane ( $B \perp c$ ) only a single SC phase is observed with  $B_{c2} = 2$  T. Thermodynamic measurements have detected another non-magnetic phase transition at  $T_0 = 0.4$  K which was interpreted as a quadrupole-density-wave (QDW) state. Here, we present new zero-field-cooled and field-cooled specific heat and thermal expansion measurements on a single crystal of CeRh₂As₂ with  $B \parallel c$  and to discuss the interplay between the SC and QDW states.

Heavy quasiparticles in Fermi surface and electronic instabilities in the heavy-fermion superconductor  $CeRh_2As_2 - \cdot EVRARD-OUICEM ELJAOUHARI and GERTRUD ZWICKNAGL - Institut f. Mathemat. Physik, TU Braunschweig, Braunschweig, Germany$ 

We present calculations of the heavy quasiparticles in the heavy-fermion compound  $CeRh_2As_2$  which exhibts multi-phase superconductivity[1]. The narrow quasiparticle bands that are derived from the Ce-4f degrees of freedom are calculated by means of the Renormalized Band (RB) method. The RB scheme provides a framework for a realistic description of the coherent low-energy excitations in a Fermi liquid which combines material-specific ab-initio methods and phenomenological considerations in the spirit of the Landau theory of Fermi liquids. The central focus of the present study is the role played by the non-symmorphic lattice structure and the consequences of the Crystalline Electric Field (CEF) which removes the orbital degeneracy of the Ce 4f states. We conjecture that the quasi-quartet CEF ground state in combination with pronounced nesting features of the Fermi surface may give rise to a quadrupole density wave [2].

This work is supported by the ANR-DFG program Fermi-NESt.

## TT 6.8 Mon 17:00 H22

Muon spin rotation/relaxation studies on the heavy-fermion superconductor  $CeRh_2As_2 - \cdot SEUNGHYUN KHIM^1$ , MANUEL BRANDO¹, OLIVER STOCKERT¹, CHRISTOPH GEIBEL¹, ZURAB GUGUCHIA², ROBERT SCHEUERMANN², DEBARCHAN DAS², and TONI SHIROKA² - ¹Max-Planck-Institut für Chemische Physik fester Stoffe, Dresden, Germany - ²Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, Villigen PSI, Switzerland

We study magnetic and superconducting (SC) properties of the unconventional superconductor CeRh₂As₂ ( $T_c \sim 0.3$  K) by means of muon spin rotation/relaxation ( $\mu$ SR) experiments. No clear evidence of oscillation is identified in zero-field µSR spectra down to 0.27 K while the relaxation rate moderately increases below ~ 0.4 K. This could be associated with the suggested quadrupoledensity-wave order at  $T_0 \approx 0.4$  K and the antiferromagnetic order at  $T_N \approx 0.27$ K. In weak transverse-field (TF)  $\mu$ SR measurements, a pronounced increase in the relaxation rate was observed in the SC state. The relaxation rate ( $\sigma_s$ ), regarded as a direct measure of the magnetic penetration depth  $\lambda$  ( $\sigma_s \propto 1 / \lambda^2$ ), almost flattens below  $T/T_c \sim 0.2$ , being strongly indicative of suppressed quasiparticle excitations. TF-µSR measurements under 2 T reveal a power-law-like *T*-dependent relaxation rate in the normal state, indicating critical fluctuations. Furthermore, this relaxation rate increases with fields in both the normal and SC state, implying unusual magnetism. Our observations suggest CeRh2As2 to have a nearly fully-gapped SC behavior in the vicinity of a peculiar quantum critical point.

# TT 6.9 Mon 17:15 H22

Anisotropy of resistivity and magnetotransport in CeRh₂As₂ — •KONSTANTIN SEMENIUK, SEUNGHYUN KHIM, and ELENA HASSINGER — Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany The recently discovered heavy-fermion superconductor CeRh₂As₂ exhibits an intriguing law temperature along the centrificing law temperature during the second sec

intriguing low-temperature phase diagram containing two superconducting states [1], a quadrupole density wave order [2], and an antiferromagnetic state [3]. The underlying mechanisms of such a behaviour are currently being explored. However, symmetry-induced Rashba spin-orbit effect, Kondo interaction and interlayer coupling have already emerged as the primary ingredients.

To quantify the electronic properties of the compound further, we conducted a comprehensive study of charge transport in  $CeRh_2As_2$ . Precise control over sample dimensions and current flow direction were achieved via focused ion beam micromachining of single crystals in a strain-free manner. Based on resistivity anisotropy measurements the three-dimensional character of the electronic structure is established. We also examine magnetoresistance and Hall effect for different orientations of magnetic field with respect to the lattice.

 $TT\ 6.10 \quad Mon\ 17:30 \quad H22$  Influence of substrate clamping in epitaxial EuPd_2Si_2 thin films — •SEBASTIAN KÖLSCH¹, CORNELIUS KRELLNER¹, HANS-JOACHIM ELMERS², and MICHAEL HUTH¹ — ¹Goethe Universität, Frankfurt (Main) — ²Johannes Gutenberg-Universität, Mainz

Europium-based ternary compounds, which crystallize in the tetragonal ThCr₂Si₂ structure, reveal a variety of interesting phenomena, which are attributed to strong electronic correlations and a competition between Kondo effect and the RKKY interaction. Recently EuPd₂Si₂ gained increased interest due to a temperature-driven valence transition from nearly Eu²⁺ above 200 K to Eu³⁺ below about 50 K. This rapid but continuous change of the Europium mean valence is accompanied by a relative change of the EuPd₂Si₂ a lattice constant by about -2 % reflecting the strong coupling of lattice and electronic degrees of freedom. For epitaxial thin films of this material the underlying substrate has to be taken into account. In this case the change of the lattice constants due to clamping to the substrate impacts the possible thermal expansion of the corresponding in-plane components. So far research has focused on optimizing single crystal growth conditions under different doping scenarios to tune the system into a critial endpoint. Epitaxial thin films instead offer the possibility to strain-engineer this correlated system by appliying biaxial strain to the thin film material upon cooling.

Here we present for the first time the successful growth of  $EuPd_2Si_2$  as epitaxial thin film and report our recent results regardings its clearly distinct properties as compared to single crystals.

TT 6.11 Mon 17:45 H22

Theory of valence-band photoemission from Am metal — •JINDRICH KOLORENC — Institute of Physics (FZU), Czech Academy of Sciences, Praha, Czech Republic

The 5f states in americium metal are generally agreed to be localized, similar to 4f states in lanthanides, being in a well-defined 5f⁶ configuration (Am³⁺). In the same time, the valence-band photoemission spectrum [1,2] cannot be interpreted as a single set of multiplet transitions  $(5f^6 \rightarrow 5f^5)$  like in lanthanides [3], and a second set of multiplets  $(5f^7 \rightarrow 5f^6)$  has to be introduced [4]. Two mechanisms were suggested as a possible origin of these additional transitions: (i) Am²⁺ layer forming at the surface of the sample or (ii) a second screening channel for the 5f hole created during the photoemission process, with the second mechanism later determined as more likely [2]. Up to now, there does not seem to be a quantitative theory that would substantiate these empirical ideas. The best attempt to date [5] combined the DFT+DMFT method with a generalized Hubbard-I impurity solver, which reproduced the  $5f^7 \rightarrow 5f^6$  part of the spectrum well, but it also generated a spurious 5f intensity at the Fermi level. Here I report a DFT+DMFT study employing a more accurate impurity solver (exact diagonalization) and demonstrate the mechanism leading to the  $5f^7 \rightarrow 5f^6$ multiplets in the Am PES spectra.

Kondo systems with periodically driven dipole transitions — •MICHAEL TU-RAEV and JOHANN KROHA — Physikalisches Institut, Universität Bonn, Nußallee 12, 53115 Bonn, Germany

In this work, we study the effects of light irradiation on a magnetic impurity. The impurity is modelled by the single impurity Anderson model where the local impurity is coupled to the conduction electrons via dipole coupling. Therefore, the application of a strong laser field induces a time-periodic hybridization. This can be treated within Floquet Green's function method combined with the slave boson non-crossing approximation [1]. What we see is that the Kondo peak is robust against small driving strengths, and then it gets strongly suppressed when the driving strength increases. However, we find that the destruction of the Kondo effect occurs much faster in terms of driving strength compared to a situation where the energy level of the impurity is itself driven independently.

Large Hall and Nernst effect from chiral spin fluctuations — KAMIL K. KOLINCIO¹, MAX HIRSCHBERGER^{2,3}, and •JAN MASELL^{3,4} — ¹Gdansk Tech, Gdansk, Poland — ²University of Tokyo, Tokyo, Japan — ³RIKEN CEMS, Wako, Japan — ⁴Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany

Magnetic materials with tilted electron spins exhibit conducting behaviour that is explained by the geometrical Berry phase, driven by a chiral (left- or righthanded) spin-habit. Dynamical and nearly random spin fluctuations, with a slight trent towards left- or right-handed chirality, represent a promising route to realizing Berry-phase phenomena at elevated temperatures. [1] Here, we re-

Location: H23

port thermoelectric and electric transport experiments on a triangular and on a slightly distorted kagomé lattice material, respectively. We show that the impact of chiral spin fluctuations is strongly enhanced for the kagomé lattice. Our modelling shows that the geometry of the kagomé lattice plays a crucial role as it helps to avoid cancellation of Berry-phase contributions already in the disordered (paramagnetic) state. Hence, the observations for the kagomé material contrast with theoretical models treating magnetization as a continuous field, and emphasize the role of lattice geometry on emergent electrodynamic phenomena.

**Revealing channel polarization of atomic contacts of ferromagnets and strong paramagnets by shot-noise measurements** — MARTIN PRESTEL, •MARCEL STROHMEIER, WOLFGANG BELZIG, and ELKE SCHEER — University of Konstanz, 78457 Konstanz, Germany

We report measurements of the shot noise of atomic contacts using the mechanically controllable break junction (MCBJ) technique at low temperatures. In accordance with theoretical predictions [1, 2] single-atom contacts of the ferromagnets Co and Gd with conductance smaller than the conductance quantum show reduced noise compared to the expectation for the spin-degenerate singlechannel transport. Additionally we focus on the strong paramagnets Pt [3], Pd [4], and Ir [5], where a nonmonotonic magnetoresistance has been reported for atomic contacts, interpreted as emerging magnetic ordering in small dimension, which is triggered by the vicinity of the respective bulk metals to a Stoner instability. Our recent measurements on Pd, Pt, and Ir reveal noise levels which are above, but close to the threshold to the spin-degenerate single-channel situation [6]. An anticorrelation between the minimum noise and the bulk Stoner parameter of these elements is observed. We discuss by how far this might indicate that spin polarization is reflected in the noise signal.

Synchronization in Josephson photonics devices with shot noise — •FLORIAN HÖHE¹, LUKAS DANNER^{1,2}, BRECHT DONVIL¹, CIPRIAN PADURARIU¹, BJÖRN KUBALA^{1,2}, and JOACHIM ANKERHOLD¹ — ¹ICQ and IQST, Ulm University, Ulm, Germany — ²Institute of Quantum Technologies, German Aerospace Center (DLR), Ulm, Germany

Phase stability is an important characteristic of radiation sources. For quantum sources exploitation and characterization of many quantum properties, such as entanglement and squeezing, may be hampered by phase instability. Josephson photonics devices, where microwave radiation is created by inelastic Cooper pair tunneling across a *dc-biased* Josephson junction connected in-series with a microwave resonator are particularly vulnerable lacking the reference phase provided by an ac-drive. To counter this issue, sophisticated measurement schemes have been used in [1] to prove entanglement, while in [2] a weak ac-signal was put in to lock phase and frequency of the emission.

The intrinsic shot noise of the Josephson-photonics device inevitably diffuses the oscillators phase and requires an extension of the classical theory [3] describing locking and synchronization to the quantum regime. Here, the shot noise, which is linked to the Full Counting Statistics, induces phase slips. Injection locking and synchronization lead to a strong narrowing of the photon emission statistics.

**Theory of difference frequency quantum oscillations** — •VALENTIN LEEB¹ and JOHANNES KNOLLE^{1,2,3} — ¹Department of Physics TQM, Technische Universität München, James-Franck-Straße 1, D-85748 Garching, Germany — ²Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany — ³Blackett Laboratory, Imperial College London, London SW7 2AZ, United Kingdom

Quantum oscillations (QO) describe the periodic variation of physical observables as a function of inverse magnetic field in metals. The Onsager relation connects the basic QO frequencies with the extremal areas of closed Fermi surface pockets, and the theory of magnetic breakdown explains the observation of sums of QO frequencies at high magnetic fields. Here we develop a quantitative theory of *difference frequency* QOs in metals with multiple Fermi pockets with parabolic or linearly dispersing excitations. We show that a non-linear interband coupling, e.g. in the form of interband impurity scattering, can give rise to otherwise forbidden QO frequencies which can persist to much higher temperatures compared to the basis frequencies. We discuss the experimental implications of our findings, for example, for materials with multifold fermion excitations.

### TT 7.5 Mon 16:00 H23

General bounds of electronic shot noise in the absence of currents — JAKOB ERIKSSON¹, •MATTEO ACCIAI^{1,2}, LUDOVICO TESSER¹, and JANINE SPLETTSTOESSER¹ — ¹Department of Microtechnology and Nanoscience (MC2), Chalmers University of Technology, S-412 96 Göteborg, Sweden — ²University of Gothenburg, S-412 96 Göteborg, Sweden

We investigate the charge and heat electronic noise in a generic two-terminal mesoscopic conductor in the absence of the corresponding charge and heat currents. Despite these currents being zero, shot noise is generated in the system. We show that, irrespective of the conductor's details and the specific nonequilibrium conditions, the charge shot noise never exceeds its thermal counterpart, thus establishing a general bound [1]. Such a bound does not exist in the case of heat noise, which reveals a fundamental difference between charge and heat transport under zero-current conditions.

Direct observation of vortices in an electron fluid — •TOBIAS VÖLKL¹, AMIT AHARON-STEINBERG¹, ARKADY KAPLAN¹, ARNAB PARIARI¹, INDRANIL ROY¹, TOBIAS HOLDER¹, YOTAM WOLF¹, ALEXANDER MELTZER¹, YURI MYASOEDOV¹, MARTIN HUBER², BINGHAI YAN¹, GREGORY FALKOVICH³, LEONID LEVITOV⁴, MARKUS HÜCKER¹, and ELI ZELDOV¹ — ¹Department of Condensed Matter Physics, Weizmann Institute of Science, Rehovot, Israel — ²Departments of Physics and Electrical Engineering, University of Colorado Denver, Denver, USA — ³Department of Physics of Complex Systems, Weizmann Institute of Science, Rehovot, Israel — ⁴Department of Physics, Massachusetts Institute of Technology, Cambridge, USA

Strongly-interacting electrons in ultrapure conductors have been shown to display signatures of hydrodynamic behavior including negative nonlocal resistance and Poiseuille flow in narrow channels. Here we provide the first visualization of current vortices in an electron fluid. By utilizing a nanoscale scanning superconducting quantum interference device on a tip we image the current distribution in a circular chamber connected through a small aperture to a current-carrying strip in the high-purity type-II Weyl semimetal WTe₂. We find that vortices are present only for small apertures, whereas the flow is laminar (non-vortical) for larger apertures. Our findings suggest a novel mechanism of hydrodynamic flow in thin pure crystals: the spatial diffusion of electrons' momenta is enabled by small-angle scattering at the surfaces, instead of the routinely invoked electronelectron scattering.

## TT 7.7 Mon 16:45 H23

**Optical dipole orientation of interlayer excitons in MoSe**₂-WSe₂ heterostacks — •Mirco Troue¹, Lukas Sigl¹, Manuel Katzer², Malte Selig², Florian Sigger¹, Jonas Kiemle¹, Johannes Figueiredo¹, Mauro Brotons-Gisbert³, Brian Gerardot³, Andreas Knorr², Ursula Wurstbauer⁴, and Alexander Holleitner¹ — ¹TU Munich — ²Technical University Berlin — ³Heriot-Watt University — ⁴University of Münster

Transition metal dichalcogenide monolayers exhibit strong light-matter interactions, which promotes them as ideal candidates for novel 2D optoelectronic applications. A vertical stacking into van der Waals heterostacks leads to the formation of long-lived interlayer excitons in adjacent layers. We present the farfield photoluminescence intensity distribution of interlayer excitons in  $MoSe_2$ - $WSe_2$  heterostacks as measured by back focal plane imaging in the temperature range between 1.7K and 20K. An analytical model describing the emission pattern from a dielectric heterostructure is used to obtain the relative contributions of the in- and out-of-plane transition dipole moments associated with the interlayer exciton photon emission. We determine the transition dipole moments for all observed interlayer exciton transitions to be  $(99 \pm 1)\%$  in-plane for R- and H-type stacking, independent of the excitation power and therefore the density of the exciton ensemble in the experimentally examined range. Moreover, we discuss the limitations of the presented measurement technique to observe correlation effects for many-body states in dense ensembles of interlayer excitons.

TT 7.8 Mon 17:00 H23

Magnetic and transport behaviour of quasi 2D NiS₂ flakes — •ROMAN HARTMANN¹, MARIO AMADO MONTERO², ELKE SCHEER¹, and ANGELO DI BERNARDO¹ — ¹Fachbereich Physik, Universität Konstanz, Germany — ²Department of Physics, University of Salamanca, Spain

Spintronics with 2D materials is emerging as a new field which enables development of devices with novel functionality compared to their three-dimensional counterparts.

We have recently managed to cleave single crystal  $NiS_2$  down to the quasi 2D limit despite it not being a layered material. Bulk  $NiS_2$  is a Mott insulator that has an interesting magnetic structure with an antiferromagnetic phase below 39 K and weak ferromagnetic ordering with a Curie temperature of 29 K. [1]

In transport measurements of thin flakes we see an increase in conductivity compared to the bulk, presumably due to the presence of metallic surface states. The ferromagnetic transition is clearly visible as kinks in the R-T curves and R-H curves . With magnetic field applied there is a complex hysteretic behaviour in the resistance with a strong asymmetry with respect to the direction of the applied field.

As a next step we are also looking into coupling the  $NiS_2$  flakes to 2D superconductors to create two-dimensional superconducting spintronic devices. [1] T. Thio et al., Phys. Rev. B 52, 5 (1995)

# TT 7.9 Mon 17:15 H23

Spectral properties of the herringbone lattice — •MIGUEL ANGEL JIMÉNEZ HERRERA^{1,2} and DARIO BERCIOUX^{2,3} — ¹Centro de Física de Materiales (CFM-MPC) Centro Mixto CSIC-UPV/EHU, 20018 Donostia-San Sebastian, Basque Country, Spain — ²Donostia International Physics Center, 20018 San Sebastián, Spain — ³IKERBASQUE, Basque Foundation for Science, Euskadi Plaza, 5, 48009 Bilbao, Spain

We investigate the spectral properties of a two-dimensional electronic lattice that belongs to a non-symmorphic space group. More specifically, we look at the herringbone lattice that is characterised by two sets of glide symmetries applied in two orthogonal directions. We describe the system using a tight-binding model with nearest neighbors divided into horizontal and vertical hopping terms. We find two non-equivalent Dirac cones inside the first Brillouin zone along a highsymmetry paths, among other features, which react to different perturbations applied to the Hamiltonian. These perturbations break the symmetries of the lattice: we begin by placing different onsite potentials in the lattice sites. We observe annihilation of Dirac cones into semi-Dirac cones and nodal lines along high symmetry paths. Finally, we perturb the system by applying a dimerization on the hoppings. We report a flow of Dirac cones inside the first Brillouin zone describing quasi-hyperbolic curves

TT 7.10 Mon 17:30 H23 Hierarchical equations of motions approach to the study of thermodynamic uncertainty relations — SALVATORE GATTO and •MICHAEL THOSS — Institute of Physics, Albert-Ludwigs-Universität Freiburg Thermodynamic uncertainty relations (TUR) are cost-precision trade-off relations in transport systems, relating the fluctuations in the heat and particle currents to the reversibility of the operation regime. While some violations have been reported for the TUR in classical systems, it has been found out that the geometry of quantum non-equilibrium steady-states alone directly implies the existence of a general quantum TUR. In this contribution, we investigate the relationship between quantum effects and current fluctuations in quantum systems. The hierarchical equation of motion approach is employed, which allows a numerically exact simulation of nonequilibrium transport in general open quantum systems involving multiple bosonic and fermionic environments.

**Bosonization for Q = 0 particle-hole excitations of 2D gapless fermions** — •SEBASTIAN MANTILLA¹ and INTI SODEMANN^{1,2} — ¹Max Planck Institute for the Physics of Complex Systems, 01187 Dresden, Germany — ²Institut für Theoretische Physik, Universität Leipzig, 04103 Leipzig, Germany

Understanding the non-perturbative effects of strong interactions on gapless phases of fermions in two-spatial dimensions is one of the major challenges in quantum condensed matter physics. Bosonization in one- and higherdimensional systems has successfully captured such effects, where the picture of excitations in higher dimensions consists of small deformations of the Fermi surface. We discuss an extension for gapless phases in fermionic systems (e.g., nodal semimetals, Dirac fermions), not describable by the previous formalism since the Fermi surface shrinks to a point and the deformation picture breaks down. The new picture consists of a collection of excitons that considers nonperturbative effects in the weak- and strong-coupling regimes. We apply the formalism in two cases involving interacting electrons in graphene: the corrections to the optical response of 2D free fermions in monolayer graphene, and the weak coupling instability due to electron-hole attractive interactions in bilayer graphene. Our results contribute to understanding the effects of strong interactions in gapless fermions and extend bosonization beyond the picture of Fermi surface deformations.

α-**RuCl₃ probed by ultrasound under hydrostatic pressure** — •ANDREAS HAUSPURG^{1,2}, S. ZHERLITSYN¹, T. HELM¹, T. YANAGISAWA³, V. TSURKAN⁴, and J. WOSNITZA^{1,2} — ¹Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, Dresden, Germany — ²Institut für Festkörper- und Materialphysik, TU Dresden, Germany — ³Department of Physics, Hokkaido University, Sapporo, Japan — ⁴Institute of Physics, University of Augsburg, Germany

As a prime candidate for a quantum spin liquid (QSL) in the frame of the Kitaev model, is the honeycomb material  $\alpha$ -RuCl₃ of particular interest. Although  $\alpha$ -RuCl₃ exhibits antiferromagnetic order below 7 K, it is considered as proximate to the QSL. The QSL features fractionalized quasiparticle excitations. A promising approach to investigate such excitations is to study the coupling between fractionalized quasiparticles and phonons. This affects the attenuation coefficient and the sound velocity of ultrasound. Our recent studies of the elastic properties of  $\alpha$ -RuCl₃ show a promising path to unveil the unconventional physics of the debated QSL phase. Here, we present low-temperature results of the sound velocity and attenuation in external magnetic fields and under hydrostatic pressures. The observed anomalies in the acoustic properties and strong magnetoelastic couplings shed new light on the unconventional physics in this compound. At a pressure of 11.3 kbar the antiferromagnetic order is completely suppressed.

# TT 8.2 Mon 17:30 H10

**Fractional Excitation-induced Phonon Renormalization in**  $\alpha$ -**RuCl**₃ — •ADRIAN MERRITT¹, XIAO WANG¹, ALEXEI BOSAK², LUIGI PAOLASINI², ALEXANDRE IVANOV³, ROLF HEID⁴, and YIXI SU¹ — ¹Jülich Centre for Neutron Science JCNS-FRM II, Forschungszentrum Jülich GmbH, Garching, Germany — ²European Synchrotron Radiation Facility (ESRF), Grenoble, France — ³Institut Laue-Langevin, Grenoble, France — ⁴Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, Karlsruhe, Germany

The quantum spin liquid (QSL) phase is of immense interest to condensed matter physicists, and have been studied for decades. With a Kitaev model that is exactly solvable and gives a QSL ground state, more recent work has focused on the  $J_{eff}=1/2$  materials and in particular,  $\alpha$ -RuCl₃. Above the critical magnetic field B_c 7T and below T 6K there is evidence for the half-integer quantized plateau possibly arising from the fractional excitations in the QSL phase. Recent theoretical work has shown that the fractional excitations can induce phonon Location: H10

renormalization via the spin-lattice coupling, and would in particular affect the acoustic phonons near the zone boundary. Our measurements have focused on the phonon dispersion in  $\alpha$ -RuCl₃ to observe this phonon renormalization effect in the putative QSL phase. We have been able to survey the acoustic phonons in the relevant scattering directions under magnetic fields using single crystals. We will discuss our results with a focus on examining the low-energy acoustic phonon branches we measured in comparison to published work as well as the observed phonon renormalization effect.

## TT 8.3 Mon 17:45 H10

Quantum Monte Carlo simulations of generalized Kitaev models: applications to  $\alpha$ -RuCl₃ — •TOSHIHIRO SATO¹ and FAKHER F. ASSAAD^{1,2} — ¹Institut für Theoretische Physik und Astrophysik, Universität Würzburg, Germany — ²Würzburg-Dresden Cluster of Excellence ct.qmat, Germany

We introduce a phase pinning approach in the realm of the auxiliary field quantum Monte Carlo (QMC) algorithm that mitigates the severity of the negative sign problem inherent to QMC methods of frustrated spin systems [1]. This allows us to access high-temperature thermodynamic and dynamical properties of the aforementioned systems and, for instance, carry out exact QMC simulations in a window of temperatures relevant to experiments for various frustrated magnets. We use our method to carry out extensive simulations of thermodynamic properties under magnetic fields in generalized Kitaev models describing  $\alpha$ -RuCl₃, and discuss the characteristic feature in the field-direction dependence of the magnetic susceptibility, the specific heat as well as the magnetotropic coefficient. Our numerical results allow for direct comparison with recent measurements of the magnetotropic coefficient in  $\alpha$ -RuCl₃ [2].

TT 8.4 Mon 18:00 H10

**RuCl₃:** Phonon (Hall) transport and sibling compounds RuBr₃, RuI₃ — •DAVID A S KAIB¹, SANANDA BISWAS¹, STEPHEN M WINTER², KIRA RIEDL¹, ALEKSANDAR RAZPOPOV¹, YING LI³, STEFFEN BACKES⁴, IGOR I MAZIN⁵, and ROSER VALENTI¹ — ¹Goethe-Universität, Frankfurt, Germany — ²Wake Forest University, Winston-Salem, NC 27109, USA — ³School of Physics, Xi'an Jiaotong University, Xi'an 710049, China — ⁴Institut Polytechnique de Paris, Route de Saclay, 91128 Palaiseau, France — ⁵George Mason University, Fairfax, VA 22030, USA

We present results of two studies related to the Kitaev candidate material RuCl₃: Recent experimental studies have pointed to the presence of significant magnetoelastic coupling in RuCl₃ and have highlighted unusual thermal transport signatures under magnetic field. We compute the pseudospin-phonon coupling in RuCl₃ from first principles and use it to model the intrinsic thermal transport from phonons scattered by spin fluctuations. This includes both the longitudinal as well as the transversal (Hall) conductivity.

In the second part of the talk, we analyze two new sibling compounds to RuCl₃: RuBr₃ and RuI₃. While current samples show a bad metal behavior in RuI₃, our first principles calculations predict a Mott insulator close to the Mott-metal transition in the pristine parent compound, with a dominant Kitaev interaction and negligible Heisenberg exchange.

TT 8.5 Mon 18:15 H10 High-field ESR studies of the cubic Iridium hexahalide compounds (NH₄)₂IrCl₆ and K₂IrCl₆ — •LAKSHMI BHASKARAN¹, ALEXEY N. PONOMARYOV², JOCHEN WOSNITZA^{1,3}, NAZIR KHAN⁴, ALEXANDER A. TSIRLIN⁴, MIKE E. ZHITOMIRSKY⁵, and SERGEI A. ZVYAGIN¹ — ¹Dresden High Magnetic Field Laboratory (HLD-EMFL) and Würzburg-Dresden Cluster of Excellence ct.qmat, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany – ²Institut für Festkörper- und Materialphysik, TU Dresden, Dresden, Germany — ⁴University of Augsburg, Augsburg, Germany — ⁵University Grenoble Alpes, Grenoble, France

We report on high-field electron spin resonance studies of two iridium hexahalide compounds,  $(NH_4)_2IrCl_6$  and  $K_2IrCl_6$  [1]. In the paramagnetic state, our measurements reveal isotropic *g*-factors g = 1.79(1) for the Ir⁴⁺ ions, in agreement with their cubic symmetries. Most importantly, in the magnetically ordered state, we observe two magnon modes with zero-field gaps of 11.3 and 14.2 K for  $(NH_4)_2IrCl_6$  and  $K_2IrCl_6$ , respectively. Based on that and using linear spin-wave theory, we estimate the nearest-neighbor exchange couplings and anisotropic Kitaev interactions,  $J_1/k_B = 10.3$  K,  $K/k_B = 0.7$  K for  $(NH_4)_2IrCl_6$ , and  $J_1/k_B = 13.8$  K,  $K/k_B = 0.9$  K for  $K_2IrCl_6$ , revealing the nearest-neighbor Heisenberg coupling as the leading interaction term, with only a weak Kitaev anisotropy.

TT 8.6 Mon 18:30 H10 Spin-orbit excitons in the  $j_{\rm eff}$ =1/2 compound K₂IrCl₆ — •Philipp Warzanowski¹, Marco Magnaterra¹, Karolin Hopfer¹, Christoph Sahle², Marco Morreti Sala³, Giulio Monaco⁴, Petra Becker⁵, LADISLAV BOHATÝ⁵, and MARKUS GRÜNINGER¹ — ¹Inst. of Physics II, University of Cologne — ²European Synchrotron Radiation Facility, Grenoble Cedex, France — ³Dip. di Fisica, Politecnico di Milano, Italy — ⁴Dip. di Fisica e Astronomia, Università di Padova, Italy — ⁵Sect. Crystallography, Inst. of Geology and Mineralogy, University of Cologne

Spin-orbit entangled Mott insulators offer new playgrounds to explore novel ground states. Iridates with a  $t_{2g}^5$  electron configuration are popular platforms to realize  $j_{\rm eff} = 1/2$  systems due to the large cubic crystal field and strong spin-orbit coupling. Spectroscopies, RIXS in particular, show that thus far all iridates harbour non-cubic crystal field distortions, which turn the ground state away from an ideal  $j_{\rm eff} = 1/2$  state. In this context, the (globally) cubic compound K₂IrCl₆ is a promising candidate to host ideal  $j_{\rm eff} = 1/2$  moments. However, both RIXS and infrared spectroscopy show a splitting of the spin-orbit exciton. Within a single-site scenario, we extract a spin-orbit coupling  $\lambda = 435$  meV and a non-cubic crystal field  $\Delta = 60$  meV, yielding a ground state of 99.8%  $j_{\rm eff} = 1/2$  character. To explore the origin of non-cubic distortions, we discuss the possible effects of i) librations [1], ii) the coupling to phonons, and iii) defects [2].

TT 8.7 Mon 18:45 H10

**Fragility of charge frustration in high-pressure**  $CsW_2O_6 - \bullet$ PASCAL REISS¹, MASAHIKO ISOBE¹, and HIDENORI TAKAGI^{1,2} – ¹Max Planck Institute for Solid State Research, Stuttgart, Germany – ²Department of Physics, The University of Tokyo, Bunkyo, Tokyo, Japan

The transition metal compound  $CsW_2O_6$  represents an intriguing example of a pyrochlore structure at quarter filling. Starting from a nominal  $W^{5.5+}$  oxidation state, the system suffers a metal-to-insulator transition around  $T_c \approx 215$  K where a breathing distortion leads to the formation of regular molecular  $W_3$  trimers with 2 localised electrons each, and a remaining  $W^{6+}$  site devoid of 5*d* electrons [1]. Recently, it was proposed that in this low-temperature phase, the interplay between a strong spin-orbital coupling and the transfer integral could realise a rare case of an intrinsically half-filled flat band dispersion with a stiff spin chirality [2].

In this talk, we will present our recent high pressures transport measurement on  $CsW_2O_6$ . With increasing pressure, we find that the low-temperature insulating phase is stabilised as the metal-to-insulator transition shifts to higher temperatures. We will discuss our results in the light of recent theoretical proposals.

Quantum light-matter fluctuations in driven open cavity BEC systems — •LEON MIXA and MICHAEL THORWART — I. Institut für Theoretische Physik, Universität Hamburg

When an ultracold atom gas strongly interacts with a pumped cavity light field, effective retarded long-range interactions are induced. They give rise to nonclassical states in the light sector, which do not necessarily require non-classical fluctuations in the matter sector. We study theoretically the quantum fluctuations in the light and the matter sectors in different driving regimes. In particular, the photon dissipation channel of the cavity allows for the direct nondestructive measurement of the fluctuations driving the phase transition known in this system. Light-induced density fluctuations drive a superradiant nonequilibrium Dicke quantum phase transition of the atom gas. The photon statistics in the presence of the strongly coupled, pumped atom gas is calculated within a Bogoliubov approach combined with analytic imaginary time path integrals Location: H23

including photon leakage of the cavity. Parameter regimes for squeezed cavity light are identified.

The free energy of the two-dimensional dilute Bose gas — •ANDREAS DEUCHERT¹, SIMON MAYER², and ROBERT SEIRINGER² — ¹University of Zurich, Institute of Mathematics, Zurich, Switzerland — ²Institute of Science and Technology Austria, Klosterneuburg, Austria

We prove bounds for the specific free energy of the two-dimensional Bose gas in the thermodynamic limit. We show that the free energy at density  $\varrho$  and inverse temperature  $\beta$  differs from the one of the non-interacting system by the correction term  $4\pi \varrho^2 |\ln(a^2 \varrho)|^{-1} (2 - [1 - \beta_c / \beta]_+^2)$ . Here *a* is the scattering length of the interaction potential,  $[x]_+ = \max\{0, x\}$  and  $\beta_c$  is the inverse Berezinskii–Kosterlitz–Thouless critical temperature for superfluidity. The result is valid in the dilute limit  $a^2 \varrho \ll 1$  and if  $\beta \varrho \ge 1$ .

Chaos in the three-site Bose-Hubbard model - classical vs quantum — •GORAN NAKERST¹ and MASUDUL HAQUE^{1,2} — ¹Institut für Theoretische Physik, Technische Universität Dresden, Dresden, Germany — ²Max-Planck-Institut für Physik komplexer Systeme, Dresden, Germany

We consider a quantum many-body system - the Bose-Hubbard system on three sites - which has a classical limit, and which is neither strongly chaotic nor integrable but rather shows a mixture of the two types of behavior. We compare quantum measures of chaos (eigenvalue statistics and eigenvector structure) in the quantum system, with classical measures of chaos (Lyapunov exponents) in the corresponding classical system. As a function of energy and interaction strength, we demonstrate a strong overall correspondence between the two cases. In contrast to both strongly chaotic and integrable systems, the largest Lyapunov exponent is shown to be a multi-valued function of energy.

the low-lying excitations, we identify the presence of the Higgs and the Goldstone modes of the superfluid, as well as the particle- and hole-like excitations in the Mott insulator phase and calculate their dispersion relations. The effective mass of the quasiparticles and -holes vanish at the tip of the Mott lobe where the Higgs energy gap also vanishes. Finally, we present the real time dynamics of the collective excitations, particularly, the Higgs mode. Our findings, particularly the dynamics of excitations support the previous mean-field-like calculations and can be relevant for cold-atom experiments. [1] U. Pohl, S. Ray, J. Kroha arXiv:2106.14860

# TT 10: Focus Session: Superconductivity in 2d-Materials and their Heterostructures

Two-dimensional crystals have become important throughout condensed matter physics. Only a few of them are intrinsic superconductors, most of these containing heavy elements. Hence, Cooper pairing is strongly affected by spin-orbit interactions that lead to exotic features like Ising pairing and mixed singlet-triplet correlations. The unconventional pairing offers novel degrees of freedom and integrates superconductivity with topological and even higher-order topological edge and hinge states. Moreover, proximity induced superconductivity displays characteristic features owing to the ballistic character and the Dirac dispersion relation of today's high-quality hexagonal boron nitride/graphene heterostructures. This makes graphene-based heterostructures an interesting platform for Andreev billiards and similar systems.

TT 10.1 Tue 9:30 H3 Two-fold symmetric superconductivity in few-layer NbSe₂ — •VLAD PRIBIAG University of Minnesota, USA

Few-layer samples of transition metal dichalcogenides (TMDs) feature a wide array of properties such as layer-dependent inversion symmetry, valley-contrasted Berry curvatures, and strong spin-orbit coupling (SOC). Among the superconducting TMDs, NbSe2 is profoundly affected by Ising SOC. Ising SOC not only helps stabilize the superconducting state against large in-plane magnetic fields, but in conjunction with other forms of SOC, it could also give rise to exotic superconducting states such as nodal topological superconductivity. This talk will discuss recent transport measurements of few-layer NbSe2, and NbSe2/CrBr3 junctions, studied under in-plane external magnetic fields. Surprisingly, although the crystal lattice has a three-fold symmetry, the magneto-resistance and critical field show a two-fold anisotropy, which is absent in the normal state. We will discuss these results in the context of a competition between the conventional s-wave pairing instability characteristic of the bulk and a competing d- or pwave instability that emerges in the few-layer limit. These results [1] suggest an unconventional character for superconducting pairing in  $\ensuremath{\text{NbSe}}_2$  and open the possibility for further discoveries, such as non-trivial topologies, in few-layer TMDs.

TT 10.2 Tue 10:00 H3

Spin-orbit coupling and triplet pairing in mesoscopic superconductors -•MARCO APRILI¹, MARKO KUZMANOVIC¹, TOM DVIR², DAVID LEBOEUF³, STEFAN ILIC⁴, MENASHE HAIM², MAXIM KHODAS², JULIA MEYER⁴, HADAR STEINBERG², and CHARIS QUAY¹ — ¹Laboratoire de Physique des Solides, Bâtiment 510, Université Paris-Saclay 91405 Orsay, France - ²Racah Institute of Physics, Hebrew University of Jerusalem, Givat Ram, Jerusalem 91904 Israel — ³Laboratoire National des Champs Magnétiques Intenses, CNRS, Grenoble, France ⁴Université Grenoble Alpes, CEA, Grenoble INP, 38000 Grenoble, France

The spin-orbit coupling which is present in in 2D materials because of inversion breaking symmetry allows a triplet component of the superconducting order parameter to appear.

In presence of an external magnetic field acting on the spin degree of freedom of the electron pairs forming the condensate, this spin-orbit coupling originates a spontaneous supercurrent and hence a phase difference. In a monolayer of a superconducting transition-metal-dichancogenides such as NbSe2, the lack of in-plane crystal inversion symmetry, results instead in a large valley Zeeman splitting which pins the spins out-of-plane and protects in fact superconductivity. Adding an external magnetic field results in a mix singlet-triplet superconducting state where the two order parameters are linearly coupled by the field. The triplet is an equal spin paring state. In this talk I'll present a series of quantum transport and tunneling spectroscopy experiments in mesoscopic superconductors that address these issues.

Invited Talk TT 10.3 Tue 10:30 H3 Supercurrent diode effect in few-layer NbSe₂ – LORENZ BAURIEDL¹, CHRIS-TIAN BÄUML¹, LORENZ FUCHS¹, CHRISTIAN BAUMGARTNER¹, NICOLAS PAULIK¹ Jonas M. Bauer¹, Kai-Qiang Lin¹, John M. Lupton¹, Takashi Taniguchi², Kenji Watanabe², Christoph Strunk¹, and •Nicola Paradiso¹ – ¹Institut für Experimentelle und Angewandte Physik, University of Regensburg, Regensburg, Germany — ²International Center for Materials Nanoarchitectonics, National Institute for Materials Science, Tsukuba, Japan

Current rectifiers are devices which display a largely different resistance for the two opposite bias polarities. Recent seminal works on Rashba superconductors have demonstrated that a simultaneous breaking of time- and inversionsymmetry leads to supercurrent rectification, where for one direction the resistance is strictly zero. Owing to the symmetry of the Rashba spin-orbit interaction, the effect is controlled by the in-plane field. In this work, we report on a supercurrent diode effect in few layer-thick NbSe2 constrictions. As predicted by theory for valley Zeeman spin-orbit interaction (SOI), the observed supercurrent rectification is controlled by the *out-of-plane* field  $B_z$ . Remarkably, the in-plane field does play a role: it determines a preferred direction for the out-ofplane field, making the rectification effect asymmetric in  $B_{z}$ . Such asymmetry is in contrast to theory expectations for pure valley Zeeman spin-orbit. Instead, it points toward the presence of an additional Rashba SOI component in NbSe2.

Superconducting devices in magic-angle twisted bilayer graphene •FOLKERT DE VRIES¹, ELIAS PORTOLES¹, GIULIA ZHENG¹, SHUICHI IWAKIRI¹, KENJI WATANABE², TAKASHI TANIGUCHI², THOMAS IHN¹, and KLAUS ENSSLIN¹ - ¹Laboratory for Solid State Physics, ETH Zurich, Otto-Stern-Weg 1, Zurich, Switzerland —  2 National Institute for Materials Science, 1-1 Namiki, Tsukuba

305-0044, Japan In situ electrostatic control of two-dimensional superconductivity is commonly limited due to large charge carrier densities, and gate-defined superconducting devices are therefore rare. Magic-angle twisted bilayer graphene (MATBG) has recently emerged as a versatile platform that combines metallic, superconducting, magnetic and insulating phases in a single crystal. Here we use multilayer gate technology and physical etching to create devices based on distinct phases in adjustable regions of MATBG. We electrostatically define the superconducting and insulating regions of a Josephson junction and observe tunable d.c. and a.c. Josephson effects. Futhermore, we form a ring shaped geometry with two Josephson junctions known as a superconducting quantum interference device. We observe the expected coherent oscillations of the supercurrent and extract characteristics such as the current phase relation and inductance. These works are an initial steps towards devices where gate-defined correlated states are connected in single-crystal nanostructures. We envision applications in superconducting electronics and quantum information technology.

Minigap and Andreev bound states in ballistic graphene - •LUCA Banszerus^{1,2}, Florian Libisch³, Andrea Ceruti¹, Stefan Blien⁴, Kenji Watanabe⁵, Takashi Taniguchi⁵, Andreas Hüttel⁴, Bernd Beschoten¹, FABIAN HASSLER¹, and CHRISTOPH STAMPFER¹ — ¹RWTH Aachen University, Germany —  2 Forschungszentrum Jülich, Germany —  3 TU Vienna, Austria -⁴University of Regensburg, Germany — ⁵National Institute for Materials Science, Japan

A finite-size normal conductor, proximity-coupled to a superconductor has been predicted to exhibit a so-called minigap, in which quasiparticle excitations are prohibited. In this talk, we demonstrate the direct observation of such a minigap through transport measurements on partially gated ballistic graphene, coupled to superconducting MoRe contacts [1]. The minigap is probed by finite bias spectroscopy through a weakly coupled junction in the graphene region and its value is given by the dimensions of the device. Besides the minigap, a distinct peak in the differential resistance is observed, which we attribute to weakly coupled Andreev bound states (ABS) located near the superconductor-graphene interface. For weak magnetic fields, the phase accumulated in the normal-conducting region shifts the ABS in quantitative agreement with predictions from tightbinding calculations based on the Bogolioubov-de Gennes equation as well as with an analytical semiclassical model.

# TT 10.6 Tue 12:15 H3

Competition of Density Waves and Superconductivity in Twisted Tungsten Diselenide — •Lennart Klebl¹, Ammon Fischer¹, Laura Classen², MICHAEL M. SCHERER³, and DANTE M. KENNES^{1,4} – ¹Institut für Theorie der Statistischen Physik, RWTH Aachen University and JARA-Fundamentals of Future Information Technology, D-52056 Aachen, Germany $-{}^2\rm Max$ Planck Institute for Solid State Research, D-70569 Stuttgart, Germany $-{}^3\rm Institut$ für Theoretische Physik III, Ruhr-Universität Bochum, D-44801 Bochum, Germany -⁴Max Planck Institute for the Structure and Dynamics of Matter, Center for Free Electron Laser Science, D-22761 Hamburg, Germany

Evidence for correlated insulating and superconducting phases around regions of high density of states was reported in the strongly spin-orbit coupled van-der Waals material twisted tungsten diselenide (tWSe₂). We investigate their origin and interplay by using a functional renormalization group approach that allows to describe superconducting and spin/charge instabilities in an unbiased way. We map out the phase diagram as function of filling and perpendicular electric field, and find that the moiré Hubbard model for tWSe₂ features mixed-parity superconducting order parameters with *s*/*f*-wave and topological *d*/*p*-wave symmetry next to (incommensurate) density wave states. Our work systematically characterizes competing interaction-driven phases in tWSe₂ beyond mean-field approximations and provides guidance for experimental measurements by outlining the fingerprint of correlated states in interacting susceptibilities.

TT 10.7 Tue 12:30 H3 Tuning lower dimensional superconductivity with hybridization at a superconducting-semiconducting interface — •M. Simonato¹, A. KAMLAPURE¹, E. SIERDA¹, M. STEINBRECHER¹, U. KAMBER¹, E. J. KNOL¹, P. KROGSTROP^{2,3}, M.I. KATSNELSON¹, A.A. KHAJETOORIANS¹, and M. RÖSNER¹ — ¹Radboud University, Institute for Molecules and Materials, Nijmegen, The Netherlands – ²Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, Copenhagen, Denmark — ³Microsoft Quantum Materials Lab Copenhagen, Lyngby, Denmark

We demonstrate that the hybrid electronic structure derived at the interface between semiconducting black phosphorus and atomically thin films of lead can drastically modify the superconducting properties of the thin metallic film. Using ultra-low temperature scanning tunneling microscopy and spectroscopy, we observe a strongly anisotropic renormalization of the superconducting gap. To study the effect of hybridization, we develop a hybrid two-band model as an extension to conventional BCS theory in the Nambu-Gorkov formalism. In this model, we obtain analytical expressions for the effective gap and link the hybridization-driven renormalization to a weighting of the superconducting order parameter that quantitatively reproduces the measured spectra. These results illustrate the effect of interfacial hybridization at superconductor-semiconductor heterostructures, and pathways for engineering quantum technologies based on gate-tunable superconducting electronics.

TT 10.8 Tue 12:45 H3

Ab inito study of the van der Waals Superconductor  $NbSe_2 - \bullet$ Mohammad HEMMATI, PHILIPP RÜSSMANN, and STEFAN BLÜGEL — Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, Jülich, Germany

Transition metal dichalcogenides (TMDCs) are a very versatile material class in which a plethora of physical phenomena can be realized. This ranges from the topological electronic structure in Weyl and Dirac semimetals to magnetic and even superconducting systems that can furthermore be combined due to the intrinsic van der Waals stacking in these materials. The TMDC NbSe₂ is an example of a layered superconducting material which shows, for instance, the unconventional Ising superconductivity that is particularly robust against magnetic fields [1]. We study bulk and single-layer NbSe2 on the basis of first-principles calculations within the Korringa-Kohn-Rostoker Green function method which allows combining the accurate description of the electronic structure on the basis of density functional theory with a description of the superconductivity via the Bogoliubov-de Gennes formalism [2,3].

This work was funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) under Germany's Excellence Strategy - Cluster of Excellence Matter and Light for Quantum Computing (ML4Q) EXC 2004/1 - 390534769.

TT 10.9 Tue 13:00 H3

Emergence of unconventional proximity effect in Cr1/3NbS2/NbS2 heterostructures — • Alfredo Spuri, Roman Hartmann, Elke Scheer, and An-GELO DI BERNARDO — University of Konstanz

The helimagnetic metal Cr1/3NbS2 has been reported to host soliton excitations based on magnetransport measurements which have been performed on flakes of this material down to the 2D limit. Investigating the proximity effect between 2D flakes of such a magnetic material and conventional 2D superconductors could lead to the discovery of unconventional spin-triplet superconducting states, with possible applications for superconducting spintronics and quantum computing. Based on these motivations, we have fabricated 2D Cr₁/3NbS₂/NbSe₂ and Cr1/3NbS2/NbS2 bilayers and investigated their low temperature magnetotransport and spectroscopic properties. In addition, we have also realized /NbSe2/Cr1/3NbS2/NbSe2 Josephson junctions and performed measurements on them. The results obtained give indication for the emergence of an unconventional proximity effect, possibly due to the emergence of spin-triplet pairing correlations.

# TT 11: Topology: Quantum Hall Systems

Time: Tuesday 9:30-12:30

# TT 11.1 Tue 9:30 H10

Quantum Hall effect induced by chiral Landau levels in topological semimetal films — •Duy-Hoang-Minh Nguyen¹, Koji Kobayashi², Jan-Erik Reinhard Wichmann³, and Kentaro Nomura² - ¹Donostia International Physics Center, Donostia-San Sebastian, Spain $-\,^2 {\rm Department}$  of Physics, Kyushu University, Fukuoka, Japan — ³Institute for Materials Research, Tohoku University, Sendai, Japan

Motivated by recent transport experiments, we theoretically study the quantum Hall effect in topological semimetal films. Owing to the confinement effect, the bulk subbands originating from the chiral Landau levels establish energy gaps that have quantized Hall conductance and can be observed in relatively thick films. We find that the quantum Hall state is strongly anisotropic for different confinement directions not only due to the presence of the surface states but also because of the bulk chiral Landau levels. As a result, we re-examine the quantum Hall effect from the surface Fermi arcs and chiral modes in Weyl semimetals and give a more general view into this problem. Also, we find that when a topological Dirac semimetal is confined in its rotational symmetry axis, it hosts both

quantum Hall and quantum spin Hall states, in which the helical edge states are protected by the conservation of the spin-z component.

TT 11.2 Tue 9:45 H10

Location: H10

Quantum Hall critical phase at topological insulator surfaces — •JOHANNES DIEPLINGER¹, MATEO MORENO-GONZALEZ², SOUMYA BERA³, MARTIN PUSCHMANN¹, MATTHEW FOSTER⁴, FERDINAND EVERS¹, and ALEXANDER ALTLAND² – ¹University of Regensburg, Regensburg, Germany – ²University of Cologne, Cologne, Germany — ³IIT Bombay, Mumbai, India — ⁴Rice University, Houston, Texas, USA

We show that an AIII three-dimensional topological insulator, when tuned away from the critical point at zero energy, realizes a finite class A critical phase on its surface, i.e. a continuum of quantum Hall critical states, instead of an naively expected quantum Hall insulator. Criticality is characterized numerically via an analysis of the multifractal exponents of the wave functions at the surface of the three dimensional bulk.

This numerical work supports a recently proposed first principle theory explaining the existence of the quantum Hall critical phase. Open questions remain concerning the nature of disordered surface states with higher topological index.

TT 11.3 Tue 10:00 H10

Universal properties of boundary and interface charges in multichannel models of one-dimensional insulators — •KIRYL PIASOTSKI¹, NIKLAS MULLER¹, DANTE KENNES^{1,2}, HERBERT SCHOELLER¹, and MIKHAIL PLETYUKHOV¹ — ¹Institut fur Theorie der Statistischen Physik, RWTH Aachen, 52056 Aachen, Germany — ²Max Planck Institute for the Structure and Dynamics of Matter, Center for Free Electron Laser Science, 22761 Hamburg, Germany

Generalizing our previous results on a one-dimensional single-channel continuum [1] and multichannel tight-binding [2] models, we present novel topological invariants to characterize boundary and interface charges in systems described by one-dimensional Schrödinger operators with periodic non-Abelian vector and scalar potentials. In particular, we prove that the change in boundary charge upon the continuous shift of the system towards the boundary by the distance  $x_{\varphi} \in [0, L]$  (*L*-period) is given by the sum of the linear function of  $x_{\varphi}$  and an integer-valued topological index  $I(x_{\varphi})$  - the boundary invariant, and provide two equivalent representations of  $I(x_{\varphi})$ . In addition, we study translationally invariant systems interrupted by a localized impurity, we show that an excess charge on the impurity is a quantized integer quantity given by a winding number expression.

 Phys. Rev. B 104, 125447 (2021)

TT 11.4 Tue 10:15 H10

antiferromagnetic chern insulator in a centrosymmetric system — •MORAD EBRAHIMKHAS¹, MOHSEN HAFEZ-TORBATI², and WALTER HOFSTETTER¹ — ¹Institut für Theoretische Physik, Goethe-Universität, 60438 Frankfurt/Main, Germany — ²Lehrstuhl für Theoretische Physik I, Technische Universität Dortmund, Otto-Hahn-Straße 4, 44221 Dortmund, Germany

An antiferromagnetic Chern insulator (AFCI) can exist if the effect of the timereversal transformation on the AF state cannot be compensated by a space group operation. Such a state has recently been reported in a noncentrosymmetric Kane-Mele-Hubbard model. We investigate the possible emergence of this phase in a centrosymmetric system. We consider a minimal extension of the time-reversal invariant Harper-Hofstadter- Hatsugai model. The next-nearestneighbor hopping opens a gap at half-filling and allows for the realization of a quantum spin Hall insulator. We add to the system a staggered potential  $\Delta$  and the Hubbard interaction U favoring a normal insulator and a Mott insulator, respectively. We map out the phase diagram of the model in the U- $\Delta$  plane and show that an AFCI with the Chern number C = 1 appears for (U~2 $\Delta$ )  $\gg$  t. We find that for a fixed  $\Delta$  upon increasing U a spin-flop transition from the C = 1 *z*-AFCI to a topologically trivial xy-AF phase takes place. Our findings can be used as a guideline in future investigations searching for an AFCI in optical lattices.

## TT 11.5 Tue 10:30 H10

Supercurrent-enabled Andreev reflection in a chiral quantum Hall edge state - ANDREAS BOCK MICHELSEN^{1,2}, PATRIK RECHER³, BERND BRAUNECKER¹, and •THOMAS L. SCHMIDT² - ¹University of St Andrews, UK - ²University of Luxembourg, Luxembourg - ³Technische Universität Braunschweig, Germany A chiral quantum Hall (QH) edge state placed in proximity to an s-wave superconductor experiences induced superconducting correlations. Recent experiments have observed the effect of proximity-coupling in QH edge states through signatures of the mediating process of Andreev reflection. We present the microscopic theory behind this effect by modeling the system with a many-body Hamiltonian, consisting of an s-wave superconductor, subject to spin-orbit coupling and a magnetic field, which is coupled by electron tunneling to a QH edge state. By integrating out the superconductor we obtain an effective pairing Hamiltonian in the QH edge state. We clarify the qualitative appearance of nonlocal superconducting correlations in a chiral edge state and analytically predict the suppression of electron-hole conversion at low energies (Pauli blocking) and negative resistance as experimental signatures of Andreev reflection in this setup. In particular, we show how two surface phenomena of the superconductor, namely Rashba spin-orbit coupling and a supercurrent due to the Meissner effect, are essential for the Andreev reflection. Our work provides a promising pathway to the realization of Majorana zero-modes and their parafermionic generalizations.

# TT 11.6 Tue 11:00 H10

Synthetic gravitational horizons in low-dimensional quantum matter — •CORENTIN MORICE¹, ALI G. MOGHADDAM^{2,3}, DMITRY CHERNYAVSKY², JASPER VAN WEZEL¹, and JEROEN VAN DEN BRINK^{2,4} — ¹Institute for Theoretical Physics and Delta Institute for Theoretical Physics, University of Amsterdam, 1090 GL Amsterdam, The Netherlands — ²Institute for Theoretical Solid State Physics, IFW Dresden, Helmholtzstrasse 20, 01069 Dresden, Germany — ³Department of Physics, Institute for Advanced Studies in Basic Sciences (IASBS), Zanjan 45137-66731, Iran —  4 Institute for Theoretical Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universitt Dresden, 01069 Dresden, German

We propose a class of lattice models realizable in a wide range of setups whose low-energy dynamics exactly reduces to Dirac fields subjected to (1+1)-dimensional gravitational backgrounds, including (anti-)de Sitter spacetime. Wave-packets propagating on the lattice exhibit an eternal slowdown for power-law position-dependent hopping integrals  $t(x) \propto x^{\gamma}$  when  $\gamma \ge 1$ , signalling the formation of black hole event horizons. For  $\gamma < 1$  instead the wave-packets behave radically different and bounce off the horizon. We show that the eternal slowdown relates to a zero-energy spectral singularity of the lattice model and that the semiclassical wave packets trajectories coincide with the geodesics on (1+1)D dilaton gravity, paving the way for new and experimentally feasible routes to mimic black hole horizons and realize (1+1)D spacetimes as they appear in certain gravity theories.

## TT 11.7 Tue 11:15 H10

Adiabatic preparation of fractional quantum Hall phases from the thin torus limit — •BENJAMIN MICHEN¹, CÉCILE REPELLIN², and JAN CARL BUDICH¹ — ¹Institute of Theoretical Physics, Technische Universität Dresden — ²Univ. Grenoble-Alpes, CNRS, LPMMC, 38000 Grenoble, France

We explore as to what extent reversing the thin torus (TT) limit enables the adiabatic preparation of fractional quantum Hall (FQH) states in quantum simulators. As a novel approach, the TT limit is taken by increasing the hopping amplitude in one direction in order to make the system effectively one-dimensional.

The regime of strongly anisotropic coupling features the expected charge density wave (CDW) ground state. The CDW state can be adiabatically connected to the FQH state by tuning the coupling back to the isotropic regime without closing the many-body excitation gap along the way. This may provide an experimental path to the adiabatic preparation of FQH states from topologically trivial CDW states.

We find that the many-body excitation gap in the TT limit decreases with system size for fully discrete models, which limits the adiabatic preparation. However, there appears to be no such restriction in a semicontinuous setup of coupled wires. In that sense, the proposed protocol could be experimentally relevant for arbitrary system sizes.

# TT 11.8 Tue 11:30 H10

**Non-Hermitian topological signatures in a quantum Hall system** — •RAGHAV CHATURVEDI¹, KYRYLO OCHKAN¹, VIKTOR KÖNYE¹, EWELINA HANKIEWICZ², JEROEN VAN DEN BRINK¹, JOSEPH DUFOULEUR¹, and COSMA FULGA¹ — ¹IFW Dresden, Deutschland — ²Julius Maximilian University of Würzburg

Reflection matrices describing waves reflected from the boundaries of insulators exhibit non-Hermitian topological signatures. Drawing from this, we propose to realize non-Hermitian topology in the quantum regime of a two dimensional condensed-matter system. Our work is based on the insight that, in the limit of maximal non-reciprocity, the Hamiltonian for the simplest topological non-Hermitian system - the Hatano-Nelson chain - effectively describes a onedimensional, unidirectionally propagating mode. This is analogous to the unidirectional boundary mode of a fully Hermitian topological insulator: the quantum Hall system. We show that the multi-terminal conductance matrix of this system exhibits a topologically protected non-Hermitian skin effect. Moreover, we show that the topological invariant characterizing these features is more robust than the Chern number, as it remains well-quantized even across quantum Hall plateau transitions. Our work shows that the transport properties of Chern insulators may exhibit signatures of non-Hermitian topology, and this paves the way for the first experimental observation of non-Hermitian topology in a quantum condensed-matter system, which will be presented by another author.

# TT 11.9 Tue 11:45 H10

Observation of non-Hermitian topology in a multi-terminal quantum Hall device — •Kyrylo Ochkan¹, Raghav Chaturvedi¹, Viktor Könye¹, Ewelina Hankiewicz², Jeroen van den Brink¹, Joseph Dufouleur¹, and Cosma Fulga¹ — ¹IFW Dresden, Deutschland — ²Julius-Maximilians-Universität Würzburg, Deutschland

One of the simplest examples of non-Hermitian topology is encountered in the Hatano-Nelson (HN) model, a one-dimensional chain where the hopping in one direction is larger than in the opposite direction. We present here the first experimental observation of non-Hermitian topology in a quantum condensed-matter system. The measurements are done in a multi-terminal quantum Hall device etched in a high mobility GaAs/AlGaAs two-dimensional electron gas ring. The conductance matrix that connects the currents flowing from the active contacts to the ground with the voltage of the active contacts is topologically equivalent to the HN Hamiltonian.

In our device, we directly measure and evidence the non-Hermitian skin effect. We also compute for our experimental device two topological invariants that are found to be more robust than the Chern number. We finally use the unique properties of our system and continuously tune the system configuration between open and periodic boundary conditions. We focus here on the experimental results, whereas the theoretical aspects of the non-Hermitian skin effect and the topological invariants will be discussed in another presentation.

## TT 11.10 Tue 12:00 H10

**Emergent non-Hermitian topology and boundary sensitivity in interacting Su-Schrieffer-Heeger chains** — •TOMMASO MICALLO, CARL LEHMANN, and JAN CARL BUDICH — Institute of Theoretical Physics, Technische Universität Dresden and Würzburg-Dresden Cluster of Excellence ct.qmat, 01062 Dresden, Germany

The exponential sensitivity of effective Non-Hermitian (NH) Hamiltonians with respect to boundary conditions has recently been predicted and observed in a broad range of settings. Here, we discuss as to what extent this remarkable phenomenon may occur in closed correlated fermionic systems that are governed by a Hermitian many-body Hamiltonian. There, an effectively NH quasiparticle description naturally arises in the Green's function formalism due to inter-particle scattering that represents a source of inherent dissipation. Using exact diagonalization, we analyze as a concrete platform extended Su-Schrieffer-Heeger (SSH) chains with interactions subject to varying boundary conditions.

## TT 11.11 Tue 12:15 H10

Absent thermal equilibration on fractional quantum Hall edges over macroscopic scale — •RON MELCER¹, BIVAS DUTTA¹, CHRISTIAN SPANSLATT^{2,3,4}, JIN-HONG PARK⁵, ALEXANDER MIRLIN^{3,4}, and VLADIMIR UMANSKY¹ — ¹Braun Center for Submicron Research, Department of Condensed Matter Physics, Weizmann Institute of Science, Rehovot, 761001, Israel — ²Department of Microtechnology and Nanoscience, Chalmers University of Technology, S-412 96, Göteborg, Sweden — ³Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, 76021, Karlsruhe, Germany — ⁴Institut für Theorie der Kondensierten Materie, Karlsruhe Institute of Technology, 76128, Karlsruhe, Germany — ⁵Institute for Theoretical Physics, University of Cologne, Zülpicher Str. 77, 50937, Köln, Germany

Two-dimensional topological insulators, and in particular quantum Hall states, are characterized by an insulating bulk and a conducting edge. Fractional states may host both downstream (dictated by the magnetic field) and upstream propagating edge modes, which leads to complex transport behavior. Here, we combine two measurement techniques, local noise thermometry and thermal conductance, to study thermal properties of states with counter-propagating edge modes. We find that, while charge equilibration between counter-propagating edge modes is very fast, the equilibration of heat is extremely inefficient, lead-ing to an almost ballistic heat transport over macroscopic distances. Moreover, we observe an emergent quantization of the heat conductance associated with a strong interaction fixed point of the edge modes.

TT 12.1 Tue 9:30 H22

Low-dimensional magnetism in ordered perovskite and Ruddlesden-Popper variants — •Ryan Morrow, Anastasiia Smerechuk, Tamara Holub, Sabine Wurmehl, and Bernd Büchner — Leibniz Institute for Solid-State and Materials Research, IFW-Dresden, 01069 Dresden, Germany

Perovskites and their myriad of structural permutations have long been studied for their intriguing properties and interplay of degrees of freedom, both chemical and physical. While generally three dimensional in nature, perovskites can provide multiple means of access to low dimensional properties as well. In this talk, new results in three different directions pertaining to this concept will be presented. The first, most common approach, is the use of the Ruddlesden-Popper and similar phases, which separate perovskite-like layers with interlaced AO layers, rendering them primarily two dimensional. Several new cation-ordered iridate and rhodate Ruddlesden-Popper phases will be presented. The second approach is that of orbital order using Cu²⁺ in the double perovskite structure to yield in-plane only square lattice like magnetic interactions (e.g. Ba₂CuWO₆). New compounds produced by substitution series and high pressure methods will be shown. The third is that of vacancy ordering. By ordering of vacancies in combination with cation ordering, hexagonal perovskite phases can be reduced to well separated triangular two dimensional magnets with variable spin sizes and frustration. Again, new compounds will be shown. In all three directions, primarily crystallographic and magnetometry data on these new inorganic transition metal oxides will be presented.

EDERER — Materials Theory, ETH Zurich, Switzerland

 $SrCrO_3$  is a complex perovskite oxides that can exhibit a plethora of interesting and technologically promising characteristics. However, available experimental reports still disagree on whether the material is metallic or semiconducting, or whether it is paramagnetic or antiferromagnetic. In a recent pre-print, Bertino et al. also reported a transition from conducting to insulating behavior for thin films of  $SrCrO_3$  grown at different levels of epitaxial strain [1]. In our work, we use density functional theory (DFT) and DFT+U to establish the basic properties of  $SrCrO_3$ . Our calculations clearly suggest a metallic C-type antiferromagnetic ground state, consistent with previous DFT studies[2]. Furthermore, we show that the electronic and magnetic properties of  $SrCrO_3$  are strongly influenced by epitaxial strain, and that the system can develop orbital order coupled to a Jahn-Teller structural distortion under tensile strain. We explore the regime where this distortion is possible and propose a mechanism for the transition to the insulating state that is consistent with the observations of [1].

TT 12.3 Tue 10:00 H22 **Thermodynamic Signatures of the Soliton Lattice in Single-Crystal TbFeO**₃ — •ALEXANDER ENGELHARDT¹, JOHANNA JOCHUM², ANDREAS BAUER¹, AN-DREAS ERB³, ASTRID SCHNEIDEWIND⁴, and CHRISTIAN PFLEIDERER¹ — ¹TU München, Garching, Germany — ²Heinz Maier-Leibnitz Zentrum (MLZ), TU München, Garching, Germany — ³Walther-Meißner-Institut, Garching, Germany — ⁴Forschungszentrum Jülich GmbH, Jülich Center for Neutron Sciences at MLZ, Garching, Germany

The properties of the orthorhombic perovskite TbFeO₃ originate from the interplay of a Tb and Fe magnetic sublattices, resulting in a complex magnetic phase diagram. Perhaps most remarkable, at low temperatures, a complex and anharmonic magnetic structure, a so-called magnetic soliton lattice, was identified by means of neutron scattering under magnetic fields up to 4 T [1]. Here, we report the single-crystal growth of TbFeO₃ using a combination of a solid-state reactions and optical float-zoning. Measurements of the magnetic ac susceptibility and the specific heat are characteristic of strong easy-plane magnetic field at 8 K and 3 K, consistent with the literature. By combining transverse-field ac susceptibility measurements with neutron scattering, we have determined the magnetic phase diagram. When a magnetic field is applied along the hard magnetic c axis, the soliton lattice may be traced up to 12 T, the highest field studied. [1] S. Artyukhin et al., Nat. Mater. 11, 694 (2012)

## TT 12.4 Tue 10:15 H22

Lattice dynamic of LiReO₃ across the continuous ferroelectric-like structural transition — •KSENIA DENISOVA¹, PETER LEMMENS¹, KANTARO MURAYAMA², XIANGYU GU², HIROSHI TAKATSU², CEDRIC TASSEL², and HIROSHI KAGEYAMA² — ¹IPKM, TU BS, Braunschweig, Germany — ²Kyoto University, Kyoto, Japan The observation of a ferroelectric instability in metallic LiOsO₃ [1] with strongly correlated electrons [2] has fueled an intense discussion on the origin of polar metallicity. A comparative Raman study [3] of the isostructural compound LiReO₃ reveals that the enlarged lattice parameters leads to softer Li vibrations and enhances fluctuations in the system. The phonon anomalies point to the phase transition at T=175 K with a crossover regime to temperatures as low as 140 K. The hysteresis in the temperature evolution of ReO₆ related modes as opposed to an abrupt softening of Li vibrations in the ferroelectric phase speaks in favour of a decoupling of polar degrees of freedom and itinerant electrons.

TT 12.5 Tue 10:30 H22 Magnetic anisotropy, magnetoelastic coupling and the phase diagram of Ni_{0.25}Mn_{0.75}TiO₃ — •Ahmed Elghandour, Lukas Gries, Lennart Singer, Kaustav Dey, and Rüdiger Klingeler — Kirchhoff Institute for Physics, Heidelberg University, Heidelberg, Germany Thermodynamic studies on high-quality single crystals of Ni_{0.25}Mn_{0.75}TiO₃ have been used to investigate magneto-structural coupling and to construct the magnetic phase diagram. Clear anomalies in the thermal expansion at the spin ordering and spin reorientation temperatures,  $T_{\rm N}$  and  $T_{\rm R}$ , evidence pronounced magneto-elastic effects. Notably, magnetic entropy is released mainly above  $T_{\rm N}$  implying considerable short range magnetic order up to about  $4T_{\rm N}$ . This is associated with a large regime of negative thermal expansion of the *c* axis. Both  $T_{\rm N}$  and  $T_{\rm R}$  exhibit the same sign of uniaxial pressure dependence which is positive (negative) for pressure applied along the *b* (*c*) axis. In addition, while our data indicate a glassy behaviour below  $T^* \approx 3.7$  K, a significant amount of Ni²⁺ moments seems neither involved in long-range order not in the glassy state.

# TT 12.6 Tue 10:45 H22

NMR investigations of a quasi-two-dimensional Heisenberg antiferromagnet under pressure — •F. Bärtl^{1,2}, D. Opherden^{1,2}, C. P. Landee³, S. MOLATTa^{1,2}, J. WOSNITZA^{1,2}, M. BAENITZ⁴, and H. KÜHNE¹ — ¹Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, Dresden, Germany — ²Institut für Festkörper- und Materialphysik, TU Dresden, Germany — ³Department of Physics, Clark University, Worcester, Massachusetts, USA — ⁴MPI for Chemical Physics of Solids, Dresden, Germany

The molecular-based material  $[Cu(pz)_2(2-HOpy)_2](PF_6)_2$  (CuPOF) is an excellent realization of a two-dimensional square-lattice quantum S = 1/2 Heisenberg antiferromagnet, with an intralayer exchange coupling  $J/k_B = 6.8$  K and an interlayer coupling  $J' \approx 10^{-4} J$ . Previously reported nuclear magnetic resonance (NMR) data revealed a low-temperature transition to a commensurate antiferromagnetic (AF) quasistatic long-range order (LRO), with a preceding crossover from isotropic Heisenberg to anisotropic XY behavior. We present further NMR studies of the low-temperature correlations in magnetic fields up to 7 T and temperatures down to 0.3 K. The application of hydrostatic pressure up to 10 kbar leads to a change of the interlayer coupling and, therefore, the magnetic correlations in the critical regime. The transition regime is probed by ¹H and ³¹P spectroscopy and relaxometry, revealing a monotonic change of  $T_N$  with increasing pressure. The commensurate AF LRO below  $T_N$  persists at high pressures, as revealed by a splitting of the ¹H NMR lines, stemming from the broken symmetry of the local spin polarizations in the LRO regime.

Electronic structure of CeTAl₃ (T=Ag, Au, Cu, Pd, Pt) studied with density functional theory — •ANDRÉ DEYERLING¹, ANDREAS BAUER¹, CHRISTIAN FRANZ², MARC A. WILDE¹, and CHRISTIAN PFLEIDERER¹ — ¹Physics Department, Technical University Munich, Garching, Germany — ²Jülich Centre for Neutron Science (JCNS) at Heinz Maier-Leibnitz Zentrum (MLZ), Garching, Germany

The CeTAl₃ family (T=Ag, Au, Cu, Pd, Pt) is prototypical of strongly correlated electron systems with a large variety of different magnetic ordering phenomena [1,2,3,4], such as ferromagnetism in CeAgAl₃ and incommensurate antiferromagnetism in CeAuAl₃. Further, in CeAuAl₃ [5] and CeCuAl₃ [6] magnetoe-lastic hybrid excitations between crystal electric fields and phonons have been observed. The electronic structure, and in particular the role of the Ce-4f electron, is key for understanding the mechanism driving these phenomena. We report electronic structure calculations for selected members of the CeTAl₃ family, where the Ce-4f electrons are described either as being itinerant or localized using DFT or DFT+U, respectively. The results of our calculations treating the 4f electrons as localized are in good agreement with the experimental data available.

Charge-carrier properties near the bandwidth-controlled Mott transition in layered organic conductors probed by magnetic quantum oscillations — •MARK V. KARTSOVNIK¹, SEBASTIAN OBERBAUER^{1,2}, SHAMIL ERKENOV^{1,2}, WERNER BIBERACHER¹, and NATALIA D. KUSHCH¹ — ¹Walther-Meißner-Institut, Garching, Germany — ²Technische Universität München, Garching, Germany

Despite the great amount of work devoted to the Mott metal-insulator transition (MIT), some key theoretical predictions in this field are still awaiting experimental verification. In particular, there is no clarity about the exact behavior of the quasiparticle mass renormalized by many-body interactions, or about the pseudogap formation in the metallic ground state close to the bandwidth-controlled first-order MIT. Here we address these issues by employing organic  $\kappa$ -type salts as exemplary quasi-2D Mott systems and gaining direct access to their charge carrier properties via magnetic quantum oscillations. We trace the evolution of

the effective cyclotron mass as the conduction bandwidth is tuned very close to the MIT by means of precisely controlled external pressure. We find that the sensitivity of the mass renormalization to subtle changes of the bandwidth strongly exceeds the theoretical predictions and is even further enhanced upon entering the transition region where the metallic and insulating phases coexist. On the other hand, even at this very edge of stability of the metallic ground state its Fermi surface remains fully coherent.

Anisotropic quasiparticle life times and magnetotransport in the doped Hubbard model — •NIKLAS WITT¹, ERIK VAN LOON², SERGEY BRENER¹, MIKHAIL KATSNELSON³, ALEXANDER LICHTENSTEIN¹, and TIM WEHLING¹ — ¹University of Hamburg, Hamburg, Germany — ²Lund University, Lund, Sweden — ³Radboud University, Nijmegen, The Netherlands

The strange metal phase of high-temperature superconducting copper oxide (cuprate) materials exhibits several unconventional transport properties like T-linear resistivity that do not conform to a conventional Fermi liquid description. The crossover to a normal metal for large dopings and the origin of the anomalous electronic properties remain unsolved problems.

Recent transport measurements [1,2] suggest that two different charge sectors exist, one with coherent quasiparticle charge carriers and the other with incoherent non-quasiparticle excitations. Only the former contributes to transport, leading to a drop of the Hall carrier density for small doping. To examine this hypothesis, we study the hole-doped Hubbard model using complementary many-body methods from the weak- and strong-coupling limit. We demonstrate that a dichotomy of the scattering rates between charge carriers from different momentum regions emerges which can lead to the reduction of the Hall carrier density already in the framework of semiclassical Boltzmann theory. TT 12.10 Tue 12:00 H22

Electron spin resonance studies on layered van-der-Waals magnets — •JOYAL JOHN ABRAHAM^{1,2}, YURII SENYK¹, ALEXEY ALFONSOV¹, YULIIA SHEMERLIUK¹, SEBASTIAN SELTER¹, SAICHARAN ASWARTHAM¹, BERND BÜCHNER^{1,3}, and VLADISLAV KATAEV¹ — ¹Leibniz IFW Dresden, D-01069 — ²Institute for Solid State and Materials Physics, TU Dresden, D-01069 — ³Institute for Solid State and Materials Physics and Wurzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, D-01062

Magnetic van-der-Waals (vdW) materials are compounds in which the planes consisting of magnetic atoms are held by weak vdW bonds. With a striking advantage of mechanical exfoliation to produce atomically thin layers, they are considered as promising candidates for studying exotic quantum phenomena and device application. Here, we present the investigation of magnetic vdW single crystals Mn_2P_2S_6 and MnNiP_2S_6, using high field/frequency electron spin resonance. Frequency dependence of resonance field reveals a change of the anisotropy from easy-axis-like in the pure Mn compound to an easy-plane-like in the mixed compound. Temperature dependence of resonance field reveals a shift in resonance from the paramagnetic position even above the transition temperature ( $T_N$ ). This could be indicative of the presence of quasi-static spin-spin shortrange correlations and hence provides insight about magnetic dimensionality of the studied material.

Magnon excitations, spin-lattice coupling and the emerging anisotropic nature of short-range order in van-der-Waals ferromagnets - M. JONAK¹, J. ARNETH¹, A. ELGHANDOUR¹, E. WALDENDY¹, S. SPACHMANN¹, C. KOO¹, M. ABDEL-HAFIEZ², S. SELTER³, S. ASWARTHAM³, and •RÜDIGER KLINGELER¹ —  1 Kirchhoff Institute for Physics, Heidelberg University, Germany $-\,^2$ Dep. of Physics & Astronomy, Uppsala University, Sweden $-\,^3$ IFW Dresden, Germany CrI₃ and Cr₂Ge₂Te₆ are quasi-2D semiconducting van der Waals ferromagnets which evolve long-range order down to the single- or double-layer limit. Quantitative determination of magnetic anisotropy and spin-lattice coupling are crucial to further exploit these materials. We report ferromagnetic resonance studies in a broad frequency regime of 30 - 330 GHz and in magnetic fields up to 18 T and high-resolution capacitance dilatometry. Our data prove significant magnetoelastic coupling and provide quantitative values of the uniaxial pressure effects. Modelling the magnon branches in CrI3 by means of a domain-based ferromagnetic resonance model provides the microscopic parameters such the anisotropy gap of 80 GHz at 2 K which remarkably remains finite at T_C and vanishes only above 80 K. In addition, we detect short-range magnetic correlations up to at least 160 K. Notably, the nature of the short-range correlations in CrI₃ changes, confirming the importance of spin-orbit coupling for the evolution of long-range ferromagnetism which develops from magnetically anisotropic short-range order.

## TT 12.12 Tue 12:30 H22

Orbital order and nematic instability in the antiferromagnetic phase of **BaCoS**₂ – •Benjamin Lenz¹, Michele Fabrizio², and Michele Casula¹ ¹Institut de minéralogie, de physique des matériaux et de cosmochimie (IMPMC), Sorbonne University - CNRS - MNHN, Paris, France — ²Scuola Internazionale Superiore di Studi Avanzati (SISSA), Trieste, Italy

We present evidence for a nematic instability in the antiferromagnetic insulating phase of BaCoS₂, which shows a Néel transition at a surprisingly high temperature of  $T_N \sim 300$ K. Based on *ab initio* simulations, we discuss several competing orders in terms of magnetic order, orbital composition and structural distortions to identify a set of nematic and orbital ordered states as possible candidates for the ground state. From these considerations we derive an effective spin-model of  $J_1 - J_2$  type and discuss the consequences of the most probable, orbital ordered ground state for its parametrization. We finally identify a driving mechanism which allows to explain the high Néel temperature by  $\mathcal{C}_4$ -symmetry breaking through orbital order and draw parallels to other quasi-2D materials such as pnictides.

TT 12.13 Tue 12:45 H22 Tuning the multiorbital Mott transition of  $BaCoS_2 - HANEEN$ Abushammala^{1,2}, Yannick Klein¹, and Andrea Gauzzi¹ - ¹IMPMC, Sorbonne University, 4, place Jussieu, 75005 Paris, France — ²Institute for Experimental Physics IV, Ruhr-Universität Bochum, Germany

The quasi-2D BaCoS₂ system displays an unusual Mott state concomitant with a stipe-type antiferromagnetic (AFM) ordering at  $T_N$ =305 K in a square-lattice of Co²⁺. Electron doping by partial Co/Ni substitution, or hydrostatic pressure drives the system into a paramagnetic and Fermi Liquid (FL) metallic phase. Interestingly, this metal-insulator transition (MIT) is not accompanied by any significant structural distortion, which offers ideal conditions to investigate the FL to non-FL crossover in a model square-lattice system in the regime of moderate electronic correlations typical of sulphides. In order to investigate the interplay between AFM order and Mott state, we have studied the effect of chemical pressure and hole doping on the AFM order by partially substituting Sr and K for Ba respectively. Contrary to the case of hydrostatic pressure, we find that chemical pressure significantly reduces  $T_N$  down to 240 K for a substitution level of 8 at%, corresponding to an effective pressure of 0.3 GPa. The K-substitution is found to induce similar suppression of the AFM order as compared to the Sr-substitution. However, its sizable value of Sommerfeld coefficient (5.7 mJ/mol.K²) suggests a metallic state induced by hole doping. Studies on single crystals may unveil whether the metallic state induced by K-doping displays FL-properties.

Precession of entangled spin and pseudospin in double quantum dots -•CHRISTOPH ROHRMEIER and ANDREA DONARINI — University Regensburg Quantum dot spin valves are characterized by exchange fields [1] which induce spin precession and generate anomalous spin resonances [2]. Analogous effects have been studied in double quantum dots, in which the orbital degree of freedom replaces the role of the spin in the valve configuration [3]. We generalize, now, this setup to allow for arbitrary spin and orbital polarization of the leads, thus obtaining an even richer variety of current resonances, stemming from the entangled precession dynamics of the spin and pseudospin [4]. We observe for both vectors a delicate interplay of decoherence, pumping and precession which can only be understood by including the dynamics of the spin-pseudospin correlators. The results are obtained in the framework of a generalized master equation within the cotunneling approximation and are complemented by a coherent

sequential tunneling model.

Pair-amplitude dynamics in superconductor-quantum dot hybrids -•MARKUS HECKSCHEN and BJÖRN SOTHMANN — Universität Duisburg-Essen, Duisburg, Deutschland

We consider a three-terminal system consisting of a quantum dot strongly coupled to two superconducting reservoirs in the infinite gap limit and weakly coupled to a normal metal. Using a real-time diagrammatic approach, we calculate the dynamics of the proximity-induced pair amplitude on the quantum dot. We find that after a quench the pair amplitude shows pronounced oscillations with a frequency determined by the coupling to the superconductors. In addition, it decays exponentially on a time scale set by the coupling to the normal metal. Strong oscillations of the pair amplitude occur also when the system is periodically driven both in the adiabatic and fast-driving limit. We relate the dynamics of the pair amplitude to the Josephson and Andreev current through the dot to demonstrate that it is an experimentally accessible quantity.

Staggered spin-orbit interaction in a nanoscale device — Lauriane Contamin¹, Tino Cubaynes¹, William Legrand¹,  $\bullet$ Magdalena Marganska², Matthieu Desjardins¹, Matthieu Dartiailh¹, Zaki Leghtas^{1,3,4}, Andre Thiaville⁵, Stanislas Rohart⁵, Audrey Cotter¹, Matthieu Delbecq¹, and Takis Kontos¹ – ¹Laboratoire de Physique de l'Ecole Normale Superieure, ENS, Universite PSL, CNRS, Sorbonne Universite, Universite Paris-Diderot, Sorbonne Paris Cite, Paris, France – ²Institute for Theoretical Physics, University of Regensburg, Germany —  3 QUANTIC Team, INRIA de Paris, Paris, France —  4 Centre Automatique et Systemes, Mines Paris-Tech, PSL Research University, Paris, France — ⁵Laboratoire de Physique des Solides, Universite Paris-Saclay, CNRS, UMR 8502, Orsay, France

The coupling of the spin and the motion of charge carriers is an important ingredient for the manipulation of the spin degree of freedom and for the emergence of topological matter. Creating domain walls in the spin-orbit interaction at the nanoscale may turn out to be a crucial resource for engineering topological excitations suitable for universal topological quantum computing or for new schemes for spin quantum bits. Realizing this in natural platforms remains a challenge. Using high resolution circuit quantum electrodynamics magneto-spectroscopy, we show how this can be implemented in carbon nanotubes with a staggered synthetic spin-orbit interaction induced by two lithographically patterned magnetically textured gates.

Jahn-Teller effects in charge transport through single-molecule junctions: a hierarchical equation of motion approach - -Christoph Kaspar and MICHAEL THOSS — University of Freiburg

Molecules with degenerate electronic states may exhibit Jahn-Teller effects [1]. In this contribution, we investigate charge transport through such molecules bound to metal electrodes within a molecular junction [2]. The study employs the hierarchical equation of motion approach [3,4] to open quantum system dynamics. This method generalizes perturbative master equation methods by including higher-order contributions as well as non-Markovian memory, thus allowing for a systematic convergence of the results. Extending previous studies [5], we find that the molecule can become trapped in a nonconducting state resulting in a current-blockade, out of which only higher-order processes such as cotunneling provide an escape mechanism.

The electrical properties of single molecules can be investigated using atomically sharp metallic electrodes in mechanically controllable break junctions (MCBJs). The current-voltage (IV) characteristics of single molecules in such junctions are influenced by the binding positions of the end groups on the tip-facets and tip-tip separation. In this talk, we present MCBJ experiments on N,N'-Bis(5ethynylbenzenethiol-salicylidene)ethylenediamine (Salen). We discuss the evolution of the single level model (SLM) parameters namely, a) the energetic level  $\epsilon$  of the dominant conducting channel and b) the coupling  $\Gamma$  of the dominant conducting channel to the metallic electrodes. The SLM-parameters were evaluated for IV-curves recorded during opening measurements and fitted to the single level model. We propose a novel, high-throughput approach to model the evolution of the SLM-parameters and explain the recurring peak-like features in the experimentally measured evolution of  $\Gamma$  with increasing tip-tip separation, which we relate to the deformation of the molecule and the sliding of the anchor group above the electrode surface.

TT 15.1 Tue 11:15 H23 Mechanical frequency control in inductively coupled electromechanical systems — •THOMAS LUSCHMANN^{1,2,3}, PHILIP SCHMIDT^{1,2}, FRANK DEPPE^{1,2,3}, ACHIM MARX¹, ALVARO SANCHEZ⁴, RUDOLF GROSS^{1,2,3}, and HANS HUEBL^{1,2,3} — ¹Walther-Meißner- Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — ²Physik-Department, Technische Universität München, Garching, Germany — ⁴Department of Physics, Universitat Autonoma de Barcelona, Bellaterra, Spain

Nano-electromechanical systems couple mechanical motion to superconducting quantum circuits at microwave frequencies. While traditional, capacitive coupling strategies operate in the weak coupling regime, inductive coupling schemes based on partially suspended superconducting interference devices (SQUID) have demonstrated significantly improved coupling rates. Such systems are expected to allow for the exploration of phenomena beyond the linearized opto-mechanical interaction. Here, we present an investigation into the tuning of the mental data quantitatively corroborates theoretical predictions for SQUID-based electromechanical systems. In addition, we observe a magnetic field dependent tuning of the mechanical resonance frequency, which we attribute to an effective interaction of the atomic lattice and the superconducting vortex lattice.

#### TT 15.2 Tue 11:30 H23

Current-induced forces in nano-electromechanical systems: A hierarchical equations of motion approach — •SAMUEL RUDGE and MICHAEL THOSS — Physikalisches Institut, Albert-Ludwigs Universität Freiburg

Current-induced forces in nanostructures provide valuable insight into the mechanisms of nonequilibrium charge transport through nanoelectromechanical systems [1]. In this contribution, we investigate specifically the electronic friction in molecular junctions using the hierarchical equations of motion approach [2-3]. Since this method is, in principle, numerically exact, it allows us to extend previous studies [4] beyond the Born-Markov approximation and incorporate strong intra-system interactions. To demonstrate the approach, we consider a resonant level model coupled to a low-frequency vibrational mode, which is treated semi-classically, and reproduce the exact electronic friction known from nonequilibrium Green's function theory [4]. We then also incorporate a high-frequency vibrational mode, which is strongly coupled to the electronic degrees of freedom and is treated fully quantum mechanically.

Generation of coherent acoustic phonons at the atomic scale with femtosecond Coulomb forces – •SHAOXIANG SHENG¹, ANNE-CATHERINE OETER¹, MOHAMAD ABDO¹, KURT LICHTENBERG¹, MARIO HENTSCHEL³, and SEBASTIAN LOTH^{1,2} – ¹University of Stuttgart, Institute for Functional Matter and Quantum Technologies, Stuttgart, Germany – ²Max Planck Institute for Solid State Research, Stuttgart, Germany – ³University of Stuttgart, 4th Physics Institute, Stuttgart, Germany

Coherent acoustic phonons enable ultrafast control of solids and have been exploited for applications in various acoustic devices. We find that localized coherent acoustic phonon wavepackets can be launched by THz-induced ultrafast Coulomb forces in a scanning tunneling microscope (STM) junction. The wavepackets induce an ultrafast displacement of the surface with several picometers amplitude and propagate into the sample with low losses. The surface displacement can be precisely controlled by varying the tip-sample distance. This non-thermal femtosecond force excitation enables localized measurements of phonon propagation with nanometer spatial resolution, can be used for diagnostics below surfaces and opens new perspectives in exploiting coherent phonons at the atomic scale.

TT 15.4 Tue 12:00 H23

**Josephson optomechanics** — •SURANGANA SEN GUPTA¹, BJOERN KUBALA^{1,2}, CIPRIAN PADURARIU¹, and JOACHIM ANKERHOLD¹ — ¹ICQ and IQST, Ulm University, Germany — ²Institute of Quantum Technologies, German Aerospace Center (DLR), Ulm, Germany

Optomechanical phenomena can be investigated in the microwave regime using a circuit-QED setup combining superconducting microwave cavities and a mechanical degree of freedom. In conventional optomechanics the cavity is usually driven to a coherent state by a laser. In contrast, in circuit optomechanics, the cavity can be driven by inelastic tunneling in a Josephson junction, which provides a large inherent non-linearity and leads to complex quantum states of light [1]. Here, we theoretically investigate a superconducting cavity with a single mode  $\omega_0$  coupled to a mechanical resonator. The cavity is driven by a dc-biased Josephson junction at  $2eV_{dc} = p\hbar\omega_0$  where each Cooper pair excites p = 1, 2, 3 photons.

(i) We characterise signatures of the mechanics in the emission spectrum for squeezed light (p = 2) and for the p = 3 case, which is challenging for optical cavities, but easily realised in our microwave cavities. The inherent nonlinearity not only allows efficient driving at  $p \ge 2$ , but can also drastically change the spectrum at p = 1, where for stronger driving Mollow-like features arise. (ii) We calculate heating and cooling rates for the mechanical degree of freedom and find in the non-linear regime enhanced and non-monotonous rates. [1] G. C. Ménard *et al.*, Phys. Rev. X **12**, 021006 (2022).

We study relaxation dynamics in a strongly-interacting three and four-site Fermi-Hubbard system (quantum dots) coupled to environment represented by fermionic baths. Starting with an ab initio approach, we derive several variants of the Lindblad master equation for the quantum dots systems by applying different approaches: local and global, secular and coherent [1,2]. At low temperatures, depending on the particular parameter ratios and applied approximations, the system tends to or destroys antiferromagnetic order [2]. In three quantum dots, the system becomes spin-frustrated and relaxes to a stable persistent spin current.

Multimethod, multimessenger approaches to models of strong correlations — •THOMAS SCHÄFER — Max Planck Research Group "Theory of Strongly Correlated Quantum Matter" (SCQM), Max Planck Institute for Solid State Research, Stuttgart, Germany

The Hubbard model is the paradigmatic model for electronic correlations. In this talk I present a general framework for the reliable calculation of its properties, which we coined multi-method, multi-messenger approach. I will illustrate the power of this approach with three recent studies: (i) an extensive synopsis of arguably all available finite-temperature methods for the half-filled Hubbard model on a simple square lattice in its weak-coupling regime, fully clarifying the impact of spin fluctuations and tracking their footprints on the one- and twoparticle level, (ii) a complementary subset of those applied to the Hubbard model on a triangular geometry, exhibiting the intriguing interplay of geometric frustration (magnetism) and strong correlations (Mottness) and (iii) a multi-method study of a model for magnetism in infinite-layer nickelates. These examples may work as a blueprint of similar future studies of strongly correlated systems.

TT 16.2 Wed 10:00 H10

Random phase approximation for gapped systems: Role of vertex corrections and applicability of the constrained random phase approximation — •ERIK VAN LOON¹, MALTE RÖSNER², MIKHAIL KATSNELSON², and TIM WEHLING³ — ¹Lund University, Lund, Sweden — ²Radboud University, Nijmegen, the Netherlands — ³University of Bremen, Bremen, Germany

The many-body theory of interacting electrons poses an intrinsically difficult problem that requires simplifying assumptions. For the determination of electronic screening properties of the Coulomb interaction, the random phase approximation (RPA) provides such a simplification. Here we explicitly show that this approximation is justified for band structures with sizable band gaps. This is when the electronic states responsible for the screening are energetically far away from the Fermi level, which is equivalent to a short electronic propagation length of these states. The RPA contains exactly those diagrams in which the classical Coulomb interaction covers all distances, whereas neglected vertex corrections involve quantum tunneling through the barrier formed by the band gap. Our analysis of electron-electron interactions provides a real-space analogy to Migdal's theorem on the smallness of vertex corrections in electron-phonon problems. An important application is the increasing use of constrained RPA calculations of effective interactions. We find that their usage of Kohn-Sham energies accounts for the leading local (excitonic) vertex correction in insulators.

#### TT 16.3 Wed 10:15 H10

**Consistency of potential energy in the diagrammatic vertex approximation** — •JULIAN STOBBE and GEORG ROHRINGER — Institute of Theoretical Physic, University of Hamburg, 20355 Hamburg, Germany

In the last decades, dynamical mean field theory (DMFT) and its diagrammatic extensions have been successfully applied to describe local and nonlocal correlation effects in correlated electron systems. Unfortunately, both of them suffer from intrinsic inconsistencies which lead to a violation of the Pauli principle (and related sum rules) as well as the conservation laws of the system. This limits the predictive power of these approaches as fundamental observables such as the kinetic and/or potential energies are not unambiguously defined. Here, we will discuss an approach to overcome the ambiguity in the calculation of the potential energy within the ladder dynamical vertex approximation (DFA) by introducing an effective mass renormalization parameter in both the charge and the spin susceptibility of the system. The applicability of the method is then demonstrated on the half filled single-band Hubbard model on a three-dimensional cubic lattice. Furthermore, the solution method will be discussed, since the new method requires careful consideration of finite approximation of infinite Matsubara sums.

ders of magnitude via the nonlinearity of Coulomb blockade. The resulting novel optomechanical system can have figures of merit close to several interesting parameter regimes, as, e.g., strong optomechanical coupling (with hybridization of vibrons and photons) and the quantum coherent limit (where manipulation is faster than thermal decoherence). With this in mind, here we discuss our ongoing work to improve the components of this system, the optomechanical coupling, and its adressing and readout. — [1] S. Blien *et al.*, Nat. TT 16.4 Wed 10:30 H10

Vertex divergences in the Anderson impurity model - From real to imaginary frequencies — •MICHAEL MEIXNER¹, JOHANNES HALBINGER², SEUNG-SUP LEE³, FABIAN KUGLER⁴, PATRICK CHALUPA-GANTNER⁵, ALESSANDRO TOSCHI⁵, JAN VON DELFT², and THOMAS SCHÄFER¹ — ¹Max Planck Institute for Solid State Research, Stuttgart, Germany — ²Arnold Sommerfeld Center for Theoretical Physics, Ludwig-Maximilians-Universität München, Munich, Germany — ³Department of Physics and Astronomy, National University, Seoul, South Korea — ⁴Department of Physics and Astronomy, Rutgers University, Piscataway, NJ, USA — ⁵Institute for Solid State Physics, TU Wien, Vienna, Austria

Generalized susceptibilities not only are at the heart of calculating momentumand frequency-dependent response functions, but can also provide direct physical insights into local magnetic moment formation and Kondo screening. In particular, recent literature has investigated the implications of divergences of the irreducible vertex function on the Matsubara axis in the charge and particleparticle channels on the physics of the Anderson impurity model. In this study we examine the divergent properties of the two-particle irreducible vertex function in the Anderson impurity model employing the numerical renormalization group (NRG). In a first step data is benchmarked against state of the art results from continuous-time quantum Monte Carlo on the imaginary frequency axis. In a second step NRG allows us to access not only imaginary frequencies but also real frequencies via the Keldysh contour at very low temperatures and without analytic continuation.

**Exact continuum representation of long-range interacting systems** — •ANDREAS ALEXANDER BUCHHEIT¹, TORSTEN KESSLER¹, PETER SCHUHMACHER², and BENEDIKT FAUSEWEH² — ¹Saarland University, 66123 Saarbrücken, Germany — ²German Aerospace Center (DLR), 51147 Cologne, Germany

Continuum limits are a powerful tool in the study of many-body systems, yet their validity is often unclear when long-range interactions are present. In this work, we rigorously address this issue and put forth an exact representation of long-range interacting lattices that separates the model into a term describing its continuous analogue, the integral contribution, and a term that fully resolves the microstructure, the lattice contribution. For any system dimension, any lattice, any power-law interaction and for linear, nonlinear, and multi-atomic lattices, we show that the lattice contribution can be described by a differential operator based on the multidimensional generalization of the Riemann zeta function, namely the Epstein zeta function. Our representation provides a broad set of tools for studying the analytical properties of the system and it yields an efficient numerical method for the evaluation of the arising lattice sums. We benchmark its performance by computing classical forces and energies in three important physical examples, in which the standard continuum approximation fails: Skyrmions, defects in ion chains, and spin waves in a pyrochlore lattice with dipolar interactions. We demonstrate that our method exhibits the accuracy of exact summation at the numerical cost of an integral approximation.

TT 16.6 Wed 11:00 H10

**Exotic phases in long-range interacting quantum lattices** — ANDREAS A. BUCHHEIT¹, •TORSTEN KESSLER¹, PETER K. SCHUHMACHER², and BENEDIKT FAUSEWEH² — ¹Saarland University, Saarbrücken, Germany — ²German Aerospace Center (DLR), Cologne, Germany

We provide a rigorous analysis of the effects of power-law long-range interactions on the phase diagram of a multi-dimensional quantum spin lattice. Starting from the discrete Hamiltonian, we use the recently developed singular Euler-Maclaurin expansion and derive an exact and parameter-free field theory that fully captures the effects due to the inherent discreteness of the lattice. For any lattice and any system dimension, we derive analytic expressions for the phase boundaries to ferromagnetic and anti-ferromagnetic phases and outline their dependence on the exponent of the power-law interaction and of the system dimension.

# TT 16.7 Wed 11:15 H10

 ${\rm SU(2)}$ -symmetric tensor network study of the classical Heisenberg model — •PHILIPP SCHMOLL¹, AUGUSTINE KSHETRIMAYUM^{1,2}, JENS EISERT^{1,2}, ROMAN ORUS^{3,4,5}, and MATTEO RIZZI^{6,7} — ¹Dahlem Center for Complex Quantum Systems, Freie Universität Berlin, 14195 Berlin, Germany — ²Helmholtz Center Berlin, 14109 Berlin, Germany — ³Donostia International Physics Center, E-20018 San Sebastián, Spain — ⁴Ikerbasque Foundation for Science, E-48013 Bilbao, Spain — ⁵Multiverse Computing, E-20014 San Sebastián, Spain — ⁶Forschungszentrum Jülich, Institute of Quantum Control (PGI-8), 52425 Jülich, Germany — ⁷Institute for Theoretical Physics, University of Cologne, D-50937 Köln, Germany

The classical Heisenberg model in two spatial dimensions constitutes one of the most paradigmatic spin models, taking an important role in statistical and condensed matter physics to understand magnetism. Despite its paradigmatic character controversies remain whether the model exhibits a phase transition at finite temperature. In this work, we make use of state-of-the-art tensor network approaches, representing the classical partition function in the thermodynamic limit over a large range of temperatures. By implementing an SU(2) symmetry in our tensor network, we are able to handle very large bond dimensions, which is crucial in detecting phase transitions. With decreasing temperatures, we find a rapidly diverging correlation length, whose behaviour is apparently compatible with the two main contradictory hypotheses known in the literature, namely a finite-T transition and asymptotic freedom, though with a slight preference for the second.

Matrix-product-state-based band-Lanczos solver for quantum cluster approaches — SEBASTIAN PAECKEL^{1,2}, THOMAS KÖHLER³, SALVATORE R. MANMANA⁴, and •BENJAMIN LENZ⁵ — ¹Arnold Sommerfeld Center of Theoretical Physics, University of Munich, Germany — ²Munich Center for Quantum Science and Technology (MCQST), Munich, Germany — ³Department of Physics and Astronomy, Uppsala University, Sweden — ⁴Institute for Theoretical Physics, Georg August University of Göttingen, Germany — ⁵Institut de minéralogie, de physique des matériaux et de cosmochimie (IMPMC), Sorbonne University, Paris, France

We present a matrix-product-states-based band-Lanczos method as a solver for quantum cluster techniques. Based on a traditional band-Lanczos technique for the calculation of the cluster Green's function, we introduce and motivate different convergence criteria and discuss their impact on the stability of the results at the example of the variational cluster approximation. The capabilities of this method to calculate the self-energy functional are demonstrated for Hubbardlike models on different cluster geometries. Finally, we show a finite-size scaling of order parameters using cluster sizes, which are out of reach for traditional exact-diagonalization-based solvers.

# TT 16.9 Wed 12:00 H10

Hierarchical equations of motion approach to open quantum system dynamics: Matrix product state formulation in twin space — •YALING KE¹, RAF-FAELE BORRELLI², and MICHAEL THOSS¹ — ¹Institute of Physics, Albert-Ludwig University Freiburg, Hermann- Herder-Strasse 3, 79104 Freiburg, Germany — ²DISAFA, Università di Torino, I-10095 Grugliasco, Italy

The hierarchical equations of motion (HEOM) approach is a numerically exact method to study the dynamics of open quantum systems with non-perturbative system-environment interaction and non-Markovian memory at finite temperatures. Although considerable progress has been made over the past few decades to extend the applicability of the HEOM approach, the numerical cost is still very expensive for reasonably large systems.

In this contribution, we present the twin-space formulation of the HEOM approach in combination with the matrix product state representation for open quantum systems coupled to a hybrid fermionic and bosonic environment. The key ideas of the approach are a reformulation of a set of differential equations for the auxiliary density matrices into a time-dependent Schrödinger-like equation for an augmented multi-dimensional wave function as well as its tensor decomposition into a product of low-rank matrices. The new approach facilitates accurate simulations of non-equilibrium quantum dynamics in larger and more complex open quantum systems with both factorized and correlated initial conditions.

## TT 16.10 Wed 12:15 H10

Single-boson-exchange-fRG application to the two-dimensional Hubbard model at weak coupling — SARAH HEINZELMANN¹, KILIAN FRABOULET¹, PIETRO BONETTI², AIMAN AL-ERYANI¹, DEMETRIO VILARDI², •ALESSANDRO TOSCHI³, and SABINE ANDERGASSEN¹ — ¹Eberhard Karls Universität Tübingen — ²Max Planck Institut Stuttgart — ³Technische Universität Wien

We illustrate the computational advantages of the recently introduced singleboson exchange (SBE) formulation for the one-loop functional renormalization group (fRG) applied to the two-dimensional Hubbard model. We present a detailed analysis of the physical susceptibilities and their evolution with temperature and interaction strength, both at half filling and finite doping. We find that the rest functions describing the corrections beyond the SBE contributions play a negligible role in the weak coupling regime. The SBE formulation of the fRG flow hence allows for a substantial reduction of the numerical effort in the treatment of the two-particle vertex function, paving a promising route for future multiboson and multiloop extensions.

## TT 16.11 Wed 12:30 H10

Connecting real- and imaginary-frequency axis for two-particle manybody propagators — •SELINA DIRNBÖCK¹, SEBASTIAN HUBER¹, SEUNG-SUP LEE^{2,3}, FABIAN KUGLER⁴, JAN VON DELFT³, KARSTEN HELD¹, and MARKUS WALLERBERGER¹ — ¹TU Wien, Austria — ²Seoul National University, South Korea — ³Ludwig-Maximilians-Universität München, Germany — ⁴Rutgers University, New Jersey, USA

Two-particle response functions are a centerpiece of quantum many-body physics, relating both to experiment, where they can be observed as susceptibilities, and to theory, where they form the basis of advanced self-consistent field theories. Yet, due to their size and complex structure, they are challenging to handle numerically.

Recently, two advances have been made to tackle this problem: firstly, the intermediate representation together with an overcomplete basis (IR+OB), which provides a highly efficient compression of propagators in imaginary frequency, and secondly, partial spectral functions (PSFs), which allow for the efficient evaluation in real frequency, by, for example, using the numerical renormalization group (NRG).

In this talk, we connect these two approaches: we show that the IR+OB and PSFs are intimately connected. We also show that the two-particle propagator obtained from NRG/PSFs on the real-frequency axis can be compressed efficiently using IR+OB on imaginary-frequency axis, reducing the memory demand by more than three orders of magnitude. Finally, we use the guidance from PSFs to develop a physical regularization scheme for the IR+OB.

## TT 16.12 Wed 12:45 H10

Trie-based ranking of quantum many-body states — •Markus Waller-BERGER and Karsten Held — TU Wien, Vienna, Austria

Ranking bit patterns – finding the index of a given pattern in an ordered sequence – is a major bottleneck scaling up numerical quantum many-body calculations, as fermionic and hard-core bosonic states translate naturally to bit patterns. Traditionally, ranking is done by bisectioning search, which has poor cache performance on modern machines.

We instead propose to use tries (prefix trees), thereby achieving a two- to tenfold speed-up in numerical experiments with only moderate memory overhead. For the important problem of ranking permutations, the corresponding tries can be compressed. These compressed "staggered" lookups allow for an additional speed-up while retaining the memory requirements of prior algorithms based on the combinatorial number system.

We use these improvements to go to larger system sizes for which three-and four-point propagators can be computed.

## TT 16.13 Wed 13:00 H10

Tetranacci polynomials in solid state phyics — • NICO LEUMER — IPCMS, CNRS, Strasbourg

In mesoscopic physics, state of the art theoretical research relies not solely but to large extend on numerical investigations. Naturally, support from analytical side is important whenever possible, in particular to appeal physical intuition. For the first time, I will introduce to a broader audience so called Tetranacci polynomials, which offer a generic technique to analytic diagonalize a variety of model Hamiltonians for finite system size and when open/free boundary conditions are imposed. As perspective, this approach is applicable on discrete physical (sub-) systems owing at least two degrees of freedom per atom, such as the Kitaev chain or the 1d Rashba-nanowire in magnetic field positioned on superconducting substrate. The use extends further to the famous Su-Schrieffer-Heeger model or to topological trivial tight-binding chains having nearest and next nearest neighbor hopping. In my presentation, I elaborate that Tetranacci polynomials extend Bloch's theorem and how they are related to eigenvectors and eigenvalues. Within the frame drawn by the illustrative example of the X-Ychain in transverse magnetic field, I demonstrate how previous diagonalization approaches are recovered by the more general Tetranacci technique. The final part of my presentation is devoted to an overview of physically distinct systems hosting Tetranacci polynomials and their common spectral features overlooked in earlier studies.

TT 17.1 Wed 9:30 H22

**TES sensors design for the CRESST experiment** — •FRANCESCA PUCCI¹, AN-TONIO BENTO^{1,2}, ANNA BERTOLINI¹, LUCIA CANONICA¹, NAHUEL FERREIRO IACHELLINI^{1,3}, ABHIJI GARAI¹, DIETER HAUFF¹, ATHOY NILIMA¹, MICHELE MANCUSO¹, FEDERICA PETRICCA¹, FRANZ PROEBST¹, and DOMINIK FUCHS¹ — ¹Max-Planck-Institut für Physik, D-80805 München, Germany — ²LIBPhys-UC, Departamento de Fisica, Universidade de Coimbra, P3004 516 Coimbra, Portugal — ³Excellence Cluster Origins, D-85748 Garching, Germany

The CRESST experiment aims at the direct detection of sub-GeV dark matter particles via elastic scattering off nuclei in different target crystals at cryogenic temperatures. Each detector consists of an absorber crystal and a Transition Edge Sensors (TES), which measures the temperature variations caused by an energy deposition in the crystal. The TES are made of tungsten thin films and they are operated in the middle of their superconducting transition, at around 15 mK. These very sensitive detectors allow for a leading energy threshold worldwide. The studies on the TES sensor design and its development at the Max Planck Institute for Physics are presented.

## TT 17.2 Wed 9:45 H22

Beta spectrometry measurements with metallic magnetic calorimeters — •MICHAEL PAULSEN¹, JÖRN BEYER¹, CHRISTIAN ENSS^{2,6}, SEBASTIAN KEMPF^{3,6}, KARSTEN KOSSERT⁴, MARTIN LOIDL⁵, RIHAM MARIAM⁵, OLE NÄHLE⁴, PHILIPP RANITZSCH⁴, MATIAS RODRIGUES⁵, and MATHIAS WEGNER^{6,3} — ¹Physikalisch-Technische Bundesanstalt, Berlin, Germany — ²Kirchhoff-Institute for Physics, Heidelberg University, Germany — ³Institute of Micro- and Nanoelectronic Systems, Karlsruhe Institute of Technology, Germany — ⁴Physikalisch-Technische Bundesanstalt, Braunschweig, Germany — ⁵Université Paris-Saclay, CEA, List, Laboratoire National Henri Becquerel, Palaiseau, France — ⁶Institute for Data Processing and Electronics, Karlsruhe Institute of Technology, Germany

Precise beta spectra measurements are important for radionuclide metrology, the validation of theoretical calculations and nuclear medicine. Metallic Magnetic Calorimeters (MMCs) with the radionuclide sample embedded in a  $4\pi$  absorber have proven to be among the best beta spectrometers in terms of energy resolution and threshold, linearity and detection efficiency, notably for low energy beta transitions. In this work, two measurements of the spectrum of the 2nd forbidden non-unique beta transition of ⁹⁹Tc (Q⁻ = 297.5 keV) are presented. They were acquired using two independent MMC based detectors in two different laboratories and show excellent agreement. The results suggest a spectral shape which deviates significantly from hitherto theoretical calculations and semi-empirical extrapolations at lower energies (< 50 keV) reported in the literature.

## TT 17.3 Wed 10:00 H22

Low-noise, impedance matched current-sensing dc-SQUIDs for magnetic microcalorimeter readout — •FABIENNE BAUER^{1,2}, CHRISTIAN ENSS¹, and SE-BASTIAN KEMPF^{1,2} — ¹Kirchhoff-Institute for Physics, Heidelberg University, Im Neuenheimer Feld 227, 69120 Heidelberg — ²Institute of Micro- and Nanoelectronics Systems, Karlsruhe Institute of Technology, Hertzstraße 16, 76187 Karlsruhe

Direct-current superconducting quantum interference devices (dc-SQUIDs) are the devices of choice for reading out low-impedance cryogenic particle detectors such as magnetic microcalorimeters (MMCs). MMCs use a paramagnetic or superconducting temperature sensor, placed in a weak magnetic field and inductively coupled to a superconducting pickup coil, to convert deposited energy into a change of magnetic flux threading the pickup coil. The latter is sensed using a low-noise SQUID. To maximize sensitivity and hence energy resolving power, impedance matching between SQUID and pickup coil as well as a SQUID white noise level close to the quantum limit are crucial. As current-sensing SQUIDs with input inductances between 1 nH and 10 nH and suited for mK-operation temperatures are rarely or not at all commercially available, custom SQUIDs for MMC readout must be developed. In this context, we discuss design and performance of three current-sensing dc-SQUIDs impedance matched to MMCs that are foreseen for neutrino mass investigation, X-ray spectroscopy and mass spectrometry, respectively. To achieve low-noise performance, the SQUIDs rely on the use of cross-type Josephson junctions to minimize junction capacitance and hence readout noise.

# TT 17.4 Wed 10:15 H22

Flux ramp modulation based hybrid microwave SQUID multiplexer — •CONSTANTIN SCHUSTER^{1,2}, MATHIAS WEGNER^{1,2}, CHRISTIAN ENSS¹, and SEBASTIAN KEMPF^{1,2} — ¹Kirchhoff-Institute for Physics, Heidelberg University, Heidelberg — ²Institute of Micro- and Nanoelectronic Systems, Karlsruhe Institute of Technology, Karlsruhe

For the readout of cryogenic detector arrays, microwave SQUID multiplexers ( $\mu$ MUXes) are presently being developed. Using non-hysteretic rf-SQUIDs, each

Wednesday

Location: H22

multiplexer channel transforms the detector signal into a change of amplitude or phase of a microwave signal probing the resonance frequency of a superconducting resonator. In this way, numerous detectors can be simultaneously read out by coupling multiple resonators to a common transmission line. The resonator bandwidth is adjusted according to the detector speed and sets a lower limit for the frequency spacing of resonators. This limit, however, can in practice only be reached if the fabrication accuracy is very high. As a result, the channel density is very often limited by fabrication rather than the inherent channel capacity of the transmission line. We present a hybrid microwave SQUID multiplexer combining two frequency-division readout techniques to allow multiplexing a given number of detectors with only a fraction of readout resonators. We present insights of our approach based on information theory and discuss benefits and drawbacks using Monte-Carlo simulations. We further discuss the performance of a prototype device indicating that our technique is very well suited for reading out ultra-large bolometric detector arrays.

# TT 17.5 Wed 10:30 H22

**Transport properties of superconducting thin films and superconducting single-photon detectors** — •FABIAN WIETSCHORKE¹, STEFAN STROHAUER², RASMUS FLASCHMANN¹, LUCIO ZUGLIANI¹, CHRISTIAN SCHMID¹, SVEN ERNST², STEFANIE GROTOWSKI², SIMONE SPEDICATO², BJÖRN JONAS¹, MIRCO METZ¹, KAI MÜLLER¹, and JONATHAN FINLEY² — ¹Walter Schottky Institute and Department for Electrical and Computer Engineering, Technical University of Munich, 85748 Garching, Germany — ²Walter Schottky Institute and Physics Department, Technical University of Munich, 85748 Garching, Germany

Superconducting single-photon detectors (SSPDs) play a crucial role in the rapidly growing field of quantum communication and computation. Hereby, NbTiN is an established candidate for superconducting thin films that is used as the active part of the SSPDs. To achieve high detection efficiencies, the superconducting properties of NbTiN films, deposited via magnetron sputtering, need to be optimized. In this contribution, we present transport measurements characterizing the influence of the deposition process onto the superconducting properties, which assists in a systematic optimization of the detectors. We are able to estimate detection efficiency and depairing current of the SSPDs, even before fabricating the nanostructures, utilizing the hotspot model and the Ginzburg-Landau model. Finally, we use the thin film transport measurements and detector measurements to assess the quality of our nanofabrication process.

## TT 17.6 Wed 11:00 H22

**Opimization of MoSi film deposition for superconducting single-photon detectors in the telecom c-band** — •STEFANIE GROTOWSKI¹, LUCIO ZUGLIANI², RASMUS FLASCHMANN², STEFAN STROHAUER¹, CHRISTIAN SCHMID², FABIAN WIETSCHORKE², SVEN ERNST¹, SIMONE SPEDICATO¹, MIRCO METZ², BJÖRN JONAS², KAI MÜLLER², and JONATHAN FINLEY¹ — ¹Walter Schottky Institute and Physics Department, Technical University of Munich, Germany — ²Walter Schottky Institute and Department for Electrical and Computer Engineering, Technical University of Munich, Germany

Superconducting single-photon detectors (SSPDs) are a crucial building block for photonic quantum technologies. With regard to the telecommunication infrastructure, SSPDs sensitive in the telecom c-band are required. A promising material in this regard is MoSi, as it unites a small superconducting energy gap enabling high sensitivity while maintaining a high transition temperature. In this work we aim at optimizing the magnetron co-sputtering deposition to achieve high transition temperatures ( $T_c$ ). We vary the stoichiometry and find maximized  $T_c$  values for Mo rich films until an upper limit of around 80% Mo is reached. Above this critical concentation grazing incidence diffration reveals the transition tempores by  $T_c$  and structure as well. We find that a low working pressure improves the  $T_c$ , but a minimum pressure is required to ensure an amorphous deposition. Finally, with the optimized parameter set we measured a  $T_c$  of 8.4 K for 20 nm and 6.2 K for 4.5 nm thin films.

## TT 17.7 Wed 11:15 H22

Superconducting single-photon detectors on lithium-niobate-on-insulator — •CHRISTIAN SCHMID¹, RASMUS FLASCHMANN¹, LUCIO ZUGLIANI¹, STE-FAN STROHAUER², BJÖRN JONAS¹, FABIAN WIETSCHORKE¹, SVEN ERNST², STE-FANIE GROTOWSKI², SIMONE SPETICATO², MIRCO METZ¹, KAI MÜLLER¹, and JONATHAN FINLEY² — ¹Walter Schottky Institute and Department for Electrical and Computer Engineering, Technical University of Munich, Germany — ²Walter Schottky Institute and Physics Department, Technical University of Munich, Germany

Superconducting single-photon detectors (SSPDs) are a key building block in photon-based quantum computation and communication. To realize a scal-

able photonic quantum computer, integration of single-photon sources, electronics and crucially SSPDs is necessary. One of the most promising material platforms for quantum photonic integration is lithium-niobate-on-insulator (LNOI), which offers a broad optical window and a large non-linearity.

In this work, we present the thin film superconducting properties of NbTiN grown on crystalline LNOI and compare them to films deposited on amorphous  $Si/SiO_2$  wafer. SSPDs fabricated from films on both substrates are further characterized with respect to their quantum efficiency, dark count rate, recovery time and timing jitter.

Cooling performance of a 4 K two-stage pulse tube cryocooler in tilted operation along main azimuthal orientations — •JACK-ANDRE SCHMIDT^{1,2}, BERND SCHMIDT^{1,2}, JENS FALTER^{1,2}, and ANDRE SCHIRMEISEN^{1,2} — ¹Justus-Liebig-University Giessen — ²TransMIT GmbH

Closed-cycle cryocoolers, here Gifford-McMahon (GM) type pulse tube cryocoolers (PTC), offer long measurement periods and low maintenance, but they exhibit undesired intrinsic effects due to the working principle [1]. Cooling performance of GM-type PTCs is strongly depending on the orientation and is set to be strictly vertical, which is not suitable for experiments where the cryostat needs to be tilted [2, 3]. We report an experimental study of the effect of tilting from vertical orientation on the cooling performance of a U-shaped 4 K pulse tube cryocooler (PTC) with 7 kW electrical input power. An investigation of cooling performance over tilt angles from 0 to 60 degree for selected azimuthal orientations of the PTC is performed. The non-coaxial arrangement of the tubes suggests an asymmetric cooling performance while tilting along the first or second stage heat exchanger due to natural convection in the pulse tubes [3]. The increase of no-load temperatures upon tilting by +/- 50 degree will be discussed. While the regime of tilt angles within 30 show moderate loss in cooling power an almost sudden decrease of cooling power is revealed and analyzed for high tilt angles.

TT 17.9 Wed 11:45 H22

**Cross Correlated Current Noise Thermometer for Milli-Kelvin Temperatures** — •CHRISTIAN STÄNDER, PASCAL WILLER, NATHALIE PROBST, ANDREAS REIFENBERGER, ANDREAS REISER, ANDREAS FLEISCHMANN, and CHRISTIAN ENSS — Kirchhoff Institute for Physics, Heidelberg University.

Within our search for easy-to-use and reliable thermometers for milli-Kelvin and micro-Kelvin temperatures we developed a noise thermometer, where the Johnson noise of a massive cylinder of high purity silver is monitored simultaneously by two current sensing dc-SQUIDs. Operating each SQUID in voltage bias mode in a 2-stage configuration allows to reduce the power dissipation of the SQUIDs to a minimum. To further reduce the parasitic effect of correlated amplifier noise, a mathematical method to suppress the noise coupled from the feedback to the input coil of the SQUIDs is introduced. By cross-correlating the two SQUID signals, the noise contribution of the read-out electronics is suppressed to a marginal level.

We recently assembled a first small series of such thermometers to best reliability, reproducibility and user friendliness. In the complete investigated temperature range from 4 K down to 5 mK, the measured noise power is linear in temperature. The 12 thermometers of the series agree within less than 0.1% in the complete temperature range and show a good agreement with the PTLS-2000 temperature scale. Also a new sensor material, with the goal of counteraction observed ageing effects, is introduced.

# **TT 18: Topological Insulators**

Time: Wednesday 9:30-11:45

TT 18.1 Wed 9:30 H23

**Exceptional topological insulators** — •MICHAEL DENNER¹, ANASTASIIA SKURATIVSKA¹, FRANK SCHINDLER^{1,2}, MARK FISCHER¹, RONNY THOMALE³, TOMÁS BZDUSEK^{1,4}, and TITUS NEUPERT¹ — ¹Department of Physics, University of Zurich, Switzerland — ²Princeton Center for Theoretical Science, Princeton University, USA — ³Institut für Theoretische Physik und Astrophysik, Universität Würzburg, Germany — ⁴Condensed Matter Theory Group, Paul Scherrer Institute, Switzerland

Since their theoretical conception and experimental discovery, 3-dimensional topological insulators have become the focal point for research on topological quantum matter. Their key feature is a single Dirac electron on the surface, representing an anomaly: in purely 2D such a state can neither be regularized on a lattice nor in the continuum. I will introduce an analog in dissipative systems, which are described by non-Hermitian operators, the exceptional topological insulator (ETI). Like normal topological insulators, the ETI hosts exotic surface states. It is characterized by a bulk energy point gap and exhibits robust surface states that cover the bulk gap as a single sheet of complex eigenvalues or with a single exceptional point. Even though it does not require any symmetry to be stabilized, I will explain how this non-Hermitian topological phase can also be inferred using symmetry-indicators of the bulk Hamiltonian. Furthermore, I will demonstrate how the ETI can be induced in gapless solid-state systems and metamaterials, thereby setting a paradigm for non-Hermitian topological matter.

# TT 18.2 Wed 9:45 H23

Berry curvature effects in high-harmonic generation in topological insulator surface states — •VANESSA JUNK¹, COSIMO GORINI², and KLAUS RICHTER¹ — ¹Institut für Theoretische Physik, Universität Regensburg, Germany — ²Université Paris-Saclay, CEA, CNRS, SPEC, 91191, Gif-sur-Yvette, France When strong-field light is interacting with a solid, it acts as an a.c. bias accelerating electrons through the bandstructure and driving non-perturbative transitions. These processes can lead to the emission of high-order harmonics containing fingerprints of the materials properties. Since in topological insulator surface states scattering is strongly suppressed, signatures of coherent transport can be found in the resulting spectra.

Recently, high-harmonics generation from the surface states of the threedimensional topological insulator  $Bi_2Te_3$  has been observed experimentally [1]. Here, we show fully quantum mechanical simulations of the electron dynamics and compare them with the experimental results. We find that the Berry curvature can not only lead to high-harmonics polarized perpendicularly to incoming radiation but also to an alternating polarization of odd and even order harmonics. This being one of the key observations in the experiment suggests the importance of Berry curvature effects in coherent high-harmonics emission.  C. Schmid, L. Weigl, P. Grössing, V. Junk, C. Spin-polarized surface state transport in gate-tunable topological insulator — •LINH DANG¹, OLIVER BREUNIG¹, HENRY LEGG², and YOICHI ANDO¹ — ¹1 II. Physikalisches Institut, Universität zu Köln, Zülpicher Str. 77, 50937 Köln, Germany — ²Department of Physics, University of Basel, Klingelbergstrasse 82, CH-4056 Basel, Switzerland

Topological insulators (TIs) possess helical spin-momentum locked surface states that can be harnessed to create a non-zero spin polarization by applying a current through the TI. Two opposite types of spin polarization have been reported on the same material, suggesting the interplay between topological surface state and Rashba spin splitting state of 2-dimensional surface electrons. These two contributing effects might be used to create a spin transistor device. In this report, we discuss the sign switching of the spin polarization by electrostatic gating based on data acquired from devices that were microfabricated on TI flakes.

## TT 18.4 Wed 10:15 H23

Chern insulating phases and thermoelectric properties of EuO/MgO(001) superlattices — •OKAN KOEKSAL and ROSSITZA PENTCHEVA — Department of Physics and Center of Nanointegration (CENIDE), University of Duisburg-Essen, 47057 Duisburg

The effect of confinement and strain on the topological and thermoelectric properties of  $(EuO)_n/(MgO)_m(001)$  superlattices (SLs) are investigated by means of DFT + U + spin-orbit coupling (SOC) calculations in conjunction with semiclassical Boltzmann transport theory. A particularly strong effect is observed in the ferromagnetic  $(EuO)_1/(MgO)_3(001)$  SL at the lateral lattice constant of MgO (a = 4.24 Å) where SOC opens a band gap of 0.51 eV due to an inversion between occupied localized Eu 4f and itinerant 5d conduction bands. This band inversion between bands of opposite parity is accompanied by a spin reorientation in the spin-texture along the contour of band surrounding the  $\Gamma$  point. The resulting Chern insulating phase with C = -1, confirmed by a single topological edge state, exhibits promising thermoelectric properties, i.e., a high Seebeck coefficient between 400 and 800  $\mu V K^{-1}$ . Somewhat lower thermoelectric values are obtained for the ferromagnetic semimetallic  $(EuO)_2/(MgO)_2(001)$  SL, where SOC also induces a band inversion and AHC with values up to  $-1.04 e^2/h$ . This work emphasizes the correlation between non-trivial topology and thermoelectricity in  $(EuO)_n/(MgO)_m(001)$  SLs with broken time-reversal symmetry [1].

Support by the DFG within CRC/TRR80, project G3 is gratefully acknowledged. [1] O. Köksal and R. Pentcheva, Phys. Rev. B **103**, 045135 (2021)

# TT 18.5 Wed 10:30 H23

**Stacking faults in weak topological insulators with time reversal symmetry** — •GABRIELE NASELLI, VIKTOR KÖNYE, and ION COSMA FULGA — Leibniz-Institut für Festkörper-und Werkstoffforschung, Dresden, Germany

In experimental observation stacking faults can play a significant role in hiding the topological properties of topological insulators. The defects break lattice symmetries which can be required for the protection of the topological states in weak topological insulators. We studied stacking faults in 3D weak topological insulators like Bi₂TeI and Bi₁₄Rh₃I₉. Both these materials are formed by 2D topological insulating layers (with time reversal symmetry and quantum spin Hall effect) stacked on top of each other in the z direction with trivial insulating spacers between them. We have built a simple tight binding model for both of these materials and got the topological properties solving the eigenvalue problem numerically. We introduced a stacking fault in our model by shifting half of the system by a fraction of the unit cell in the z direction. We mapped the stacking surface in the WTI into a Su-Schrieffer-Heeger chain, considering the effective hoppings between the TI layers on the left and right side of the stacking fault. When all the TI layers on the left side are strongly interacting with the TI layers on the right side of the defect the corresponding SSH model is in the trivial phase and we did not find conducting states. Instead when the stacking fault has two weakly interacting TI layers at its boundaries the corresponding SSH chain is in the topological phase and we have found localized conducting states at the defect.

**Dynamic impurities in two-dimensional topological insulator edge states** – •SIMON WOZNY¹, MARTIN LEIJNSE¹, and SIGURDUR I. ERLINGSSON² – ¹Division of Solid State Physics and NanoLund, Lund University, Box 118, S-22100 Lund, Sweden – ²School of Science and Engineer- ing, Reykjavik University, Menntavegi 1, IS-101 Reykjavik, Iceland

Two-dimensional topological insulators host one-dimensional helical states at the edges. These are characterized by spin-momentum locking and time-reversal symmetry protects the states from backscattering by potential impurities. Magnetic impurities break time-reversal symmetry and allow for backscattering.

We have investigated the effects of random, aligned but harmonically rotating magnetic impurities. Using the time dependent Green's function (GF) for the system we calculate the time-averaged density of states (DOS) and extract the transmission via a Floquet scattering formalism. For slow driving the DOS and transmission match an average over static impurity orientations, whereas fast driving results in a flat low-energy DOS and transmission with resonances at higher energies related to Floquet sub-band crossings. Resonant driving leads to a nontrivial DOS and transmission. We also investigate the dependence on the ratio between potential and magnetic strength of the impurities.

Quantum phase transitions and a disorder-based filter in a Floquet system — •BHARGAVA BALAGANCHI ANANTHA RAMU, SANJIB KUMAR DAS, and ION COSMA FULGA — IFW Dresden and Wurzburg-Dresden Cluster of Excellence ct.qmat, Helmholtzstrasse 20, 01069 Dresden, Germany

Two-dimensional periodically-driven topological insulators have been shown to exhibit numerous topological phases, including ones which have no static analog, such as anomalous Floquet topological phases. We study a two dimensional model of spinless fermions on a honeycomb lattice with periodic driving. We show that this model exhibits a rich mixture of weak and strong topological phases, which we identify by computing their scattering matrix invariants. Further, we do an in-depth analysis of these topological phases in the presence of spatial disorder and show the relative robustness of these phases against imperfections. Making use of this robustness against spatial dis-order, we propose a filter which allows the passage of only edge states, and which can be realized using existing experimental techniques.

## **Topological phases of Su-Schrieffer-Heeger alternating ladders** — •ANAS AB-DELWAHAB — Leibniz Universität Hannover, Hannover, Germany

Alternating ladders are constructed from unit cells consisting of rungs with odd number of sites connected with rungs with even number of sites [1]. These systems can be constructed using several options of equivalent unit cells. Two onesite rungs connected with two two-site rungs as well as two three-site rungs connected with two two-site rungs are investigated. Rich phase diagrams of topological insulating phases separated by critical lines are identified using the Su-Schrieffer-Heeger (SSH) model that describe such ladder systems. The phase diagrams depend on the choices between the equivalent unit cells. One could identify cases with flat bands close to the Fermi level. In principle, these simple models can be realized in designer quantum materials such as artificial lattices constructed by manipulation of atoms using a tip of scanning tunnelling microscope (STM) [2,3].

Coulomb-blockade spectroscopy in topological insulator-superconductor hybrid devices — •Benedikt Frohn, Tobias W. Schmitt, Wilhelm Wittl, DENNIS HEFFELS, MICHAEL SCHLEENVOIGT, ABDUR R. JALIL, DETLEV GRÜTZ-MACHER, and PETER SCHÜFFELGEN — Peter Grünberg Institut, Forschungszentrum Jülich & JARA Jülich-Aachen Research Alliance, D-52425 Jülich, Germany In the search for fault tolerant quantum computing, Majorana zero modes resemble a promising platform [1]. We investigate an island of a topological insulator (TI) nanoribbon,  $(Bi,Sb)_2Te_3$ , proximitized with a superconductor (S) for signatures of these states using Coulomb-blockade spectroscopy. One possible signature would be a change in charge periodicity once the island is tuned into the topological regime. We successfully created tunneling barriers made from Al₂O₃ and obtained the characteristic Coulomb diamond structure. Nb provides excellent interface transparency towards TI and was capped insitu, yet we found no change in charge periodicity. Al, however, is known to show these signatures in comparable experiments. Since Al diffuses heavily into the TI when put directly into contact, we fabricated Josephson junctions (JJs) with different thin interlayers between (Bi,Sb)₂Te₃ and Al to characterize the influence of these diffusion barriers on the transport properties of the JJs. We find four possible interlayers that allow for engineering a transparent S-TI interface. These results will enable us to perform Coulomb-blockade experiments with Al as a S.

**Periodic supercurrent oscillations in topological insulator nanowire Josephson junctions in an axial magnetic field** — •MICHAEL BARTH¹, JACOB FUCHS¹, COSIMO GORINI^{1,2}, and KLAUS RICHTER¹ — ¹Institute of Theoretical Physics, University of Regensburg, D-93040 Regensburg, Germany — ²Université Paris-Saclay, CEA, CNRS, SPEC, 91191, Gif-sur-Yvette, France

Helical surface states of 3-dimensional topological insulator (TI) nanowires are expected to have very promising physical properties like forbidden backscattering [1]. Moreover it is predicted that a topological superconducting state which could possibly host Majorana fermions can be realized by bringing a normal s-wave superconductor in close proximity to a TI [2]. We theoretically study the influence of an axial magnetic field on the supercurrent flow in TI nanowire Josephson junctions. The wire is modeled by an effective 2 dimensional setup and we take into account the special surface geometry by incorporating the partial superconducting simulations [3] and a semiclassical analytical approach [4], we show that the critical current can exhibit periodic oscillations, where the period corresponds to half of the superconducting flux quantum.

Superconductivity in HgTe based quantum point contacts — •JOHANNES BAU-MANN, MARTIN STEHNO, HARTMUT BUHMANN, and LAURENS MOLENKAMP — Institute for Topological Insulators and Physikalisches Institut, Experimentelle Physik 3, Universität Würzburg, 97074 Würzburg, Germany

Quantum point contacts have been suggested as tunable transmission elements in topological quantum circuits. We etched narrow constrictions into the weak links of topological Josephson junctions prepared from high-mobility, bandinverted HgTe quantum wells (2D topological insulator). In such devices, the conductance and supercurrent transmission decrease step-wise as we deplete the carriers in the constriction electrostatically with a gate. In the entire gating range, the supercurrent diffraction pattern in a perpendicular magnetic field exhibits a slow decay indicative of a small number of Andreev bound states funnelling through the constriction. Under microwave irradiation, odd Shapiro steps are suppressed in the current-voltage characteristic of the open constriction. This observation has been linked to the appearance of a 4pi-periodic contribution to the supercurrent of topological Josephson devices. Surprisingly, we recover all

596

steps as we reduce the transmission to a small number of channels. We discuss possible origins of the effect and implications for topological quantum devices.

TT 19.3 Wed 12:15 H23 **Tunable**  $4\pi$ -periodic supercurrent in HgTe-based topological nanowires — •RALF FISCHER¹, JORDI PICÓ-CORTÉS^{2,3}, WOLFGANG HIMMLER¹, GLORIA PLATERO², MILENA GRIFONI³, DIMITRY KOZLOV⁴, NIKOLAY MIKHAILOV⁴, SERGEY DVORETSKY⁴, CHRISTOPH STRUNK¹, and DIETER WEISS¹ — ¹Experimental and Applied Physics, University of Regensburg — ²Instituto de Ciencia de Materiales de Madrid — ³Institute of Theoretical Physics, University of Regensburg — ⁴Novosibirsk, Russia

Topological insulator nanowires in proximity to conventional superconductors have been proposed as a tunable platform to realize topological superconductivity. The tuning is done using an axial magnetic flux  $\Phi$  which allows transforming the system from trivial at  $\Phi = 0$  to topologically nontrivial when half a magnetic flux quantum  $\Phi = \Phi_0/2$  threads the cross-sectional area of the wire.

In our work, we investigate Josephson junctions based on HgTe nanowires and probe the Shapiro step spectrum. From the suppression of odd Shapiro steps, we extract the  $4\pi$ - and  $2\pi$ -periodic portion of the supercurrent  $I_{4\pi}$  and  $I_{2\pi}$  using a resistively and capacitively shunted junction model. The ratio  $I_{4\pi}/I_{2\pi}$  changes from a small value of few percent at  $\Phi = 0$  up to a maximum at  $\Phi = \Phi_0/2$ . The presence of  $I_{4\pi}$  at  $\Phi = 0$  and small magnetic fields indicate that in this regime Landau-Zener transitions cause the  $4\pi$ -periodic current. By disentangling the  $4\pi$ -periodic supercurrent of trivial an topological origin, our data suggest that topological  $4\pi$ -periodic supercurrents dominate at axial magnetic fields above  $\Phi_0/4$ .

TT 19.4 Wed 12:30 H23 Complex magnetic ground states and topological electronic phases of atomic spin chains on superconductors — •JANNIS NEUHAUS-STEINMETZ¹, ELENA VEDMEDENKO¹, THORE POSSKE², and ROLAND WIESENDANGER¹ — ¹Department of Physics, University of Hamburg, 20355 Hamburg, Germany —

²I. Institute for Theoretical Physics, University of Hamburg, D-20355 Hamburg, Germany

Understanding the magnetic properties of atomic chains and nanoscopic wires on superconductors is an essential cornerstone on the road towards controlling and constructing topological matter. Yet, even in the simplest models of suspended chains, the classes of available magnetic ground states remain debated. Ferromagnetic (FM), antiferromagnetic (AFM), and spiral configurations have been suggested and experimentally detected, while additionally non-coplanar and complex collinear phases have been conjectured. Here, we resolve a recent controversy by determining the magnetic ground states of chains of magnetic atoms in proximity to a superconductor with Monte-Carlo methods, which employ the initial tight-binding model directly without further simplifications. We confirm the existence of FM, AFM and spiral ground states, and identify additional more complex ground states. We topologically classify the electronic structures, and investigate the stability of the magnetic states against increasing superconductivity. In addition, we introduce a computationally efficient alternative for approximating the magnetic ground state with an effective Heisenberg model, which we demonstrate by using our previous results as a benchmark for this new method.

The possibility to combine topological electronic band structures and superconductivity (SC) opens new pathways towards engineering exotic quantum matter. Proximity induced superconductivity in the topological surface state of topological insulators (TIs) offers the possibility to realize a chiral *p*-wave superconductor. Such a superconductor is an exotic state of matter which supports non-Abelian anyons and is of great interest for Majorana-based quantum computing applications. Material-specific insights into the microscopic details of such SC/TI interfaces are of great interest and an indispensable ingredient in the challenging materials optimization problem.

Here we first introduce the recent Bogoliubov de-Gennes (BdG) extension to the all electron full potential relativistic Korringa-Kohn-Rostoker (KKR) Green function code JuKKR [1]. We apply the KKR-BdG method to the s-wave superconductor Nb [2] and investigate the proximity induced superconductivity in the topological surface state of a SC/TI heterostructure. Effects of in-plane polarised light on graphene: Band gap, spin and topological quantum numbers — •FREDERIK BARTELMANN¹, MARTA PRADA², and DANIELA PFANNKUCHE^{1,3} — ¹University of Hamburg, I. Institute of Theoretical Physics — ²University of Hamburg, Institute of Nanostructure and Solid State Physics — ³The Hamburg Centre for Ultrafast Imaging

If it were not for the effects of spin-orbit interaction, the band gap in graphene would close at the K-points, resulting in perfect Dirac cones. In this work, a graphene tight-binding band structure involving atomic s-, p- and d-orbitals is modified by irradiation with light. The light is polarised in-plane to affect the  $d_{xz}$ - and  $d_{yz}$ -orbitals, which are coupled via spin-orbit interaction, and the  $p_z$ -orbitals, which are predominant in the valence and conduction band. Floquet formalism is used to obtain dressed states and an altered band structure. The changes to valence and conduction band and thus the band gap are studied for a range of frequencies in the PHz regime. Along these studies, the correlation between real- and sublattice spin is probed as well as topological properties and how they behave under a change of frequency. Since the focus lies on the effects due to changes in the orbital composition of the dressed states, inter-band couplings are prioritised over intra-band ones. The goal of the studies is to gauge the effect of different irradiated frequencies on graphene and to evaluate possible applications of dressed states for topological quantum computers.

Quantum anomalous hall devices on magnetically doped topological insulator films — •ROOZBEH YAZDANPANAH RAVARI¹, GERTJAN LIPPERTZ^{1,2}, ANJANA UDAY¹, ANDREA BLIESENER¹, ALEXEY TASKIN¹, and YOICHI ANDO¹ — ¹University of Cologne, Cologne, Germany — ²KU Leuven, Leuven, Belgium

Magnetic doping opens an exchange gap in the surface states of topological insulators (TIs) at the Dirac point by breaking time reversal symmetry. Such systems manifest the quantum anomalous Hall (QAH) effect which is characterized by quantized Hall resistance and zero longitudinal resistance. To explore this phenomena, devices are fabricated on thin films of V-doped  $(Bi_{1-x}Sb_x)_2Te_3$ . This contribution highlights our effort to better understand this effect, including a study of the QAH breakdown where in high current densities or small dimensions, the quantized state is lost. Another ongoing effort focuses on interfacing the quantum anomalous hall insulator (QAHI) system with a superconductor (SC) through devices with different geometries, where the obtained results suggest high transparency of the QAH/SC interface.

**Entanglement spectrum of Su-Schrieffer-Heeger model** — •MAHSA ALSADAT SEYED HEYDARI¹ and JAHANFAR ABOUEI² — ¹University of Konstanz, Germany — ²Institute for Advanced Studies in Basic Sciences (IASBS), Iran

We investigate the ground state properties of a one dimensional topological insulator, the Su-Schrieffer-Heeger (SSH) chain in the absence/presence of an alternative spin-orbit coupling (SOC), employing single-particle entanglement spectrum (ES). In the presence of SOC, owing to the spin-flip processes, different topologically trivial and non-trivial phases appear in the ground state phase diagram of the model. Using the matrix of single-particle correlation functions, we obtain the single-particle ES as well as the entanglement entropy, and show that they behave differently in these phases. We introduce an indicator, called entanglement gap, defined as the difference between the lowest positive entanglement level and the highest negative level, and demonstrate that this indicator distinguishes the topological phases from the trivial phase of the model.

#### TT 20.6 Wed 15:00 P1

**Current increase by weakening site-site interaction in SSH lattices** — •MIRKO ROSSINI, BRECHT DONVIL, and JOACHIM ANKERHOLD — Institute for Complex Quantum Systems and IQST, Ulm University, Germany

One of the simplest models supporting topologically protected states is the wellknown Su-Schrieffer-Heeger (SSH) model. As a 1D chain with staggered NN hopping amplitudes, it can host two protected 0-energy modes when the distribution of hopping amplitudes is properly adjusted. These edge states are energetically relatively stable against ambient noise. thus providing natural protection from any excitation living on an edge of the chain.

In this poster, we show the realization of a current through such a chain, which in the topological regime could provide a naturally protected channel for the safe transport of excitations in space. The current is created by terminating the SSH chain at particle reservoirs. It has been shown that the edge-to-edge transport of particles in such a system is exponentially suppressed with respect to the length of the chain, preventing the practical use of this model for the stated purposes. Therefore we propose, after a brief introduction to the main properties of the SSH model, an extended model for the 1D lattice that, by weakening a small selection of hopping parameters along the chain, is able to increase the current through the edges while preserving some of the topological protection offered by the original SSH model.

## TT 20.7 Wed 15:00 P1

Search for new europium-based intermetallic 122 materials with non-trivial topological properties — •SARAH KREBBER, KRISTIN KLIEMT, CORNELIUS KRELLNER, and ASMAA EL MARD — Max-von-Laue Straße 1, 60438 Frankfurt am Main, Physikalisches Institut

Today, more and more Eu-based compounds come into focus of magnetic topological nontrivial materials. The first examples were thin films of EuS on  $Bi_2Se_3$  [1]. In recent studies, the material  $EuCd_2As_2$  has attracted a lot of attention due to emergence of a variety of topological phases and magnetic phenomena [2,3]. Recently, a spin fluctuation induced Weyl semimetal state in the paramagnetic phase of  $EuCd_2As_2$  [2] and its tunability by pressure [4] was discovered. Furthermore, the similar material  $EuCd_2P_2$  has been explored due to its strong colossal magnetoresistance effect [5]. In this work we present the single crystal growth and characterization of the related system  $EuT_2X_2$ , with T = Cd, Zn, Mn and X = P, crystallizing in the same trigonal structure (P-3m1) in order to search for similar effects in these materials. The physical properties of the compounds are explored via magnetization, electrical transport and heat capacity.

De Haas-van Alphen (dHvA) measurements at low temperatures and fields up to 18 T provided insight into the band structure of the topological semimetal PdGa which is presented in this poster. Previous investigation of PtGa revealed the topological character [1] of this sister compound of PdGa. Hence, angle-resolved measurements of the dHvA effect were performed on PdGa and showed a good agreement with the calculated band structure. This revealed a multitude of Fermi surfaces and eight spin-splitted bands crossing the Fermi energy. In particular, the calculations show a similar band structure as for PtGa, including two topologically protected multifold degenerate band-touching nodes. Furthermore, we analyzed the temperature dependence of the dHvA oscillations to determine the effective masses for field aligned along the crystallographic [100] axis. The low masses also show a good agreement to the calculations and, therefore, indicate insignificant correlations of the electrons.

Current phase relation of HgTe nanowire Josephson junctions in an axial magnetic field — •N. HÜTTNER¹, W. HIMMLER¹, D. A. KOZLOV², N. N. MIKHAILOV², S. A. DVORETSKY², D. WEISS¹, and C. STRUNK¹ — ¹Experimental and Applied Physics, University of Regensburg, D-93040 Regensburg, Germany — ²Novosibirsk, Russia

Topological insulators (TIs) such as HgTe nanowires host topological surface states. Their band structure can be tuned to a Dirac shape via the application of an axial magnetic field ( $B_{\parallel}$ ) [1]. For proximitized nanowires this is expected to tune between trivial and topological supercurrents as recent experiments suggest [2]. Here we directly probe the current phase relation (CPR) of a tunable TI Josephson junction. The TI junction consists of a HgTe nanowire proximitized by superconducting Nb contacts embedded into an asymmetric DC-SQUID together with an Al/AlOx/Al junction. Beeing in the short junction regime [2], the TI junction features a strongly anharmonic CPR [3,4] with a high average transparency of  $D \approx 0.95$  for  $n \approx 9 \pm 2$  channels [4]. Varying  $B_{\parallel}$  controls the magnetic flux enclosed by the nanowire surface. In the range  $0 - 1.5\Phi_0$  we observe a strong modulation of the critical current and interference of phase shifted contributions of individual channels creating a great variety of CPR shapes.

**Ground-state splitting of parafermions zero modes at a finite distance** – •RAPHAEL L R C TEIXEIRA^{1,2}, AMAL MATHEW^{2,3}, ROSHNI SINGH^{2,3}, SOLOFO GROENEDIJK², ANDREAS HALLER², EDVIN G IDRISOV², LUIS G G V DIAS DA SILVA¹, and THOMAS L SCHMIDT² – ¹Instituto de Fisica - Universidade de Sao Paulo, Sao Paulo Brazil – ²Department of Physics and Materials Science Université du Luxembourg, Luxembourg, Luxembourg – ³Indian Institute of Technology, Bombay, India

Parafermion bound states can be regarded as fractional excitations that generalize Majorana bound states. Parafermions appear in strongly-correlated systems, and in particular, fractional Quantum Hall (FQH) edge states with induced superconductivity can be used to create localized  $\mathbb{Z}_{2n}$  parafermion modes. Previous works have used the single-instanton approximation to calculate the groundstate energy splitting in the limit of a large distance between the parafermions. In this work, we go beyond this approximation to determine the energy splitting in shorter systems, paving the way to better understanding experimentally relevant systems. We discuss the implications of a finite length in the coupling between parafermions and how it goes beyond the corresponding effect for Majorana bound states.We The analytical results agreed with Monte Carlo simulations implying the corrections we found cannot be neglected.

## TT 20.11 Wed 15:00 P1

**Full counting statistics of electron transport through a Majorana singlecharge transistor** — •ERIC KLEINHERBERS, ALEXANDER SCHÜNEMANN, and JÜRGEN KÖNIG — Faculty of Physics and CENIDE, University Duisburg-Essen, 47057 Duisburg, Germany

We study full counting statistics of electron transport through a Majorana singlecharge transistor (MSCT) [1]. The MSCT can host both Majorana bound states and Cooper pairs. In addition, the system is coupled to a superconducting and a metallic lead. A current through the system is realized by means of the Josephson-Majorana cycle [2], where sequential tunneling (normal and anomalous) of two electrons into the system is followed by the transfer of a Cooper pair into the superconductor. We find a highly correlated electron transfer which can be indicated by a sign violation of factorial cumulants. Moreover, when the

superconductor is only weakly coupled to the MSCT, we find for large bias voltages a strong suppression of the electron current. This effect is explained by the excitation of a dark state that effectively decouples from the leads. [1] A. Zazunov et al., Phys. Rev. B 84, 165440 (2011)

Single crystal growth and characterization of  $Eu(Pd_{1-x}Au_x)_2Si_2 - \bullet$ ROBERT MÖLLER, MARIUS PETERS, CORNELIUS KRELLNER, and KRISTIN KLIEMT — Physikalisches Institut, Goethe-Universität Frankfurt, Germany

In a general phase diagram for Eu compounds [1], the intermediate valent EuPd₂Si₂,  $T_V \sim 150$  K, is located very close, but slightly at the high-pressure side of a second order critical endpoint [2]. The analysis of polycrystalline samples of Eu(Pd_{1-x}Au_x)₂Si₂ revealed that in this series a critical endpoint can be found which separates the region of continuous from first order transitions. It was shown that the valence state of the material can be tuned via Au substitution and that for x between 0.05 and 0.2 the transition becomes a first order phase transition [3]. In this contribution, we present the Czochralski growth and the characterization of Eu(Pd_{1-x}Au_x)₂Si₂ single crystals. Using magnetization and heat capacity measurements, we study the changes in the nature of the phase transition in detail.

**Single crystal growth of EuPd**₂**Si**₂ **under enhanced gas pressure** — •ALEXEJ KRAIKER, MARIUS PETERS, KRISTIN KLIEMT, and CORNELIUS KRELLNER — Physikalisches Institut, Goethe Universität Frankfurt, 60438 Frankfurt am Main, Germany

The study of collective phenomena raising from enhanced coupling between electrons and phonons is focussed on materials exhibiting phase transitions involving both, electronic and lattice-degrees of freedom. One system providing such a strongly coupled phase transition is  $EuPd_2Si_2$  crystallizing in the  $ThCr_2Si_2$  structure type. Because of the the high vapor pressure of Eu, high-quality single crystals of  $EuT_2X_2$ -compounds are very challenging to grow in larger size. One way to prevent Eu from evaporating out of the melt, is growing the crystals in argon overpressure. In this contribution, we present the crystal growth of  $EuPd_2Si_2$  single crystals with a 20 bar Czochralski-furnace as well as the commissioning of a 150 bar high-pressure furnace which will provide the possibility of both the growth by the Czochralski and the Bridgman method.

## TT 21.4 Wed 15:00 P1

 $\label{eq:YbIn_1_x} \textbf{Ag}_x \textbf{Cu}_4 \text{: single crystal growth and characterisation} & - \bullet \text{Michelle} \\ \text{Ocker, Bereket Ghebretinsae, Kristin Kliemt und Cornelius Krellner} \\ - Physikalisches Institut, Goethe-Universität Frankfurt, 60438 Frankfurt/Main, Germany}$ 

The compound YbInCu₄ undergoes a 1st order valence transition at T_v =42 K by changing the temperature. Thus, ytterbium in the compound is present in the Yb^{2.9+} state at high temperatures and as Yb^{2.7+} at low temperatures [1]. In analogy to Eu compounds, the first order valence transition is suspected to end in a second order critical endpoint [2]. In order to study this valence transition in more detail, single crystal samples can be prepared in In-Cu flux which are substituted with silver [3]. With increasing Ag content, negative chemical pressure within the crystal is increased and the characteristics of the valence transition changes significantly. Here, we report on the single crystal growth with different Ag substitution levels and the results of our structural, chemical and physical characterization.

TT 21.5 Wed 15:00 P1

Elastoresistance of Eu₂T₂P₂ (T=Fe, Ru, Co) systems close to a collapsed tetragonal phase transition — •TESLIN ROSE THOMAS¹, N. S. SANGEETHA¹, THANH DUC NGUYEN², JULIAN REUSCH², MARIUS PETERS², KRISTIN KLIEMT², CORNELIUS KRELLNER², and ANNA E. BÖHMER¹ — ¹Lehrstuhl für Experimentalphysik IV, Ruhr-Universität Bochum, Universitätsstraße 150, 44801 Bochum — ²Physikalisches Institut, Goethe-Universität Frankfurt, Max-von-Laue-Straße 1, 60438 Frankfurt am Main

Manipulation of the properties of materials by applying anisotropic strain is an increasingly common method used in the study of correlated electron materials. In particular, the nematic state of several unconventional superconductors has been studied intensively using elastoresistance as a probing tool. In the current project, we employ elastoresistance to study the state close to the uncollapsed to collapsed- tetragonal transitions in Eu₂T₂P₂ (T=Fe, Ru, Co) and CaCo₂As₂ 122 systems. In contrast to investigations of nematicity, where the response to uniaxial strain is studied, we apply bi-axial strain which is by symmetry well suited. The corresponding elastoresistance is compared for the different compounds and at different temperatures. The results are then compared with the temperature and pressure dependence of lattice constants, which show the tetragonal collapse.

We acknowledge support from the German Research Foundation (DFG) under CRC/TRR 288 (Project A02).

## TT 21.6 Wed 15:00 P1

Valence fluctuations and structural collapse in Eu-based phosphides  $EuT_2P_2$  — MARIUS PETERS¹, •KRISTIN KLIEMT¹, JULIAN DOMINIK REUSCH¹, THANH DUC NGUYEN¹, FRANZISKA WALTHER¹, MICHAEL MERZ², GASTON GARBARINO³, SOFIA MICHAELA SOULIOU², MATTHIEU LE TACON², AMIR-ABBAS HAGHIGHIRAD², and CORNELIUS KRELLNER¹ — ¹Kristall- und Materiallabor, Physikalisches Institut, Goethe University Frankfurt, Max-von-Laue-Str. 1, D-60438 Frankfurt — ²Karlsruhe Institute of Technology, Institute for Quantum Materials and Technology, D-76021 Karlsruhe — ³European Synchrotron Radiation Facility (ESRF), F-38043 Grenoble

Studies of enhanced coupling between electrons and phonons is focussed on materials exhibiting phase transitions involving both electronic and lattice degrees of freedom. Europium in intermetallic systems can exhibit different magnetic ground states: If the ground state is  $Eu^{2+}$ , the system shows long range magnetic order; if the ground state is  $Eu^{3+}$ , no magnetic order is observed. Instead, valence fluctuations occur in intermediate valent states [1].

In this work, we report on the structural collapse in divalent europium systems  $EuT_2P_2$  (T = Fe, Co, Ru), which is connected to a change of europium's ground state by using single crystal diffractometry at pressures up to 15 GPa at 15 K and 300 K. Additionally, we show characterizations of the electronic and structural contributions to valence fluctuations in  $EuNi_2P_2$ .

# TT 21.7 Wed 15:00 P1

Crystal growth and characterization of  $LnCo_2P_2$  (Ln = Pr, Nd) — •FABIAN FIEDLER, MARIUS PETERS, KRISTIN KLIEMT, and CORNELIUS KRELLNER -Physikalisches Institut, Goethe-Universität Frankfurt, 60438 Frankfurt/Main, Germany

In condensed matter systems, the 4f-driven temperature scales at the surfaces of correlated materials have increasingly come into the focus of research efforts. Here, we present the crystal growth of  $LnCo_2P_2$  (Ln = Pr, Nd) in tin flux and the corresponding structural/physical characterization.

Using temperatures of up to 1400°C and a vertical temperature-gradient, we optimized the growth, resulting in large high-quality single crystals, allowing for physical characterization, especially by means of thermodynamic measurements and angle-resolved photoemission spectroscopy.

The structural and chemical characterization is performed by X-ray powder diffractometry, energy-dispersive X-ray spectroscopy and the Laue-method.

Magnetic properties of these systems, arising from the combination of the 4fmoments of Ln³⁺-ions and the 3d-moments of Co³⁺, are investigated by measurements of magnetization, heat capacity and resistivity.

TT 21.8 Wed 15:00 P1

Growth and characterization of  $KFe_{1-x}Ag_{1+y}Ch_2 - \bullet J$ UTTA PÜTTMANN, N. S. SANGEETHA, ANDREAS KREYSSIG, and ANNA É. BÖHMER — Experimentalphysik IV, Universitätstraße 150, 44801 Bochum

Iron-based 122-compounds with ThCr₂Si₂ structure have been intensely studied over the past decades. K-based chalcogenides, such as  $K_x Fe_{2-\delta}Se_2$  have attracted attention due to their high-temperature superconductivity, their strong electronic correlations, and their complex microstructure dominated by vacancies and phase separation. Recently, KFe_{0.8}Ag_{1.2}Te₂ has been found to provide the possibility to study an iron chalcogenide 122-systems without vacancies on the alkali site and to investigate a superstructure in the Fe/Ag plane with an interesting magnetic and nematic ordering [1, 2].

The growth of K-based single crystals is challenging due to the high vapor pressure and reactivity of potassium. We developed a new, affordable and efficient growth technique using containers made from high-temperature resistant stainless steel that can be sealed without any air-exposure of the starting materials. The growth of  $KFe_{1-x}Ag_{1+y}Ch_2$ -crystals by self-flux was optimized with respect to the starting material composition. The obtained crystals were characterized by EDX and XRD. The XRD patterns were analyzed for signs of superstructure in the Fe/Ag plane. Additionally, low-temperature measurements were carried out to confirm the magnetic transitions.

## TT 21.9 Wed 15:00 P1

Classical Ising-like dipolar antiferromagnet DyScO3 with slow spin dynamics - •NIKITA ANDRIUSHIN¹, STANISLAV NIKITIN^{2,3}, and ANDREY PODLESNYAK⁴ ⁻¹TU Dresden, Germany — ²MPI CPfS, Dresden, Germany — ³PSI, Villigen, Switzerland —  4 ORNL, Tennessee, USA

The usual timescale of the spin flip process in common magnetic systems is femto- to picoseconds. In this work we show with the help of both AC and DC magnetization measurements and classical Monte-Carlo calculations that the spin dynamics in DyScO3 can be slowed down to milliseconds and further. The orthorhombic DyScO₃ has a large uniaxial anisotropy caused by the strong crystalline electric field (CFT), which freezes magnetic moments below a certain temperature. Large anisotropy and long-range dipolar interaction result in an Ising-like antiferromagnetic ordering with critical temperature  $T_{\rm C}$  = 3.14 K. Magnetization and susceptibility measurements revealed a magnetization relaxation on a timescale of minutes, which is unexpected for an antiferromagnet. As a classical approach for modeling Ising-like spin systems, the Monte-Carlo calculations with METROPOLIS algorithm were used. Our calculations, taking into account the dipole-dipole interaction energy, comprehensively reproduce the observed magnetic behavior, correctly predict the ground state, critical temperature and capture slow magnetization dynamics.

# TT 21.10 Wed 15:00 P1

Hierarchical equations of motion approach to open quantum dynamics: Matrix product state formulation in twin space — •YALING KE¹, RAFFAELE BORRELLI², and MICHAEL THOSS¹ - ¹Institute of Physics, Albert-Ludwig University Freiburg, Hermann-Herder-Strasse 3, 79104 Freiburg, Germany -²DISAFA, Università di Torino, I-10095 Grugliasco, Italy

The hierarchical equations of motion (HEOM) is a numerically exact approach to studying open quantum dynamics with strong non-perturbative and non-Markovian system-environment interactions at finite temperatures. Although considerable progress has been made over the past few decades to extend the applicability of the HEOM approach, the numerical cost is still very expensive for reasonably large systems.

In this contribution, we present the twin-space formulation of the HEOM approach in combination with the matrix product state representation for an open quantum system coupled to a hybrid fermionic and bosonic environment. The

key ideas are a reformulation of a set of differential equations for the auxiliary density matrices into a time-dependent Schroedinger-like equation for an augmented multi-dimensional wave function as well as its tensor decomposition into a product of low-rank matrices. The new approach facilitates accurate simulations of non-equilibrium quantum dynamics in larger and more complex open quantum systems with both factorized and correlated initial condition.

## TT 21.11 Wed 15:00 P1

Quantum criticality of  $2k_F$  density wave order in two-dimensional metals – •LUKAS DEBBELER and WALTER METZNER — Max Planck Institute for Solid State Research

We analyze the quantum critical point at the transition towards incommensurate charge or spin density wave order with a  $2k_{\rm F}$  wave vector that connects a single pair of hot spots on the Fermi surface. Perturbative renormalization group (RG) calculations confirm non-Fermi liquid behavior with anomalous frequency scaling and renormalization of the Fermi surface in proximity to the hot spots. Employing a functional RG approach we treat frequency and momentum dependence as well as fermionic and bosonic degrees of freedom on equal footing. This approach does not lead to a self consistent solution with a peak of the static polarization function at the  $2k_F$ -vector. We explore the possibility of a self consistent quantum critical solution via a scaling ansatz.

#### TT 21.12 Wed 15:00 P1

Field dependence of the low-energy magnon modes and a spin-cholesteric phase in  $Sr_3Fe_2O_7$  — •Nikolai Pavlovskii¹, Yuliia Tymoshenko¹, Darren C. PEETS¹, ALEXANDRE IVANOV², JACQUES OLLIVIER², BERNHARD KEIMER³, and DMYTRO INOSOV¹ - ¹TU Dresden, Germany - ²ILL, Grenoble, France ^{- ³}MPI for Solid State Research, Stuttgart, Germany

We systematically studied low-energy magnon excitations in the helimagnetically ordered bilayer perovskite  $\mathrm{Sr_3Fe_2O_7}.$  The magnetic ground state was previously believed to be characterized with a single-q magnetic order parameter that results from a frustration of exchange interactions, resulting in two types of equivalent helimagnetic domains. Our present results suggest that it could be instead a double-q state. Our elastic neutron-scattering measurements in a magnetic field applied along one of the (110) crystal directions further reveal an additional phase transition within the magnetic phase, associated with the destruction of long-range order along the direction orthogonal to the field, leading to an unusual spin-cholesteric magnetic phase that breaks both chiral symmetry and translational symmetry along only one of the crystal directions. In the orthogonal direction, we observe only short-range quasielastic spin dynamics. Across the transition from the magnetically ordered to the spin-cholesteric phase, these slow spin fluctuations fill in the spin gap in the spin-wave spectrum, as we can see in the high-resolution inelastic neutron-scattering spectra, and ultimately dominate the low-energy magnetic excitation spectrum after the long-range magnetic order is destroyed.

#### TT 21.13 Wed 15:00 P1

Crystal Growth and Characterization of  $ZrFe_4Si_2 - \bullet$ Katharina M. Zoch, ISABEL REISER, ALEXANDER BODACH, KRISTIN KLIEMT, and CORNELIUS KRELL-NER — Physikalisches Institut, Goethe-Universität Frankfurt, 60438 Frankfurt am Main, Germany

The ZrFe₄Si₂-structure consists of edge-linked Fe-tetrahedra along the crystallographic c-direction. This type of arrangement is prone to show frustration and low dimensional fluctuations. First results on polycrystalline samples indicate that ZrFe₄Si₂ displays some sort of weak magnetic order, for an Fe-based compound, unusual low temperatures as well as deviant behavior in specific heat and resistivity compared to normal metals [1,2]. To investigate these features further, we are in need of single crystals. The crystal growth is a challenging subject. The compound is strongly peritectic melting and its elements are reactive with common crucible materials. Crystal growth experiments utilizing the Czochralski methods were performed, and the structure as well as magnetic, thermodynamic and electrical transport properties of the material were analyzed. TT 21.14 Wed 15:00 P1

Magnetic properties of monocrystalline euchroite Cu₂(AsO₄)(OH)₃(H₂O) – •Yannis Hilgers, Leonie Heinze, Dirk Menzel, and Stefan Süllow — IPKM, TU Braunschweig, Braunschweig, Germany

Previous studies of magnetic susceptibility and magnetisation on a natural polycrystalline sample of euchroite (Cu₂(AsO₄)(OH)₃(H₂O)) suggested that euchroite may be understood as a representation of a delta spin chain and exhibits a spin gap of about 50 K. In order to test this notion, we have performed a corresponding study on a monocrystalline sample, determining these properties along the three crystallographic axes. Magnetic susceptibility from 2 K to 300 K and magnetisation for magnetic fields up to 5 T were measured on a natural monocrystalline sample, previously characterized for crystallinity by Laue diffraction, of euchroite. From our data, we establish Curie-Weiss temperatures  $\Theta_{CW,a} = -150(20)$  K,  $\Theta_{CW,b} = -140(10)$  K,  $\Theta_{CW,c} = -140(10)$  K,  $\Theta_{CW,c} = -140(10)$  K,  $\Theta_{CW,c} = -150(20)$  K,  $\Theta_{CW,b} = -140(10)$  K,  $\Theta_{CW,c} = -100(10)$  K,  $\Theta_{CW,c} = -100(10)$ 

140(10) K, significantly larger in value than  $\Theta_{CW} = -50$  K by Kikuchi et al. Moreover, we find that at low temperatures, magnetic susceptibility exhibits a spin gap, and a residual magnetisation at low temperatures can be understood in terms of about 1 % free magnetic impurity (S = 1/2) moments. Fitting a Brillouin-function to the magnetisation data with S = 1/2 results in saturation magnetisations of  $M_{s,a} = 89,2(2,1)$  emu mol⁻¹,  $M_{s,b} = 94,0(1,7)$  emu mol⁻¹,  $M_{s,c} = 108,2(5,8)$  emu mol⁻¹. From this, the minimal length  $l_{min}$  of the delta spin chain segments can be estimated to  $l_{min} = 350(50)$  Å. Altogether, our data are consistent with euchroite as a delta spin chain material with a spin gap of about 50 K.

## TT 21.15 Wed 15:00 P1

Bond-directional nearest-neighbor excitations in the proximate Kitaev spin liquid Na₂IrO₃ probed by RIXS — •MARCO MAGNATERRA¹, ALESSANDRO REVELLI¹, KAROLIN HOPFER¹, CHRISTOPH SAHLE², MARCO MORETTI SALA³, GIULIO MONACO⁴, JAN ATTIG⁵, CIARÁN HICKEY⁵, ANTON JESCHE⁶, PHILIPP GEGENWART⁶, SIMON TREBST⁵, PAUL H. M. VAN LOOSDRECHT¹, JEROEN VAN DEN BRINK⁷, and MARKUS GRÜNINGER¹ — ¹II. Physikal. Physik, Universitä zu Köln — ⁶Exp. Physics VI, University of Augsburg — ⁷Inst. for Theo. Solid State Physics, IFW Dresden

The Kitaev model hosts a spin-liquid ground state with Majorana fermion excitations. It is based on bond-directional exchange, i.e. Ising-like interactions that couple different spin components on different bonds. In Na₂IrO₃, resonant inelastic x-ray scattering (RIXS) revealed fingerprints of Kitaev physics in the magnetic excitations [1]. In fact, the RIXS intensity shows a sinusoidal **q** dependence that proves the nearest-neighbor or single-bond character of the excitations. We report on refined RIXS measurements where we exploit the polarization dependence of the different spin channels and the **q** dependence of the different bonds to demonstrate the direct connection between spin component and bond direction. Our results establish the bond-directional nearest-neighbor character of magnetic excitations in Na₂IrO₃.

## TT 21.17 Wed 15:00 P1

Berry Phases of Vison Transport in  $\mathbb{Z}_2$  Topological Ordered States from Exact Fermion-Flux Lattice Dualities — CHUAN CHEN^{1,2}, •PENG RAO², and SODE-MANN INT1^{2,3} — ¹Institute for Advanced Study, Tsinghua University, 100084 Beijing, China — ²Max-Planck Institute for the Physics of Complex Systems, 01187 Dresden, Germany — ³Institut für Theoretische Physik, Universität Leipzig, 04103 Leipzig, Germany

We develop an exact map of all states and operators from 2D lattices of spins-1/2 into lattices of fermions and bosons with mutual semionic statistical interaction that goes beyond previous dualities of  $\mathbb{Z}_2$  lattice gauge theories because it does not rely on imposing local conservation laws and captures the motion of 'charges' and 'fluxes' on equal footing. This map allows to explicitly compute the Berry phases for the transport of fluxes in symmetry enriched topologically ordered states that can be either chiral, non-chiral, abelian or non-abelian, and whose numerical complexity reduces to diagonalizing free-fermion Hamiltonians. Among other results, we establish numerically the conditions under which the Majorana-carrying flux excitation in Ising-Topologically-Ordered states enriched by translations acquires 0 or  $\pi$  phase when moving around a single plaquette.

## TT 21.18 Wed 15:00 P1

Linked cluster expansions for a perturbed topological phase — •VIKTOR KOTT, MATTHIAS MÜHLHAUSER, and KAI PHILLIP SCHMIDT — Friedrich-Alexander-Universität, Erlangen-Nürnberg, Germany

We investigate the robustness of Kitaev's toric code in a uniform magnetic field on several two-dimensional lattices by perturbative linked cluster expansions using a full graph decomposition. In particular, the full graph decomposition allows to correctly take into account the non-trivial mutual exchange statistics of the anyonic elementary excitations. This allows us to calculate the ground-state energy and excitation energies of the topological phase which are then used to study the quantum phase transitions out of the topologically ordered phase as a function of the field direction.

TT 21.19 Wed 15:00 P1

Linked-cluster expansions for Rydberg atom arrays on the Kagome lattice — •ANTONIA DUFT, MATTHIAS MÜHLHAUSER, PATRICK ADELHARDT, and KAI PHILLIP SCHMIDT — Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Deutschland

We investigate a model of hardcore bosons on the links of a Kagome lattice subject to a long-range decaying van-der-Waals interaction. This model is known to be the relevant microscopic description of Rydberg atom arrays excited by a detuned laser field which has been realized in experiments recently. We apply high-order linked cluster expansions about different limits to investigate the quantum phase diagram. One particular interest is to find further evidence for the proposed topological phase in this quantum platform.

## TT 21.20 Wed 15:00 P1

Fractal quantum criticality in the Newman-Moore model in a transverse field investigated by linked cluster expansions — •RAYMOND WIEDMANN, MATTHIAS MÜHLHAUSER, and KAI PHILLIP SCHMIDT — Friedrich-Alexander-Universität, Erlangen-Nürnberg, Germany

The zero-temperature phase transition in the two-dimensional self-dual quantum Newman-Moore model is investigated using perturbative linked cluster expansions. The model exhibits type-II fracton excitations that have a highly restricted mobility on the lattice. High-order series expansions of the energy gap for different quasi-particle sectors as well as the vacuum energy are calculated using perturbative continuous unitary transformations and matrix perturbation theory, respectively. Our results indicate a first-order phase transition between the fractal phase and the polarized phase at the self-dual point in the model.

## TT 21.21 Wed 15:00 P1

Improved EPR spectroscopy on single molecular magnets - •MICHAEL Schulze¹, Daniel Schroller¹, Gheorghe Taran¹, Eufemio Pineda³, Mario Ruben 2 , Christoph Sürgers 1 , and Wolfgang Wernsdorfer 1  — ¹Physikalisches Institut, KIT, Karlsruhe — ²Institut für Nanotechnologie, KIT, Karlsruhe — ³Departamento de Química, Universidad de Panamá, Panama City The quantum nature and large magnetic anisotropies in lanthanide-based single molecular magnets (SMMs) provides potential for interesting applications in quantum computing and information storage. The development of the micro-SQUID technique provides a tool for high-resolution magnetization measurements of SMM single crystals from the mK-range up to several Kelvin. EPR spectroscopy, where different spin states are excited by resonant absorption of radiofrequency radiation, serves as a powerful extension of the micro-SQUID technique to gain further insight into the magnetic properties of SMMs. This project strives to improve various features of this combined setup, such as higher coupling strengths, better thermalization, and coherent spin manipulation of SMMs.

## TT 21.22 Wed 15:00 P1

Electrical read out of the nuclear spin and implementation of quantum algorithms on Tb₂Pc₃ triple decker — •LUCA KOSCHE¹, FRANCK BALESTRO², MARIO RUBEN^{3,4,5}, and WOLFGANG WERNSDORFER^{1,2,3,4} — ¹Physikalisches Institut, Karlsruhe Institute of Technology (KIT), Karlsruhe — ²CNRS, Institut Néel, Univ. Grenoble Alpes, France — ³Institute of Nanotechnology (INT), KIT — ⁴Institute for Quantum Materials and Technology (IQMT), KIT — ⁵Centre Européen de Sciences Quantiques (CESQ), Strasbourg Cedex, France

Single-molecular magnets (SMMs) have emerged as an excellent link between the two disciplines of spintronics and molecular electronics. Their ultimate small size, excellent single spin characteristics, and long coherence times at low temperatures make them promising candidates for fundamental quantum operations. In this project we investigate spin-transistors comprising a SMM trapped in a nanometer sized gap coupled to a back gate thereby forming a quantum dot. The gap is achieved by electromigration of a gold constriction. Low-noise electrical transport measurements enable the read out of the four nuclear spin states of a single terbium ion in a TbPc₂ double decker. First quantum algorithms, most importantly the Grover's algorithm, have been implemented on this system. Recent measurements of more complex multi-state systems such as the Tb₂Pc₃ triple decker showed that the interactions between the two terbium nuclear spins can be detected. Here we pursue to use the increased Hilbert space dimension of coupled molecular spins for more complex quantum algorithms.

## TT 21.23 Wed 15:00 P1

Synthesis, structure and property investigations of low-dimensional magnetism in double perovskite variants — •ANASTASIIA SMERECHUK, SABINE WURMEHL, BERND BÜCHNER, and RYAN MORROW — Leibniz Institute for Solid-State and Materials Research, IFW-Dresden, 01069 Dresden, Germany For many years perovskites in various modifications have been occupying a significant place in solid-state physics. The main feature of these materials is a large number of possible permutations of the structure. Although perovskites are mostly three-dimensional materials, low-dimensional magnetism can also be achieved in the special case. Current research is focused on two different approaches for that purpose. Experiments with the substitution of various compounds in double perovskites with  $Cu^{2+}$  were conducted at ambient and high pressure to acquire the magnetic interactions on a square lattice. Also, our research was concentrated on defect double perovskites, where vacancies have been ordered along with the ordering of cations. Then the hexagonal phases of perovskite can be transformed into triangular frustrated two-dimensional magnets. New inorganic transition metal oxides were synthesized. The crystallographic and magnetometry data will be discussed in detail in the poster.

TT 21.25 Wed 15:00 P1 Magnetic quantum oscillations in the molecular conductor  $\kappa$ - (BEDT-TTF)₂Cu[N(CN)₂]Cl near and away from the Mott transition — •SHAMIL ERKENOV^{1,2}, SEBASTIAN OBERBAUER^{1,2}, VLADIMIR ZVEREV³, WERNER BIBERACHER¹, NATALIA KUSHCH¹, and MARK KARTSOVNIK¹ — ¹Walther-Meißner-Institut, Garching, Germany — ²Technische Universität München, Garching, Germany — ³Chernoglovka, Russia

Magnetic quantum oscillations have been extensively used for exploring correlated-electron materials near various correlation-driven instabilities of the normal metallic state. Applying this technique to the quasi-two-dimensional bandwidth-controlled Mott insulator  $\kappa$ -(BEDT-TTF)₂Cu[N(CN)₂]Cl, we have recently disclosed several anomalies in the behavior of the effective mass and scattering rate, apparently inconsistent with theoretical predictions. For clarifying the role of the proximity to the Mott transition in these anomalies it is instructive to track their evolution in a broader range of the phase diagram, both very close to and far away from the metal-insulator phase boundary. To this end, we have measured quantum oscillations of magnetoresistance in the pressure interval 20 to 1000 MPa, which drives the system from the very edge of stability of the metallic phase to a "good metal" region of the phase diagram by means of the conducting bandwidth variation. We have also studied the possibility of changing the balance between the charge correlations and magnetic interactions governing the insulating instability by applying a strong magnetic field.

TT 21.26 Wed 15:00 P1 Building Blocks for Cluster Mott Insulators — •VAISHNAVI JAYAKUMAR and CIARÁN HICKEY — Institute for Theoretical Physics, University of Cologne, Germany

The Hubbard model provides a rich playground for investigating the physics of a wide range of strongly correlated systems. An important limit in the model is the Mott insulating regime, where, at half-filling, electrons get localized on single atomic sites. In this work, we investigate extensions of the idea to cluster Mott insulators- where electrons are now localized on clusters of sites. To that end, we study the Hubbard model on a plethora of different clusters, at different integer fillings, by constructing a general Hamiltonian for each cluster. This allows us to explore different regimes of the interplay of strong correlations and hopping within these clusters, and their respective emergent effective degrees of freedom. We then go beyond the single-orbital "cluster" Hubbard model and include multiple orbitals and interactions between them. Once these building blocks have been established, it is possible to introduce inter-cluster hopping terms into the picture; depending on the nature of the resulting effective interactions, they can give rise to novel Hamiltonians, which might possibly host highly correlated and/or frustrated phases.

## TT 21.27 Wed 15:00 P1

Chern insulators in twisted bilayer graphene under hydrostatic pressure — •ISRAEL DÍAZ¹, JOSÉ GONZÁLEZ², and TOBIAS STAUBER¹ — ¹Materials Science Factory, Instituto de Ciencia de Materiales de Madrid, CSIC, E-28049, Madrid, Spain — ²Instituto de Estructura de la Materia, CSIC, E-28006, Madrid, Spain

It is well-known that high hydrostatic pressures can be used to induce flat bands in twisted bilayer graphene, at twist angles larger than those realizing the usual magic-angle condition. We show that these twisted graphene bilayers, tuned at such larger magic angles, are prone to fall into Chern insulator phases. We characterize such states by relying on a self-consistent real-space Hartree-Fock approach that accounts for the long-range Coulomb interaction between all the carbon atoms in the moiré unit cell, and which is exact at the Hartree-Fock level as we incorporate all the moiré minibands in the calculation. In our flat-band models with twist angles between 2 and 4 degrees, we show that a gap opens up at the charge neutrality point due to the dynamical breakdown of time-reversal invariance. At 2 hole-doping, the dominant order parameter corresponds instead to valley symmetry breaking, but there is a critical coupling of the interaction above which a gap opens up due to the condensation of the Haldane mass. These Chern insulator phases seem to be absent in twisted bilayer graphene at the usual small magic angle, probably because they are hindered by the effects of in-plane relaxation, but they become manifest at the larger twist angles we study, leading to interesting phenomena like dissipationless edge states and anomalous Hall effect.

TT 21.28 Wed 15:00 P1

**Calculating moments for many-electrons systems** — •ELAHEH ADIBI and ERIK KOCH — Institute for Advanced Simulation, Forschungszentrum Jülich, 52425 Jülich, Germany

We present a technique for computing the moments  $\langle E^M \rangle = \text{Tr } H^M$  of the manyelectron spectrum. Taking the trace over a basis of Slater determinants  $|I\rangle$  and expressing the Hamiltonian in the same orbital basis, matrix elements  $\langle I|H^M|I\rangle$ can only be non-zero when the orbital indices of the creation operators are a permutation of those of the annihilation operators. Writing the permutations in cycle notation and realizing that the trace over a cycle with different orbital indices only depends on the number of descends, we can write the trace as a sum over products of Eulerian numbers times binomial factors involving the number of orbitals and electrons. For non-interacting electrons this further simplifies to a sum over Bell polynomials.

## TT 21.29 Wed 15:00 P1

Multiloop fRG analysis of the attractive Hubbard model — •AIMAN AL-ERYANI¹, SARAH HEINZELMANN¹, ANNA KAUCH², ALESSANDRO TOSCHI², and SABINE ANDERGASSEN¹ — ¹University of Tuebingen — ²TU Wien

We analyse the effect of multiloop corrections in the 2D Attractive Hubbard Model. In a TU-fRG scheme where the conventional multi-loop self-energy flow equations are replaced with a Schwinger-Dyson flow, we demonstrate the importance of self-energy iteration in the convergence to reference Parquet results. Furthermore, we study the feedback of the s-wave pairing fluctuations on the charge density wave order.

## TT 21.30 Wed 15:00 P1

Single-boson exchange fRG application to the two-dimensional Hubbard model at weak coupling — KILIAN FRABOULET¹, •SARAH HEINZELMANN¹, PIETRO BONETTI², AIMAN AL-ERYANI¹, DEMETRIO VILARDI², ALESSANDRO TOSCHI³, and SABINE ANDERGASSEN¹ — ¹Institut für Theoretische Physik and Center for Quantum Science, Universität Tübingen, Auf der Morgenstelle 14, 72076 Tübingen, Germany — ²Max Planck Institute for Solid State Research, Heisenbergstrasse 1, D-70569 Stuttgart, Germany — ³Institute of Solid State Physics, Vienna University of Technology, 1040 Vienna, Austria

The functional renormalization group (fRG) is one of the most modern implementation of the renormalization group and has proven successful in the description of various many-body quantum systems, in condensed matter theory and beyond (quantum chromodynamics, nuclear physics, ...). We illustrate in this work the computational advantages of the recently introduced single-boson exchange (SBE) formulation for the one-loop fRG applied to the two-dimensional Hubbard model.

We present a detailed analysis of the physical susceptibilities and their evolution with temperature and interaction strength, both at half filling and finite doping. We find that the rest functions describing the corrections beyond the SBE contributions play a negligible role in the weak coupling regime. The SBE formulation of the fRG flow hence allows for a substantial reduction of the numerical effort in the treatment of the two-particle vertex function, paving a promising route for future multiboson and multiloop extensions.

## TT 21.31 Wed 15:00 P1

Linked cluster expansions via hypergraph decompositions — •MATTHIAS MÜHLHAUSER and KAI PHILLIP SCHMIDT — Institute for Theoretical Physics I, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany

We present a hypergraph expansion which facilitates the direct treatment of quantum-spin-models with effective many-site interactions via perturbative linked cluster expansions. The main idea is to generate all relevant subclusters and sort them into equivalence classes essentially governed by hypergraph isomorphism. Concretely, a reduced König representation of the hypergraphs is used to make the equivalence relation accessible by graph isomorphism. [1] M. Mühlhauser and K. P. Schmidt, arXiv:2202.03366 (2022)

# TT 21.32 Wed 15:00 P1

Efficient and flexible approach to simulate low-dimensional quantum lattice models with large local Hilbert spaces at the example of the Holstein model — •THOMAS KÖHLER¹, JAN STOLPP², and SEBASTIAN PAECKEL³ — ¹Uppsala University, Sweden — ²Georg-August-Universität Göttingen, Germany — ³University of Munich, Germany

Quantum lattice models with large local Hilbert spaces emerge across various fields in quantum many-body physics. Problems such as the interplay between fermions and phonons, the BCS-BEC crossover of interacting bosons, or decoherence in quantum simulators have been extensively studied both theoretically and experimentally. In recent years, tensor network methods have become a successful tool to treat such lattice systems numerically. Nevertheless, systems with large local Hilbert spaces remain challenging. Here, we introduce a mapping that allows to construct artificial U(1) symmetries for any type of lattice model. Exploiting the generated symmetries, numerical expenses that are related to the local degrees of freedom decrease significantly. Based on an intimate connection between the Schmidt values of the corresponding matrix-productstate representation and the single-site reduced density matrix, this allows for an efficient treatment of systems with large local dimensions. We demonstrate this new mapping, provide an implementation recipe, and perform example calculations for the Holstein model at half filling. We studied systems with a very large number of lattice sites up to L=501 while accounting for  $N_{\rm ph}=63$  phonons per site with high precision in the CDW phase.

# TT 21.33 Wed 15:00 P1

Electronic correlations in inhomogeneous model systems: Numerical simulation of spectra and transmission — •ANDREAS WEH¹, WILHELM H. APPELT¹, ANDREAS ÖSTLIN², LIVIU CHIONCEL², and ULRICH ECKERN¹ — ¹Institute of Physics, University of Augsburg, 86135 Augsburg — ²EKM & ACIT, Institute of Physics, University of Augsburg, 86135 Augsburg

We investigate the effects of electronic correlations on the spectral and transport properties of inhomogeneous model systems. The models are based on the single-band Hubbard Hamiltonian, and electronic correlations are treated within dynamical mean-field theory (DMFT). In particular, continuous-time quantum Monte Carlo (CT-QMC) as well as the more recent tensor network methods (DMRG+TDVP) are employed as impurity solvers to study the spectral function of half-metallic ferromagents; a Bethe lattice as well as layered square-lattice structures are considered [1]. The transport properties through a barrier made of such a single interacting half-metallic layer is studied [2] employing the Meir-Wingreen formalism. In particular, we demonstrate that even for a single halfmetallic layer, highly polarized transmissions are achievable.

Fifth harmonic generated currents in conventional s-wave superconductor — •PASCAL DERENDORF and ILYA EREMIN — Institut für Theoretische Physik III, Ruhr-Universität Bochum, Bochum, Germany

Recent advances in the field of THz spectroscopy allow for controlled experiments to measure the Higgs modes signature in the Fifth Harmonic Generation (FHG), which was first measured by Z.X. Wang et al [1]. Here, we analyze a periodic multicycle pulse setup, where the driving electromagnetic field solely points into the direction of a lattice vector. We investigate the role of the Higgs mode in the clean-limit FHG of a s-wave superconductor and compare it to other contributing mechanisms, such as charge density fluctuations (CDF) and the phase mode. Further, we show that the signal in the FHG is dominated by the CDF, similar to the third harmonic generated currents. We predict a double peak signature in the frequency resolved intensity amplitude of the FHG for all three mechanisms with one peak being located at  $2\Omega = 2\Delta$  and the other one at  $2\Omega = \Delta$ . The resonant enhancement at  $2\Omega = \Delta$  is indicative of the next higher order coupling to the Higgs mode implying that it carries  $4\Omega$ . The other resonance at  $2\Omega = 2\Delta$  is reminiscent of the Third Harmonic Generation and could therefore describe e.g. the Higgs mode interacting with 3 single photons. [1] Z. X. Wang et al., arXiv: 2107.07488

TT 21.35 Wed 15:00 P1 **Transfer-matrix summation of path integrals for transport through nanos tructures** — •ALEXANDER HAHN, SIMON MUNDINAR, JÜRGEN KÖNIG, and AL-FRED HUCHT — Theoretische Physik, Universität Duisburg-Essen and CENIDE, 47048 Duisburg, Germany

We develop a transfer-matrix style approach based on the numerical iterative summation of path integrals (ISPI) scheme [1,2] to solve non-equilibrium quantum transport. The usage of a transfer-matrix approach combined with further simplifications allows for the development of a method able to work in the stationary limit (TraSPI). Additionally, using the numerical properties of the transfer-matrix element calculation and Gray code, one can use the Woodbury formula to move inside the configuration space. Afterwards, the method is applied to a single-electron transistor with a single-level quantum dot as a central island.

TT 21.36 Wed 15:00 P1

**Driven magnets: Domain wall motion in ferrimagnets in an oscillating magnetic field** — •DENNIS HARDT and ACHIM ROSCH — Institute for Theoretical Physics, University of Cologne, Germany

Transition regions between two magnetic domains are described by domain walls (DWs).

In this work, we numerically study a 1D ferrimagnet with anisotropy term given by a symmetric double-well potential in magnetization in z-direction. This establishes a Goldstone mode as rotation in the x-y-plane which can be activated by driving the system with an oscillating magnetic field in z-direction.

At T = 0 (noise-free case) this leads to a spontaneous symmetry breaking visible in the collective movement of all DWs in one direction (left or right). We also found an analytical description for this limit.

At finite temperature, DW-pairs can also be created meaning that there is a competition between the annihilation (2 DWs meet due to diffusion and driving) and the creation (due to noise).

The noise-created domain walls are driven randomly in left or right direction. This leads to a suppression of the total number of DWs compared to the nondriven thermal case.

TT 21.37 Wed 15:00 P1

Rate functions and quantum adiabatic theorem in many-body systems — •VIBHU MISHRA — Institute for Theoretical Physics, Georg-August-Universität Goettingen, Friedrich-Hund-Platz 1, 37077 Goettingen, Germany

We investigate the quantum adiabatic theorem in many body systems for XXZ and ANNNI spin chains. In order to have a well-defined quantitative measure of adiabacity in the thermodynamic limit we calculate a rate function defined via the overlap between the ground state of the final Hamiltonian and the time evolved initial state. The parameters in the Hamiltonian are varied with a linear ramp and we investigate how the rate function behaves with decreasing ramping speed (adiabatic limit). Our main tool is exact diagonalization, which is complemented by bosonization in the XY phase of the XXZ spin chain.

TT 21.38 Wed 15:00 P1

**Pump-probe AC susceptibility of LiHo**_x $Y_{1-x}F_4$  (x = 4.5%) — •MICHAEL LAMPL, ANDREAS WENDL, MARKUS KLEINHANS, LAURA STAPF, MARC A. WILDE, and CHRISTIAN PFLEIDERER — Physik Department, Technical University of Munich, 85748 Garching, Germany

LiHoF₄ under a transverse magnetic field exhibits one of the best understood examples of a quantum critical point. Substitutional doping of Ho with non-magnetic Yttrium may be used to study the effects of disorder [1]. In the highly diluted system LiHo_xY_{1-x}F₄ (x = 4.5%), investigated in our study, the nature of the ground state is still subject to intense experimental and theoretical studies [2]. To explore the ground state properties of this system, multiple studies employed so-called pump-probe susceptibility measurements [3-5]. We revisit this question and report a study of the pump-probe susceptibility as a function temperature and field orientation, covering a wide parameter range.

A deeper understanding of the normal-state properties of  $Sr_2RuO_4$  is crucial also to determine its superconducting state symmetry. Using low-energy muon spin rotation spectroscopy, we have found evidence for a new form of magnetism on the surface of  $Sr_2RuO_4$  in its normal state. We detect weak static dipolar fields with a relatively high onset temperature above 50 K. The magnetism observed is not conventional, and we demonstrate that it arises due to orbital loop currents at the reconstructed  $Sr_2RuO_4$  surface. Our results [1] set a reference for the observation of orbital loop current magnetism in other materials and shed light onto a new mechanism that can affect the superconducting state of  $Sr_2RuO_4$ . [1] R. Fittipaldi et al., Nat. Commun. 12, 5792 (2021)

## TT 22.2 Wed 15:30 H10

TT 22.1 Wed 15:00 H10

Optimization of  $Sr_2RuO_4$  thin films and devices based on single-crystals flakes — •PRIYANA PULIYAPPARA BABU¹, ROMAN HARTMANN¹, SOHAILA ZAGHLOUL NOBY¹, ELKE SCHEER¹, ANGELO DI BERNARDO¹, ROSALBA FITTIPALDI², and ANTONIO VECCHIONE² — ¹University of Konstanz, 78457 Konstanz, Germany — ²University of Salerno, 84084 Fisciano, Italy

Since its discovery in 1994,  $Sr_2RuO_4$  has been the subject of intensive studies aiming at shedding light on the nature of its superconducting order parameter (OP). Despite earlier reports suggesting an unconventional nature of the  $Sr_2RuO_4$  superconductivity, conflicting results have been recently reported and a definitive conclusion about the superconducting OP symmetry has not been yet achieved.

To address some of the open questions, it is crucial to fabricate superconducting devices based on high-quality superconducting thin films of  $Sr_2RuO_4$ . Thin films of  $Sr_2RuO_4$  with very low density of defects, high residual resistivity ratio (> 30) and fully metallic down to low temperatures have been grown from single crystal target of  $Sr_3Ru_2O_7$ . The growth parameters that can be further optimized to get fully superconducting thin films have also been identified. In parallel, we are also fabricating superconducting devices based on  $Sr_2RuO_4$  flakes produced by mechanical exfoliation of single crystals. Different fabrication routes involving lithography patterning followed by Inductively Coupled Plasma (ICP) etching and patterning with a helium ion microscope have been successfully employed to fabricate superconducting devices from  $Sr_2RuO_4$  single-crystal flakes.

## TT 22.3 Wed 15:45 H10

Angular dependence of superfluid density in  $Sr_2RuO_4 - \cdot JAVIER LANDAETA^1$ , KONSTANTIN SEMENIUK¹, JOOST ARETZ¹, ISMARDO BONALDE², and ELENA HASSINGER¹ - ¹Max Planck Institute for Chemical Physics of Solids, 01187 Dresden, Germany - ²Centro de Física, Instituto Venezolano de Investigaciones Científicas, Caracas 1020-A, Venezuela

Although being extensively studied for more than 25 years, the nature of the superconducting order parameter (SOP) of Sr₂RuO₄ is still debated. In recent years, experimental evidence revealed the possibility of two component SOPs. These results constrain the SOP to only a few allowed symmetries. To get insight on the nodal structure of the SOP, we carried out a comprehensive study of the temperature dependence of the superfluid density  $n_s$  at various angles. By measuring the superconducting lower critical field  $H_{c1}(T)$  in a spherical sample with ac-susceptibility, we obtained the temperature dependence of  $n_s = H_{c1}(T)/H_{c1}(0)$  down to 0.03  $T_c$ . Our results show that  $n_s(T)$  is identical for all the studied angles showing a low temperature power law of  $T^2$ , which rules out the possibility of horizontal line nodes in Sr₂RuO₄. These results impose strong constraints over the remaining allowed symmetries for SOPs.

## TT 22.4 Wed 16:00 H10

Spin-fluctuation pairing and Hund's pairing in Sr₂RuO₄ — MERCÈ ROIG¹, ASTRID T. RØMER¹, THOMAS A. MAIER², •ANDREAS KREISEL³, PETER J. HIRSCHFELD⁴, and BRIAN M. ANDERSEN¹ — ¹Niels Bohr Institute, University of Copenhagen — ²Center for Nanophase Materials Sciences, Oak Ridge National Laboratory — ³Institut für Theoretische Physik, Universität Leipzig — ⁴Department of Physics, University of Florida

The unconventional superconductor  $Sr_2RuO_4$  has been subject of enormous experimental investigations in the last two decades, but until now the form of its order parameter has not been explicitly determined. Given the exclusion of spin-

triplet superconductivity by recent experiments, the time-reversal symmetry breaking linear combinations of *s*-, *d*- and *g*-wave one-dimensional (1D) irreducible representations are strong candidates. However, also a two-dimensional representation  $E_g$ , stabilized within the so-called Hund's coupling mean-field pairing scenario, has been proposed. In this work, we examine Hund's pairing on equal footing with spin-fluctuation pairing using a three dimensional electronic structure for Sr₂RuO₄ and a model that does not exhibit clear nesting features. For the latter, the superconducting state generated by the Hund's mechanism agrees well with that from the full fluctuation exchange vertex for large J/U ratios. On the other hand, for systems characterized by a peaked finite-momentum susceptibility, spin-fluctuation pairing generally dominates over Hund's pairing. We conclude that Hund's pairing states (and therefore also the  $E_g$  pairing) are unlikely to be realized in systems like Sr₂RuO₄.

TT 22.5 Wed 16:15 H10

**Thermal conductivity of the two-phase superconductor CeRh**₂**As**₂ — SEITA ONISHI¹, •ULRIKE STOCKERT¹, SEUNGHYUN KHIM¹, JACINTHA BANDA¹, MANUEL BRANDO¹, and ELENA HASSINGER^{1,2} — ¹MPI for Chemical Physics of Solids, Dresden, Germany — ²Physics Department, Technical University Munich, Germany

 ${\rm CeRh_2As_2}$  is an unconventional superconductor with  $T_c=0.26$  K. Two neighbouring superconducting phases are observed for a magnetic field H applied along the c-axis with an almost constant transition field  $H^\star$  of about 4 T. In addition, antiferromagnetic order, quadrupole-density-wave order and the proximity of this material to a quantum-critical point have been reported: The coexistence of these phenomena with superconductivity is currently under discussion.

We present thermal conductivity,  $\kappa$ , and electrical resistivity,  $\rho$ , measured on single crystals of CeRh₂As₂ between 60 mK and 200 K and in magnetic fields ( $H \parallel c$ ) up to 8 T. The extrapolation of our normal-state data to zero temperature is in line with the Wiedemann-Franz law. No clear anomaly is observed in the temperature dependence of  $\kappa$  at any of the reported phase transitions. Instead,  $\kappa(T)$  shows a pronounced, field-dependent drop below  $T_c$  which is attributed to superconductivity. The field-dependence of the normalized thermal conductivity at 120 mK exhibits a change in slope around  $H^*$ , similar to the specific heat coefficient  $\gamma$ . Measurements at higher fields and lower T are required to confirm that this is really due to the transition between the two superconducting phases.

## TT 22.6 Wed 16:30 H10

**Consequences of density-wave order in a staggered Rashba superconductor** — •ANASTASIIA SKURATIVSKA^{1,2}, MANFRED SIGRIST¹, and MARK H FISCHER³ — ¹University of Zurich, Zurich, Switzerland — ²Donostia International Physics Center, Donostia-San Sebastian, Spain — ³Institute for Theoretical Physics, ETH Zurich, Zurich, Switzerland

Superconductors with local inversion-symmetry breaking can exhibit properties usually associated with non-centrosymmetric systems, such as local mixing of even and odd superconducting order parameters or unusual magnetic response. An example of a system with such local non-centrosymmetricity is a stack of layers with alternating Rashba spin-orbit coupling due to mirror symmetry breaking with respect to the individual layers. Motivated by recent experiments on the Ce-based superconductor CeRh₂As₂, which were interpreted as showing possible quadrupole-density-wave order, we investigate the effect of density-wave order on the physics related to local inversion-symmetry breaking. In particular, we study how the partial gapping out of the Fermi surface changes the effect of local inversion-symmetry.

## TT 22.7 Wed 16:45 H10

Anisotropic vortex squeezing in Rashba superconductors: a manifestation of Lifshitz invariants — LORENZ FUCHS¹, •DENIS KOCHAN², CHRISTIAN BAUMGARTNER¹, SIMON REINHARDT¹, SERGEI GRONIN³, GEOFFREY GARDNER³, TYLER TILER LINDEMANN⁴, MICHAEL MANFRA³, CHRISTOPH STRUNK¹, and NICOLA PARADISO¹ — ¹Institut für Experimentelle und Angewandte Physik, University of Regensburg, 930 40 Regensburg, Germany — ²Institut für Theoretische Physik, University of Regensburg, 930 40 Regensburg, Germany — ³Microsoft Quantum Purdue, Purdue University, West Lafayette, Indiana 47907 USA

Most of 2D superconductors are of type II, i.e., they are penetrated by quantized vortices when exposed to out-of-plane magnetic fields. In a presence of a supercurrent, a Lorentz-like force acts on the vortices, leading to drift and dissipation. The current-induced vortex motion is impeded by pinning at defects. Usually, the pinning strength decreases upon any type of pair-breaking interaction perturbs a system.

In the talk we will discuss surprising experimental evidences showing an unexpected enhancement of pinning in synthetic Rashba 2D superconductors when applying an in-plane magnetic field. When rotating the in-plane component of the field with respect to the driving current, the vortex inductance turns out to be highly anisotropic. We explain this phenomenon as a direct manifestation of Lifshitz invariant that is allowed in the Ginzburg-Landau free energy by symmetry when space-inversion and time-reversal symmetries are broken.

#### 15 min. break

# Invited TalkTT 22.8Wed 17:15H10Role of the film geometry in the electronic reconstruction of infinite-layer<br/>nickelates on SrTiO3(001) — •BENJAMIN GEISLER — Fakultät für Physik, Uni-<br/>versität Duisburg-Essen

The recent discovery of superconductivity in infinite-layer NdNiO₂ films on SrTiO₃(001) has sparked significant interest [1]. However, details of the physical mechanism behind this observation remained so far elusive, since in contrast to the thin films [2] bulk NdNiO₂ shows neither superconductivity nor the antiferromagnetic interactions characteristic of high- $T_c$  cuprates.

First-principles simulations unravel the key role of the interface: Polarity mismatch drives a surprising electronic reconstruction that results in the emergence of a correlated two-dimensional electron gas (2DEG) in the  $SrTiO_3(001)$ substrate. The concomitant depletion of the self-doping Nd 5*d* states renders infinite-layer nickelates close to cuprate superconductors [3,4]. Recent work identifies an unexpected interface composition that completely quenches the 2DEG, but preserves the electronic reconstruction in the nickelate film [5]. This supports the notion of nickelate superconductivity as novel quantum phase, induced in film geometry by electronic reconstruction.

TT 22.9 Wed 17:45 H10 **Importance of electronic correlations in nickelates** — •PAUL WORM¹, LIANG St¹, MOTOHARU KITATANI², RYOTARO ARITA^{3,4}, and KARSTEN HELD¹ — ¹Institute of Solid State Physics, TU Wien, 1040 Vienna, Austria — ²Department

¹Institute of Solid State Physics, TU Wien, 1040 Vienna, Austria — ²Department of Material Science, University of Hyogo, Ako, Hyogo 678-1297, Japan — ³RIKEN Center for Emergent Matter Sciences (CEMS), Wako, Saitama, 351-0198, Japan — ⁴Research Center for Advanced Science and Technology, University of Tokyo, Komaba, Tokyo, 153-8904, Japan

Motivated by the recent discovery of superconductivity in the pentalayer nickelate Nd₆Ni₅O₁₂ [1], we calculate its electronic structure and superconducting critical temperature. First we analyse the compound by means of state of the art density functional theory and dynamical mean field theory (DFT+DMFT) and find that electronic correlations remove the Nd pockets from the Fermi surface, which crucially changes the filling of the Ni  $d_{x^2-y^2}$  band. An *effective* singleorbital Hamiltonian can be constructed for the five layers and we show that its properties are stunningly similar to the infinite layer case. Subsequently we solve this *effective* model within the dynamical vertex approximation to determine the transition temperature. We further study the related bilayer nickelate and propose a suitable dopant to achieve a doping level where superconductivity is expected.

TT 22.10 Wed 18:00 H10 Collective Modes Contributions in Third-Harmonic Generation in Noncentrosymmetric Superconductors — •SIMON KLEIN, MATTEO PUVIANI, and DIRK MANSKE — Max Planck Institute for Solid State Research, Stuttgart, Germany

Recent interest for collective amplitude (Higgs) and phase (Leggett) excitations in single- and multi-band superconductors have led to various studies focused on third-harmonic generation (THG) experiments, both for singlet s- and d-wave gap structure. A resonance in the THG intensity appears, when matching the driving frequency to the energy of the corresponding investigated mode, leading to a phase jump at the resonance frequency. We extend these studies to superconductors without an inversion symmetry, which can be effectively described by a two-band model with an order parameter, consisting of spin singlet (even parity) and spin triplet (odd parity) components. We calculate the THG signal for the non-centrosymmetric compound CePt3Si, showing that it contains contributions from three distinguishable sources, namely the Higgs mode, the Leggett mode and quasiparticles. In the clean limit, only diamagnetic Ramanlike processes contribute to the THG signal, whereas the quasiparticle contributions dominate the collective modes for all singlet-triplet ratios of the gap structure. In the dirty limit, we find a significant enhancement of the Higgs mode contributions to the THG signal, due to the inclusion of non-vanishing paramagnetic diagrams. We notice a significant change in the phase jump, which helps to differentiate between diamagnetic and paramagnetic results and thus between clean and dirty superconductors.

TT 22.11 Wed 18:15 H10

**High-field superconductivity in UTe**₂ — •TONI HELM^{1,2}, MOTOI KIMATA³, KENTA SUDO³, JULIA STIRNAT^{1,5}, ATSUHIKO MIYATA¹, MARKUS KÖNIG², TOBIAS FÖRSTER¹, JEAN-PASCAL HORNUNG^{1,5}, GERARD LAPERTOT⁴, JEAN-PASCAL BRISON⁴, ALEXANDRE POURRET⁴, GEORG KNEBEL⁴, DAI AOKI³, and JOCHEN WOSNITZA^{1,5} — ¹Dresden High Magnetic Field Laboratory, HZDR, Germany — ²MPI CPfS Dresden, Germany — ³Tohoku University, Oarai, Ibaraki, Japan — ⁴CEA, IRG-PHELIQs, Grenoble, France — ⁵Technical University Dresden, Gremany

The potential spin-triplet superconductor UTe₂ with  $T_c = 1.6$  K has attracted a lot of attention recently. The material is a highly anisotropic paramagnet that exhibits a metamagnetic transition at  $H_{\rm M} = 35$  T. In addition to its field-enhanced and pressure-induced superconducting ground state, high-field superconductivity (hfSC) was observed setting in for a particular field orientation just above  $H_{\rm M}$ . We investigated magnetortransport and magnetic torque in pulsed magnetic fields up to 70 T for FIB-microfabricated samples of UTe₂. Our findings confirm the existence of the hfSC above 40 T for a narrow angular range around  $\approx 30^\circ$  tilt off the *b* axis. The upper critical field,  $H_{c2}$ , reaches almost 75 T and exhibits a temperature dependence that strongly deviates from the low-field SC phase. Excitingly, the Hall effect experiences a drastic suppression for field orientations exactly where the hfSC emerges. The anomalous angle-dependence in high field poses a challenge to the theoretical understanding of the electronic ground state of UTe₂.

TT 22.12 Wed 18:30 H10

**Two bands Ising superconductivity from Coulomb interactions in monolayer NbSe**₂ — SEBASTIAN HÖRHOLD, JULIANE GRAF, •MAGDALENA MARGANSKA, and MILENA GRIFONI — Institute for Theoretical Physics, University of Regensburg, Germany

The nature of superconductivity in monolayer transition metal dichalcogenides is still object of debate. It has already been argued that repulsive Coulomb interactions, combined with the disjoint Fermi surfaces around the K,K' valleys and at the  $\Gamma$  point, can lead to superconducting instabilities in monolayer NbSe₂. Here, we demonstrate the two bands nature of superconductivity in NbSe2. In our approach it arises from repulsive Coulomb interactions, long range (resulting in intravalley scattering) and short range (intervalley scattering), together with Ising spin-orbit coupling. The two distinct superconducting gaps, one for the upper and one for the lower spin-orbit splitted band, both consist of a mixture of s-wave and f-wave components. Using a microscopic multiband BCS approach, we derive and self-consistently solve the gap equation, demonstrating the stability of nontrivial solutions in a realistic parameter range. The temperature dependence of the gaps and of the critical in-plane field are consistent with various sets of existing experimental data. Our results, although derived for NbSe2, are however universal and apply to almost all systems with disjoint Fermi surfaces connected by two competing scattering processes.

## TT 22.13 Wed 18:45 H10

Superconductivity in CrB₂ under pressure: Role of electron-phonon coupling and spin-fluctuations — •SANANDA BISWAS¹, ANDREAS KREISEL², RONNY THOMALE³, ROSER VALENTÍ¹, and IGOR MAZIN⁴ — ¹Goethe Universität, Frankfurt, Germany — ²Universität Leipzig, Leipzig, Germany — ³Julius-Maximilians-Universität Würzburg, Würzburg, Germany — ⁴George Mason University, Fairfax, VA, USA

Superconductivity has recently been discovered in  $\text{CrB}_2$  under pressure with maximum reported  $T_c$  to be 7 K. Iso-structural to MgB₂, CrB₂ exhibits spindensity-wave (SDW) ground state at ambient pressure. In this talk, I will focus on the role of spin-fluctuations and electron-phonon coupling (EPC) in determining the  $T_c$ . We have performed ab-initio density functional perturbation theory to determine the EPC of this system and to study the spin-fluctuation, random-phase-approximation (RPA) has been employed.

 $TT \ 22.14 \quad Wed \ 19:00 \quad H10 \\ \textbf{p-wave superconductivity in Luttinger semimetals} \ -- \textbf{J} ULIA \ M. \ LINK^1 \ and \\ IGOR \ F. \ HERBUT^2 \ -- \ ^1TU \ Dresden, \ Dresden, \ Germany \ -- \ ^2Simon \ Fraser \ University, \ Burnaby, \ Canada$ 

We consider the three-dimensional spin-orbit-coupled Luttinger semimetal of "spin" 3/2 particles in presence of weak attractive interaction in the l=1 (p-wave) channel, and determine the low-temperature phase diagram for both particleand hole-dopings [1]. The phase diagram depends crucially on the sign of the chemical potential, with two different states (with total angular momentum j=0 and j=3) competing on the hole-doped side, and three (one j=1 and two different j=2) states on the particle-doped side. The ground state condensates of Cooper pairs with the total angular momentum j=1,2,3 are selected by the quartic, and even sextic terms in the Ginzburg-Landau free energy. Interestingly, we find that all the p-wave ground states that appear in the phase diagram, while displaying different patterns of reduction of the rotational symmetry, preserve the time reversal symmetry. The resulting quasiparticle spectrum is either fully gapped or with point nodes, with nodal lines being absent.

Numerical linked cluster expansion for magnetostriction of frustrated magnets — •ALEXANDER SCHWENKE and WOLFRAM BRENIG — Institute for Theoretical Physics, Technical University Braunschweig, D-38106 Braunschweig, Germany

Thermodynamic and magnetoelastic properties of the frustrated *J*-*K*- $\Gamma$  quantum spin model for proximate Kitaev magnets on the honeycomb lattice in a finite magnetic field  $\vec{B}$  are studied using the numerical linked cluster expansion (NLCE) [1]. Calculations are performed on clusters of sizes up to ~  $\mathcal{O}(11)$ . First, the specific heat and the magnetization are analyzed for in- as well as for out-of-plane configurations of  $\vec{B}$ . Second, we present results of the linear magnetostriction coefficient  $\lambda(\vec{B}, T)$ . This displays strongly anisotropic behavior and a clear indication for a field-induced transition. Third, employing exchange parameters as proposed for the proximate quantum spin-liquid (QSL) candidate  $\alpha$ -RuCl₃, we show that our results for  $\lambda$  are very similar to recently observed experimental data [2] on this material.

**Dynamic structure factor of the antiferromagnetic Kitaev model in large magnetic fields** — •ANDREAS SCHELLENBERGER, MAX HÖRMANN, and KAI PHILLIP SCHMIDT — FAU Erlangen-Nürnberg, Erlangen, Deutschland

We investigate the dynamic structure factor of the antiferromagnetic Kitaev honeycomb model in a magnetic field by applying perturbative continuous unitary transformations about the high-field limit. One- and two-quasi-particle properties of the dressed elementary spin flip excitations of the high-field polarized phase are calculated which account for most of the spectral weight in the dynamic structure factor. We discuss the evolution of spectral features in these quasi-particle sectors in terms of one-quasi-particle dispersions, two-quasiparticle continua, the formation of anti-bound states, and quasi-particle decay. In particular, a comparably strong spectral feature above the upper edge of the upmost two-quasi-particle continuum represents three anti-bound states which form due to nearest-neighbor density-density interactions. ## TT 23.3 Wed 15:30 H22

Fractionalized quantum criticality in spin-orbital liquids from field theory beyond the leading order — Shouryya Ray¹, BERNHARD IHRIG², •DANIEL KRUTI³, JOHN A. GRACEY⁴, MICHAEL M. SCHERER², and LUKAS JANSSEN¹ — ¹TU Dresden — ²University of Cologne — ³University of Cologne and Jülich Research Centre — ⁴University of Liverpool

Two-dimensional spin-orbital magnets with strong exchange frustration have recently been predicted to realise a quantum critical point in the Gross-Neveu-SO(3) universality class. In contrast to previously known Gross-Neveu-type universality classes, this quantum critical point separates a Dirac semimetal and a long-range-ordered phase, in which the fermion spectrum is only partially gapped out. Here, we characterise the quantum critical behaviour of the Gross-Neveu-SO(3) universality class by employing three complementary fieldtheoretical techniques beyond their leading orders. We compute the correlationlength exponent v, the order-parameter anomalous dimension  $\eta_{\phi}$ , and the fermion anomalous dimension  $\eta_\psi$  using a three-loop 4- $\epsilon$  expansion, a secondorder large-N expansion (with the fermion anomalous dimension obtained even at the third order), as well as a functional renormalisation group approach. The results from the different methods agree well with each other and provide a prime benchmark for future complementary calculations. Averaging over them, we obtain the estimates 1/ $\nu$  = 1.03(15),  $\eta_{\phi}$  = 0.42(7), and  $\eta_{\psi}$  = 0.180(10) for the physically relevant case of N = 3 flavours of two-component Dirac fermions in 2+1 space-time dimensions.

TT 23.4 Wed 15:45 H22

Spin excitations in the frustrated helimagnet FeP — •ALEKSANDR SUKHANOV, YULIIA TYMOSHENKO, ANTON KULBAKOV, and DMYTRO INOSOV — Institut für Festkörper- und Materialphysik, Technische Universität Dresden, D-01069 Dresden

The metallic compound FeP belongs to the class of materials that feature a complex noncollinear spin order driven by the magnetic frustration. While its double-helix magnetic structure with a period  $\lambda_s \approx 5c$ , where *c* is the lattice constant, was previously well determined, the relevant spin-spin interactions that lead to that ground state remain unknown. By performing extensive inelastic neutron scattering measurements, we obtained the spin-excitation spectra in a large part of the momentum-energy space. The spectra show that the magnons are gapped with a gap energy of ~5 meV. Despite the 3D crystal structure, the magnon modes display strongly anisotropic dispersions, revealing quasi-one-dimensional character of the magnetic interactions in FeP. The physics of the

Location: H22

material, however, is not determined by the dominating exchange, which is ferromagnetic. Instead, the weaker two-dimensional antiferromagnetic interactions between the rigid ferromagnetic spin chains drive the magnetic frustration. Using linear spin-wave theory, we were able to construct an effective Heisenberg Hamiltonian with an anisotropy term capable of reproducing the observed spectra. This enabled us to quantify the exchange interactions in FeP and determine the mechanism of its magnetic frustration.

## TT 23.5 Wed 16:00 H22

NMR and magnetization studies of helical correlations within the stretched diamond lattice of LiYbO₂ — •S. LUTHER^{1,2}, S. WILSON³, M. M. BORDELON³, J. WOSNITZA^{1,2}, M. BAENITZ⁴, and H. KÜHNE¹ — ¹Hochfeld-Magnetlabor Dresden (HLD-EMFL), HZDR, Dresden, Germany — ²Institut für Festkörper- und Materialphysik, TU Dresden, Germany — ³University of California, Santa Barbara, USA — ⁴MPI for Chemical Physics of Solids, Dresden, Germany

The Yb-based delafossite LiYbO₂ hosts a stretched diamond lattice. The resulting three-dimensional geometric frustration is in strong contrast to the recently reported 2D-type Yb-based triangular-lattice delafossites. Further, the combination of a strong spin-orbit coupling together with crystalline-electric-field effects leads to a pseudospin-1/2 ground state of the Yb³⁺ ions. A recent study of LiYbO₂ by means of specific heat and neutron powder diffraction established the formation of helical order with non-trivial phasing between the two interpenetrating Yb sublattices below 1.1 K [1]. In order to further explore the H-T phase diagram and magnetic correlations, we performed low-temperature magnetometry and ⁷Li NMR of polycrystalline LiYbO₂. Our magnetometry and 1/*T*₁ NMR data are fully consistent with the reported specific-heat results. The ⁷Li NMR spectroscopy yields a monotonic and asymmetric spectral broadening towards low temperatures in the paramagnetic state. In the helical ordered state, a spontaneous and pronounced increase of the spectral width is observed, in agreement with the neutron-diffraction experiments.

TT 23.7 Wed 16:45 H22

Magneto-thermodynamics of the  $J_1$ - $J_2$  Heisenberg antiferromagnet on the square lattice — •ANDREAS HONECKER¹, JOHANNES RICHTER^{2,3}, JÜRGEN SCHNACK⁴, ALEXANDER WIETEK³, and MIKE E. ZHITOMIRKSY⁵ — ¹LPTM, CY Cergy Paris Université, France — ²Institut für Physik, Universität Magdeburg, Germany — ³Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — ⁴Fakultät für Physik, Universität Bielefeld, Germany — ⁵Université Grenoble Alpes, CEA, IRIG, PHELIQS, France

We investigate the finite-temperature properties of the  $J_1$ - $J_2$  Heisenberg antiferromagnet on the square lattice in the presence of an external magnetic field. We focus on the highly frustrated regime around  $J_2 \approx J_1/2$ . The *H*-*T* phase diagram is investigated with particular emphasis on the finite-temperature transition into the "up-up-up-down" state that is stabilized by thermal and quantum fluctuations and manifests itself as a plateau at one half of the saturation magnetization in the quantum case. Furthermore, we discuss the enhanced magnetocaloric effect associated to the ground-state degeneracy that arises at the saturation field for  $J_2 = J_1/2$ . Computations for the spin-1/2 system are carried out using finite-temperature Lanczos and quantum typicality approaches.

# TT 23.8 Wed 17:00 H22

**One-** and two-particle dynamics of the  $J_1$ - $J_2$ -Heisenberg bilayer — •ERIK WAGNER and WOLFRAM BRENIG — TU Braunschweig, Braunschweig, Germany The antiferromagnetic  $J_1$ - $J_2$  Heisenberg-model on the square lattice is one of the pillars of frustrated quantum magnetism, with Néel- and collinearly ordered ground states competing for large and small  $J_1/J_2$ , and with a quantum disordered phase of still unsettled nature in between. Probing fingerprints of such phases by approaching them out of a well controlled dimer phase is one of the rationals for studying bilayer versions of frustrated spin models. Here, and starting from the limit of decoupled dimers, we use the perturbative Continuous Unitary Transformation (pCUT), based on the flow equation method, to perform series expansion in order to analyze the spectrum of the square lattice  $J_1$ - $J_2$ -Heisenberg bilayer up to the two-triplon excitations. Evaluating the ground state energy and the one-particle dispersion up to 7th order in  $J_{1,2}$  as well as the two-particle interactions and spectrum up to 5th order, we find emerging (anti-)bound twoparticle states, which can be classified by total spin and real-space symmetry, consistent with results found for the  $J_1$ -only bilayer on the square lattice [1]. We analyze the phase boundary of the dimer phase with respect to one- and twoparticle excitations and find reasonable agreement with recent coupled-cluster calculations [2], while also uncovering prospects for an additional phase introduced by two-particle boundstate condensation.

Entanglement measures of a frustrated spin-1/2 Heisenberg octahedral chain within the localized-magnon approach — •OLESIA KRUPNITSKA — Institute for Theoretical Physics, Technical University Braunschweig, D-38106 Braunschweig, Germany — Institute for Condensed Matter Physics, NASU, Svientsitskii Str. 1, 79011 Lviv, Ukraine

The localized-magnon theory [1] is a powerful tool for the rigorous determination of the ground state and detailed study of the thermodynamic properties of a special class of frustrated quantum Heisenberg antiferromagnets at high magnetic fields and low temperatures. We study different measures of two-spin entanglement [2] between the nearest- and between next-nearest-neighbor spins on the square of the spin-1/2 octahedral Heisenberg chain. It was shown that the localized-magnon theory can be modified for simpler calculation of concurrence [3], which may serve as a measure of the bipartite entanglement of the octahedral chain. Furthermore, we calculate the entanglement of formation and the negativity [4] within the localized-magnon concept. We demonstrate that localized-magnon theory can be straightforwardly adapted in order to calculate the respective entanglement measures for a wide class of flat-band quantum Heisenberg antiferromagnets.

Towards analyzing phase-transitions with continuous similarity transformation: Easy-axis square-lattice XXZ and  $J_1$ - $J_2$  models — •MATTHIAS R. WALTHER¹, DAG-BJÖRN HERING², GÖTZ S. UHRIG², and KAI P. SCHMIDT¹ — ¹Friedrich-Alexander-Universität Erlangen-Nürnberg, Institut für Theoretische Physik I, Staudtstraße 7, 91058 Erlangen — ²Technische Universität Dortmund, Department of Physics, Condensed Matter Theory, Otto-Hahn-Str. 4, 44227 Dortmund

The method of non-perturbative continuous similarity transformations (CST) in momentum space captures the physics of the isotropic spin 1/2 antiferromagnetic Heisenberg model on the square lattice (IHM) quantitatively [1,2]. We discuss the potential of the CST to study critical behavior. To this end, the easy-axis square-lattice XXZ-model serves as a straight-forward extension of the IHM with a gapped phase away from the isotropic point. Its critical behavior is described by an established mean-field theory [3]. The CST is able to capture this criticality quantitatively. For further insights on the general capability of the CST for spin models we extend the study towards the frustrated square-lattice spin 1/2 antiferromagnetic  $J_1$ - $J_2$  model and analyze the breakdown of the magnetically ordered quantum phases and their gapless spin wave excitations [4,5].

"Stripe-yz" magnetic order in KCeS₂ — •ANTON KULBAKOV^{1,2}, STANISLAV AVDOSHENKO³, INÉS PUENTE-ORENCH^{4,5}, JACQUES OLLIVIER⁵, MAHMOUD DEEB¹, MATHIAS DOERR¹, PHILIPP SCHLENDER⁶, THOMAS DOERT⁶, and DMYTRO INOSOV^{1,2} — ¹IFMP, TU Dresden, Germany — ²Würzburg-Dresden ct.qmat, TUD, Dresden, Germany — ³IFW, Dresden, Germany — ⁴INMA, Zaragoza, Spain — ⁵ILL, Grenoble, France — ⁶Fakultät für Chemie und Lebensmittelchemie, TU Dresden, Germany

We have solved the magnetic structure for the antiferromagnetic state below  $T_{\rm N} = 400$  mK, which was recently revealed in the effective spin-1/2 triangularlattice antiferromagnet KCeS₂. It represents the so-called "stripe-yz" type of antiferromagnetic order with spins lying approximately in the triangular-lattice planes orthogonal to the nearest-neighbor Ce—Ce bonds, possibly with a small out-of-plane canting of the magnetic moments. The thermal expansion remains very small below 120 K, which we confirmed for the *c* lattice constant using capacitive dilatometry. Our experimental results also indicate that cerium oxysulphide, Ce₂O₂S, which was present in our sample as a minority phase, does not order magnetically down to 20 mK and may therefore represent a promising spin-liquid candidate deserving a separate study. For details, see [1]. Neutron time-of-flight spectroscopy of low-energy excitations in the ordered state of KCeS₂ reveals an unusual spin-wave band with an intensity maximum at **Q** = 0, unlike in KCeO₂ and KYbSe₂.

TT 23.13 Wed 18:15 H22

**Quantum Skyrmion lattices in Heisenberg ferromagnets** — •ANDREAS HALLER, SOLOFO GROENENDIJK, ALIREZA HABIBI, ANDREAS MICHELS, and THOMAS L. SCHMIDT — Department of Physics and Materials Science, University of Luxembourg, L-1511 Luxembourg, Luxembourg

Skyrmions are topological magnetic textures that can arise in noncentrosymmetric ferromagnetic materials. In most systems experimentally investigated to date, skyrmions emerge as classical objects. However, the discovery of skyrmions with nanometer length scales has sparked interest in their quantum properties. In this talk, we present the results of our matrix product state simulations of the ground states of two-dimensional spin-1/2 Heisenberg lattices with Dzyaloshinskii-Moriya interactions. We discovered a broad region in the zero-temperature phase diagram which hosts quantum skyrmion lattices. The quantum skyrmion lattice phase can be detected experimentally in the magnetization profile via local magnetic polarization measurements as well as in the spin structure factor measurable via neutron scattering experiments. Finally, we show the real-space polarization profile of individual quantum skyrmions and show that it is a non-classical state featuring entanglement between quasiparticle and environment mainly localized near the boundary spins of the skyrmion.

# TT 24: Quantum-Critical Phenomena

Time: Wednesday 15:00-19:00

TT 24.1 Wed 15:00 H23 Quantum criticality on a compressible lattice — •Saheli Sarkar, Lars FRANKE, NIKOLAS GRIVAS, and MARKUS GARST — Karlsruhe Institute of Technology, Karlsruhe, Germany As an example of quantum criticality on a compressible lattice we study the Lorentz invariant  $\Phi^4$  theory with an N-component field  $\Phi$ , where strain couples to the square of the order parameter. In three spatial dimensions this coupling as well as the self-interaction of the  $\Phi$  field are both marginal on the tree-level.

Location: H23

We compute the one-loop renormalization group equations treating the  $\Phi$  field as well as the phonons on the same footing. We find that the velocities of the  $\Phi$  field as well as of the phonons are renormalized yielding an effective dynamical exponent z>1. The renormalization group flow is found to depend on the number of components N. Whereas we find run-away flow for N<4 a new fixed-point emerges for N>=4. We discuss the relation to known results for classical criticality. Our findings are directly relevant to insulating quantum critical anti-ferromagnets.

# TT 24.2 Wed 15:15 H23

**Metallic and deconfined quantum criticality in Dirac systems** — •ZIHONG LIU¹, MATTHIAS VOJTA², FAKHER ASSAAD¹, and LUKAS JANSSEN² — ¹Institut für Theoretische Physik und Astrophysik and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, 97074 Würzburg, Germany — ²Institut für Theoretische Physik and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, 01062 Dresden, Germany

Motivated by the physics of spin-orbital liquids, we study a model of interacting Dirac fermions on a bilayer honeycomb lattice at half filling, featuring an explicit global SO(3)×U(1) symmetry. Using large-scale auxiliary-field quantum Monte Carlo (QMC) simulations, we locate two zero-temperature phase transitions as function of increasing interaction strength. First, we observe a continuous transition from the weakly-interacting semimetal to a different semimetallic phase in which the SO(3) symmetry is spontaneously broken and where two out of three Dirac cones acquire a mass gap. The associated quantum critical point can be understood in terms of a Gross-Neveu-SO(3) theory. Second, we subsequently observe a transition towards an insulating phase in which the SO(3) symmetry is restored and the U(1) symmetry is spontaneously broken. While strongly first order at the mean-field level, the QMC data is consistent with a direct and continuous transition. It is thus a candidate for a new type of deconfined quantum critical point that features gapless fermionic degrees of freedom.

## TT 24.3 Wed 15:30 H23

**Deconfined multi-critical point** — •ZHENJIU WANG¹ and ADAM NAHUM² — ¹Max-Planck Institute for the Physics of Complex Systems, D-01187, Dresden, Germany — ²Laboratoire de Physique, Ecole Normale Superieure, CNRS, Universit*e PSL, * Sorbonne Universite, Universite de Paris, 75005 Paris, France We numerically investigate a deconfined quantum critical point (DQCP) that happens between Neel and valence bond solid phase in a 3-dimensional loop model. Amazingly, this DQCP is an Liftshitz tricritical point due to an explicit lattice symmetry breaking term. This perturbation breaks lattice translational symmetry as well as a mirror-reflection symmetry whereas production of these two operations leave system invariant, hence only an additional vector potential term is coupled to the non-linear sigma model in IR theory. A helical valence bond solid state with spatially modulated valence bond order parameter separates VBS and Neel state due to this explicit vector potential, and a continuous phase transition between Neel and HVB state is simply described by the criticality of DQCP with an emergent Lorenz invariance in IR limit.

## TT 24.4 Wed 15:45 H23

Specific heat and magnetocaloric effect at transverse-field quantum criticality in LiHoF₄ — •ANDREAS WENDL¹, HEIKE EISENLOHR², JAN SPALLEK¹, CHRISTOPHER DUVINAGE¹, MATTHIAS VOJTA², and CHRISTIAN PFLEIDERER^{1,3,4} — ¹Physik Department, TU München, Garching, Germany — ²Institut für Theoretische Physik and Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, Dresden, Germany — ³Centre for QuantumEngineering (ZQE), TU München, Garching, Germany — ⁴Munich Centre for Quantum Science and Technology (MCQST), TU München, Garching, Germany

The perhaps best understood example of a quantum critical point is the response of the dipolar Ising ferromagnet LiHoF₄ under a transverse field [1-3]. We report an experimental and theoretical study of the specific heat and magneto-caloric effect of LiHoF₄ as a function magnetic field down to mK temperatures using a bespoke experimental set-up permitting studies under arbitrary magnetic field orientations. We derive the low temperature entropy landscape and discuss our findings in terms of a theoretical model taking quantitatively into account the non-Kramers nature of the Ho ions, the effects of hyperfine coupling and the presence of magnetic domains.

## TT 24.5 Wed 16:00 H23

Muon spin rotation and relaxation study on Nb_{1-y}Fe_{2+y} — •JANNIS WILLWATER¹, DANIELA EPPERS^{1,2}, THOMAS KIMMEL¹, ELAHEH SADROLLAHI^{1,3}, JOCHEN LITTERST¹, MALTE GROSCHE⁴, CHRISTOPHER BAINES⁵, and STEFAN SÜLLOW¹ — ¹IPKM, TU Braunschweig, Germany — ²PTB, Braunschweig, Germany — ³IFMP, TU Dresden, Germany — ⁴Cavendish Laboratory, University of Cambridge, United Kingdom — ⁵PSI, Villigen, Switzerland

The study of metallic materials with a ferromagnetic quantum critical transition revealed a plethora of novel and exotic behavior. In  $Nb_{1-y}Fe_{2+y}$ , a well-known example, the magnetic ground state reacts extremely sensitively to the chemical

composition. Previous experiments show that by varying y, two ferromagnetic ultralow-moment and a SDW phase can be reached in the phase diagram. In particular, the magnetism disappears in a narrow range which is associated with the occurrence of a quantum critical point.

Here, we present a comprehensive study of the magnetic behaviour of  $Nb_{1-y}Fe_{2+y}$  by means of muon spin rotation and relaxation. After establishing the muon stopping site, we studied and validated the magnetic phase diagram on different single and polycrystals. The focus of our study was the first investigation of a quantum critical sample, which shows no signs of long-range order, using a microscopic measurement technique. We demonstrate that magnetism at the lowest temperatures is dominated by magnetic fluctuations and that  $Nb_{1-y}Fe_{2+y}$  emerges to be uniquely suited to study quantum criticality close to weak itinerant ferromagnetic order.

## TT 24.6 Wed 16:15 H23

Quantum criticality of the long-transverse-field Ising model extracted by Quantum Monte Carlo simulations — •JAN ALEXANDER KOZIOL, ANJA LANGHELD, SEBASTIAN C. KAPFER, and KAI PHILLIP SCHMIDT — Lehrstuhl für Theoretische Physik I, Staudtstraße 7, Friedrich-Alexander Universität Erlangen-Nürnberg, D-91058 Erlangen, Germany

The quantum criticality of the ferromagnetic transverse-field Ising model with algebraically decaying interactions is investigated by means of stochastic series expansion quantum Monte Carlo, on both the one-dimensional linear chain and the two-dimensional square lattice. Utilizing finite-size scaling (FSS), we extract the full set of critical exponents as a function of the decay exponents of the long-range interactions. We resolve the three different regimes predicted by field theory, ranging from the nearest-neighbor Ising to the long-range Gaussian universality classes with an intermediate regime giving rise to a continuum of critical exponents. Focusing on the non-trivial intermediate regime, we verify our study by the well-known limiting regimes. In the long-range Gaussian regime, we treat the effect of dangerous irrelevant variables on the homogeneity laws by means of a modern FSS formalism.

## TT 24.7 Wed 16:30 H23

Quantum criticality of the long-range antiferromagnetic Heisenberg ladder — •PATRICK ADELHARDT and KAI PHILLIP SCHMIDT — Friedrich-Alexander-Universität Erlangen-Nürnberg

The Mermin-Wagner theorem excludes the breaking of a continuous symmetry in one-dimensional spin systems at zero temperature for sufficiently shortranged interactions. Introducing algebraically decaying long-range couplings on the antiferromagnetic Heisenberg two-leg ladder, we show that a direct secondorder quantum phase transition between the topologically ordered rung-singlet phase in the short-range limit and a conventionally Néel-ordered antiferromagnet can be realized in a one-dimensional system. We study the quantum-critical breakdown in the rung-singlet phase using the method of perturbative continuous unitary transformations (pCUT) on white graphs in combination with classical Monte Carlo simulations for the graph embedding in the thermodynamic limit supplemented with linear spin-wave calculations to extract the critical point. Exploiting (hyper-)scaling relations, the pCUT method is used to determine the entire set of canonical critical exponents as a function of the decay exponent. We find that the critical behavior can be divided into a long-range mean-field regime and a regime of continuously-varying exponents similar to the long-range transverse-field Ising model despite the presence of distinct orders on different sides of the critical point and the absence of criticality in the short-range limit.

## TT 24.8 Wed 16:45 H23

**Electronuclear quantum criticality** — JACINTHA BANDA¹, DANIEL HAFNER¹, JAVIER F. LANDAETA¹, ELENA HASSINGER^{1,2}, KEISUKE MITSUMOTO³, MAURO GIOVANNINI⁴, JULIAN SERENI⁵, CHRISTOPH GEIBEL¹, and •MANUEL BRANDO¹ — ¹Max Planck Institute for Chemical Physics of Solids, D-01187 Dresden, Germany — ²Technical University Munich, Physics department, 85748 Garching, Germany — ³Liberal Arts and Sciences, Toyama Prefectural University, Imizu, Toyama 939-0398, Japan — ⁴Department of Chemistry and Industrial Chemistry (DCCI), University of Genova, 16100 Genova, Italy — ⁵Department of Physics, CAB-CNEA, CONICET, 8400 San Carlos de Bariloche, Argentina We present here a rare example of electronuclear quantum criticality in a metal.

We present here a rare example of electronuclear quantum critically in a inetal. The compound YCu_{4.6}Au_{0.4} is located at an unconventional quantum critical point (QCP). The relevant Kondo and RKKY exchange interactions are very weak, of the order of 1 K with a strong competition between antiferromagnetic and ferromagnetic correlations, possibly due to geometrical frustration within the fcc Yb sublattice. This causes strong spin fluctuations which prevent the system to order magnetically. Because of the very low Kondo temperature the Yb³⁺ 4f-electrons couple weakly with the conduction electrons allowing the coupling to the nuclear moments of the ¹⁷¹Yb and ¹⁷³Yb isotopes to become important. Thus, the quantum critical fluctuations observed at the QCP derive not from purely electronic states but from entangled 'electronuclear' states. This is evidenced in the anomalous temperature and field dependence of the specific heat at very low temperatures.

# TT 24.9 Wed 17:15 H23

Bosonization duality in 2+1 dimensions and critical current correlation functions in Chern-Simons U(1)*U(1) Abelian Higgs model — •VIRA SHYTA¹, FLAVIO NOGUEIRA¹, and JEROEN VAN DEN BRINK^{1,2} — ¹Institute for Theoretical Solid State Physics, IFW Dresden, Helmholtzstr. 20, 01069 Dresden, Germany — ²Institute for Theoretical Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, 01069 Dresden, Germany

While the phase structure of the U(1)*U(1)-symmetric Higgs theory is still under debate, we have shown that a version of this theory with an additional Chern-Simons term undergoes a second-order phase transition. We established that such a theory is a bosonized dual of a topological field theory of massless fermions featuring two gauge fields. Here we elaborate on several aspects of this duality, focusing on the critical current correlators and on the nature of the critical point as reflected by the bosonization duality. The current correlators associated to the U(1)*U(1) symmetry and the topological current are shown to coincide up to a universal prefactor, which we find to be the same for both U(1) and U(1)*U(1) topological Higgs theories. The established duality offers in addition another way to substantiate the claim about the existence of a critical point in the bosonic Chern-Simons U(1)*U(1) Higgs model: a Schwinger-Dyson analysis of the fermionic dual model shows that no dynamical mass generation occurs. The same cannot be said for the theory without the Chern-Simons term in the action.

## TT 24.10 Wed 17:30 H23

**Fixed-point structure and critical behavior of generalized Gross-Neveu models in 2+1 dimensions** — •KONSTANTINOS LADOVRECHIS, SHOURYYA RAY, TOBIAS MENG, and LUKAS JANSSEN — Institute for Theoretical Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, Germany

The universal behavior of matter near points of continuous phase transitions is an intriguing phenomenon in condensed matter and statistical physics. At quantum critical points, the presence of gapless fermion degrees of freedom leads to new quantum universality classes without any classical analogues. Here, we discuss zero-temperature phase transitions between two-dimensional Dirac semimetals and long-range-ordered phases, in which spin and/or charge symmetries are spontaneously broken. These transitions are described by generalized Gross-Neveu models in 2+1 dimensions. We identify and classify fixed points of the renormalization group in the theory space spanned by a basis of short-range interactions compatible with the given symmetries, and we compute the corresponding quantum critical behaviors. Implications for the physics of interacting Dirac systems will be discussed as well.

## TT 24.11 Wed 17:45 H23

Torus spectroscopy of the chiral Heisenberg quantum phase transition -•THOMAS C. LANG¹, DAVIDE BREONI^{1,2}, SETH WHITSITT³, MICHAEL SCHULER¹, STEFAN WESSEL⁴, and ANDREAS M. LÄUCHLI^{1,5} - ¹Institute for Theoretical Physics, University of Innsbruck, Austria — ²Institute for Theoretical Physics II: Soft Matter, Heinrich Heine-Universität Düsseldorf, Germany — ³Joint Quantum Institute, NIST and the University of Maryland, College Park, Maryland, USA — ⁴Institut für Theoretische Festkörperphysik, JARA-FIT and JARA-HPC, RWTH Aachen University, 52056 Aachen, Germany – ⁵Institute of Physics, École Polytechnique Fédérale de Lausanne (EPFL), 1015 Lausanne, Switzerland We establish the universal torus low-energy spectra at the strongly coupled chiral Heisenberg fixed point in D = (2 + 1) dimensions by means of quantum Monte Carlo simulations and exact diagonalization. The fixed point and the associated Gross-Neuveu-Yukawa field theory are directly relevant for the long-wavelength physics of certain interacting Dirac systems, such as repulsive spinfull fermions on the honeycomb lattice, or  $\pi$ -flux square lattice and are compared against results from SLAC fermions. The torus energy spectrum has been shown previously to serve as a characteristic fingerprint of relativistic fixed points and is a powerful tool to discriminate quantum critical behavior in numerical simulations. We are able to address the subtle crossover physics of the low-energy spectrum flowing from the Dirac fixed point to the chiral Heisenberg fixed point, and compare against earlier attempts to extract the Fermi velocity renormalization.

# TT 24.12 Wed 18:00 H23

Finite size spectrum of the staggered six-vertex model with  $U_q(\mathfrak{sl}(2))$ -invariant boundary conditions — •SASCHA GEHRMANN¹ and HOLGER FRAHM² — ¹Institute of Theoretical Physics, Leibniz University Hannover, Germany — ²Institute of Theoretical Physics, Leibniz University Hannover, Germany

The finite-size spectrum of the critical  $\mathbb{Z}_2$ -staggered spin-1/2 XXZ model with quantum group invariant boundary conditions is presented. The conformal weights, which are found to have a continuous component, can be described in terms of the non-compact  $SU(2, \mathbb{R})/U(1)$  Euclidean black hole conformal field theory (CFT) for a range of the staggering parameter. Besides the continuous part of the spectrum of this CFT, we find also levels from the discrete part emerging as the anisotropy is lowered. The finite size amplitudes of both the continuous and the discrete levels can be parameterized by the corresponding eigenvalues of a quasi-momentum operator which commutes with the Hamiltonian and the transfer matrix of the model.

## TT 24.13 Wed 18:15 H23

**Fixed-point annihilation and duality in the SU(2)-symmetric spin-boson model** – •MANUEL WEBER¹ and MATTHIAS VOJTA² – ¹Max-Planck-Institut für Physik komplexer Systeme, Dresden, Germany – ²Institut für Theoretische Physik and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, Germany

The annihilation of two intermediate-coupling renormalization-group (RG) fixed points is of interest in diverse fields from statistical mechanics to highenergy physics and has so far been studied using perturbative techniques. Here we present high-accuracy quantum Monte Carlo results for the SU(2)-symmetric S = 1/2 spin-boson (or Bose-Kondo) model. We study the model with a powerlaw bath spectrum  $\propto \omega^s$  where, in addition to a critical phase predicted by perturbative RG, a stable strong-coupling phase is present. Using a detailed scaling analysis, we provide direct numerical evidence for the collision and annihilation of two RG fixed points at  $s^* = 0.6540(2)$ , causing the critical phase to disappear for  $s < s^*$ . Moreover, we uncover a surprising duality between the two fixed points, corresponding to a reflection symmetry of the RG beta function, which we utilize to make analytical predictions at strong coupling which are in excellent agreement with numerics. We comment on the consequences for impurity moments in critical magnets.

## TT 24.14 Wed 18:30 H23

Applying continuous unitary transformations to open quantum systems — •LEA LENKE, MATTHIAS MÜHLHAUSER, and KAI PHILLIP SCHMIDT — Lehrstuhl für Theoretische Physik I, Staudtstraße 7, Universität Erlangen-Nürnberg, D-91058 Erlangen, Germany

We generalize the method of continuous unitary transformations (CUTs) to certain types of open systems. In some cases – such as gain-loss Hamiltonians – there exists an effective description in terms of non-Hermitian Hamiltonians. For the latter we successfully apply a perturbative CUT (pCUT) to two non-Hermitian PT-symmetric quantum spin models in order to determine their lowenergy physics [1]. In a next step, we aim at generalizing this method further to dissipative frustrated systems described by a Lindblad master equation. [1] L. Lenke, M. Mühlhauser, K. P. Schmidt, Phys. Rev. B 104, 195137 (2021)

#### TT 24.15 Wed 18:45 H23

Finite-size scaling at quantum phase transitions above the upper critical dimension — •ANJA LANGHELD, JAN ALEXANDER KOZIOL, PATRICK ADELHARDT, SEBASTIAN C. KAPFER, and KAI PHILLIP SCHMIDT — Lehrstuhl für Theoretische Physik I, Staudtstraße 7, Friedrich-Alexander Universität Erlangen-Nürnberg, D-91058 Erlangen, Germany

The hyperscaling relation and standard finite-size scaling (FSS) are known to break down above the upper critical dimension due to dangerous irrelevant variables. The upper critical dimension becomes experimentally accessible, for instance, in systems with long-range interactions such as the long-range transverse-field Ising model, which can be realized in systems of trapped ions.

We present a coherent formalism for FSS at quantum phase transitions above the upper critical dimension following the recently introduced Q-FSS formalism for thermal phase transitions. Contrary to long-standing belief, the correlation sector is affected by dangerous irrelevant variables. The presented formalism recovers a generalized hyperscaling relation and FSS form.

Using this new FSS formalism, we determine the full set of critical exponents for the long-range transverse-field Ising chain in all criticality regimes ranging from the nearest-neighbor to the long-range mean field regime. For the same model, we also explicitly confirm the effect of dangerous irrelevant variables on the characteristic length scale.

# **TT 25: Topological Semimetals**

Time: Thursday 9:30-13:15

## Invited Talk

TT 25.1 Thu 9:30 H3

**Topology: Open and with diverse backgrounds** — •TOBIAS MENG — Institute of Theoretical Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, 01069 Dresden, Germany

The advent of topological physics has been a major disruption in the way we think about condensed matter physics. In its most basic form, topological physics relies on the definition of topological invariants defined from the wave functions in the Brillouin zone, including for example the Chern number governing the Hall effect. Implicitly, this view of topological physics requires closed systems with translation invariance.

In this talk, I will show that the fact that any experimental system is open (coupled to its environment) and never fully translationally invariant can be a resource rather than a nuisance. When suitable couplings to environments and inhomogeneities are induced, topological systems exhibit a plethora of novel phenomena, including black hole analogies and new Hall responses. This highlights that the study of topological systems out of their "comfort zone" (closed and translational invariant) is a worthwhile direction for future research.

# TT 25.2 Thu 10:00 H3

Chirality flip of Weyl nodes and its manifestation in strained  $MoTe_2$ — •VIKTOR KÖNYE¹, ADRIEN BOUHON², ION COSMA FULGA¹, ROBERT-JAN SLAGER³, JEROEN VAN DEN BRINK^{1,4}, and JORGE I. FACIO¹ — ¹IFW Dresden and Würzburg-Dresden Cluster of Excellence ct.qmat, Dresden, Germany — ²Nordic Institute for Theoretical Physics (NORDITA), Stockholm, Sweden — ³CM Group, Cavendish Laboratory, University of Cambridge, Cambridge, United Kingdom — ⁴Institute for Theoretical Physics, TU Dresden, Dresden, Germany

Due to their topological charge, or chirality, the Weyl cones present in topological semimetals are considered robust against arbitrary perturbations. One well-understood exception to this robustness is the pairwise creation or annihilation of Weyl cones, which involves the overlap in energy and momentum of two oppositely charged nodes. Here we show that the topological charge can in fact change sign, in a process that involves the merging of not two, but three Weyl nodes. This is facilitated by the presence of rotation and time-reversal symmetries, which constrain the relative positions of Weyl cones in momentum space. We analyze the chirality flip process, showing that transport properties distinguish it from the conventional, double Weyl merging. Moreover, we predict that the chirality flip occurs in MoTe₂, where experimentally accessible strain leads to the merging of three Weyl cones close to the Fermi level. Our work sets the stage to further investigate and observe such chirality flipping processes in different topological materials.

# TT 25.3 Thu 10:15 H3

Thermoelectric properties in TaRhTe₄, TaIrTe₄ and Mo_xW_{1-x}Te₂ Weyl semimetals — •MAHDI BEHNAMI¹, HELENA REICHLOVA^{1,3}, FEDERICO CAGLIERIS^{1,2}, MATTHIAS GILLIG¹, DMITRIY EFREMOV¹, GRIGORY SHIPUNOV¹, SAICHARAN ASWARTHAM¹, OCHKAN KYRYLO¹, JOSEPH DUFOULEUR¹, and BERND BÜCHNER^{1,3} — ¹IFW Dresden, P.O. Box 270116, 01171 Dresden, Germany — ²SPIN Consiglio Nazionale delle Ricerche — ³Technische Universit at Dresden, 01062 Dresden, German

Magneto- and thermo transport are the key properties of metals that not only can be used to study the electronic bands [1] but also have potential applications for heat harvesting. Here we report our results on the thermoelectric properties of Weyl semimetals TaRhTe₄, TaIrTe₄ and Mo_xW_{1-x}Te₂ [2,3,4]. All of these materials show an anomaly in the Nernst and Seebeck effects, while no anomaly can be seen in the standard magnetotransport. We discuss the origin of this anomaly and compare the results obtained with those for two compounds from the same family of materials, WTe₂ and MoTe₂.

# TT 25.4 Thu 10:30 H3

Ab initio study of nonlinear optical effects on the Weyl semimetal TaIrTe₄ — •ÁLVARO RUIZ PUENTE¹, IVO SOUZA^{1,2}, STEPAN S. TSIRKIN³, and JULEN IBAÑEZ-AZPIROZ^{1,2} — ¹Centro de Física de Materiales, Universidad del País Vasco, 20018 Donostia-San Sebastián, Spain — ²Ikerbasque Foundation, 48013 Bilbao, Spain — ³Department of Physics, University of Zurich, Winterthurerstrasse 190, 8057 Zurich, Switzerland

We investigate the bulk photovoltaic effect (BPE), which describes a d.c. nonlinear photocurrent taking place in crystals lacking inversion symmetry. TaIrTe₄ is a type II Weyl semimetal displaying such a large d.c. response [1]. In this work we use nonlinear response theory to address the optical properties of the solid and isolate the contribution of the Weyl points to it, calculating the 2nd

order shift [2] and 3rd order jerk [3] current contributions. Our analysis relies on a Wannier-interpolation scheme built over *ab initio* calculations. We put our theoretical calculations in context with the experimentally measured data, since these effects are expected to account for the measured photocurrent.

TT 25.5 Thu 10:45 H3

**Control of topological nodal planes in MnSi** — •MARC A. WILDE^{1,2}, MATTHIAS DODENHÖFT¹, ARTHUR NIEDERMAYR¹, ANDREAS BAUER^{1,2}, MORITZ M. HIRSCHMANN³, KIRILI ALPIN³, ANDREAS P. SCHNYDER³, and CHRISTIAN PFLEIDERER^{1,2,4} — ¹Physik Department, Technische Universität München, Garching, Germany — ²Center for QuantumEngineering (ZQE), Technische Universität München, Garching, Germany — ³Max Planck Institute for Solid State Research, Stuttgart, Germany — ⁴MCQST, Technische Universität München, Garching, Germany

Topologically protected band crossings occurring at points or along lines in reciprocal space have generated widespread interest. In contrast, the existence of entire surfaces on which bands are forced to cross and which can also carry a topological charge has been largely overlooked. This is especially intriguing, since (i) the conditions required for the crossing to occur exactly at the Fermi levels are dramatically relaxed by the two-dimensional nature of the planes and (ii) the reciprocal space separation between partner charges is maximal.

In the field-polarized phase of the chiral magnet MnSi the existence or absence of such topological nodal planes is enforced by the existence of absence of magnetic screw rotation symmetries. By using a combination of symmetry analysis, density functional theory and de Haas-van Alphen quantum oscillation experiments we demonstrate switching of the topological nodal planes by an applied magnetic field [1].

## TT 25.6 Thu 11:00 H3

High-mobility surface conduction in FeSi at low temperatures — •CAROLINA BURGER, ANDREAS BAUER, VIVEK KUMAR, MICHAEL WAGNER, RALF KORNT-NER, and CHRISTIAN PFLEIDERER — Physik-Department, Technische Universität München, D-85748 Garching, Germany

We report a study of the correlated small-band-gap semiconductor FeSi, exhibiting a saturation of resistivity below temperatures of a few Kelvin. The magnetic field dependence of the electrical transport properties provides strong evidence of a high-mobility surface conduction channel, that is insensitive to the additional presence of an impurity band in the bulk. The surface conduction channel shares great similarities with properties reported for topological insulators, but displays a striking lack of sensitivity to the presence of ferromagnetic impurities as studied by means of a series of single crystals with slightly different starting compositions. Here, we report measurements of the specific heat and the magnetic torque in order to shed further light on the nature of the high-mobility surface conduction.

Network of topological nodal planes, multifold degeneracies, and Weyl points in CoSi — •Nico Huber¹, Kirill Alpin², Andreas P. Schnyder², CHRISTIAN PFLEIDERER¹, and MARC A. WILDE¹ — ¹TU Munich — ²MPI for Solid State Research, Stuttgart

The discovery of multifold-fermions [1,2] and symmetry-enforced topological band crossings that are generically located at the Fermi level [3] has recently generated tremendous interest. However, the putative relationship between all topological charges remained unexplored up to now. We report the experimental identification of symmetry-enforced nodal planes (NPs) in CoSi which together with point degeneracies form a network of topological band crossings. In our study [4] we combined measurements of Shubnikov-de Haas (SdH) oscillations with first-principle electronic structure calculations, a symmetry analysis of SG 198, as well as a direct calculation of the topological charges. The observation of two nearly dispersionless SdH frequency branches is shown to provide clear evidence of four Fermi surface sheets around the R point and their pairwise degeneracy at the NPs on the Brillouin zone boundary. Our results further show

Thursday

that the crystalline symmetry enforces a topological charge of the NPs. Taken together, the comprehensive identification of all topological band crossings in the electronic structure of CoSi we report represents a showcase of an entire network of interconnected topological charges.

Anomalous evolution of the Nernst effect in trigonal PtBi₂ — •FEDERICO CAGLIERIS^{1,2,3}, DMITRIY EFREMOV³, GRIGORY SHIPUNOV³, SAICHARAN ASWARTHAM³, ARTHUR VEYRAT³, JOSEPH DUFOULEUR³, CHRISTIAN HESS^{5,3}, BERND BUECHNER^{3,4}, and DANIELE MARRÉ^{1,2} — ¹University of Genova, Via Dodecaneso 33, 16146 Genova (IT) — ²CNR-SPIN, Corso Perrone 24, 16142 Genova (IT) — ³Leibniz-Institute for Solid State and Materials Research IFW-Dresden, 01069 Dresden (DE) — ⁴Institut fuer Festkoerperphysik, TU Dresden, 01069 Dresden (DE) — ⁵Fakultaet fuer Mathematik und Naturwissenschaften, Bergische Universitaet Wuppertal, 42097 Wuppertal (DE)

Trigonal PtBi₂ represents an exceptional playground for the exploration of topological materials. In fact, it is a Weyl semimetal with broken inversion symmetry and strong spin-orbit coupling, showing also superconductivity at low temperatures. The Nernst effect has been proven to be a powerful technique to investigate the fermiology of unconventional materials. Moreover, in systems characterized by non-trivial topology, the Nernst coefficient often assumes distinctive features, as observed in various Weyl semimetals. In this work, we deeply investigate the evolution of the Nernst coefficient in a sigle crystal of trigonal-PtBi₂ as a function of different parameters: temperature (T), magnetic field (B) and angle ( $\check{0}3b8$ ) between the magnetic field direction and the c-axis of the sample. In particular, we found an anomalous phenomenology, which could be ascribed to peculiar properties of the Fermi surface.

TT 25.9 Thu 12:00 H3

**Fermi surface of the chiral topological semimetal PtGa** – •B.V. SCHWARZE^{1,2}, M. UHLARZ¹, J. HORNUNG^{1,2}, S. CHATTOPADHYAY¹, K. MANNA^{3,4}, S. SHEKHAR³, C. FELSER³, and J. WOSNITZA^{1,2} – ¹Hochfeld-Magnetlabor Dresden (HLD-EMFL) and Würzburg-Dresden Cluster of Excellence ct.qmat, HZDR, Germany – ²Institut für Festkörper- und Materialphysik, TU Dresden, Germany – ³Max Plank Institute for Chemical Physics of Solids, Germany – ⁴Indian Institute of Technology Delhi, India

PtGa is a chiral topological semimetal hosting two band-touching nodes with a maximal Chern number of four. Previously, we reported on angle-resolved photoemission spectroscopy measurements revealing giant spin-split Fermi arcs verifying the topology [1]. Here, we present our detailed investigation of the bulk Fermi surfaces of PtGa with angular-dependent de Haas-van Alphen (dHvA) measurements and band-structure calculations. Strong spin-orbit coupling leads to well separated spin-split bands. Eight bands cross the Fermi energy forming a multitude of Fermi surfaces resulting in intricate dHvA spectra. The assignment of the experimentally observed dHvA frequencies to the corresponding calculated extremal orbits is challenging, because of their considerable quantity and proximity. Yet, the experiment is in good agreement with the calculations further confirming the topological character of PtGa.

TT 25.11 Thu 12:30 H3 **Magnetic Kagome metal ErMn**₆**Sn**₆ — YISHUI ZHOU¹, FABIO ORLANDI², DMITRY KHALYAVIN², PASCAL MANUEL², THOMAS BRÜCKEL³, and •YIXI SU¹ — ¹Jülich Centre for Neutron Science JCNS at MLZ, Forschungszentrum Jülich, 85747 Garching, Germany — ²ISIS Facility, STFC, Rutherford Appleton Laboratory, Didcot OX11 0QX, UK — ³Jülich Centre for Neutron Science JCNS-2 and Peter Grünberg Institute PGI-4, Forschungszentrum Jülich, 52425 Jülich, Germany

Following the discovery of a quantum-limit magnetic Chern phase in  $TbMn_6Sn_6$ , the correlated topological metal series  $RMn_6Sn_6$  (R=Gd-Yb, and Y, Lu etc.), that possess an ideal kagome lattice of Mn, have emerged as a new platform to explore the interplay between geometric frustration, non-trivial band topology and magnetism. In particular, for magnetic rare-earth ions contained  $RMn_6Sn_6$ , it has been recently found that the topological transport properties, such as the anomalous Hall effect (AHE) and the topological Hall effect (THE), can be engineered intrinsically by rare-earth ions, thus suggesting a close relationship between the localized rare-earth magnetism, itinerant Mn magnetism and non-trivial properties characterization of this series of magnetic kagome metals. Our single-crystal neutron diffraction investigation of ErMn_6Sn_6 has uncovered a range of magnetic field induced complex magnetic orders that are likely associated to the observed THE in this compound.

## TT 25.12 Thu 12:45 H3

**Designing 3-dimensional flat bands in nodal-line semimetals** — •Alexander Lau¹, Timo Hyart², Carmine Autieri¹, Anffany Chen³, and Dmitry I. PIKULIN⁴ — ¹Institute of Physics Polish Academy of Sciences, Warsaw, Poland — ²Aalto University, Espoo, Finland — ³University of British Columbia, Vancouver, Canada — ⁴Microsoft Quantum, Redmond, USA

In materials with flat energy bands, the kinetic energy of the electrons is quenched leading to an enhancement of correlation effects. Research efforts, both theoretically and experimentally, have so far focused on materials and superlattices with two-dimensional energy bands. Two dimensions, however, put severe restrictions on the stability of the low- temperature phases due to enhanced fluctuations. Only three-dimensional flat bands can solve the conundrum of combining exotic flat-band phases with stable order existing at high temperatures. Here, we present a viable way to generate three-dimensional flat bands through strain engineering in topological nodal-line semimetals. We shed light on the underlying mechanism and discuss the competition of the arising superconducting and magnetic orders. The required strain profile can be realized, for instance, by bending the sample, which allows for in situ tuning of the emerging correlated phases and the transition temperatures. We show that these systems support a nontrivial 3D quantum geometry giving rise to large superfluid weight and supercurrents along all directions. Moreover, we identify rhombohedral graphite and CaAgP as promising material candidates to realize our proposal.

**Weyl-point teleportation** — •GYÖRGY FRANK^{1,2}, DÁNIEL VARJAS³, GERGÖ PINTÉR^{1,2}, and ANDRÁS PÁLYI^{1,2} — ¹Department of Theoretical Physics, Budapest University of Technology and Economics, Hungary — ²MTA-BME Exotic Quantum Phases Group, Budapest University of Technology and Economics, Hungary — ³Department of Physics, Stockholm University, AlbaNova University Center, 106 91 Stockholm, Sweden

In this work, we describe the phenomenon of Weyl-point teleportation. Weyl points usually move continuously in the configuration parameter space of a quantum system when the control parameters are varied continuously. However, there are special transition points in the control space where the continuous motion of the Weyl points is disrupted. In such transition points, an extended nodal structure (nodal line or nodal surface) emerges, serving as a wormhole for the Weyl points, allowing their teleportation in the configuration space. A characteristic side effect of the teleportation is that the motional susceptibility of the Weyl point diverges in the vicinity of the transition point, and this divergence is characterized by a universal scaling law. We exemplify these effects via a two-spin model and a Weyl Josephson circuit model. We expect that these effects generalize to many other settings including electronic band structures of topological semimetals.

Time: Thursday 9:30-13:00

 $TT 26.1 \quad Thu \ 9:30 \quad H10$ Microwave spectroscopy of a long Josephson junction strongly coupled to a resonator — •Micha Wildermuth¹, Mikhail Fistul², Jan Nicolas Voss¹, Andre Schneider¹, Hannes Rotzinger^{1,3}, and Alexey V. Ustinov^{1,3} — ¹Institute of Physics, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany — ²Theoretische Physik III, Ruhr-Universität Bochum, 44801 Bochum Germany — ³Institute for Quantum Materials and Technology, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany

Long Josephson junctions are interesting physical systems due to their strongly nonlinear spatial and temporal dynamics. In the past, most of experiments were performed by coupling long junctions galvanically to measurement lines and recording their DC current-voltage characteristics. Here we explore an alternative approach, where the long junction is attached to a passive microwave resonator and the whole coupled system is measured with an RF technique. This configuration opens up new opportunities of low-dissipative tests and applications, in particular, for Josephson vortex qubits. We present fabrication results, microwave spectroscopy data and numerical simulations of this high-impedance hybrid system.

# TT 26.2 Thu 9:45 H10

Quantum interference in a 1d array of three-terminal Josephson junctions — •Johanna Berger¹, Christian Baumgartner¹, Lorenz Fuchs¹, Sergei GRONIN², GEOFF GARDNER², MICHAEL MANFRA², NICOLA PARADISO¹, and CHRISTOPH STRUNK¹ — ¹Experimental and Applied Physics, University of Regensburg (Germany) — ²Purdue University, West Lafayette, Indiana (USA) We present DC transport measurements of an 1d array of three-terminal Josephson junctions based upon an epitaxial Al-InAs heterostructure. Two terminals are connected via a superconducting loop. Under the influence of perpendicular magnetic fields the critical current displays a complex diffraction pattern resembling the superposition of a Fraunhofer pattern-like envelope and SQUID oscillations. In the presence of an additional in-plane magnetic field this pattern develops two asymmetries: The main lobe shows clear supercurrent diode behavior [1], which results in different critical currents depending on the applied current direction. With increasing in-plane magnetic field the diffraction pattern acquires an overall skewness with respect to the perpendicular magnetic field, leading to differently pronounced side lobes. Unlike the diode effect this skewness is not suppressed at higher magnetic fields.

Highly-packed Nb-C Josephson junction arrays prepared by focused-ionbeam nanoprinting — •FABRIZIO PORRATI¹, FELIX JUNGWIRTH¹, SVEN BARTH¹, GIAN CARLO GAZZADI², STEFANO FRABBONI², OLEKSANDR V. DOBROVOLSKIY³, and MICHAEL HUTH¹ — ¹Goethe-University, Institut of Physics, Frankfurt a. M. — ²Nanoscience Institute-CNR, Modena — ³University of Vienna, Faculty of Physics, Vienna

Focused ion beam-induced deposition (FIBID) is a direct-write technique for the fabrication of nanostructures of any shape and dimension with high lateral resolution. Here, FIBID is employed to prepare Josephson junction arrays (JJA) consisting of superconducting Nb-C dots coupled through the proximity effect via a thin granular metal layer. The fabrication of the device is straightforward and it takes place in a few seconds. The microstructure and the composition of the JJA are investigated by transmission electron microscopy (TEM) and energy dispersive x-ray spectroscopy (EDS). The superconductor-to-metal transition of the JJA is studied directly by tuning the Josephson junction resistance in 70 nmspaced Nb-C dots. The observed magnetoresistance oscillations with a period determined by the flux quantum give evidence for the coherent charge transport by paired electrons.

## TT 26.4 Thu 10:15 H10

A particle conserving approach to AC-DC driven interacting quantum dots with superconducting leads — •JULIAN SIEGL, JORDI PICÓ-CORTÉS, and MILENA GRIFONI — Universität Regensburg, Regensburg, Germany

The combined action of a DC bias and a microwave drive on the transport characteristic of a superconductor-quantum dot-superconductor junction is investigated. To cope with non-equilibrium effects and interactions in the quantum dot, we develop a general formalism for the dynamics of the density operator based on a particle conserving approach to superconductivity. An exact generalized master equation for the reduced dot operator is obtained that treats the interaction inside the dot exactly and showcases the characteristic bichromatic response due to the combination of the AC Josephson effect and an AC voltage. In the weak coupling limit, analytical expressions for the stationary current and the reduced dot operator are provided. In this regime, beside quasiparticle transport, we show that superconducting correlations manifest in anomalous pair tunneling processes involving the tunneling of a Cooper pair. Photon assisted processes allow for subgap transport and rich current-voltage characteristics. For example, we find total current inversion, in which the current flows against the applied DC bias for suitable parameter regimes.

# TT 26.5 Thu 10:30 H10

**Model-independent determination of the gap function of nearly localized superconductors** — •DUŠAN KAVICKÝ¹, FRANTIŠEK HERMAN^{1,2}, and RICHARD HLUBINA¹ — ¹Department of Experimental Physics, Comenius University, Mlynská Dolina F2, 842 48 Bratislava, Slovakia — ²Institute for Theoretical Physics, ETH Zurich, CH-8093, Switzerland

The gap function  $\Delta(\omega)$  carries essential information on both, the pairing glue as well as the pair-breaking processes in a superconductor. Unfortunately, in nearly

localized superconductors with a non-constant density of states in the normal state, the standard procedure for extraction of  $\Delta(\omega)$  cannot be applied. Here, we introduce a model-independent method that makes it possible to extract  $\Delta(\omega)$  also in this case. The feasibility of the procedure is demonstrated on the tunneling data for the disordered thin films of TiN. We find an unconventional feature of  $\Delta(\omega)$  which suggests that the electrons in TiN are coupled to a very soft pairbreaking mode.

## TT 26.6 Thu 10:45 H10

The DC Josephson effect for a single level weak link: a Green's function formulation within a particle conserving theory of superconductivity — •ANTON BLEIBAUM and MILENA GRIFONI — Institute for Theoretical Physics, University of Regensburg, 93053 Regensburg, Germany

In traditional transport set-ups a current only flows when a bias voltage is applied. In the presence of superconducting electrodes a super-current can flow through a tunneling barrier even in thermodynamic equilibrium. This phenomenon is called DC-Josephson effect. Most of its features can be captured within mean field BCS-theory, according to which the supercurrent is a function of the phase difference between the two superconductors.

How can this result be reconciled with charge conservation in a physical system? In this work we compute the DC Josephson current in transport setups consisting of two superconducting electrodes coupled to a single level noninteracting quantum dot. The computation is based on a particle conserving theory of superconductivity. We first provide a current formula in terms of particle conserving Green's functions. In a second step the infinite hierarchy of equations for the relevant Green's function is solved. The Andreev bound states spectrum naturally follows from the poles of the retarded Green's function, and the DCcurrent has the form known from BCS theory.

TT 26.7 Thu 11:00 H10 Engineering the speedup of quantum tunneling in Josephson systems via dissipation — •DOMINIK MAILE¹, JOACHIM ANKERHOLD¹, SABINE ANDERGASSEN², WOLFGANG BELZIG³, and GIANLUCA RASTELLI⁴ — ¹Institut für komplexe Quantensysteme, Universität Ulm, Germany — ²Institut für Theoretische Physik, Universität Tübingen, Germany — ³Fachbereich Physik, Universität Konstanz, Germany — ⁴NO-CNR BEC Center and Dipartimento di Fisica, Università di Trento, Povo, Italy

We theoretically investigate the escape rate occurring via quantum tunneling in a system affected by tailored dissipation [1]. Specifically, we study the environmental assisted quantum tunneling of the superconducting phase in a currentbiased Josephson junction. We consider Ohmic resistors inducing dissipation both in the phase and in the charge of the quantum circuit. We find that the charge dissipation leads to an enhancement of the quantum escape rate. This effect appears already in the low Ohmic regime and also occurs in the presence of phase dissipation that favors localization. Inserting realistic circuit parameters, we address the question of its experimental observability and discuss suitable parameter spaces for the observation of the enhanced rate.

TT 26.8 Thu 11:30 H10

Nonreciprocity in current-biased Josephson junctions in the presence of Yu-Shiba-Rusinov bound states — •MARTINA TRAHMS¹, BHARTI MAHENDRU¹, IDAN TAMIR¹, LARISSA MELISCHEK¹, JACOB F. STEINER¹, NILS BOGDANOFF¹, OLOF PETERS¹, GAËL REECHT¹, CLEMES B. WINKELMANN², FELIX VON OPPEN¹, and KATHARINA J. FRANKE¹ — ¹Fachbereich Physik, Freie Universität Berlin, 14195 Berlin, Germany — ²Univ. Grenoble Alpes, Institute Néel, 38042 Grenoble, France

Magnetic impurities on superconducting surfaces are known to locally disturb Cooper pairs and form Yu-Shiba-Rusinov (YSR) states. We employ currentbiased Josephson spectroscopy in a scanning tunnelling microscope to study the phase dynamics of Josephson junctions in the presence of YSR states. For that purpose Mn and Cr adatoms are evaporated on a superconducting Pb(111) surface and investigated with a superconducting Pb tip. We observe switching currents that are significantly larger than the retrapping currents, identifying the junction as underdamped. In the presence of magnetic atoms, a local reduction of switching currents is observed. Additionally, we find a nonreciprocal behavior of the retrapping currents with respect to the current-sweep direction, i.e., the absolute value of the retrapping current depends on whether the current sweep starts at positive or negative bias values. In our experiment both species of magnetic atoms lead to a nonreciprocal retrapping-current behavior, albeit with a different directionality. We suggest a correlation between the damping of the Josephson junction and the electron-hole asymmetry of the YSR states.

#### TT 26.9 Thu 11:45 H10

Josephson effect through two superconducting magnetic impurity states – •FABIAN ZIESEL¹, CIPRIAN PADURARIU¹, BJÖRN KUBALA^{1,2}, and JOACHIM ANKERHOLD¹ – ¹ICQ and IQST, Ulm University, Germany – ²Institute of Quantum Technologies, German Aerospace Center (DLR), Ulm, Germany

A mK-STM functionalized with a magnetic impurity at the tip can probe a sample with a second impurity, thus realizing tunneling between Yu-Shiba-Rusinov (YSR) states [1]. We study the Josephson effect in such a system as a sensitive probe of the magnetic orientation of the impurities. Using Keldysh Green's functions, we show that the subgap bound states are spin-polarized and give rise to a spin polarized Josephson current. At low transmission, the YSR states of the impurities hybridize weakly, whereas at large transmission, the bound states are strongly phase-dependent, resembling spin split Andreev bound states [2]. The spin structure of the current becomes strongly phase-dependent. For aligned or anti-aligned magnetic impurities, we show that an unusual quantum phase transition emerges. While such a Josephson current can be used as a sensitive spin probe, we find that it is accompanied by significant feedback in the form of a Josephson spin torque acting to align/anti-align the impurities.

Spin-orbit coupling assisted transport phenomena in superconducting magnetic tunnel junctions — •ANDREAS COSTA and JAROSLAV FABIAN — University of Regensburg, Germany

Superconducting magnetic junctions exhibit fascinating physical phenomena, making them essential building blocks for modern technologies like quantum computing. Particularly attractive are multicomponent junctions in which the broken space-inversion symmetry additionally rises strong spin-orbit coupling (SOC). Pairing the interplay of these two most important spin interactions— exchange and SOC—with superconducting coherence has already been demonstrated to lead to unique signatures in spectroscopy and transport, and is furthermore expected to induce topological superconductivity hosting Majorana states. In this theory talk, we will focus on the most intriguing transport ramifications of SOC in superconducting magnetic junctions, covering giant transport magnetoanisotropies in the junctions' conductance and Josephson-current flow [1], the possibility to generate sizable transport and supercurrent-diode characteristics in proximitized 2DEG Josephson junctions [4] that were experimentally classified through robust Josephson-inductance measurements.

TT 26.11 Thu 12:15 H10 Non-equilibrium transport in Josephson junctions through interacting nanostructures — •JORDI PICÓ CORTÉS^{1,2}, GLORIA PLATERO², and MILENA GRIFONI¹ — ¹Theoretische Physik, Universität Regensburg, 93040 Regensburg, Germany — ²Instituto de Ciencia de Materiales de Madrid (CSIC) E-28049, Spain Thursday

Studying transport through interacting nanostructures is challenging due to the interplay between strong interactions and the coupling to large thermalized leads. In the case of superconducting leads, this is further complicated by a number of features particular to Josephson junctions, chiefly the effect of Cooper pairs and the resulting anomalous transport. In this work, we develop a diagrammatic approach to transport through weakly coupled Josephson junctions [1,2,3] which treats the interaction inside the dot exactly and employ it to describe the conventional and Josephson currents. The dynamics of Cooper pairs out of equilibrium are described in a particle-conserving formalism, which avoids issues arising from the usual BCS treatment, allowing us to extend the description of electron pairing inside the dot and the  $0 - \pi$  transition beyond the usual equilibrium treatment.

Interplay of Cooper pair and quasiparticle tunneling in the dynamics of an Anderson pseudospin — •CHRISTOPH ROHRMEIER, JORDI PICÓ-CORTÉS, ANDREA DONARINI, and MILENA GRIFONI — Institute of Theoretical Physics, University of Regensburg, Germany

In an interacting quantum dot coupled to superconducting reservoirs, the state of the system can be described in terms of a pseudospin [1] where "up" represents a fully occupied and "down" means an empty dot [2]. We investigate the dynamics of this Anderson pseudospin with the help of a generalized master equation based on a particle-conserving approach to superconductivity [3]. Superconducting correlations involved in Cooper pair and quasiparticle tunneling manifest in the pseudospin dynamics. The pseudospin precession is governed by an effective magnetic field [4] of which we give an analytical expression including finite gap, bias as well as interaction.

**Evolution of Andreev bands in half-filled superconducting periodic Anderson model** — •VLADISLAV POKORNY¹ and PANCH RAM² — ¹Institute of Physics, Czech Academy of Sciences, Na Slovance 2, CZ-18221 Praha 8, Czech Republic — ²Faculty of Mathematics and Physics, Charles University, Ke Karlovu 5, CZ-12116 Praha 2, Czech Republic

Two-dimensional systems where the surface of a superconductor is coated with a molecular layer draw recently a lot of attention as they represent ideal setups for studying the competition between magnetism and superconductivity. The physics of such system can be studied using the superconducting periodic Anderson model which describes a conduction band with superconducting pairing hybridized with a non-dispersive band of correlated electrons. We use the dynamical mean-field theory to solve this problem by mapping the lattice model to the superconducting impurity Anderson model with a self-consistent bath. This method neglects spatial correlations between lattice sites while local quantum fluctuations are fully taken into account. We show the behavior of the in-gap Andreev bands and how the singlet-doublet (zero-pi) quantum phase transition in the impurity model is reflected in the induced pairing in the correlated band.

Gralmonium: Granular aluminum nano-junction Fluxonium qubit — •DENNIS RIEGER, SIMON GÜNZLER, MARTIN SPIECKER, PATRICK PALUCH, PATRICK WINKEL, LOTHAR HAHN, JUDITH K. HOHMANN, ANDREAS BACHER, WOLFGANG WERNSDORFER, and IOAN M. POP — Karlsruhe Institute of Technology, Germany

Mesoscopic Josephson junctions (JJs), consisting of overlapping superconducting electrodes separated by a nanometer thin oxide layer, provide a precious source of nonlinearity for superconducting quantum circuits and are at the heart of state-of-the-art qubits, such as the transmon and fluxonium. Here, we show that in a fluxonium qubit the role of the JJ can also be played by a lithographically defined, self-structured granular aluminum (grAl) nano-junction: a superconductor-insulator-superconductor (SIS) JJ obtained in a single layer, zero-angle evaporation. The measured spectrum of the resulting qubit, which we nickname gralmonium, is indistinguishable from the one of a standard fluxonium qubit. Remarkably, the lack of a mesoscopic parallel plate capacitor gives rise to an intrinsically large grAl nano-junction charging energy in the range of 10 – 100 GHz, comparable to its Josephson energy  $E_J$ . We measure average energy relaxation times of  $T_1 = 10 \,\mu$ s and Hahn echo coherence times of

 $T_2^{\text{echo}} = 9\mu s$ . The exponential sensitivity of the gralmonium to the  $E_J$  of the grAl nano-junction provides a highly susceptible detector. Indeed, we observe spontaneous jumps of the value of  $E_J$  on timescales from milliseconds to days, which offer a powerful diagnostics tool for microscopic defects in superconducting materials.

#### TT 27.3 Thu 10:00 H22

Quantum dynamics of disordered arrays of interacting superconducting qubits: Signatures of quantum collective states — MIKHAIL FISTUL, •OLIVER NEYENHUYS, ANTONIA BOCAZ, and ILYA EREMIN — Theoretische Physik III, Ruhr-Universität Bochum, Bochum 44801, Germany

We study theoretically the collective quantum dynamics occurring in various interacting superconducting qubits arrays (SQAs) in the presence of a spread of individual qubit frequencies. The interaction is provided by mutual inductive coupling between adjacent qubits (short-range Ising interaction) or inductive coupling to a low-dissipative resonator (long-range exchange interaction). In the absence of interaction the Fourier transform of the temporal correlation function of the total polarization (z-projection of the total spin), i.e. the dynamic susceptibility  $C(\omega)$ , demonstrates a set of sharp small magnitude resonances corresponding to the transitions of individual superconducting qubits. We show that even a weak interaction between qubits can overcome the disorder with a simultaneous formation of the collective excited states. This collective behavior manifests itself by a single large resonance in  $C(\omega)$ . In the presence of a weak non-resonant microwave photon field in the low-dissipative resonator, the positions of dominant resonances depend on the number of photons, i.e. the collective ac Stark effect. Coupling of an SQA to the transmission line allows a straightforward experimental access of the collective states in microwave transmission experiments and, at the same time, to employ SQAs as sensitive single-photon detectors.

#### TT 27.4 Thu 10:15 H22

Heat transport and rectification in an ultrastrongly-coupled qubit-resonator system — •LUCA MAGAZZU¹, MILENA GRIFONI¹, and ELISABETTA PALADINO² — ¹University of Regensburg — ²University of Catania

Inspired by the recent experimental developments in the field of heat transport in the quantum regime, we consider a flux qubit coupled to a superconducting resonator as a composite open quantum system. The two elements of this open quantum Rabi system interact with two heat baths held at different temperatures. At the steady state, a heat current is established which is the result of photon exchanges between the system and the baths. Due to the geometry of the setup, the coupling to the heat baths is asymmetric. In turn this entails the presence of a preferred direction for the heat current, to a degree quantified by the heat rectification.

We calculate the heat current and rectification in different coupling regimes and considering a periodic driving applied to the qubit. The rectification displays the signatures of multi-photon processes that occur when the qubit-resonator coupling enters the nonperturbative regime

**Probing the coherence of superconducting Fluxmon qubits** — •BENEDIKT BERLITZ, ALEXANDER NEUMANN, ALEXANDER BILMES, JÜRGEN LISENFELD, and ALEXEY V. USTINOV — Physikalisches Institut, Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany

The Fluxmon qubit combines a transmission line resonator with a DC-SQUID and offers wide control over the circuit's potential energy via two independently applied bias flux channels. This allows one to operate the qubit as a phase or flux qubit, provides means for fast single-shot qubit readout, and offers a path to characterize decoherence due to surface spins and tunneling defects in a wide frequency range. We will review the Fluxmon qubit design and fabrication, and present measurements of its potential energy landscape which demonstrate single- and double well qubit physics. Our time-resolved measurements confirm that the Fluxmon qubit's performance is strongly limited by microscopic sources of decoherence, which might render it a suitable detector for defect spectroscopy applications.

#### TT 27.6 Thu 10:45 H22

Mapping the positions of individual material defects in superconducting transmon qubits — •ALEXANDER K. HÄNDEL, BENEDIKT BERLITZ, ALEXANDER BILMES, JÜRGEN LISENFELD, and ALEXEY V. USTINOV — Physikalisches Institut, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany

In superconducting quantum bits, material defects at the surface of circuit electrodes and the substrate constitute a major source of decoherence. In our experiment, we detect individual defects with a transmon qubit while tuning their resonance frequencies with applied static electric fields. We fabricated samples that feature on-chip gate electrodes that are placed close to the qubit island. By measuring the coupling strength of each detected defect to various electrodes, we are able to deduce the defect's position on the qubit chip. Our goal is to create two-dimensional maps of defect distribution over qubit electrodes. This will help to identify circuit components which contain majority of coherence-breaking defects and improve fabrication methods towards more coherent qubits.

Crystal electric field effects in yttrium orthosilicate doped with paramagnetic rare-earth ions — •Tim Hofmann, Andreas Bauer, Fabian Kessler, and Christian Pfleiderer — Chair for the Topology of Correlated Systems, Department of Physics, Technical University of Munich, Germany

Monoclinic yttrium orthosilicate  $Y_2SiO_5$  doped with several ten ppm of rareearth ions, such as  $Er^{3+}$ ,  $Yb^{3+}$ , or  $Nd^{3+}$ , represents a candidate material for optical applications in quantum information technology. The amount of dopants directly influences key properties, such as the linewidth or the coherence time, and in turn precise control on the doping levels is essential. The quantitative determination of doping on ppm level is challenging when using conventional characterization techniques. Here, we report the magnetic characterization of rare-earth doped yttrium orthosilicate single crystals. We infer information from magnetization measurements at low temperatures down to 2 K for magnetic fields up to 14 T applied along the optical axes *b*, *D*1, and *D*2, exhibiting paramagnetic contributions characteristic of rare-earth ions. Distinct crystalline anisotropy and the substitution of yttrium on two magnetically inequivalent sites is observed, indicating the importance of crystal electric field effects for both the fundamental characterization and potential applications in quantum information technology.

#### TT 27.9 Thu 11:45 H22

**Synchronized coherent charge oscillations in coupled double quantum dots** — •ERIC KLEINHERBERS¹, PHILIPP STEGMANN², and JÜRGEN KÖNIG¹ — ¹Faculty of Physics and CENIDE, University Duisburg-Essen, 47057 Duisburg, Germany — ²Department of Chemistry, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

We study coherent charge oscillations in double quantum dots tunnel-coupled to metallic leads [1]. If two such systems are coupled by Coulomb interaction, there are in total six (instead of only two) oscillation modes of the entangled system with interaction-dependent oscillation frequencies. By tuning the bias voltage, one can engineer decoherence such that only one of the six modes, in which the charge oscillations in both double quantum dots become synchronized in antiphase, is singled out. We suggest to use waiting-time distributions and the  $g^{(2)}$ -correlation function to detect the common frequency and the phase locking.

General super-exchange Hamiltonians for magnetic and orbital physics in  $e_g$ and  $t_{2a}$  systems — •XUEJING ZHANG¹, ERIK KOCH^{1,2}, and EVA PAVARINI^{1,2} — ¹Institute for Advanced Simulation, Forschungszentrum Jülich, D-52425 Jülich, Germany — ²JARA High-Performance Computing, 52062, Aachen, Germany In strongly-correlated transition-metal oxides, spin- and orbital-ordering or spin- and orbital-liquid phenomena are often studied with low-energy superexchange Hamiltonians, derived from multi-band Hubbard models in highly symmetric cases and in the basis of pseudo-spin operators. This captures the essence of the Kugel-Khomskii[1] super-exchange mechanism. Recently, via an irreducible-tensor operator representation, we derived the orbital superexchange Hamiltonian for  $t_{2g}^1$  perovskites and successfully used it, in combination with many-body calculations based on dynamical mean-field theory, to explain the orbital physics in these systems. Then, we generalize our method to  $e_q^n$  and  $t_{2q}^n$  systems at arbitrary integer filling *n*, including both spin and orbital interactions[2,3]. Here, we identified the  $t_{2g}^2$  perovskite LaVO₃ as a rare case in which orbital-ordering is indeed controlled by the KK super-exchange interaction[4].

Fluctuations analysis of the spin susceptibility: Néel ordering revisited in dynamical mean field theory — •GEORG ROHRINGER¹ and LORENZO DEL RE² · ¹Institute of Theoretical Physic, University of Hamburg, 20355 Hamburg, Germany — ²Department of Physics, Georgetown University, 37th and O Sts., NW, Washington, DC 20057, USA

We revisit the antiferromagnetic (AF) phase diagram of the single-band threedimensional Hubbard model on a simple cubic lattice studied within the dynamical mean field theory. Although this problem has been investigated extensively in the literature, a comprehensive understanding of the impact of the different one- and, in particular, two-particle local correlation functions of DMFT on the AF transition temperature is still missing. We have, hence, performed a fluctuation analysis of  $T_N$  with respect to different local bosonic fluctuations (charge, spin, particle-particle) contained in the two-particle vertex of DMFT. Our results indicate that, beyond weak coupling, the screening of the DMFT vertex by local fluctuations leads to an enhancement of  $T_N$  with respect to a random phase approximation (RPA) like calculation where this vertex is replaced by the bare interaction. The overall suppression of  $T_N$  in DMFT with respect to RPA is then solely due to the incoherence introduced by the DMFT self-energy in the one-particle Green's functions. This illustrates the Janus-faced role of the local moment formation in the DMFT solution of the Hubbard model, which leads to completely opposite effects in the one- and two-particle correlation functions.

#### TT 28.3 Thu 10:00 H23

Phase diagram of SU(N) antiferromagnet on a square lattice – •JONAS SCHWAB, FRANCESCO PARISEN TOLDIN, and FAKHER F. ASSAAD — Institut für Theoretische Physik und Astrophysik and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, 97074 Würzburg, Germany

We investigate the ground state phase diagram of an antiferromagnetic, SU(N)symmetric spin model on a square lattice, where the chosen irreducible representation of the  $\mathfrak{su}(N)$  algebra is described by a square Young tableaux with N/2 rows and 2S columns. Using approximation-free fermionic quantum Monte Carlo simulations for  $S \in \{1/2, 1, 3/2\}$  and even values of N in the range  $N \in [2, 20]$ , we present a phase diagram for this model. Our results are in line with the seminal work of Read and Sachdev. For any value S, we find Néel order

We present a microscopic theoretical analysis of interactions between a ferromagnet (FM) and superconductor (SC) mediated by photons in a cavity. This facilitates interactions over macroscopic distances, in contrast with extensively researched FM-SC proximity systems, and ensures there is no interfacial suppression of their respective order parameters. The spatial separation between the materials also means the FM and SC may be held at different temperatures, and has potential applications as a bridge in spintronic-superconducting circuitry. Specifically, we deduce the anisotropy field induced across the FM due to the presence of the SC when the system is subjected to a symmetry-breaking external field. Other quantities such as renormalized dispersion relations can also be deduced. The model is a modification and quantum mechanical extension of the principle presented in Janssøn et al. PRB 102, 180506(R) (2020).

Location: H23

at small values of N, and disordered valence-bond solid (VBS) states at large N. The degeneracy of the VBS state, 4 for S = 1/2 and 3/2 and 2 for S = 1, close to the Néel state follows the lower bound obtained by analyzing monopole singularities in the large-S limit. In contrast in the large-N limit, the VBS ground state shows a four fold degeneracy for all values of S. In order to best image the dimerization patterns, so as to confirm the above, we use a pinning field approach.

Field-tunable Berezinskii-Kosterlitz-Thouless correlations in a quasi-2d riend-tunable berezinskii-kosteriniz-induless correlations in a quasi-zu spin-1/2 Heisenberg lattice — D. OPHERDEN¹, M.S.J. TEPASKE^{2,3}, F. BÄRTL^{1,4}, M. WEBER³, M.M. TURNBULL⁵, T. LANCASTER⁶, S.J. BLUNDELL⁷, M. BAENITZ⁸, J. WOSNITZA^{1,4}, C.P. LANDEE⁹, R. MOESSNER³, D.J. LUITZ^{2,3}, and •H. KÜHNE¹ — ¹Hochfeld-Magnetlabor Dresden, HZDR — ²Physikalisches Institut, Univ. Bonn — ³MPI PKS, Dresden — ⁴IFMP, TU Dresden — ⁵Carlson School of Chemistry, Clark Univ. — ⁶Durham Univ., Centre for Materials Physics ⁷Clarendon Laboratory, Univ. of Oxford – ⁸MPI CPfS, Dresden – ⁹Department of Physics, Clark Univ.

We discuss the manifestation of field-induced Berezinskii-Kosterlitz-Thouless (BKT) correlations in the weakly-coupled spin-1/2 Heisenberg layers of the material  $[Cu(pz)_2(2-HOpy)_2](PF_6)_2$  (CuPOF). Due to the moderate intralayer exchange coupling of  $J/k_{\rm B}$  = 6.8 K, laboratory magnetic fields induce a substantial XY anisotropy of the spin correlations. This provides a significant BKT regime, as the tiny interlayer exchange  $J'/k_{\rm B} \approx 1$  mK only induces 3d correlations upon close approach to the BKT transition. We employed NMR and  $\mu^+$ SR measurements to probe the spin correlations that determine the critical temperatures of the long-range order and the BKT transition. Further, we performed stochastic series expansion QMC simulations based on the experimentally determined model parameters. Finite-size scaling of the spin stiffness yields an excellent agreement of the critical temperatures between theory and experiment.

TT 28.5 Thu 10:30 H23 Towards an *ab-initio* theory of Anderson localization for correlated electrons

- •LIVIU CHIONCEL — University of Augsburg, Augsburg, Germany Great progress has been made in recent years towards understanding the properties of disordered electronic systems. This is made possible by recent advances in quantum effective medium methods which include Dynamical Mean-Field Theory and the Coherent Potential Approximation, and their cluster extension, the Dynamical Cluster Approximation. The recently developed typical medium dynamical cluster approximation captures disorder-induced localization and provides an order parameter for the Anderson localized states. We present an overview of various recent applications of the typical medium single-site and dynamical cluster approximation to the Hubbard model, and its combination to realistic systems in the framework of Density Functional Theory.

TT 28.6 Thu 11:15 H23

The crucial influence of side groups on magnetic superexchange - a modification of the Goodenough-Kanamori-rules – DIJANA MILOSAVLJEVIC¹, Oleg Janson², Stefan-Ludwig Drechsler², and •Helge Rosner¹ –  1 Max-Planck-Institut für Chemische Physik fester Stoffe, 01187 Dresden, Germany -²IFW Dresden, Helmholtzstraße 20, 01069 Dresden, Germany

According to the famous Goodenough-Kanamori-Anderson rules, the key structural feature that determines the magnetic exchange coupling constant for superexchange in magnetic insulators is the magnetic ion-ligand-magnetic ion bond angle. Here, we demonstrate that this angle is not the only factor. An at least equally important influence on the exchange coupling has the presence of the side groups attached to the ligands. Applying density functional calculations and subsequently derived realistic parameters for a multiband model tight-binding model, we provide a quantitative analysis for the example case of edge-sharing Cu-O chains with bond angles near 90 degrees. We find that a single parameter, the difference in onsite energies of the ligand orbitals parallel and perpendicular to the Cu-O chain, is at least as important as the bond angle for sign and size of the superexchange. This parameter strongly depends on the position of side groups outside the superexchange pathway. For a fixed bond angle, changes of a side group position, only, can cause changes in the superexchange of several hundred Kelvin and thus dramatic changes in the magnetic ground state.

#### TT 28.7 Thu 11:30 H23

The shared universality of charged black holes and the many many-body SYK model - • JAN LOUW - Institute for Theoretical Physics, Georg-August-Universität Goettingen, Friedrich-Hund-Platz 1, 37077 Goettingen, Germany We investigate the charged q/2-body interacting Sachdev-Ye-Kitaev (SYK) model in the grand-canonical ensemble. By treating q as a large parameter, we are able to analytically study its phase diagram. By varying the chemical potential or temperature, we find that the system undergoes a phase transition between low and high entropies, in the maximally chaotic regime. A similar transition in entropy is seen in charged AdS black holes transitioning between a large and small event horizon. Approaching zero temperature, we find a first-order chaotic-tointegrable quantum phase transition, where the finite extensive entropy drops to zero. This again has a gravitational analogue-the Hawking-Page (HP) transition between a large black hole and thermal radiation. An analytical study of the critical phenomena associated with the continuous phase transition provides us with two sets of critical exponents. These sets define two separate universality classes, both of which include several charged AdS black hole phase-transitions. Together, these findings indicate a connection between the charged large q SYK model and black holes.

TT 28.8 Thu 11:45 H23

Scrambling and Many-Body Localization in the XXZ-Chain — •NIKLAS BÖL-TER and STEFAN KEHREIN — Institut für Theoretische Physik, Universität Göttingen

The tripartite information is an observable-independent measure for scrambling and delocalization of information. Therefore one can expect that the tripartite information is a good observable-independent indicator for distinguishing between many-body localized and delocalized regimes, which we confirm for the XXZ-chain in a random field. Specifically, we find that the tripartite information signal spreads inside a lightcone that only grows logarithmically in time in the many-body localized regime similar to the entanglement entropy. We also find that the tripartite information eventually reaches a plateau with an asymptotic value that is suppressed by strong disorder.

Nonlinear response theory and three-particle diagrams in strongly correlated systems — •PATRICK KAPPL, FRIEDRICH KRIEN, CLEMENS WATZENBÖCK, and KARSTEN HELD — Institute of Solid State Physics, TU Wien, Austria

We study three-particle correlation functions of the Anderson impurity model by means of quantum Monte Carlo simulations in the hybridization expansion. We analyze the parameter regime in which vertex corrections beyond the bare bubble term become relevant for the three-particle correlator. Such three-particle correlators are hitherto by-and-large terra incognita and become relevant for the next level of diagrammatic extensions of dynamical mean-field theory. We here restrict ourselves to correlators consisting of three densities *n* and spins  $S_{x,y,z}$ . These are related to nonlinear response theory and its zero-frequency component to the density-dependence of the electronic compressibility.

#### TT 28.10 Thu 12:15 H23

Superconductivity in 2D and 3D lattice models of correlated fermions - combining matrix-product states with mean-field theory — GUNNAR BOLLMARK¹, SVENJA MARTEN², •THOMAS KÖHLER¹, LORENZO PIZZINO³, YIQI YANG⁴, JOHANNES-STEPHAN HOFMANN⁵, HAO SHI⁶, SHIWEI ZHANG⁷, SAL-

VATORE R. MANMANA², THIERRY GIAMARCHI³, and ADRIAN KANTIAN^{1,8} — ¹Uppsala University, Sweden — ²Georg-August-Universität Göttingen, Germany — ³University of Geneva, Switzerland — ⁴College of William and Mary, Williamsburg, Virginia, USA — ⁵Weizmann Institute of Science, Rehovot, Israel — ⁶University of Delaware, Newark, USA — ⁷Flatiron Institute, New York, USA — ⁸Heriot-Watt University, Edinburgh, United Kingdom

Correlated electron states are at the root of many important phenomena including unconventional superconductivity (USC), where electron-pairing arises from repulsive interactions. Computing the properties of correlated electrons, such as the critical temperature Tc for the onset of USC, efficiently and unbiased remains a major challenge. Here, we combine matrix-product states (MPS) with static mean field (MF) to provide a solution to this challenge for 2D/3D materials comprised of weakly coupled correlated chains. This framework of Q1D fermions is developed and validated for attractive Hubbard systems and further enhanced via analytical field theory. Finally, we investigate the formation of transient non-equilibrum SC by a real-time evolution of a 3D extended Hubbard system out-of-equilibrium.

TT 28.11 Thu 12:30 H23

Non-local correlations and criticality in the triangular lattice Hubbard model — •MARIO MALCOLMS DE OLIVEIRA¹, JULIAN STOBBE², HENRY MENKE³, MARCEL KLETT¹, GEORG ROHRINGER², and THOMAS SCHÄFER¹ — ¹Max Planck Institute for Solid State Research — ²University of Hamburg — ³University of Erlangen-Nuremberg

We investigate the role of non-local electronic correlations at finite temperatures in the half-filled triangular lattice Hubbard model using the dynamical vertex approximation (DГA), a diagrammatic extension [1] of the dynamical meanfield theory (DMFT). We analyze the impact of (quantum) phase transitions on finite temperature properties at the one- and two-particle level. We discuss the absence of magnetic ordering at finite temperatures due to the fulfilment of the Mermin-Wagner theorem and the (Mott) metal-insulator crossover. In addition we compare the results of this method to the ones obtained by other cuttingedge techniques like DMFT, its real-space cluster extension cellular dynamical mean-field theory (CDMFT) and diagrammatic Monte Carlo (DiagMC) [2].

Non-local correlation and entanglement of ultracold bosons in the twodimensional Bose-Hubbard lattice at finite temperature — ULLI POHL, •SAYAK RAY, and JOHANN KROHA — Physikalisches Institut, Rheinische Friedrich-Wilhelms-Universität Bonn, Nußallee 12, 53115, Bonn, Germany

The temperature-dependent behavior emerging in the vicinity of the superfluid (SF) to Mott-insulator (MI) transition of interacting bosons in a 2D optical lattice, described by the Bose-Hubbard model is investigated. The equilibrium phase diagram at finite temperature is computed using the cluster mean-field (CMF) theory including a finite-cluster-size-scaling. The SF, MI, and normal fluid (NF) phases are characterized as well as the transition or crossover temperatures between them are estimated by computing physical quantities such as the superfluid fraction, compressibility and sound velocity using the CMF method. It is found that the nonlocal correlations included in a finite cluster, when extrapolated to infinite size, leads to quantitative agreement of the phase boundaries with quantum Monte Carlo results as well as with experiments. Moreover, it is shown that the von Neumann entanglement entropy within a cluster corresponds to the system's entropy density and that it is enhanced near the SF-MI quantum critical point (QCP) and at the SF-NF boundary. The behavior of the transition lines near this QCP, at and away from the particle-hole symmetric point located at the Mott-tip, is also discussed.

Relaxation dynamics in two quantum dots coupled to the environment: The role of coupling asymmetry — •LUKAS LITZBA, ERIC KLEINHERBERS, NIKODEM SZPAK, and JÜRGEN KÖNIG — Fakultät für Physik, Universität Duisburg-Essen, Lotharstraße 1, 47057 Duisburg, Germany

We study a strongly interacting two-site Fermi-Hubbard model representing two coupled quantum dots and couple them each with different strengths to Marko-

vian baths. We start with the Born-Redfield equation (without second Markov approximation) and approximate it by the coherent Lindblad master equations [1]. Using this technique we observe that the long-time dynamics of a quantum state, in particular the contribution from the energy coherences, depends strongly on the asymmetry between the bath coupling strengths of the dots. In contrast to the Born-Redfield equation and the coherent Lindblad master equations the popular secular approximation fails to properly describe the interdot and bath-dot currents in the asymmetric coupling case. To compare the quality of the approximations we use the exact solution in the case of no Coulomb interaction.

TT 29.2 Thu 15:00 P1

**Manipulating molecular spins with carbon nanotube SQUIDs** — •TIM AL-THUON, ALJOSCHA AUER, TINO CUBAYNES, and WOLFGANG WERNSDORFER — Karlsruher Institut für Technologie (KIT), 76131 Karlsruhe

Single-molecule magnets (SMMs) are promising candidates for spin-qubits due to their small size, cheap and reproducible chemical synthesis in a bottom-up approach and the opportunity to engineer their chemical properties such as the magnetic moment. However, an integration of SMMs with nanoscale diameters into electronic circuits is challenging. A solution to this problem could be to graft these molecules on carbon nanotubes (CNTs) which are comparable to SMMs in the diameter and possess unique sensing properties.

The CNT can be included as a weak-link Josephson junction into a superconducting quantum interference device (SQUID). Such a nano-SQUID is expected to have a large coupling between the magnetic moment of a molecule grafted on the CNT and the flux through the SQUID loop, giving rise to a very simple and precise detection of the spin of a single molecule.

Our CNTs are grown on separate chips with chemical vapor deposition and can then be integrated into prepatterned electronic circuits. For this purpose we use a novel, ultraclean, dry-transfer technique of CNTs where the CNTs are never exposed to air. This contribution will mainly focus on the integration of suspended CNTs into electronic circuits including preliminary results on the characterization of the devices at room and milli-Kelvin temperatures.

#### TT 29.3 Thu 15:00 P1

A carbon-nanotube nanoelectromechanical system coupled to a singlemolecule magnet — •ALJOSCHA AUER, SVENJA MÜLLER, TIM ALTHUON, TINO CUBAYNES, and WOLFGANG WERNSDORFER — Karlsruher Institut für Technologie, 76131 Karlsruhe

The one-dimensional structure of carbon nanotubes (CNTs) as well as their low weight and high Young*s modulus make them an excellent candidate for nanoelectromechanical systems (NEMS). With their mechanical resonance frequency in the hundreds of MHz regime combined with a large quality factor they are suited for high sensitivity experiments. In addition, the conductivity of CNTs can be tuned nicely by applying an electric field tuning the energy levels of charge carriers. For our experiments we want to use a suspended, top-down fabricated carbon nanotube, grown by chemical vapour deposition connecting two electrodes or using a stamping technique where the CNT is grown on a separate chip. Five local gates below the suspended nanotube enable us to manipulate the system by application of a tunable electric field. Furthermore, we want to attach a single-molecule magnet (SMM) to the nanotube by thermal evaporation, therefore creating a system using spin-phonon-coupling to address a single individual spin. The possible measurements in this configuration are manifold, ranging from magnetoresistive effects, spin valves respectively, and double quantum dot transport measurements to electron-phonon coupling measurable in transport measurements in a mechanical resonator.

Investigation of Hall effects in freestanding SrRuO₃ nanomembranes — •STEFAN PETERSEN, ROMAN HARTMANN, ELKE SCHEER, and ANGELO DI BERNARDO — University of Konstanz, Konstanz, Germany

 $SrRuO_3$  (SRO) is a one of the most intensively studied ferromagnetic oxides with a Curie temperature of about 150 K. In addition to being ferromagnetic, SRO is also interesting because of its high conductivity at low temperatures, high chemical stability and good lattice matching with other oxides.

Recently, a new technique has been developed to manufacture freestanding nanomembranes of oxide thin films grown on a water-soluble  $Sr_3Al_2O_6$  (SAO) sacrificial layer [1]. In our group, we have recently reproduced this process and been able to obtain freestanding nanomembranes of SRO.

We have investigated the anomalous Hall effect (AHE) and topological hall effect (THE) in SRO nanomembranes as a function of thickness and temperature, using SRO thin films grown on SrTiO₃ substrates as benchmark for comparison. We have also studied the evolution of these effects in SRO nanomembranes under a voltage-driven strain exerted by a piezoelectric substrate in contact with the nanomembrane. Our results are preliminary to the fabrication of devices with electric control of the AHE and THE.

Curvature control of the superconducting proximity effect in diffusive ferromagnetic nanowires — •TANCREDI SALAMONE¹, HENNING HUGDAL¹, MORTEN AMUNDSEN², and SOL JACOBSEN¹ — ¹QuSpin Center for Quantum Spintronics, NTNU, Trondheim, Norway — ²Nordita, KTH Royal Institute of Technology, Stockholm, Sweden

There is currently great interest in the inclusion of superconducting components in spintronic devices, because they can provide dissipationless currents, greatly enhancing device performances for spin-based data processing. Coupling a conventional s-wave superconductor to a ferromagnet allows, via the proximity effect, to generate superconducting triplet correlations. The generation of triplet correlations can be employed to achieve a superconducting triplet spinvalve effect in superconductor-ferromagnet (SF) hybrid structures, for example by switching the magnetizations of the ferromagnets between parallel and antiparallel configurations in F₁SF₂ and SF₁F₂ trilayers, or in SF bilayers with both Rashba and Dresselhaus spin-orbit coupling. It was recently reported that geometric curvature can control the generation of long ranged triplets [1]. In our most recent work [2], we use this feature to show that the superconducting critical temperature of the hybrid structure can be tuned by varying the curvature of the ferromagnetic wire alone, with no need of another ferromagnet or SOC. Furthermore, we show that the variation of the critical temperature as a function of the curvature can be exploited to obtain a robust, curvature-controlled, superconducting triplet spin-valve effect.

Electronic transport through single-molecule junctions of photoswitchable diarylethenes — •Valentin Barth¹, Lukas Holz¹, Thomas Huhn¹, Franz Herbst¹, Gautam Mitra¹, Christopher Weaver², Sergii Snegir¹, Tim Albrecht², and Elke Scheer¹ — ¹University of Konstanz, Konstanz, Germany — ²University of Birmingham, Birmingham, UK

Single-molecule junctions represent the conceptually simplest molecular devices. It is important to determine their electronic transport properties. Here we report on the transport characteristics of diarylethene-oligophenylene (DAE-OPE) molecule junctions at room and low temperature [1]. DAE molecules exist in two distinct stable states switched by irradiation of either visible or UV-light. Measurements are executed with the mechanically controllable break junction (MCBJ) method. Connection between the molecule and the gold electrodes is achieved by thiol end groups. The aim of the project is to distinguish the two states by their electrical transport properties. For this purpose, conductance histograms and current-voltage curves are measured separately for both states and compared afterwards. At room temperature, the conductance histograms of the states show small differences. These can be highlighted with the help of dimension reduction methods and neural networks [2]. Molecular vibration modes and thereby the current pathway through the molecule are determined for both states, by Inelastic electron tunneling spectroscopy (IETS). [1] Sendler et al., Adv. Sci. 2 (2015) 1500017

TT 29.7 Thu 15:00 P1

Low-temperature contact engineering for MoS₂ microtubes — •JONATHAN NEUWALD¹, ROBIN T. K. SCHOCK¹, MATTHIAS KRONSEDER¹, WOLFGANG MÖCKEL¹, SIMON REINHARDT¹, LUKA PIRKER², MAJA REMŠKAR², and ANDREAS K. HÜTTEL¹ — ¹Institute for Experimental and Applied Physics, University of Regensburg, 93040 Regensburg, Germany — ²Solid State Physics Department, Institute Jožef Stefan,1000 Ljubljana, Slovenia

Planar molybdenum disulphide  $MoS_2$ , a 2d material similar to graphene, displays a multitude of interesting electronic properties. Nevertheless, only few electronic experiments on  $MoS_2$  nanotubes and microtubes exist. A central reason for this is the difficulty of obtaining stable and transparent Ohmic contacts to transition metal dichalcogenides in general. At the metal-semiconductor interface, the Fermi level in  $MoS_2$  is typically strongly pinned close to the conduction band edge. To avoid a high contact resistance from the formation of a Schottky-barrier, low-work function metals have to be chosen. However, these etch into the  $MoS_2$  structure and therefore damage the tube. Following a recent publication,¹ we use the half-metal bismuth as a contact material, which disables the Fermi level pinning. We optimize the bismuth layer thickness to lower contact resistance and therefore improve the controllability and clarity of transport effects at millikelvin temperatures.

TT 29.8 Thu 15:00 P1

Andreev reflection in gated bilayer graphene — •PANCH RAM¹, DETLEF BECKMANN², ROMAIN DANNEAU², and WOLFGANG BELZIG¹ — ¹Fachbereich Physik, Universität Konstanz, D-78457 Konstanz, Germany — ²Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, D-76021 Karlsruhe, Germany

In this poster, we will present our recent theoretical study of the NS junction Andreev reflection and differential conductance on the bilayer graphene including different (equal and opposite) onsite potential for each monolayer graphene. We employ the Dirac-Bogoliubov de Gennes (DBdG) equation for the low-energy bilayer graphene Hamiltonian and calculate the Andreev reflection (retroreflection as well as specular) and differential conductance (within the Blonder-Tinkham-Klapwijk formalism [1-2]) for the junction in two different parameters limits: (i) interlayer coupling is larger energy scale (ii) superconductingside doping potential is larger energy scale [3-5]. We obtain the Andreev retroreflection (specular reflection) below (above) the normal-side Fermi energy when the bias voltage is less than the superconducting gap. We also observe that both retro and specular Andreev reflections are strongly modified by the gate field.

**Coulomb blockade effects in minimally twisted bilayer graphene** – •PATRICK WITTIG¹, FERNANDO DOMINGUEZ¹, CRISTOPHE DE BEULE², and PATRIK RECHER^{1,3} – ¹Institute for Mathematical Physics, TU Braunschweig, 38106 Braunschweig, Germany – ²Department of Physics and Materials Science, University of Luxembourg, L-1511 Luxembourg – ³Laboratory of Emerging Nanometrology, 38106 Braunschweig, Germany

In the presence of a finite interlayer electric field, minimally twisted bilayer graphene displays a triangular network of chiral valley Hall states that propagate along the AB/BA interfaces and scatter at the metallic AA regions. Previous studies model the chiral network using a phenomenological scattering matrix approach based entirely on the symmetries of the system. So far, the physics of the metallic AA scattering regions has been disregarded, and indeed, the finite size of the AA regions (order of nm) can give rise to similar physics as quantum dots: a discrete energy spectrum and also interacting effects such as Coulomb blockade physics. In our contribution, we include these effects and study the resulting network of chiral modes and quantum dots through the energy spectrum and magneto-conductance calculations.

Interaction effects in graphene/2D polymer heterostructures — •FRANCESCA FALORSI¹, KEJUN LIU², MIROSLAV POLOZIJ², CHRISTIAN ECKEL¹, THOMAS HEINE², XINLIANG FENG², RENHAO DONG², and THOMAS WEITZ¹ — ¹I. Physical Institute -Georg-August-University, Friedrich-Hund-Platz 1 37077 Göttingen Göttingen — ²Faculty of chemistry and food chemistry, Technische Universität Dresden, Mommsenstraße 4 01069 Dresden

This work explores the interlayer interaction effects of van-der-Walls heterostructures (HS) formed by graphene and a new class of two-dimensional polymers bonded by covalent bonds (C2DPs). These materials can be synthesized with multiple compositions and topology and therefore offer large tunability of their electronic properties. Via density functional theory calculations, it was possible to predict that coupling of different C2DPs with monolayer graphene should generate new interesting physical phenomena, including band flattening and trivial and non-trivial bandgap opening. The first system studied is the HSs formed by a mechanically exfoliated graphene on top of a C2DP that comprises metal-free porphyrin and perylene units linked by imide bonds. Different techniques are used for the first characterization of the structure: Raman, KPFM, SNOM, and ARPES. These different measurement techniques indicate the existence of interaction effects in the HSs. Electrical measurements on the HSs were also performed and showed that the polymer highly p-dopes the graphene.

Inductive coupling schemes in nano-electromechanics — •LUKAS NIEKAMP^{1,2}, Thomas Luschmann^{1,2,3}, Philip Schmidt^{1,2}, FRANK Deppe^{1,2,3}, Achim Marx¹, Rudolf Gross^{1,2,3}, and Hans Huebl^{1,2,3} — ¹Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany – ²Physik-Department, Technische Universität München, 85748 Garching, Germany — ³Munich Center for Quantum Science and Technology, 80799 Munich Nano-electromechanics studies the opto-mechanical interaction between microwave frequency resonators and mechanical components in the nanometer regime. Recently, the concept of inductive coupling has been demonstrated, allowing for the modulation of the resonator frequency by the mechanical displacement [1, 2]. This coupling scheme results in higher vacuum optomechanical coupling rates compared to previous capacitive coupling schemes. Therefore, devices based on inductive coupling are considered as potential pathway for realizing vacuum strong-coupling. This regime allows to harness the full nonlinearity of the optomechanical interaction offering opportunities like the generation of mechanical quantum states. The device presented here consists of a flux-tunable dc-SQUID with mechanically compliant strings integrated into a microwave resonator. The mechanical displacement of the strings modulates the external flux and hence the microwave resonator's frequency. Here, we present recent experiments on the path to strong photon-phonon interaction. [1] Rodrigues, Bothner, Steele, Nat. Commun. 10, 5359 (2019)

**Full counting statistics in periodically driven systems** — •JOHANN ZÖLLNER, ERIC KLEINHERBERS, and JÜRGEN KÖNIG — Theoretische Physik, Universität Duisburg-Essen and CENIDE, Lotharstr. 1, 47048 Duisburg

By calculating the full counting statistics of tunnelling electrons one can obtain information about quantum dot systems. We focus on the factorial cumulants [1] of the full counting statistics in periodically driven systems, which can be calculated using Floquet theory [2]. Higher-order factorial cumulants show signatures that can not be observed in the tunnelling current. To obtain analytical expressions we use the adiabatic approximation for small frequencies or the Magnus expansion for large frequencies. For the adiabatic limit we observe frequencydoubling in all factorial cumulants.

Light emission in  $\Delta T$ -driven mesoscopic conductors — •MATTHIAS HÜBLER and WOLFGANG BELZIG — University Konstanz

The scattering approach paves the way for the description of electron transport and current fluctuations in mesoscopic conductors. If fluctuations are coupled to an electromagnetic field, then they are related to the rate at which the field transfers energy to or receives energy from the conductor. The non-symmetrized current-current correlator characterizes the emission and absorption spectrum. Recent interest is concerned with  $\Delta T$  noise, which is the non-equilibrium noise caused by a temperature difference between the terminals. Here we generalize the notion of  $\Delta T$  noise to the non-symmetrized current-current correlator at finite frequencies. The spectrum is investigated for energy-independent scattering and for a resonant level as an example of energy-dependent scattering. We find that a temperature difference  $\Delta T$  leads to a partially negative  $\Delta T$  noise spectrum. This is a consequence of temperature broadening in combination with a frequency shift of the involved Fermi distributions. In the case of energyindependent scattering, the lowest order is a quadratic  $\propto (\Delta T)^2$  correction of the thermal-like noise spectrum. For the resonance, there arises an additional contribution to the  $\Delta T$  noise spectrum that is  $\propto \Delta T$  at the lowest order.

Symmetry-protected Bose-Einstein condensation of interacting hardcore bosons — •REJA WILKE¹, THOMAS KÖHLER², FELIX PALM¹, and SEBASTIAN PAECKEL¹ — ¹Department of Physics, Arnold Sommerfeld Center for Theoretical Physics, University of Munich, Germany — ²Department of Physics and Astronomy, Uppsala University, Sweden

We introduce a mechanism stabilizing a one-dimensional quantum many-body phase, characterized by a certain wave vector via the protection of an emergent Z2 symmetry. We illustrate this mechanism by constructing the solution of the full quantum many-body problem of hardcore bosons on a wheel geometry, which are known to form a Bose-Einstein condensate. The robustness of the condensate is shown numerically by adding nearest-neighbor interactions to the wheel Hamiltonian. We discuss further applications such as geometrically inducing finite-momentum condensates.

Low temperature photoluminescence investigation of light-induced degradation in boron doped CZ-silicon — •KATHARINA PEH¹, KEVIN LAUER^{1,2}, AARON FLÖTOTTO¹, DIRK SCHULZE¹, and STEFAN KRISCHOK¹ — ¹TU Ilmenau, Institut für Physik und Institut für Mikro- und Nanotechnologien, Ilmenau, Germany — ²CiS Forschungsinstitut für Mikrosensorik GmbH, Konrad-Zuse-Str. 14, 99099 Erfurt, Germany

Light-induced degradation (LID) in boron doped Czochralski grown (CZ) silicon is a severe problem for silicon devices such as solar cells or radiation detectors. In this contribution boron doped CZ silicon is investigated by low temperature photoluminescence (LTPL) spectroscopy. As already demonstrated on indium p-doped silicon samples, we suspect an ASi-Sii defect also in boron pdoped silicon samples [1]. To find the defect in connection with an additional LID PL peak which was also published by Vaqueiro-Contreras et al. [2], we carried out numerous measurements on boron-doped samples with the help of LTPL at 10 K.

**Design and construction of low temperature probe for transport measurement** — •REZA FIROUZMANDI, VILMOS KOCSIS, PABLO PEDRAZZINI, TINO SCHREINER, DANNY BAUMANN, and BERND BÜCHNER — Leibniz Institute for Solid State and Materials Research (IFW), 01069 Dresden, Germany

Electrical and thermal transport experiments are fundamental tools of basic research not only because of their potential to reveal new phenomena in condensed matter physics but also to discover novel applications. Here we report on our newly constructed, highly versatile, custom-built, low-temperature transport probes, which will allow us to perform high-precision measurements of electrical and thermal transport properties in a wide series of materials. The probes will allow measurements in the temperature range between 5K and 300K, under applied magnetic fields up to 16T, as well as high electric voltages up to 500V. The probes will be used in the investigation of novel quantum materials and multiferroics.

#### TT 29.17 Thu 15:00 P1

Lab::Measurement – measurement control with Perl 5 — MIA SCHAMBECK, ERIK FABRIZZI, FABIAN WEINELT, SIMON REINHARDT, and •ANDREAS K. HÜT-TEL — Institute for Experimental and Applied Physics, Universität Regensburg, Regensburg, Germany

Lab::Measurement is a collection of object-oriented Perl 5 modules providing control of test and measurement devices. It allows for quickly setting up complex tasks with diverse hardware. Instruments can be connected via GPIB (IEEE 488.2), USB or VXI-11 / raw network sockets on Ethernet. Internally, third-party backends as, e.g., Linux-GPIB, the NI-VISA library, or Zurich Instruments' LabOne API are used, in addition to lightweight drivers for USB and TCP/IP-based protocols. The wide range of supported backends enables cross-platform portability of measurement scripts between Linux and Windows machines. Based on roles within Moose that provide communication standards such as SCPI, dedicated instrument driver classes take care of internal details. A high-level sweep layer allows for fast and flexible creation of nested measurement loops, where, e.g., several input variables are varied and data is logged into a customizable folder structure. Features include live plotting or obtaining attested timestamps for measurement data.

Lab::Measurement is free software and available at https://www.labmeasurement. — Reference: S. Reinhardt *et al.*, Comp. Phys. Comm. **234**, 216 (2019)

TT 29.18 Thu 15:00 P1

**Theory of difference frequency quantum oscillations** — •VALENTIN LEEB¹ and JOHANNES KNOLLE^{1,2,3} — ¹Department of Physics TQM, Technische Universität München, James-Franck-Straße 1, D-85748 Garching, Germany — ²Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany — ³Blackett Laboratory, Imperial College London, London SW7 2AZ, United Kingdom

Quantum oscillations (QO) describe the periodic variation of physical observables as a function of inverse magnetic field in metals. The Onsager relation connects the basic QO frequencies with the extremal areas of closed Fermi surface pockets, and the theory of magnetic breakdown explains the observation of sums of QO frequencies at high magnetic fields. Here we develop a quantitative theory of *difference frequency* QOs in metals with multiple Fermi pockets with parabolic or linearly dispersing excitations. We show that a non-linear interband coupling, e.g. in the form of interband impurity scattering, can give rise to otherwise forbidden QO frequencies which can persist to much higher temperatures compared to the basis frequencies. We discuss the experimental implications of our findings, for example, for materials with multifold fermion excitations.

## TT 30: Superconductivity: Poster Session

By tradiiton the poster sessions in the Low Temperature Physics ivision are long (3-4 hours). Since temporal overlap with interesting oral sessions cannot be completely avoided, we suggest the poster presenters to leave a note at their posters indicating when they would be available for discussion.

**Optimization of single-crystal growth of Fe(Se,S)** — •MAIK GOLOMBIEWSKI, TESLIN ROSE THOMAS, N. S. SANGEETHA, ANDREAS KREYSSIG, and ANNA E. BÖHMER — Lehrstuhl für Experimentalphysik IV, Fakultät für Physik und Astronomie, Ruhr-Universität Bochum, Universitätsstraße 150, 44801 Bochum The iron-based superconductor FeSe and its substitution series Fe(Se,S) have been studied intensively for over a decade. Large (mm-sized) homogeneous single crystals are highly desirable for the accurate characterization of this material. An effective technique to grow Fe(Se,S) single crystals is chemical vapor transport with Cl-salts. However, the sulfur substitution makes the growth of large single crystals harder the higher the substitution percentage is.

We examine which parameters have an influence on the size and homogeneity of our Fe(Se,S) single crystals, namely furnace tilt, quartz ampoule dimensions and form, starting material preparation and temperature gradient. The composition of the single crystals is analyzed with a scanning electron microscope and properties are characterized by resistance measurements as well as x-ray diffraction experiments.

We find that we can consistently grow single crystals with masses ranging from 3 mg to more than 10 mg, depending on S-content. Other types of chemical substitution are explored.

## TT 30.2 Thu 15:00 P1

Magnetic order in transition-metal doped  $CaKFe_4As_4$  and the interplay with superconductivity — •ANDREAS KREYSSIG — Institute for Experimental Physics 4, Ruhr-Universität Bochum, 44801 Bochum, Germany — Ames Laboratory, U.S. DOE, and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011, USA

CaKFe₄As₄ is an iron arsenide superconductor in which partial substitution of Fe by a transition metal shifts the ground state from superconducting to antiferromagnetically ordered. The magnetic structure is a hedgehog spin-vortex crystal arrangement within the Fe planes. This magnetic order is different from the stripe-type spin density wave observed in other iron arsenide superconductor, however, related to the same entangled propagation vectors based on Fermisurface nesting. In this presentation the determination of the magnetic order will be reviewed and the interplay of the magnetism with superconductivity will be discussed in detail.

This work was supported by the U. S. DOE, BES, DMSE, under Contract DE-AC02-07CH11358. This research used resources at HFIR, a U. S. DOE Office of Science User Facility operated by the Oak Ridge National Laboratory.

#### TT 30.3 Thu 15:00 P1

Feedback of non-local  $d_{xy}$  nematicity on the magnetic anisotropy in FeSe — •STEFFEN BÖTZEL and ILYA EREMIN — Institut für theoretische Physik III, Ruhr-Universität Bochum, Bochum, Germany

Details of the nematic state in FeSe and its connection to superconductivity are still a matter of debate. We analyze theoretically the magnetic anisotropy in this state by computing the spin and the orbital susceptibilities from a microscopic multiorbital model. In particular, we consider both the xz/yz and the recently proposed non-local xy nematic ordering. The latter is believed to have a significant impact on the bandstructure and to force a Lifshitz transition. Its inclusion could play a crucial role in reproducing the experimentally measured temperature dependence of the magnetic anisotropy. This provides a direct fingerprint of the different nematic scenarios on the magnetic properties of FeSe.

Microscopic theory of the multi-orbital FFLO phase in the iron-based superconductors — •LUKA JIBUTI and ILYA EREMIN — Institute für Theoretische Physik III, Ruhr-Universität Bochum, D-44801 Bochum, Deutschland

We study the superconducting Frude-Ferrel-Larnik-Ovchinnikov (FFLO) phase, a superconducting phase, where Cooper pairs having non-zero center-of-mass momentum  $\vec{q}$ , in iron-based superconductors. We develop a microscopic theory model considering two  $\Gamma$ -centered hole pockets created by xz and yz orbitals. We write the low energy effective Hamiltonian of the form  $\hat{H} = \hat{H}_0 + \hat{H}_{int}$ , where the first term includes the kinetic therm, the  $\vec{k}$ -independent spin orbit coupling and the Zeeman field. We introduce the superconducting pairing between fermions in xz and yz orbitals and we restrict ourselves with the interactions which lead to the inter-band pairing of Cooper pairs. Writing the system Hamiltonian initially in orbital basis allowes us to observe the changes of the orbital weights at the Fermi energy when making the transition from Normal to FFLO phase and pinpoint the direction and value of the center-of-mass momentum  $\vec{q}$  that connects particles within the same orbital. From the mean field calculations for magnetic field just above the Pauli limit and for temperatures close to absolute zero, we are able to observe that  $\pm \vec{q}$  vectors connect particles within yz and xz orbitals respectively. We also observe that  $\vec{q}$  is highly dependent on the magnetic field and temperature, and the increase of the SOC constant destroys the FFLO phase.

#### TT 30.5 Thu 15:00 P1

In search of the superconducting symmetries of CeRh₂As₂ — •FABIAN JAKUBCZYK^{1,2}, JULIA M. LINK^{1,2}, and CARSTEN TIMM^{1,2} — ¹Institute of Theoretical Physics, Technische Universität Dresden, 01062 Dresden, Germany — ²Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, 01062 Dresden, Germany

Multiphase unconventional superconductivity is a rare phenomenon, which has recently been discovered in the heavy-fermion compound CeRh₂As₂. Here, the transition between two distinct superconducting phases occurs as a function of magnetic field applied along the c axis.At  $\mu_0 H^* \approx 4$  T the superconductor changes from a low-field to a high-field state with a large critical field of

 $\mu_0 H_{c2} = 14$  T. However, for in-plane fields only the low-field phase appears, with  $\mu_0 H_{c2} = 2$  T. Furthermore, at  $T_0 \approx 0.4$  K a transition to a suggested quadrupole-density-wave state was reported, whilst the low-field superconducting state is reached at  $T_c = 0.26$  K. Intriguingly, this quadrupole-density-wave state seems to be suppressed by a c axis field of about  $H^*$ , such that the low-field phase lies within it, whereas the high-field state does not. It seems reasonable to assume that the change of superconducting properties might be triggered by the disappearing density-wave state. In order to analyze this and other possible scenarios, we first conduct a symmetry analysis of the locally noncentrosymmetric CeRh_2As_2. Moreover, we construct a Landau-type energy functional including the superconducting and density-wave order parameters, as well as the applied magnetic field. From this we can give a statement about the potential symmetries of the superconducting phases.

#### TT 30.6 Thu 15:00 P1

Ising superconductors: the signatures of triplet pairings in the density of states and vanishing of the "mirage" gap — •SOURABH PATIL¹, GAOMIN TANG², and WOLFGANG BELZIG¹ — ¹Universität Konstanz, Konstanz, Germany — ²University of Basel, Basel, Switzerland

The conventional 2D superconductors are governed by the critical in-plane magnetic field above which the superconductivity is destroyed. Monolayer transition-metal dichalcogenides lack inversion symmetry and along with a strong spin-orbit coupling, lead to valley-dependent Zeeman-like spin splitting. This is the Ising spin-orbit coupling (ISOC) which then lifts the degeneracy of the two valleys and enhances the in-plane critical magnetic field. The finite energy pairings are thus obtained in such systems. The main superconducting gap-like feature shifted to finite energy is observed and termed a mirage gap.

The triplet pairings are introduced by the applied field. The equal-spin triplet pairing is always coupled to the singlet pairing, reflected in the self-consistent equations. Importantly, as the applied field is increased, we observe that the mirage gap closes (vanishes) and reopens. We obtain a phase diagram for such vanishing of the mirage gap in the 3D parameter space of the applied field, temperature, and the critical triplet temperature, for a fixed ISOC. The role of topology in such a mirage gap closing and any observable physical effects on the superconductivity would be our topic of study.

#### TT 30.7 Thu 15:00 P1

**Time-reversal symmetry breaking in the superconducting state of ScS** – •ARUSHI ARUSHI^{1,2}, ROSHAN KUMAR KUSHWAHA¹, DEEPAK SINGH³, ADRIAN HILLIER³, MATHIAS S SCHEURER⁴, and RAVI PRAKASH SINGH¹ – ¹Indian Institute of Science Education and Research Bhopal, Bhopal, India – ²Max Planck Institute for Chemical Physics of Solids, Dresden, Germany – ³ISIS Facility, STFC Rutherford Appleton Laboratory, Didcot, United Kingdom – ⁴Institute for Theoretical Physics, University of Innsbruck, Austria

The study of unconventional superconductors, which go beyond the BCS theory, is a crucial pillar of modern condensed-matter research and it is driven by the potential of these superconductors for applications and by fundamental scientific question, such as understanding their pairing mechanism. For the latter, time reversal-symmetry-breaking superconductivity might be particularly interesting since it is rare in nature and the underlying pairing mechanism must involve more than the conventional electron-phonon coupling. In this regard, we studied the superconducting state of ScS(rocksalt structure) using macroscopic and microscopic measurements such as muon spin rotation/relaxation( $\mu$ SR). All the performed measurements confirmed the bulk superconductivity at 5.1(1) K. Specific heat together with transverse-field  $\mu$ SR measurements indicate a full gap, while our zero-field  $\mu$ SR study reveals the presence of spontaneous static or quasi-static magnetic fields emerging when entering the superconducting state. We discuss various theoretical possibilities of pairing mechanisms, hint towards an unconventional superconducting state in ScS.

#### TT 30.8 Thu 15:00 P1

Topological phase transition away from the Fermi surface in multiband superconductors — •MASOUD BAHARI¹, SONG-BO ZHANG², CHANG-AN LI¹, CARSTEN TIMM³, and BJÖRN TRAUZETTEL¹ — ¹Institute for Theoretical Physics and Astrophysics, University of Würzburg, D-97074 Würzburg, Germany — ²Department of Physics, University of Zurich, Winterthurerstrasse 190, 8057, Zurich, Switzerland — ³Institute of Theoretical Physics, Technische Universität Dresden, 01062 Dresden, Germany

We demonstrate theoretically that odd-parity multiband superconductors with inversion symmetry host dispersive topological surface states induced solely by interband pairing away from the Fermi surface. The normal state requires to have at least a pair of energy bands with different effective masses. In this regard, spin-orbit coupling is a key ingredient. The topological phase transition occurs between electrons with different quantum numbers at finite excitation energies. Such phase transition happens at direction where the inter- and intraband electron pairings are finite and vanishing at the same time. To capture the underlying physics, we develop a generic theory in the interband representation of Bogoliubov-de Gennes Hamiltonian. We apply our theory to  $j{=}3/2$  systems and we discuss the pairing channels hosting such surface states.

#### TT 30.9 Thu 15:00 P1

Majorana flat bands at structured surfaces of nodal noncentrosymmetric superconductors — •CLARA JOHANNA LAPP and CARSTEN TIMM — Institute of Theoretical Physics, Technische Universität Dresden, 01062 Dresden, Germany Surfaces of nodal noncentrosymmetric superconductors can host flat bands of Majorana modes, which provide a promising platform for quantum computation if one can find methods for manipulating localized Majorana wave packets. We study the fate of such flat bands when part of the surface is subjected to an exchange field induced by a ferromagnetic insulator. Exact diagonalization is used to find the eigenstates and eigenenergies of the Bogoliubov-de Gennes Hamiltonian of a model system, for which an exchange field is applied along a strip on the surface of a slab. Moreover, we discuss a setup with a small exchange field applied to the previously field-free strip with the goal of introducing a linear dispersion. By switching this dispersion on and off, a wave packet could be moved in a certain direction. We find that in our model system, a linear dispersion can indeed be achieved. The qualitative features of this dispersion can be predicted from the momentum-dependent spin polarization of the field-free surface.

#### TT 30.10 Thu 15:00 P1

**Piezoelectric control of the electrical field-effect in superconductors** — •LEON RUF, SARA KHORSHIDIAN, SOHAILA NOBY, JENNIFER KOCH, ELKE SCHEER, and ANGELO DI BERNARDO — Department of Physics, University of Konstanz, Konstanz, Germany

Superconducting (sc) transistors are promising building blocks for future superconductors by virtue of their low energy consumption. For real applications this requires devices with Complementary metal-oxide-semiconductor (CMOS) compatibility, high switching speed and high scalability. Some realizations of superconductor/semiconductor hybrid systems, such as Nanocryotrons (nTrons) [1] or thermal driven sc-nanowires (hTron) [2] have already been put forward. An alternative promising architecture are gate-controlled sc devices. Reversible switching via gate-controlled sc-transistors (EF-Trons) has been independently seen for various BCS superconductors, such as Ti [3] and V [4]. Still the physical effect of the EF-Trons is not fully understood and is under debate [5]. By coupling epitaxial piezo-/ferroelectrics to the EF-Trons, we investigate the role of strain and amplification of the electric field through these materials on the switching behavior. We present first results of the growth of epitaxial piezo-/ferroelectrics and characterization of EF-Trons coupled with piezo-/ferroelectrics.

Gate effect on superconducting metal and metal oxide-based nanodevices — •SOHAILA MOHAMMED, SARA KHORSHIDIAN, ANGELO DI BERNARDO, and ELKE SCHEER — Physics Department, University of Konstanz

Quantum devices based on superconducting materials provide various technological applications, such as e.g. current limiters, electronic filters, routers, digital receivers, and photon detectors. The recent discovery of the reversible modulation of the superconducting critical current  $(I_c)$  in nanowires and Dayem bridges under the application of a gate voltage has raised a lot of interest for the possible application of this phenomenon towards the realization of superconducting logic devices. The threshold voltages necessary for the full suppression of  $I_c$ , however, remain high and correspond to an electrostatic field of ~ 4 MV/cm. Also, the physical origin of the effect remains controversial. To better understand the mechanism responsible for the suppression of I_c and to determine the physical parameters that can be useful to reduce the high electrostatic fields currently needed for the switching, we have performed a systematic investigation of gatecontrolled superconducting devices made of different metal and metal-oxide superconductor materials. We report on our findings and discuss the physical parameters relevant to assess the performance of gate-controlled superconducting devices including their maximum operational temperature, kinetic inductance, leakage currents and switching voltages.

#### TT 30.12 Thu 15:00 P1

Gate-voltage mediated supercurrent suppression in a superconducting nanobridge — •SUBRATA CHAKRABORTY, DANILO NIKOLIC, and WOLFGANG BELZIG — Fachbereich Physik, Universität Konstanz, D-78467 Konstanz, Germany Voltage-gated supercurrent suppression in a superconducting nano-bridge is a hot topic for research in present days. Recent experiments on this effect demonstrate a sudden supercurrent suppression in the bridge with high gate-voltage [1-6]. The microscopic understanding of this is not settled till now. According to the experimental researches, there are three distinct tentative mechanisms,

which could be responsible for this event. These mechanisms suggest that at high

gate voltage there could be either a direct surface-pair breaking-induced phase

620

transition, superconductivity suppression with induced nonequilibrium phonon distribution due to Joule heating in the gate or supercurrent suppression due to nonequilibrium electronic quasiparticles via a direct small leakage current. In our work, we theoretically investigate the role of gate-voltage induced surfacepair breaking on the supercurrent suppression of superconducting nano-bridge. We speculate this work would present some generic theoretical predictions of this effect allowing to further test it experimentally.

Tunable superconducting single electron transistors: from weak to strongcoupling regime — •Oliver Irtenkauf¹, Laura Sobral-Rey¹, David Ohnmacht¹, Wolfgang Belzig¹, Jens Siewert², and Elke Scheer¹ — ¹Univ. Konstanz — ²Univ. del Pais Basque, Bilbao, Spain

An island coupled to two leads and a gate forms a single electron transistor (SET) that shows Coulomb blockade (CB). All-superconducting SETs have shown to enable a multitude of possible charge transport processes, not all of them are well understood [1], in particular in the strong-coupling regime [2]. The conceptually simpler SSN-SET reduces the number of possible processes. We study a device consisting of a S island coupled to a N lead via an oxide tunnel barrier, and to a S lead with a mechanically controlled break junction (MCBJ). Via the MCBJ, different coupling regimes can be studied from a tunnel contact to a point contact [2]. For weak coupling, our experimental findings in the N state can be understood in terms of the Orthodox Theory of CB [3,4]. For stronger coupling, we observe Andreev and Josephson transport as well as, in the N state, a renormalization of the charging energy [5,6]. We describe our experimental results in the S state with simulations based on a generalized master equation approach [7].

Interplay between charging effects and superconducting transport in a tunable SET — •DAVID CHRISTIAN OHNMACHT¹, LAURA SOBRAL REY¹, JENS SIEWERT², WOLFGANG BELZIG¹, and ELKE SCHEER¹ – ¹Universität Konstanz, Konstanz, Deutschland —  $^2 \mathrm{University}$  of the Basque Country, Bilbao, Spain All-superconducting single electron transistors (SSS-SETs) have shown to enable a multitude of possible charge transport processes which are not well understood, in particular in the strong-coupling regime [1]. To disentangle these processes, the conceptually simpler (SSN)-SET, which has never been investigated experimentally before is considered [2]. Electron tunneling, Cooper pair tunneling and (multiple) Andreev reflection ((M)AR) are possible in the S-S mechanically controlled break junction (MCBJ) which can be adjusted to cover all coupling regimes: from a tunnel contact to a point contact with a small number of highly transmissive transport channels. The experimental data is compared to theoretical results obtained by using a master equation approach, including the rates of different transport mechanisms [3]. In order to account for MAR, we include the rates for the individual processes which are obtained from the theory of full counting statistics into the master equation framework [4]. The rates for MAR are computed using transmission probabilities according to the experimental data taking into account the presence of multiple transport channels. The limits of this master equation approach for a SSN-SET with a MCBJ are discussed in detail. Finally, it is shown that the charging energy decreases as the coupling of the MCBJ increases.

TT 30.15 Thu 15:00 P1

**Preparation of Nb/MnSi heterostructures** — •JULIUS GREFE¹, RODRIGO DE VASCONCELLOS LOURENÇO², MARKUS ETZKORN^{2,3}, STEFAN SÜLLOW¹, and DIRK MENZEL^{1,3} — ¹IPKM, TU Braunschweig, Germany — ²IAP, TU Braunschweig, Germany — ³LENA, TU Braunschweig, Germany

Motivated from theoretical predictions [1], the preparation of Nb/MnSi heterostructures, which are candidates for the usage as superconducting spin valves, is introduced. The substrates are obtained by cutting oriented Triarc-Czochralski grown MnSi single crystals into thin disc-shaped wafers. The surfaces of these substrates are prepared by various polishing steps, wet chemical etching, Ar sputtering and thermal annealing. After these processes the surfaces have been investigated by AFM and TEM and show surface roughnesses in the order of 1 nm. In order to investigate proximity effects between the chiral magnet MnSi and a superconductor we have deposited onto the substrates thin Nb films using molecular beam epitaxy. These heterostructures have been investigated in terms of magnetoresistivity measurements.

**Orientation-dependent magnetoresistance of Nb/MnSi heterostructures** — •PHILIP SCHRÖDER¹, JULIUS GREFE¹, STEFAN SÜLLOW¹, and DIRK MENZEL^{1,2} — ¹Institut für Physik der Kondensierten Materie, TU Braunschweig, Germany

-²Laboratory for Emerging Nanometrology, TU Braunschweig, Germany During high-resolution four probe (magneto-)resistivity measurements the reliability of the data strongly depends on the contacts' characteristics. If a vector magnet is not available the change of the sample orientation with respect to the field always requires demounting, reorientation and recontacting of the sample. We have measured the resistivity of a superconducting Nb thin film deposited on a helimagnetic MnSi substrate as function of the angle between the surface and the external magnetic field. In order to maintain the same four-probe configuration without recontacting an experimental setup has been developed allowing 720° sample rotation in a homogeneous field up to 1.1 T. The setup is used to accurately investigate the shift due to the proximity effect of the critical temperature  $T_c$  of the Nb film in contact to a magnetic system exhibiting a non-collinear spin structure. We show that the spin-helix orientation of the MnSi substrate is able to tune the  $T_c$  of Nb so that this heterostructure can be used as a two-component superconducting spin valve.

Decoupling of NbSe₂ monolayers in tailored SnSe-based multilayers — •O. CHIATTI¹, K. MIHOV¹, T. GRIFFIN¹, C. GROSSE¹, M. B. ALEMAYEHU², K. HITE², D. HAMANN², A. MOGILATENKO³, D. C. JOHNSON², and S. F. FISCHER¹ — ¹Novel Materials Group, Humboldt-Universität zu Berlin, 10099 Berlin, Germany — ²Solid State Chemistry, University of Oregon, Eugene OR 97403-1253, U.S.A. — ³Ferdinand-Braun-Institut, Leibniz-Institut für Höchstfrequenztechnik, 12489 Berlin, Germany

Van-der-Waals superlattices with two-dimensional (2D) superconducting layers of a transition-metal dichalchogenide (TMD) embedded between other materials have received a lot of attention [1]. Here, we examine the coupling between the NbSe₂ monolayers in  $[(SnSe)_{1+\delta}]_m$ [NbSe₂] ferecrystals [2]. *m* is an adjustable parameter to control the spacing between NbSe₂ layers and tune the inter-layer coupling, with a crossover from 3D to 2D superconductivity. The electric transport shows three regions: I. for m = 1 - 4 the films resemble "good" metals and 3D anisotropic superconductors, with inter-layer coupling enhanced by proximity effect in the SnSe layers and charge transfer from NbSe₂ to SnSe; II. for m = 5 - 9 the films are "dirty" metals and 3D anisotropic superconductors, with inter-layer coupling reduced by disorder and smaller charge transfer; III. for m > 9 they are "bad" insulators and a stack of disordered quasi-2D superconductors, with Josephson coupling between NbSe₂ monolayers. Spin-orbit effects in the vortex inductance of Al/InAs heterostructures — •JAYDEAN SCHMIDT, LORENZ FUCHS, DENIS KOCHAN, MAXIMILLIAN UFER, SIMON REINHARDT, MICHAEL PRAGER, MATTHIAS KRONSEDER, DOMINIQUE BOUGEARD, NICOLA PARADISO, and CHRISTOPH STRUNK — University of Regensburg (Germany)

In this work, we demonstrate the interplay of spin-orbit interaction and in-plane magnetic field in synthetic Rashba superconductors. We investigate the vortex inductance of epitaxially grown Al/InAs heterostructures containing an high-mobility surface-near InAs quantum well covered with a epitaxial layer of aluminum. An AC-current drives vortex oscillations around pinning centers which can be probed via inductance. The vortex inductance was found to be orders of magnitude larger than the kinetic inductance. When applying an in-plane field, the vortex inductance drops in particular for  $B_{\parallel} \perp I_{AC}$  signaling an increase of the pinning force. With respect to the angle between magnetic field and accurrent, a prominent two-fold anisotropy is observed. The unusual behavior of the vortex inductance signals a deformation of the vortex cores and can be theoretically explained by introducing an additional term in the Ginzburg-Landau free energy of a superconductor, resulting from the Rashba spin-orbit interaction [1].

TT 30.19 Thu 15:00 P1

Generalising Beenakker equation to take into account evanescent modes — •DANIEL KRUTI and ROMAN-PASCAL RIWAR — Institute for Theoretical Nanoelectronics (PGI-2), Jülich Research Centre and Institute for Theoretical Physics, University of Cologne

Superconductor-normal-metal-superconductor Josephson junctions have been examined extensively in past years. In particular, the case where the normal region is modelled by an ideal normal conductor with an intermittent scattering region can be well described by the celebrated Beenakker equation. Strictly speaking however, this equation is applicable only in the asymptotic plain wave limit, neglecting evanescent modes. However, the situation is changing by recent experimental advances. First, conductor regions are now fabricated with significantly decreased impurity scattering, leading to situations where scattering is dominated by the junction geometry. Second, miniaturisation is advancing such that evanescent modes should no longer be neglected. While this regime has already been captured by numerical methods, we here strive for an explicit analytical treatment, and generalise the Beenakker equation to short junctions with geometric scattering.

TT 30.20 Thu 15:00 P1

Controlling the Critical Current in Ferromagnetic Josephson-Junctions by Magnetization and Microwave Irradiation — •LUKAS KAMMERMEIER, AN-DREAS BLOCH, OLIVER IRTENKAUF, and ELKE SCHEER — Universität Konstanz, Konstanz, Germany

A key building block in superconducting spintronics is a controllable superconducting device that accomodates long-ranged triplet currents [1]. It has been suggested to create long range triplets with the help of ferromagnetic resonance in superconductor-ferromagnet-superconductor (SFS) structures made of conventional s-wave superconductors [2]. Here we explore this possibility by studying the electronic transport in SFS junctions in different geometries and realizations of the F spacer, subject to microwave irradiation, with spin injection and as function of the magnetization state of the ferromagnet. We show that we can manipulate the critical current of overdamped S-S/F-S proximity junctions by several percent by flipping a single domain in the ferromagnet. First results on spin injection will be presented.

A Ballistic Graphene Cooper Pair Splitter — PREETI PANDEY¹, ROMAIN DANNEAU², and •DETLEF BECKMANN² — ¹Institute of Nan- otechnology, Karlsruhe Institute of Technology, D-76021 Karlsruhe, Germany — ²Institute for Quantum Materials and Technologies, Karl- sruhe Institute of Technology, D-76021 Karlsruhe, Germany

We report an experimental study of a Cooper pair splitter based on ballistic graphene multiterminal junctions. In a two transverse junction geometry, namely the superconductor-graphene-superconductor and the normal metalgraphene-normal metal, we observe clear signatures of Cooper pair splitting in the local as well as nonlocal electronic transport measurements. Our experimental data can be very well de- scribed by our beam splitter model. These results open up possibilities to design new entangled state detection experiments using ballistic Cooper pair splitters.

#### TT 30.22 Thu 15:00 P1

**Coupling of supercurrent and quasiparticle excitations in superconductor nanostructures** — •PAUL MAIER and DETLEF BECKMANN — Institut für Quantenmaterialien und Technologien, Karlsruher Institut für Technologie

We report on the experimental observation of coupling between nonequilibrium modes of the quasiparticle excitations in thin superconducting films in the presence of supercurrent and high parallel magnetic fields. The coupling is due to a difference in the number of available quasiparticle states, depending on their relative propagation direction to the supercurrent. Recently the occurrence of a spin-energy (spin-antisymmetric charge imbalance) current in the presence of energy imbalance was predicted [1]. Here the resulting spin-energy imbalance for a spatial gradient in the energy imbalance was probed in nonlocal conductance measurements with spectral resolution. The measurements show excellent agreement with numerical models and provide proof of the coupling of energy and spin-energy modes.

TT 30.23 Thu 15:00 P1

Bloch oscillation effects in ultrasmall Josephson junctions embedded in high-inductance environment — •FABIAN KAAP and SERGEY LOTKHOV — Physikalisch-Technische Bundesanstalt, Bundesallee 100 38116, Deutschland Braunschweig

The adiabatic transport of Cooper pairs, also known as Bloch oscillations (BO), can be of high interest in future applications for metrology, due to the fundamental current-to-frequency relation,  $I_{\rm B} = 2e \times f_{\rm B}$ . In order for the BO in ultrasmall Josephson junctions to be observed, one has to suppress the quantum fluctuations of charge by means of embedding the junctions into a high impedance environment.

For this purpose, we elaborated a dedicated inductively-resistive planar biasing circuit, which includes high-kinetic-inductance meanders made from granulated aluminium and high-ohmic microstrips of partially oxidized titanium. Using this approach, we were able to measure the characteristic back-bending in an *IV*-curve of a dc-biased SQUID with Josephson junction of sub-100nm-sizes. By varying the ratio of the Josephson energy  $E_J$  and the charging energy  $E_C$ , using an external magnetic field, we were able to manipulate the shape of the *IV*-curves back-bending, which can be explained by a modification of the lowest Bloch energy band of Cooper pairs. With this biasing technique the way is paved to circumvent the microwave coupling issues hindering the realization of dual Shapiro step experiments.

#### TT 30.24 Thu 15:00 P1

Superconductor-insulator transition in ultra-thin granular aluminum films – •THOMAS HUBER¹, AVIV MOSHE², GUY DEUTSCHER², and CHRISTOPH STRUNK¹ – ¹Institute for Experimental and Applied Physics, University of Regensburg, Regensburg, Germany – ²Raymond and Beverly Sackler School of Physics and Astronomy, Tel Aviv University, Tel Aviv, Israel

The relation between homogenously disordered and granular superconductors is so far not clearly understood. In particular, the existence of highly insulating states in grAl has yet not been demonstrated. Here we investigate ultra-thin grAl films in the truely 2D limit and find a superconducting transition for sample S with  $R_{\Box}(4K) \approx 3k\Omega$  and insulating behavior for sample I with  $R_{\Box}(4K) \approx 7.75 k\Omega$  (d-SIT). By increasing the perpendicular magnetic field we drive both samples (deeper) into the insulating regime (B-SIT), where we find activated behavior in a temperature range T*(B) < T <  $\approx$  800mK. For T < T* and B <  $\approx$  1T, the R(T) curves saturate, indicating an intermediate anomalous metallic state [1] on both sides of the SIT [2]. The resistance  $R_{\Box}$ , the activation energy  $E_A$  and the threshold voltage  $V_T$  depend on magnetic field and show strong similarities to the behavior of both regular Josephson junction arrays [3] and homogenously disordered films [4].

#### TT 31.1 Thu 15:00 P1

**Modular architecture for circuit quantum electrodynamics** — •SOEREN IHSSEN¹, SIMON GEISERT¹, MARTIN SPIECKER², PATRICK PALUCH², ELIE DE SEZE^{1,3}, WOLFGANG WERNSDORFER^{1,2}, PATRICK WINKEL⁴, and IOAN POP^{1,2} — ¹Institute for Quantum Materials and Technologies, KIT, Germany — ²Physikalisches Institut, KIT, Germany — ³ENS Paris-Saclay, France — ⁴Yale University, USA

Superconducting quantum circuits play a pioneering role in finding a scalable architecture for the realization of a coherent quantum processor. In this context, keeping the integrity, individual addressability and controllability of each circuit component while increasing the complexity of the whole system is paramount to building a functional device. Fulfilling these key requirements becomes more difficult when increasing the connectivity in the circuit since parasitic cross-talk and the number of decay channels increase at the same time. Therefore, the coupling, readout and control mechanisms of every architecture need to be understood in great detail. Here, we investigate a flip-chip architecture in which

Location: P1

we implement the readout and flux control of generalized flux qubits. With our approach, circuits serving different tasks within the system can be prepared individually and exchanged in case they do not fulfil the requirements. In our first realization, a bandpass Purcell filter for readout and an on-chip flux bias line are fabricated and tested regarding their microwave properties. The developed circuit enables a suitable easy-access framework for future experiments on qubit-qubit coupling in a well-controlled microwave environment.

TT 31.2 Thu 15:00 P1

Flip chip implementation for generalized flux qubits — •SIMON GEISERT¹, SÖREN IHSSEN¹, MARTIN SPIECKER^{1,2}, PATRICK PALUCH^{1,2}, DENNIS RIEGER², SIMON GÜNZLER², ELIE DE SEZE³, WOLFGANG WERNSDORFER^{1,2}, PATRICK WINKEL^{1,4}, and IOAN POP^{1,2} — ¹Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology (KIT), Germany — ²Physikalisches Institut, KIT, Germany — ³ENS Paris-Saclay, France — ⁴Yale University, USA Superconducting flux qubits are a versatile and promising platform to implement coherent and tunable qubits with high anharmonicity. In this work, we investigate a generalized flux qubit consisting of a single Josephson junction (JJ) shunted by a capacitance and a granular aluminum inductor. When biased at the flux degeneracy point, the potential landscape can be widely engineered by exploring the parameter space of the flux qubit, which includes the loop inductance, the Josephson energy of the JJ and the total capacitance across the latter. We demonstrate a high engineerability of the qubit frequency, yielding flux qubits in the range of 150 MHz to 7.6 GHz. Dispersive readout of the qubit state is performed via an embedded harmonic mode that is inductively coupled through an asymmetry of the qubit loop. The readout mode is capacitively coupled to a control chip, which is used to excite, read out and flux bias the qubit. This flip chip approach allows very well isolated qubits to be tested in a modular architecture and enables coupling to two distinct coupler chips, effectively creating a unit cell that can be scaled up to an array of coupled qubits.

#### TT 31.3 Thu 15:00 P1

Simultaneous quantum jumps on multiple Fluxonium qubits — •NICOLAS GOSLING, MARTIN SPIECKER, PATRICK PALUCH, SIMON GEISERT, and IOAN M POP — Karlsruhe Institut of Technology

Superconducting quantum circuits have become one of the front runners for the implementation of scalable quantum processors. Hereby, the ability to design and implement multiple artificial atoms and their couplings has become an important task for many researchers. Therefore it is imperative to understand how events on one qubit influence other qubits on the same chip. Here, we take simultaneous quantum jump traces of multiple Fluxonium qubits on the same chip using a frequency multiplexed readout scheme through dispersive measurement. The simultaneity is ensured by the frequency multiplexing, enabling both signals to use the same input and output lines. The resulting quantum jump traces are then analysed for simultaneous events in respect to the stochastically expected coherences for perfectly uncoupled quantum systems.

TT 31.4 Thu 15:00 P1 Characterization of Josephson photonics devices as microwave sources for a quantum radar — •LUKAS DANNER^{1,2}, CIPRIAN PADURARIU², JOACHIM ANKERHOLD², and BJÖRN KUBALA^{1,2} — ¹Institute for Quantum Technologies, German Aerospace Center (DLR), Ulm, Germany — ²ICQ and IQST, Ulm University, Ulm, Germany

In Josephson photonics devices, microwave radiation is created by inelastic Cooper pair tunneling across a dc-biased Josephson junction connected in-series with a microwave resonator [1]. Various resonances are accessed by tuning the dc-voltage, where, e.g., each tunneling Cooper pair creates one, two or three photonic excitations in the resonator. If excitations are created in two different resonators, the device could be used in a quantum radar which exploits the quantum correlations of the photons [2]. The source can be characterized by the steady-state Wigner density of the cavities, showing e.g. two-mode squeezing or other phase-space symmetries for multi-photon creation. Wigner-state tomography is expensive and in Josephson photonics devices especially challenging due to lacking phase stability. Therefore, we propose an alternative approximative characterization scheme which requires measuring only a few expectation values. A different way of dealing with the instability of the phase-space angle by a locking mechanism [3] is discussed in the contribution of F. Höhe.

#### TT 31.5 Thu 15:00 P1

Reflection-type superconducting microwave resonators for spin-based quantum memories —  $\bullet$ JULIAN FRANZ^{1,2}, PATRICIA OEHRL^{1,2}, MANUEL MÜLLER^{1,2}, THOMAS LUSCHMANN^{1,2,3}, RUDOLF GROSS^{1,2,3}, and HANS HUEBL^{1,2,3} — ¹Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — ²Physik-Department, Technische Universität München, Garching, Germany — ³Munich Center for Quantum Science and Technologies (MC-QST), Munich, Germany

Solid-state spin ensembles are considered as excellent candidates for quantum memory applications due to their long coherence times and frequency compatibility with superconducting quantum circuits. The realization of such quantum memory requires the conversion of quantum microwave signals to excitations in the spin ensemble, their storage, and retrieval. This requires the detailed understanding and design optimization of the employed microwave circuit. The excitation transfer is typically measured by using a hanger type resonator. However, in a reflection-type geometry, all of the signal power is available for measurement, which gives nominally a factor of 2 improvement of the signal-to-noise ratio relative to the hanger configuration [1]. Here, we discuss the design concepts for superconducting microwave circuits with emphasis on tuning the coupling rates to the microwave circuit environment and the spin ensemble. In addition, we present experimental data using thin film NbTiN and Nb reflection-type resonators and characterize their performance at mK temperatures. [1] H. Wang *et al.*, Quantum Sci. Technol., **6** (3), 035015 (2021) TT 31.6 Thu 15:00 P1

MOCCA: A 4k-pixel molecule camera for the position and energy resolved detection of neutral molecule fragments — •DANIEL KREUZBERGER¹, CHRISTIAN ENSS¹, ANDREAS FLEISCHMANN¹, LISA GAMER², LOREDANA GASTALDO¹, CHRISTOPHER JAKOB², ANSGAR LOWACK¹, OLDŘICH NOVOTNY², ANDREAS REIFENBERGER¹, DENNIS SCHULZ¹, and ANDREAS WOLF² — ¹Heidelberg University — ²Max Planck Institute for Nuclear Physics, Heidelberg

The MOCCA detector is a 4k-pixel high-resolution molecule camera based on metallic magnetic calorimeters and read out with SQUIDs that is able to detect neutral molecule fragments with keV kinetic energies. It will be deployed at the Cryogenic Storage Ring CSR at the Max Planck Institute for Nuclear Physics in Heidelberg, a storage ring built to prepare and store molecular ions in their rotational and vibrational ground states, enabling studies on electron-ion interactions. To reconstruct the reaction kinematics, MOCCA measures the energy and position of incident particles on the detector, even with multiple particles hitting the detector simultaneously.

We present a new read-out scheme which uses only 32 SQUID channels for the 4096 pixels of the detector as well as some new fabrication details including a new thermalization system and first experimental results.

#### TT 31.7 Thu 15:00 P1

From ECHo-1k to ECHo-100k: Optimisation of the High-Resolution Metallic Magnetic Calorimeters with Embedded ¹⁶³Ho — •MARKUS GRIEDEL¹, AR-NULF BARTH¹, SEBASTIAN BERNDT^{2,3}, LORENZO CALZA¹, HOLGER DORRER³, CHRISTOPH DÜLLMANN^{3,4,5}, CHRISTIAN ENSS¹, ANDREAS FLEISCHMANN¹, DANIEL HENGSTLER¹, TOM KIECK^{3,4,5}, NINA KNEIP², NEVEN KOVAC¹, FEDER-ICA MANTEGAZZINI¹, ANDREAS REIFENBERGER¹, ALEXANDER KAROL SLAWIK¹, KLAUS WENDT², and LOREDANA GASTALDO¹ — ¹Kirchhoff-Institute for Physics, Heidelberg University — ²Institute of Physics, Johannes Gutenberg University Mainz — ³Department of Chemistry - TRIGA Site, Johannes Gutenberg University mersity Mainz — ⁴GSI Helmholtzzentrum für Schwerionenforschung GmbH — ⁵Helmholtz Institute Mainz

The ECHo collaboration aims to determine  $m(v_e)$  by analysing the ¹⁶³Ho electron capture spectrum. Arrays of tens to hundreds of Metallic Magnetic Calorimeters (MMCs) implanted with ¹⁶³Ho have been chosen because of their excellent energy resolution in the range of a few eV, their fast response time below 1  $\mu$ s and their good linearity. The MMC array enclosing ¹⁶³Ho fabricated for the ECHo-1k phase has been fully characterised in terms of detector response, energy resolution and ¹⁶³Ho activity. Based on these results a new 64-pixel-array design has been conceived for ECHo-100k, featuring an optimised single pixel geometry and allowing for a ¹⁶³Ho activity of 10 Bq per pixel. First wafers, each with 40 ECHo-100k chips, have been fabricated and characterised. The obtained results show that the ECHo-100k array achieved the expected performance, especially an average energy resolution of 3.5 eV, fulfilling the requirements for the ECHo-100k phase.

#### TT 31.8 Thu 15:00 P1

Towards large-area 256-pixel MMC arrays with multiplexed read-out based on flux-ramp modulated dc-SQUIDs — •A. ABELN, S. ALLGEIER, L. EISEN-MANN, D. HENGSTLER, N. KAHNE, F. KRÄMER, D. MAZIBRADA, L. MÜNCH, A. STOLL, A. FLEISCHMANN, and C. ENSS — Kirchhoff-institute for Physics, Heidelberg University

Metallic Magnetic Calorimeters (MMCs) are energy-dispersive cryogenic particle detectors. Operated at about 20 mK, they provide very good energy resolution of down to 1.6 eV at 6 keV, high quantum efficiency as well as linearity over a large energy range. In many precision based experiments on high resolution X-ray spectroscopy the photon flux is small, thus a large active detection area is desirable. Therefore, arrays with a large number of MMC pixels are beneficial. For a cost-effective read-out of a growing number of detector channels we develop different multiplexing techniques.

In this contribution we present the design of a novel 16 × 16 pixel MMC array. Each pixel provides an active detection area of 250  $\mu$ m×250  $\mu$ m yielding a total active detection area of about 4 mm × 4 mm. With a thickness of 5  $\mu$ m the absorbers made of gold ensure a quantum efficiency of at least 50 % for energies up to 20 keV. The designed energy resolution according to numerical simulations is  $\Delta E_{\rm FWHM} = 1.4 \, {\rm eV}$  at an operation temperature of 20 mK. We also present the current status of flux-ramp multiplexing that allows to reduce the number of read-out channels by at least a factor of four compared to a conventional read-out.

#### TT 31.9 Thu 15:00 P1

**PrimA-LTD: Magnetic microcalorimeters for primary activity standardization** — •MICHAEL MÜLLER, RIA-HELEN ZÜHLKE, PETER KÄHLER, and SEBAS-TIAN KEMPF — Institute of Micro- and Nanoelectronic Systems, Karlsruhe Institute of Technology, Karlsruhe

Magnetic microcalorimeters (MMC) are cryogenic, energy-dispersive singleparticle detectors that consist of a paramagnetic temperature sensor which is in strong thermal contact with a particle absorber. The sensor is magnetized by a magnetic field generated by a persistent current in an underlying superconducting pickup coil. The resulting change of sensor magnetization upon an energy input into the detector is read out by a SQUID. Due to their excellent energy resolution as well as the very low threshold, MMCs are a key technology in the frame of the EMPIR-project "PrimA-LTD" aiming to measure decay spectra of several isotopes with unprecedented precision to enable activity standardization for medicine and industry. Within this project we designed three MMC based layouts optimized for measuring the spectra of  $\alpha$ -,  $\beta$ - and electron capture-decaying nuclides. We further developed a novel electroplating setup for the microfabrication of highly pure, 3D-structured particle absorbers made of Au to enable fast thermalization of the detector without position dependencies. Moreover, we started to develop a passive persistent current switch for injecting the persistent current allowing for easier detector handling and higher integration density in comparison to conventionally used heat switches. We summarize the present state of the project and outline ongoing next steps.

#### TT 31.10 Thu 15:00 P1

PrimA-LTD: Towards new primary activity standardization methods based on low-temperature detectors — •ALEXANDER GÖGGELMANN¹, JOERN BEYER², CHRISTIAN ENSS^{3,6}, SEBASTIAN KEMPF^{4,6}, KARSTEN KOSSERT¹, MARTIN LOIDL⁵, MICHAEL MÜLLER⁴, OLE NÄHLE¹, MICHAEL PAULSEN², PHILIPP CHUNG-ON RANITZSCH¹, MATIAS RODRIGUES⁵, and MATHIAS WEGNER^{4,6} — ¹Physikalisch-Technische Bundesanstalt (PTB), Braunschweig, Germany — ²Physikalisch-Technische Bundesanstalt (PTB), Berlin, Germany — ³Kirchhoff-Institute for Physics, Heidelberg University, Germany — ⁴Institute of Micro- and Nanoelectronic Systems, Karlsruhe Institute of Technology, Karlsruhe, Germany — ⁵CEA, LIST, Laboratoire National Henri Bequerel, Saclay, France — ⁶Institute for Data Processing and Electronics, Karlsruhe Institute of Technology, Karlsruhe, Germany

Radionuclide metrology, and in particular, activity standardization, is based on well-established measurement techniques that have been used and improved for decades. The methods and the achievable uncertainty are, however, very dependent on the type of radiation that is emitted and the quality of the available decay data. A major part of the EMPIR project "PrimA-LTD" consists in developing new primary techniques and in particular the high-resolution spectrometry of  241 Am,  129 I and  55 Fe using magnetic microcalorimeters (MMCs). The presentation will focus on the experimental details including the MMC detector setup, sample preparation and planned spectral measurements with more than 108 counts and energy thresholds below 50 eV.

## TT 31.11 Thu 15:00 P1

Fabrication process for Nb/Al-AlO_x/Nb Josephson tunnel junction based SQUIDs for magnetic microcalorimeter readout — •MARTIN NEIDIG, PAUL KAHRMANN, and SEBASTIAN KEMPF — Institute of Micro- and Nanoelectronic Systems, Karlsruhe Institute of Technology, Karlsruhe, Germany

Magnetic microcalorimeters (MMCs) are cryogenic particle detectors providing an excellent energy resolution, very fast signal rise time, an almost ideal linear detector response and a large dynamic range. These properties combined with a maturing fabrication process motivate the implementation of large MMC based detector arrays which poses the challenge of developing a suitable readout method. Small-scale arrays are typically readout using single-channel dc-SQUIDs with individual wiring, while large-scale arrays require a multiplexed readout scheme. One such multiplexing scheme is the microwave SQUID multiplexer which allows for the readout of hundreds of detectors via a common feedline. The realization of either readout method requires the use of SQUIDs and therefore a reliable fabrication process for high quality Josephson junctions.

For this purpose we established a fabrication process for Nb/Al-AlO_x/Nb based window-type Josephson tunnel junctions. Within this contribution, we outline the present status of our fabrication technology and, moreover, we discuss the performance of the fabricated junctions and results of our prototype dc-SQUIDs, which are presently used for several MMC based experiments.

#### TT 31.12 Thu 15:00 P1

Noise Thermometers for Milli-Kelvin Measurements in High Magnetic Fields and for Micro-Kelvin Temperatures — • PASCAL WILLER, CHRISTIAN STÄNDER, NATHALIE PROBST, SARAH PHILIPS, ANDREAS REISER, ANDREAS FLEISCHMANN, and CHRISTIAN ENSS — Kirchhoff-Institute for Physics, Heidelberg University. To measure the temperature in the presence of high magnetic fields is one of the big challenges in solid state physics labs. We recently started to construct a prototype of a cross-correlated, current sensing noise thermometer for mKtemperatures for application in high magnetic fields. The basic concept relies on the thermal movement of charge carriers in a resistor. DC-SQUIDs detect the corresponding noise signal which is then recorded via two identical but independent amplifier chains. The method of cross correlation is used to eliminate uncorrelated noise contributions from the amplifier chains. As resistor material we use an alloy of platinum and thungsten, Pt₉₂W₈, since this material is characterized by an extremely small temperature dependence of the electrical resistivity as well as the smallest magneto-resistance known to date. We show that this approach towards a relative primary thermometer for high magnetic fields is able to operate over a wide range of temperatures within less than 1% uncertainty.

Additionally, we developed a second noise thermometer based on an alloy of copper and silver called "CuSil" to measure down to  $\mu$ K-temperatures in the absence of magnetic fields.

We discuss the design and the necessary considerations of both thermometers and present first experimental results at mK temperatures.

TT 31.13 Thu 15:00 P1

Microprocessor controlled temperature measurement with Allen-Bradleycarbon- and Platinum-100-Sensors — •JELKO SEIBOTH and ANDREAS WIECK — Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum

This poster illustrates the setup of a device for the determination of temperatures between RT (294 K) and 4 K using Pt100 sensors and Allen-Bradley resistors with a RT value between 100  $\Omega$  and 1 k $\Omega$ . To measure the resistance, a Raspberry Pi with an analog-to-digital converter and upstream connected operational amplifiers is used. This combination provides a low price and easy further development.

The measurement is carried out with four-point technology, whereby, to reduce the temperature increase due to the electrical power consumed by the sensor, the supply of the Pt100 sensors is provided with constant current and that of the Allen-Bradley sensors with constant voltage. The device allows calibration for specific resistors and calculates the temperature from a polynomial fit function [1,2].

The determined value is shown on a display, recorded in a subsequently exportable file and output to a proportional connector with a voltage corresponding to the temperature. As the Raspberry Pi supports network connections via Ethernet and Wi-Fi, a remote retrieval or external database storage of the measurements may be implemented in the future. Calibration and temperature measurements were successfully taken to prove the functionality.

TT 31.14 Thu 15:00 P1

Characterization and optimization of different regenerator matrices on a single-stage pulse tube cryocooler — •DOMINIK SOARE^{1,2}, JACK-ANDRÉ SCHMIDT^{1,2}, BERND SCHMIDT^{1,2}, JENS FALTER², and ANDRÉ SCHIRMEISEN^{1,2} — ¹Justus-Liebig University Giessen — ²TransMIT GmbH

Closed-cycle cryocoolers have become an important cooling concept tool for scientific research at low temperatures [1]. We here focus on Gifford-McMahon (GM) type pulse tube cryocoolers (PTC), which offer long measurement periods and low maintenance. The regenerator of any regenerative cryocooler is essential for the cooling process [2]. The regenerator offers heat capacity as a storage for the gas temperature during the cooling cycle. It pre-cools or -heats the working gas and therefore the regenerator matrix is an important optimization factor.

The poster will display the influence of different regenerator matrices on the cooling performance of a single stage pulse tube cryocooler driven by a helium compressor with 2kW input power. Using the results, it is possible to get new insights of the optimization of the first stage of two-stage cryocoolers and therefore their overall cooling performance.

TT 31.15 Thu 15:00 P1

Materials losses in superconducting circuits based on tantalum thin films — •RITIKA DHUNDHWAL¹, THOMAS REISINGER¹, HAORAN DUAN², DIRK FUCHS¹, MATTHIEU LE TACON¹, JASMIN AGHASSI-HAGMANN², and IOAN M. POP¹ — ¹Institut für Quantenmaterialien und technologie (IQMT), Karlsruher Institut für Technologie (KIT) — ²Institut für Nanotechnologie (INT), Karlsruher Institut für Technologie (KIT)

Superconducting quantum circuits have very promising applications in the fields of quantum computing and detection. In general, their performance is limited by a variety of dissipation and noise sources. For mitigating these, the focus has been on improving microwave design and better fabrication processes. Another approach, recently in the spotlight, is to explore new materials entirely. One promising candidate superconducting material is Tantalum (Ta), which recently enabled record-breaking Transmon qubit lifetimes. However, there is a lack of conclusive evidence of the dominant loss mechanisms related to Ta. Here, we present a study of losses in epitaxial Ta films deposited using magnetron sputtering, with the aim of relating basic material properties and loss mechanisms. A variation in the deposition parameters (mainly substrate temperature) leads to structurally different films. We characterized these using high-resolution Xray diffraction, scanning electron microscopy and measurements of the superconducting transition temperature. In addition, we fabricated lumped element resonators from the films using e-beam lithography and measured their quality factors as a function of photon number and temperature.

#### TT 31.16 Thu 15:00 P1

The Influence of Continuous Electric Bias Fields on the Dielectric Loss of Atomic Tunneling Systems — •JAN BLICKBERNDT, CHRISTIAN STÄNDER, LUKAS MÜNCH, MARCEL HAAS, ANDREAS REISER, ANDREAS FLEISCHMANN, and CHRISTIAN ENSS — Kirchhoff-Institute for Physics, Heidelberg, Germany

The low temperature properties of amorphous solids are mainly determined by atomic tunneling systems (TSs), which are known to act as a major source of noise and decoherence in superconducting quantum devices. We investigate the non-equilibrium dielectric loss of atomic tunneling systems under the influence of continuous electric bias fields at very low temperatures. By measuring the quality factor of a micro-fabricated superconducting resonator, the dielectric loss of the sample is obtained. Simultaneously, an electric bias field can be applied via a cover electrode, which allows us to sweep TSs through resonance by modulating their energy splitting. Experimentally, we found that for slow changing bias fields, TSs are saturated by the driving field leading to a constant loss. For faster bias rates, more and more TSs are swept through resonance and therefore contribute to an increasing loss. In the limit of fast continuous bias sweeps relaxation in between consecutive crossings diminishes and multiple coherent Landau-Zener transitions are possible, reducing the loss back to the saturation limit. We are able to verify these experimental results with a Monte Carlo based numerical simulation that shows good qualitative agreement.

#### TT 31.17 Thu 15:00 P1

Electrically and Acoustically Biased Resonators for Investigations of Dielectric Low Temperature Properties of Amorphous Solids — •CHRISTIAN STÄN-DER, JAN BLICKBERNDT, JOYCE GLASS, BENEDIKT FREY, ANDREAS REIFEN-BERGER, ANDREAS FLEISCHMANN, ANDREAS REISER, and CHRISTIAN ENSS — Kirchhoff Institute for Physics, Heidelberg University, D-69120 Heidelberg

The low temperature properties of amorphous solids are governed by atomic tunnelling systems, which can be described as two-level systems (TLS) with a distribution of their energy splitting E, as assumed by the phenomenological standard tunnelling model. Recent interest in these systems due to their deteriorative effects on the performance of superconducting quantum devices lead to novel experimental investigations of atomic tunnelling systems driven by novel measurement techniques.

We use newly designed microfabricated superconducting LC-resonators to study the dielectric rf-response of the amorphous sample in the presence of an electric bias field. A novel method of applying this electrical bias field was introduced to the resonators. Compared to previous experiments, the bias field is applied via an electrode placed above the resonator chip. We present first results of this new way of introducing a bias, which modifies the energy splitting *E* of a TLS.

In addition we tried to achieve a similar effect as with the electrical bias field with a mechanical strain field. To induce such a strain field, the amorphous substrate of the resonator chip was flexed by a piezo-actuator.

#### TT 31.18 Thu 15:00 P1

**Quantum electrodynamics of cold deposited granular aluminum** – •AMEYA NAMBISAN¹, DENNIS RIEGER², SIMON GÜNZLER¹, WOLFGANG WERNSDORFER^{1,2,3}, and IOAN M POP^{1,2} – ¹Institute for Quantum Materials and Technology (IQMT), Karlsruhe Institute of Technology (KIT), Germany – ²Physikalisches Institut (PHI), Karlsruhe Institute of Technology (KIT), Germany – ³Institute Néel, CNRS Grenoble, France

In recent times, superconducting granular aluminium (grAl) has found increasing interest in the superconducting quantum circuits community because of its promising characteristics such as its tunable kinetic inductance, low microwave losses, high in-plane critical magnetic field, and a higher critical temperature compared with pure Al.

In general, the critical temperature of a grAl film depends on its resistivity until it reaches a superconducting-to-insulator transition. For samples evaporated at room temperature, a maximum of around 2.2K is reached for resistivity of about 1000  $\mu\Omega$ . The critical temperature rises even above 3K when grAl is deposited on a substrate held at a lower temperature of 100K.

This project aims to answer the question of increased Tc, which is yet to be understood microscopically, and other consequences of cold deposition, such as how a generally smaller – while more homogeneous – grain size positively affects the electrodynamics of the film. The test-bed used to characterise the electrodynamics are stripline resonators fabricated entirely from cold-deposited grAl, and measured in a cylindrical copper waveguide sample holder at cryogenic temperatures.

#### TT 31.19 Thu 15:00 P1

Compact high-kinetic inductance using stacked Josephson junctions — •ALEX S. KREUZER¹, THILO KRUMREY¹, HANNES ROTZINGER^{1,2}, and ALEXEY V. USTINOV^{1,2} — ¹Physikalisches Institut (PHI), Karlsruher Institut für Technologie (KIT) — ²Institut für Quantenmaterialien und -technologien (IQMT), Karlsruher Institut für Technologie (KIT)

Highly inductive elements are often required in modern superconducting quantum circuits, e.g. to form, together with a suitable capacitance, a large nondissipative impedance. One way of creating such a high inductance is to employ series arrays of Josephson junctions, as it is done in the fluxonium qubit. For conventionally made chains of Josephson junctions, a major limitation arises from the stray capacitance of the islands forming the junctions. This capacitance leads to undesirable parasitic resonances at GHz frequencies, which degrade the quantum coherence of the qubit.

We propose a new way of creating high-inductance elements by stacking Josephson junctions vertically thus avoiding the influence of the throughsubstrate capacitive coupling of the junction electrodes to the environment. Furthermore, we demonstrate that our approach allows for making extremely compact circuit components.

TT 31.20 Thu 15:00 P1

Towards machine learning models for NISQ processors — •ANDRAS DI GIOVANNI¹, HANNES ROTZINGER^{1,2}, ALEXEY V. USTINOV^{1,2}, ADRIAN AASEN³, MORITZ REH³, and MARTIN GÄRTTNER³ — ¹Karlsruhe Institute for Technology, Karlsruhe, Germany — ²Institut für QuantenMaterialien und Technologien, Karlsruhe, Germany — ³Heidelberg University, Heidelberg, Germany

Quantum simulators promise insights into quantum many-body problems in regimes where classical simulation methods hit a complexity wall. One challenge towards this goal is to develop well characterized building blocks that allow to scale up system sizes while conserving reliability in terms of errors. A promising platform for building such NISQ (noisy, intermediate-scale quantum) devices are superconducting quantum circuits. Our goal is to characterize small scale quantum processors with minimal experimental and post-processing cost. For this we implement schemes for machine learning assisted adaptive Bayesian tomography and apply them to experimental data obtained from a prototype few-qubit superconducting chip.

TT 31.21 Thu 15:00 P1

**Exploring the parameter regimes of superconducting Quarton qubits coupled via cross-Kerr nonlinearity** — •HOSSAM TOHAMY¹, ALEX SIEGFRIED KREUZER¹, THILO KRUMREY¹, HANNES ROTZINGER^{1,2}, and ALEXEY V. USTINOV^{1,2} — ¹Physikalisches Institut, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany — ²Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, 76021 Karlsruhe, Germany

Over the last two decades, tremendous efforts have been directed into studying superconducting qubits as a promising architecture for noisy intermediate-scale quantum processors to implement quantum simulations and algorithms. A recent superconducting qubit named the "Quarton" represents a generalized flux qubit featured by a quartic potential profile. It can offer positive, strong cross-Kerr nonlinearity compared to the ordinary linear dispersive coupling between qubits and resonators. This nonlinearity can be essential, e.g., to achieve the next milestones in quantum simulation, such as the simulation of model Hamiltonians where strong photon-photon interactions are possible via nonlinear elements.

To employ the quarton as a qubit and a coupler, a system of two primary quarton qubits coupled via a quarton qubit coupler is studied. We report on numerical results demonstrating the normal modes of the system. The calculations are based on a Hamiltonian derived from a circuit quantization model. The work is linked to ongoing experimental efforts for realizing multiqubit architecture based on quartons.

TT 31.22 Thu 15:00 P1

**Multilayer surface acoustic wave resonators at cryogenic temperatures** – •ALEXANDER JUNG^{1,2}, THOMAS LUSCHMANN^{1,2,3}, ACHIM MARX¹, RUDOLF GROSS^{1,2,3}, and HANS HUEBL^{1,2,3} – ¹Walther-Meissner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany – ²Physik-Department, Technische Universitaet Muenchen, Garching, Germany – ³Munich Center for Quantum Science and Technologies (MCQST), Munich, Germany

Circuit quantum acoustodynamics uses the piezoelectric coupling of surface acoustic waves (SAW) to superconducting qubits for the implementation of concepts known from circuit quantum electrodynamics [1,2]. In this approach, the role of electromagnetic field is replaced by an acoustic wave propagating at the speed of sound. Moreover, the wavelength of acoustic waves is of the order of the size of the artificial atom, and thus their interaction with the qubit can no longer be treated pointlike. SAW resonators are an essential building block for quantum acoustodynamics. Of particular interest is the integration of SAWs using a piezoelectric on a silicon substrate to combine highly coherent qubits with excellent SAW properties. However, this changes the properties of the SAWs in particular for thin piezoelectric films. Here, we present simulations and experimental studies of SAW resonators fabricated on bulk and thin film piezoelectric substrates at cryogenic temperatures to understand the SAW as multilayer system.

#### TT 31.23 Thu 15:00 P1

Flux-pumped Josephson Traveling Wave Parametric Amplifier - •DANIIL E. BAZULIN^{1,2}, KEDAR E. HONASOGE^{1,2}, LEON KOCH^{1,2}, YUKI NOJIRI^{1,2}, THOMAS LUSCHMANN^{1,2}, ACHIM MARX¹, STEFAN FILIPP^{1,2,3}, and KIRILL G. FEDOROV^{1,2} — ¹Walther-Meißner-Institut, 85748 Garching, Germany — ²Physik-Department, Technische Universität München, 85748 Garching, Germany - ³Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany

Development of scalable superconducting quantum computers requires an efficient read-out of multiple quantum bits. This goal can be achieved by exploiting broadband Josephson Traveling Wave Parametric Amplifiers (JTWPAs). These are typically based on arrays of superconducting nonlinear elements, such as various types of Superconducting Quantum Interference Devices (SQUIDs). Here, we report on fabrication and characterization of a specific type of the JTWPA based on aluminium asymmetric SQUIDs exploiting the three-wave mixing down-conversion process. With this approach we circumvent inherent JTWPA problems with phase-matching and are able to spatially separate signal and pump paths.

#### TT 31.24 Thu 15:00 P1

Measurement of single NV centers inside a solid immersion lens at mK temperature — •Amer Hasecic, IOANNIS KARAPATZAKIS, MARCEL SCHRODIN, RAINER KRAFT, and WOLFGANG WERNSDORFER — Physikalisches Institut, Karlsruher Institut für Technologie, Karlsruhe, Deutschland

A solid immersion lens (SIL) prevents refraction on a diamond-air surface and therefore increases the collection efficiency of detected photons [1]. SILs are nanofabricated by removing bulk material via focused ion beam technique. Here, we rely on accelerated gallium ions. The photon collection from single Nitrogen-Vacancy (NV) centers inside a solid immersion lens in bulk diamond is examined at mK temperatures. We aim to improve readout times for electron spin and nuclear spin states with the later being a promising system in quantum computing [2].

Quantum manipulation of NV centers in diamond with on-chip coplanar waveguides at mK temperatures — •IOANNIS KARAPATZAKIS, AMER HASE-CIC, MARCEL SCHRODIN, RAINER KRAFT, and WOLFGANG WERNSDORFER -Physikalisches Institut, Karlsruher Institut für Technologie, Karlsruhe, Deutschland

Quantum information technology is advancing in several physical fields. Optically addressable spins such as Nitrogen-Vacancy (NV) centers in the solid-state structure of diamond stand out for their versatile applications in quantum mechanics which range from quantum processing of information [1] to magnetic field sensing [2]. NV centers can be reliably initialized optically and have long coherence and relaxation times.

Here, the quantum manipulation of NV centers is shown inside a dilution refrigerator (sionludi) at mK temperatures. Using lithographically fabricated onchip coplanar waveguide circuits, Rabi oscillations can be driven with frequencies above 100 MHz at comparatively low microwave insertion power of 100 mW (20 dBm). This allows for fast manipulation of the NV center spin states at mK temperatures without excessive heating of the sample.

Navigation system for a low temperature STM - •TIMO KANDRA, ROMAN HARTMANN, MARCEL STROHMEIER, SARA KHORSHIDIAN, and Elke Scheer -University of Konstanz, Germany

To obtain spatially resolved spectroscopic information in laterally confined superconducting heterostructures, such as nanowires and flakes on insulating substrates, tunneling spectroscopy on distinct locations on those structures shall be performed. For this purpose a coarse approach system is needed that allows to locate the STM tip at the point of interest without crashing the tip and while operating at very low temperature, here, 300 mK. We developed a braille-like pattern that allows to determine the absolute position of the tip within a 100x100  $\mu m^2$ scan range by scanning any area of size  $1x1\mu m^2$ . The search structure made of gold is patterned by electron beam lithography and is realized by a topographical pattern composed of squares. With this method it is possible to navigate to the point of interest by using an *xy*-table.

## TT 32: Focus Session: Topological Devices (joint session TT/KFM)

The properties of topological phases of matter give rise to unique phenomena, such as edge or surface transport, spin-momentum locking, or topological protection against perturbations. Many years after their conception, several topological platforms have reached maturity, and research interests have shifted towards mesoscopic devices unveiling rich and new topological physics, driven in part by the perspectives of novel topological quantum computation. Within this Focus Session, recent examples of devices exploring or exploiting the topological properties of various phases of matter shall be discussed.

TT 32.1 Thu 15:00 H10 Supercurrents in HgTe-based topological nanowires - • DIETER WEISS stitute for Experimental and Applied Physics, University of Regensburg, 93040 Regensburg/Germany

Topological insulator (TI) nanowires in proximity to conventional superconductors constitute a tunable platform to realize topological superconductivity and Majorana zero modes [1]. Tuning is done by an axial magnetic flux  $\phi$  transforming the system from trivial at  $\phi = 0$  to topologically nontrivial when a magnetic flux quantum  $\phi_0 = h/2e$  threads the wire's cross-section. Here, we investigate the evolution of the supercurrent in ballistic HgTe Josephson junctions as a function of axial magnetic flux  $\phi$  and examine the periodicity of the supercurrent utilizing microwave irradiation and probing Shapiro steps. Suppressed odd Shapiro steps herald the existence of  $4\pi$ -periodic supercurrents, a signature of topological superconductivity. Our data suggest that at small  $\phi$  this  $4\pi$ -periodic supercurrent is of trivial origin but that at magnetic fields above  $\phi_0/2$ , topological  $4\pi$ -periodic supercurrents take over [2].

Majorana bound states and non-reciprocal transport in topological insulator nanowire devices — •HENRY LEGG — Department of Physics, University of Basel

I consider devices consisting of a three-dimensional topological insulator (TI) nanowire placed in proximity to an s-wave superconductor.

First, I will show that a non-uniform chemical potential induced, for instance, by gating enables the device to be brought into a topological superconducting phase at relatively weak magnetic fields with Majorana bound states (MBSs) present for an exceptionally large region of parameter space in realistic systems. I also consider the experimental challenges posed by the metallization effect that occurs as a result of bringing a TI nanowire into proximity with a superconductor.

Second, I will discuss non-reciprocal transport evidence for the subband splitting that is central to the proposal to achieve MBSs in TI nanowires. I will show that a giant magnetochiral anisotropy observed in the normal state of the TI nanowire provides strong evidence for the artificial breaking of inversion symmetry due to gating effects. Furthermore, I will argue that the superconducting diode effect can be used as measure of inversion symmetry breaking in the presence of a superconductor and to determine when the TI nanowire is in the region of parameter space where topological superconductivity is expected.

#### Invited Talk TT 32.4 Thu 16:45 H10 Universal fluctuations of the induced superconducting gap in an elemental nanowire — Lauriane Contamin, Lucas Jarjat, William Legrand, Audrey COTTET, TAKIS KONTOS, and •MATTHIEU DELBECQ — Laboratoire de Physique de l'Ecole Normale Supérieure, ENS, Université PSL, CNRS, Sorbonne Université, Université Paris-Diderot, Sorbonne Paris Cité, Paris, France.

Proximity induced superconductivity in a normal conductor is a rich field of experimental and theoretical investigations. Lately it has been at the heart of the quest for realizing topological modes in hybrid superconductor-nanowire nanodevices. Yet it turns out that there was a lack of investigations in elemental systems. In this work we therefore investigate an ultra-clean carbon nanotube coupled to a superconducting lead. We observe for the first time a long standing prediction of random matrix theory (RMT) that mesoscopic fluctuations of the mini-gap in a conductor follow a universal distribution with a clear transition when time reversal symmetry is broken, as predicted by RMT. Interestingly, mesoscopic fluctuations of the minigap were precisely predicted to lead to ubiquitous nontopological edge states clustering towards zero energy. We do indeed observe ubiquitous and robust zero bias conductance peaks under magnetic field in our device that cannot host topological modes by design. The RMT predictions that are compatible with our observations are very general and should be present in any system showing disorder. It therefore calls for alternatives to transport measurement to identify Majorana modes in 1D systems with microwave photons in a cavity as a promising platform.

#### **Invited Talk**

TT 32.5 Thu 17:15 H10 Exploring the full potential of edge channel transport in HgTe based two-dimensional topological insulators — •SAQUIB SHAMIM^{1,2}, WOUTER Beugeling^{1,2}, Pragya Shekhar^{1,2}, Jan Böttcher³, Andreas Budewitz^{1,2}, JULIAN-BENEDIKT MAYER³, LUKAS LUNCZER^{1,2}, JONAS STRUNZ^{1,2}, JOHANNES KLEINLEIN^{1,2}, EWELINA HANKIEWICZ³, BJÖRN TRAUZETTEL³, HARTMUT BUHMANN^{1,2}, and LAURENS MOLENKAMP^{1,2} — ¹Experimentelle Physik III, Physikalisches Institut, Universität Würzburg, Am Hubland, Würzburg, Germany — ²Institute for Topological Insulators, Universität Würzburg, Am Hubland, Würzburg, Germany — ³Institut für Theoretische Physik und Astrophysik, Universität Würzburg, Am Hubland, 97074 Würzburg, Germany.

In this talk, I will discuss some of our recent results on HgTe-based twodimensional topological insulators. Over the past few years, we have developed a chemical wet-etch technique to fabricate high-quality microstructures in HgTe quantum wells. Firstly, I will discuss some important achievements due to the wet-etch fabrication process: We fabricated quantum point contacts in topological HgTe quantum wells and investigated the interactions among helical edge channels. We also fabricated microstructures from (Hg,Mn)Te quantum wells and observed quantized conductance in these devices. Secondly, I will introduce a gate training method that allows us to approach conductance quantization in macroscopic devices. Finally, I will present recent magnetotransport results on

(Hg,Mn)Te quantum wells and the emergence of quantum Hall plateaus at extremely low magnetic fields (~ 50 mT).

#### TT 32.6 Thu 17:45 H10

Quantum non-Hermitian topological sensors —  $\ensuremath{\bullet}\xspace{Florian}$  Koch and Jan CARL BUDICH — Institute of Theoretical Physics, Technische Universität Dresden

Recent discoveries regarding the exceptional spectral and topological properties of non-Hermitian (NH) tight-binding models, e.g. their striking boundarysensitivity, have triggered the quest for constructing novel sensors [1,2]. Here, using quantum master equations we promote the architecture of such sensing devices to a fully quantum-mechanical framework. Specifically, we study a setting of weakly-coupled bosonic modes arranged in an array with broken ring geometry that would realize a NH topological phase in the classical limit. Employing methods from quantum-information theory of Gaussian states, we show that a small coupling induced between the ends of the broken ring may be detected with a precision that increases exponentially in the number of coupled modes. Our findings pave the way towards designing quantum NH topological sensors (QUANTOS) that may observe with high precision any physical observable that couples to the boundary conditions of the device [3].

#### TT 32.7 Thu 18:00 H10

First magnetic field measurements of a topological insulator based Transmon Qubit — •Anne Schmidt¹, Tobias W. Schmitt¹, Chenlu Liu², Albert Hertel¹, Christian Dickel³, Michael Schleenvoigt¹, Malcolm R. Connolly^{2,4}, Yoichi Ando³, Detlev Grützmacher¹, and Peter  ${\tt Schüffelgen}^1-{}^1{\tt Peter}$ Grünberg Institute & Jülich-Aachen Research Alliance, Forschungszentrum Jülich —  2 Blackett Laboratory, Imperial College London — ³Institute of Physics II, University of Cologne — ⁴London Centre for Nanotechnology, University College London

Hybrid topological insulator (TI) - superconductor (S) heterostructures are a promising platform for the realization of topologically protected quantum computation based on Majorana zero modes. This promises fewer physical qubits for creating a logical qubit compared to conventional superconducting qubits. Our full in situ device fabrication, which combines selective area growth of thin (Bi,Sb)₂Te₃ films and stencil deposition of superconductive Nb has already shown to create highly transparent S-TI interfaces. Recently, we have demonstrated that this fabrication process can readily be integrated into cQED structures as building block for a transmon qubit and performed coherence measurements at zero magnetic field. Here, we will expand these measurements to finite magnetic fields, as in-plane magnetic fields are a requirement for restoring the topological phase in confined (Bi,Sb)₂Te₃ nanostructures. We present initial results on the magnetic field dependence of the T₁ lifetime and the qubit's anharmonicity.

TT 32.8 Thu 18:15 H10 Kondo interactions of quantum spin Hall edge channels with charge pud-dles — •Christopher Fuchs^{1,2}, Pragya Shekhar^{1,2}, Saquie Shamim^{1,2}, Lena Fürst^{1,2}, Johannes Kleinlein^{1,2}, Jukka I. Väyrynen³, Hartmut Buhmann^{1,2}, and Laurens W. Molenkamp^{1,2} - ¹Physikalisches Institut, Universität Würzburg, Würzburg, Germany — ²Institute for Topological Insulators, Universität Würzburg, Würzburg, Germany — ³Department of Physics and Astronomy, Purdue University, West Lafayette, USA

Quantum spin Hall edge channels are protected against backscattering by timereversal symmetry. However, since the first observation of the quantum spin Hall effect in HgTe in 2007 it is known that reproducible fluctuations shape the quantization plateau when the chemical potential is tuned through the bulk gap. Here, those fluctuations are examined in high-quality micron-sized quantum well structures of HgTe at millikelvin temperatures. By performing temperature and gate-dependent measurements, we conclude that the observed conductance fluctuations indicate interactions of the edge channel electrons with individual charge puddles – microscopic fluctuations in the potential landscape commonly observed in narrow gap semiconductors - that act like Kondo correlated quantum dots. The resulting spin-flip backscattering gives rise to a distinct Kondolike temperature dependence of the conductance fluctuations, which is backed up by theoretical modelling. Our results provide insight into the leading mechanism of decoherence of quantum spin Hall edge channels.

TT 33.1 Thu 15:00 H22

Investigating the non-equilibrium dynamics of two-level systems at low temperature — •MARCEL HAAS, MAREIKE DINGER, LUKAS MÜNCH, JAN BLICK-BERNDT, ANDREAS REISER, ANDREAS FLEISCHMANN, and CHRISTIAN ENSS — Kirchhoff-Institute for Physics, Heidelberg, Germany

The dielectric loss of amorphous materials along with noise and decoherence is the major limiting factor in many applications like superconducting circuits, Josephson junctions and quantum computing. It is mainly determined by atomic tunneling systems described by quantum mechanical two-level systems (TLS), which are broadly distributed low-energy excitations in the sample. The spontaneous phonon emission of an excited TLS gives rise to a relaxation time  $T_1$  and the interaction between TLSs with their thermally excited surrounding induces a decoherence time  $T_2$ . These effects mainly determine the measurable dielectric loss in the observed material, which we ascertain by measuring the quality factor of a bridge type superconducting LC-resonator. The dielectric medium in between the capacitor plates is a sputter deposited a-SiO₂ film. The setup shows a unique property when two off-resonant pump tones are applied symmetrically. In this limit, the resonator is emitting at the intermediate frequency of the driving fields. The underlying mechanism can therefore be explained by a nonlinear interaction of the rf-field with the TLSs and the resonator which is creating additional lines in the frequency spectrum. We present first measurements at a frequency of 1 GHz performed with a micro-fabricated superconducting resonator.

#### TT 33.2 Thu 15:15 H22

**Photoinduced prethermal order parameter dynamics in the two-dimensional large-N Hubbard-Heisenberg model** — •ALEXANDER OSTERKORN and STEFAN KEHREIN — University of Göttingen, Göttingen, Germany

A central topic in current research in non-equilibrium physics is the design of pathways to control and induce order in correlated electron materials with time-dependent electromagnetic fields. The theoretical description of such processes, in particular in two spatial dimensions, is very challenging and often relies on phenomenological modelling in terms of free energy landscapes. We discuss a semiclassical time evolution scheme that includes dephasing dynamics beyond mean-field and allows to simulate the light-induced manipulation of prethermal order in a two-dimensional model [1] with competing phases microscopically. We calculate the time evolution of the relevant order parameters subsequent to driving with a short laser pulse [2]. The induced prethermal order does not depend on the amount of absorbed energy alone but also explicitly on the driving frequency and amplitude. While this dependency is pronounced in the low-frequency regime, it is suppressed at high driving frequencies.

#### TT 33.3 Thu 15:30 H22

Nonequilibrium dynamics in pumped Mott insulators — •SATOSHI EJIMA¹, FLORIAN LANGE², and HOLGER FEHSKE^{1,2} — ¹Institut für Physik, Universität Greifswald, Greifswald, Germany — ²Erlangen National High Performance Computing Center, Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany

The study of systems under optical excitation receives tremendous attention because of both the recent rapid developments of ultrafast pump lasers and the discovery of striking phenomena not observable in equilibrium. Various numerical techniques have been applied to optically excited systems to study nonequilibrium dynamics, e.g., the time-dependent version of exact-diagonalization technique or dynamical mean-field theory. Results for nonequilibrium dynamics based on tensor-network algorithms are still rare, however.

In this talk, we propose a direct numerical scheme in the matrix-productstates (MPS) representation for the computation of nonequilibrium dynamic response functions, which can be used for general (quasi-)one-dimensional systems. Using time-evolution techniques for (infinite) MPS, we calculate, directly in the thermodynamic limit, the time-dependent photoemission spectra and dynamic structure factors of the half-filled Hubbard chain after pulse irradiation. These quantities exhibit clear signatures of the photoinduced phase transition from insulator to metal that occurs because of the formation of so-called  $\eta$  pairs. [1] S. Ejima et al., Phys. Nonequilibrium non-Markovian steady states in open quantum many-body systems: Persistent oscillations in Heisenberg quantum spin chains — •REGINA FINSTERHOELZL¹, MANUEL KATZER², and ALEXANDER CARMELE² — ¹Department of Physics, University of Konstanz, Germany — ²Institute of Theoretical Physics, Technical University Berlin, Germany

We investigate the effect of a non-Markovian, structured reservoir on an open Heisenberg spin chain by applying coherent time-delayed feedback control to it. The structured reservoir couples frequency-dependent to the spin chain and therefore induces a memory, thus the spin chain interacts partially with its own past. We demonstrate that with this new paradigm of a non-Markovian temporal driving scheme, it is possible to generate persistent oscillations within the many-body system and thus induce highly non-trivial states which dynamically store excitation within the chain. These oscillations occur at special points in the stability landscape and persist for different chain lengths and different initial excitations within the chain. We propose a non-invasive partial characterization of the chain by exploiting the fact that the different trapping conditions which arise each relate to specific steady states within the chain.

**Approaching the time-dependent quantum many-body problem with Artificial Neural Networks** — •PIT NEITEMEIER and DANTE KENNES — RWTH Aachen Institut für Theorie der statistischen Physik

Numerical solutions to quantum many body problems pose a significant challenge due to the curse of dimensionality. In this work I propose a novel Artificial Neural Network (ANN) ansatz and an unsupervised learning scheme to efficiently and flexibly solve time dependent quantum many-body problems. Contrary to previous work I do not rely on ODE Solvers for the time evolution, but parametrize the full wave function using an ANN. This enables a constant cost evaluation and full differentiablity of the wave function. Furthermore I show that it is possible to learn solution bundles that continuously represent the solution for a range of external parameters. The training of these ANNs is highly parallelizeable and reduces sequential operations significantly in comparison to previous work. I benchmark the ansatz for quantum quenches, ramps and pulses of the magnetic field using 1D Ising and Heisenberg Chains.

**Entanglement phase transitions in correlated 1D spin chains** — •MONALISA SINGH ROY, JONATHAN RUHMAN, EMANUELE G. DALLA TORRE, and EFRAT SHIMSHONI — Department of Physics, Bar-Ilan University, Ramat Gan, Israel Entanglement phase transitions have attracted immense attention in recent years especially in the context of monitored quantum circuits. In such systems the dynamics due to unitary evolution compete with the localization induced by measurements. The phase transition of quantum systems from a phase where its entanglement entropy exhibits volume law for weak monitoring, to a quantum Zeno like phase with where the entanglement entropy obeys area law is well known in many models with unitary dynamics. Some recently proposals have identified a critical phase with a logarithmic scaling of entanglement in non-Hermitian models. We explore such a critical transition in a monitored quantum spin chain model and identify the entanglement transitions in the system under both unitary and non-unitary evolutions.

#### TT 33.7 Thu 16:30 H22

**Feynman-Vernon influence functional approach to quantum transport in interacting nanojunctions: An analytical hierarchical study** — •LUCA MAGAZZU and MILENA GRIFONI — University of Regensburg

We present a nonperturbative and formally-exact approach to the charge transport in interacting nanojunctions using a real-time path-integral method based on the Feynman-Vernon influence functional. Expansion of the influence functional in terms of the number of tunneling transitions results in an exact generalized master equation for the populations in the occupation-number representation, and in a formally exact expression for the current. We apply our method to the exactly solvable resonant level model (RLM) and to the single-impurity Anderson model (SIAM). For both systems, we demonstrate a hierarchical diagrammatic structure. While the hierarchy closes at the second tier for the RLM, this is not the case for the interacting SIAM. Upon inspection of the current kernel, known results from various perturbative and nonperturbative approximation schemes to quantum transport in the SIAM are recovered. Using a simplified fourth-tier scheme, analytical results for the interacting SIAM are presented both in equilibrium and nonequilibrium and with an applied magnetic field. [1] L. Magazzù and M. Grifoni, Phys. Rev. B 105, 125417 (2022)

Periodically driven quantum many-body systems host unconventional behavior not realized at equilibrium. Here we investigate such a setup for strongly interacting spinless fermions on a chain, which at zero temperature and strong

#### Location: H22

interactions form a charge density wave insulator. Using unbiased numerical matrix product state methods for time-dependent spectral functions, we find that driving of the correlated charge-density wave insulator leads not only to a renormalization of the excitation spectrum as predicted by an effective Floquet Hamiltonian [1], but also to a cosine-like in-gap feature [2]. This is not obtained for a charge density wave model without interactions. A mean-field treatment provides a partial explanation in terms of doublon excitations. However, the full picture needs to take into account strong correlation effects. [1] Phys. Rev. Lett. 120, 127601 (2018) [2] arXiv:2205.09557

Non-equilibrium phases of matter in 2D using Projected Entangled Pair States — •AUGUSTINE KSHETRIMAYUM^{1,2}, DANTE KENNES³, and JENS EISERT^{1,2} — ¹Freie University Berlin, Germany — ²Helmholtz-Zentrum Berlin, Germany — ³RWTH Aachen University, Germany

We explore the highly challenging realm of non-equilibrium physics in two spatial dimensions using infinite Projected Entangled Pair States (iPEPS), a twodimensional tensor network ansatz directly in the thermodynamic limit. By adding disorder in a translationally invariant setting through the use of auxiliary states, we find evidence of Many-body localization (MBL) and Quantum time crystals in 2D.

In our discrete disorder setting, we show that many levels of disorder is required in order to achieve localization and ultimately time crystalline behavior. We discuss how our setting can be realized in programmable quantum simulators.

**Charge transport in hybrid semiconductor-cavity systems: an exact diagonalization study** — •SEBASTIAN STUMPER and JUNICHI OKAMOTO — Institute of Physics, University of Freiburg, Freiburg, Germany

Recent experiments demonstrate that the conductivity of organic semiconductors can be enhanced by hybridization with a plasmonic surface [Nat. Mat. 14, 1123 (2015)]. Motivated by these findings, we study a two-band tight-binding chain resonantly coupled to a photonic mode by an exact diagonalization technique. First, we argue that the exciton density and photon number are suppressed by the band gap, an effect which is neglected by the commonly used rotating wave approximation. Second, we determine the excitation of the semiconductor and its impact on the conductivity beyond the rotating wave approximation, i.e., including the off-resonant terms. Clean and disordered cases are compared. Finally, we discuss the real-time dynamics of electrons and holes under a uniform electric field.

Interplay of disorder and interactions in a periodically driven ultracold atomic system — •ARIJIT DUTTA — Institut für Theoretische Physik, Goethe-Universität, 60438 Frankfurt am Main, Germany

Periodically driven clean noninteracting systems are known to host several interesting topological phases. Particularly, for high frequency driving, they have been found to host the analogues of equilibrium topological phases, like the Haldane phase. However, upon lowering the driving frequencies these systems have been found to host anomalous phases with robust edge modes despite all Chern numbers being zero. Moreover, theoretical works have shown that adding disorder to such anomalous phases leads to quantized charge pumping through the edge modes even when all bulk states become localised. We investigate the fate of these phases in presence of electron-electron interactions of the Falicov-Kimball type.

TT 33.12 Thu 18:00 H22 Non-equilibrium optical conductivity for striped states: A time-dependent Gutzwiller analysis for the single-band Hubbard model — •CHRISTIAN MARTENS and GÖTZ SEIBOLD — BTU Cottbus-Senftenberg, Institute of Physics, 03046 Cottbus, Germany

In recent years pump-probe experiments have turned out as a powerful tool to investigate the dynamics of correlated materials, e.g. transition metals or heavy fermion systems. In these experiments the system is prepared in a non-equilibrium state by a strong laser pulse, where the relaxation is afterwards examined by standard optical techniques. This method has also been applied to stripe ordered nickelates and cuprate superconductors where it allows to study the coupled order-parameter dynamics of charge- and spin-density waves and superconductivity.

Here we use the time-dependent Gutzwiller approximation for the singleband Hubbard model to analyse the non-equilibrium dynamics for stripe ground states of different symmetry. In particular we are interested in the interplay between spin and charge dynamics which is analysed by quenching the system in the charge or spin sector. This allows us to investigate the coupled relaxation dynamics as a function of the inserted energy. In contrast to the Hartree-Fock + random-phase-approximation the optical conductivity shows high-energy double occupancy fluctuations in addition to the low-energy collective mode. In the out-of equilibrium regime we find a softening of both modes depending on the inserted energy. Moreover the double occupancy exitation broadens into a continuum.

**The fate of the spin polaron in the 1D t-J model** — •PIOTR WRZOSEK — Institute of Theoretical Physics, Faculty of Physics, University of Warsaw, Pasteura 5, PL-02093 Warsaw, Poland

We study the intrinsic origin of the well-established differences in the motion of a single hole in the 1D and 2D antiferromagnet. To this end, we consider a 1D t-J model, perform the slave fermion transformation to the holon-magnon basis, and solve the obtained model in a numerically exact manner. We explicitly show that the spin polaron quasiparticle, which is well-known from the studies of a single hole in the 2D antiferromagnet, is destroyed in the 1D t-J model by the magnon-magnon interactions. Nevertheless, we observe surprising similarities between the spectra obtained with and without magnon-magnon interactions, indicating that some of the key features of the spin polaron physics are still preserved in 1D.

#### TT 34.2 Thu 15:15 H23

Huge enhancement of the thermal conductivity in the Tomonaga-Luttingerliquid region of YbAlO₃ — •PARISA MOKHTARI^{1,2}, ULRIKE STOCKERT¹, and ELENA HASSINGER^{1,2} — ¹Max-Planck-Institute for Chemical Physics of Solids, Dresden, Germany — ²Physics Department, Technical University of Munich, Garching, Germany

In 2019, Wu et al. found the typical excitation spectrum of the spinons in the Q-1D material YbAlO₃ via neutron scattering at 1 K. YbAlO₃ exhibit AFM ( $J_c$ =2.3 K) and FM ( $J_a$ =0.8 K) exchange interaction along and perpendicular to the chain direction, respectively [1, 2]. In zero field, a 3D AFM order is established at 0.88 K. For fields along a, perpendicular to the chain, this order is suppressed and replaced by an IC-AFM state, until the FI-FM state occurs for B >1.5 T.

It is an open question, if magnetic excitations in this material carry heat, and how they interact with phonons. Hence, we investigate the low-T  $\kappa$  of YbAlO₃ down to 30 mK in fields up to 4 T. The phase diagram is successfully reproduced with pronounced anomalies in both T and B sweeps. A clear additional anomaly

Location: H23

in the field dependence at low T confirms a crossover within the IC phase, which was suggested before based only on a tiny plateau appearing in the magnetisation. We find a large variation of the  $\kappa$  throughout the phase diagram indicating strong magneto-elastic coupling. In addition, a substantial enhancement of kappa is observed in the proposed TLL region.

Counting statistics in interacting one-dimensional conductors — •OLEKSIY KASHUBA¹, ROMAN RIWAR¹, FABIAN HASSLER², and THOMAS SCHMIDT³ — ¹Forschungszentrum Jülich — ²RWTH Aachen — ³Luxemburg Uni

The calculation of the cumulant generating function of a given observable, such as the charge, is nontrivial even for the non-interacting systems. This problem is closely connected to the problem of Toeplitz eigenvalues and the Szego-Kac theorem [1]. The application of the latter leads to a violation of the moment generating function's periodicity along the counting field. This periodicity can be restored using the Fisher-Hartwig conjecture, as was shown for non-interacting one-dimensional electrons [2]. Here, we aim to go beyond and include interactions. For weak interactions, a modification of the Matsubara diagrammatic approach was developed, allowing us explicit calculation of the interaction corrections to the cumulant generating function. All obtained terms preserve the periodic constraint of the moment generating function. The obtained result is in a good agreement at low filling with the noise suppression in Luttinger liquid for K<1. We also found a surprising counterpart of the charge-density wave effect in the cumulant generating function.

Enhancement of pair correlations in the asymmetric Hubbard ladder — •ANAS ABDELWAHAB and ERIC JECKELMANN — Leibniz Universität Hannover, Hannover, Germany

We investigated an extension of the asymmetric two-leg Hubbard ladder model [1,2] that consists of different on-site interaction  $U_y$  and intra-hopping  $t_y$  on each leg y using the density matrix renormalization group method. We calculated pair binding energy, charge, spin and single particle gaps as well as pairing correlation functions for several sets of model parameters. It is possible to adjust the asymmetry of model parameters to retain finite pair binding energy and enhanced pairing correlation functions similar to those appearing in symmetric two-leg Hubbard ladders. Such adjustment represents an interpolation between doped Mott insulator and doped charge transfer insulator.

Magnetic properties of a quantum spin ladder material in proximity to the isotropic limit — •SERGEI ZVYAGIN — Dresden High Magnetic Field Laboratory (HLD-EMFL), Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany

We report on the synthesis, crystal structure, magnetic, thermodynamic, and electron-spin-resonance properties of the coordination complex  $[Cu_2(pz)_3(4-HOpy)_4](ClO_4)_4$  [pz = pyrazine; 4-HOpy = 4-hydroxypyridine] [1]. This material is identified as a spin-1/2 Heisenberg ladder system with exchange-coupling parameters  $J_{rung}/k_B = 12.1(1)$  K and  $J_{leg}/k_B = 10.5(3)$  K [ $J_{rung}/J_{leg} = 1.15(4)$ ]. For single crystals our measurements revealed two critical fields,  $\mu_0H_{c1} = 4.63(5)$  T and  $\mu_0H_{c2} = 22.78(5)$  T (for  $H \parallel a^*$ ), separating the gapped spin-liquid, gapless Tomonaga-Luttinger-liquid, and fully spin-polarized phase. No signature of a field-induced transition into a magnetically ordered phase was found at temperatures down to 450 mK. The material bridges an important gap by providing an excellent physical realization of an almost isotropic spin-1/2 strong-rung Heisenberg ladder system with modest exchange-coupling energy and critical-field scales.

Finite-temperature optical conductivity with density-matrix renormalization group methods for the Holstein polaron and bipolaron with dispersive phonons — •DAVID JANSEN¹, JANEZ BONČA^{2,3}, and FABIAN HEIDRICH-MEISNER¹ — ¹Institute for Theoretical Physics, University of Göttingen — ²J. Stefan Institute, Ljubljana — ³Faculty of Mathematics and Physics, University of Ljubljana

We compute the optical conductivity for the Holstein polaron and bipolaron with dispersive phonons at finite temperature using a matrix-product state based method. We combine purification [1], to obtain the finite-temperature states, together with the parallel time-dependent variational principle (pTDVP) [2] algorithm to compute the real time current-current correlation functions. The pTDVP algorithm utilizes local basis optimization [3] to efficiently treat the phononic degrees of freedom. For the polaron, we find that the phonon dispersion alters the optical conductivity at several temperatures in the weak, intermediate, and strong coupling regime. In the two first cases, we see that the spectrum goes from being continues to discrete when going from a downwards to a upwards phonon dispersion. In the strong coupling regime, the dispersion leads to a shift of the center of the spectrum. For the bipolaron, we study the effect of dispersion in both the weak and strong electron-phonon coupling regime, and thus see its influence on both a delocalized and a localized bipolaron.

This research was supported by the DFG via SFB 1073.

**Cavity-induced long-range interactions in strongly correlated systems** — •PAUL FADLER¹, JIAJUN LI², KAI PHILLIP SCHMIDT¹, and MARTIN ECKSTEIN¹ — ¹Friedrich-Alexander-Universität Erlangen-Nürnberg — ²Paul Scherrer Institut In recent years, the coupling of optical cavity modes to solid states systems has emerged as a possible way to control material properties. Here we investigate cavity-induced long-range interactions between spins in a Mott insulator, which are a new feature of the coupling to the quantized cavity field, and are absent in a control of magnetism by classical light. In detail, for the Fermi-Hubbard model at half filling we show that the cavity coupling leads to long-range four-spin terms in the effective low spin model at large onsite interaction *U*, in addition to the conventional antiferromagnetic Heisenberg exchange interaction.

To obtain these long-range interactions, we compare exact diagonalization, a perturbative approach based on the effective spin-photon Hamiltonian descrip-

tion of the system, and fourth-order perturbation theory in the Hubbard model. We show that the phenomenologically motivated spin-photon Hamiltonian fails to describe the interactions properly close to resonances of the cavity and charge excitations. It is therefore not possible to perturbatively treat cavity coupled correlated systems in an effective spin basis.

Magnetism and Mottness in the anisotropic triangular lattice Hubbard model: a cellular dynamical mean-field study — •MARCEL KLETT¹, HENRI MENKE², MICHEL FERRERO³, ANTOINE GEORGES³, and THOMAS SCHÄFER¹ — ¹Max Planck Institute for Solid State Research, Stuttgart, Germany — ²University of Erlangen-Nuremberg, Erlangen, Germany — ³College de France, Paris, France

We investigate the phase diagram of the anisotropic triangular lattice Hubbard model in a center-focused cellular dynamical mean-field theory (CDMFT) approach using an impurity with 7 sites. We investigate the Mott metal-to-insulator transition and crossover region as well as the superconducting phase. Using a spin symmetry-broken approach of the CDMFT, allowing for a rotations of spins on the Bloch sphere, we are able to investigate the magnetic ordering of the different cluster schemes.

TT 34.9 Thu 17:15 H23

Competing orders in a two-dimensional Su-Schrieffer-Heeger model — •ANIKA GÖTZ¹, MARTIN HOHENADLER^{1,2}, and FAKHER ASSAAD^{1,3} — ¹Institut für Theoretische Physik und Astrophysik, Universität Würzburg, 97074 Würzburg, Germany — ²Independent Researcher, Josef-Retzer-Str. 7, 81241 Munich, Germany — ³Würzburg-Dresden Cluster of Excellence ct.qmat, Am Hubland, 97074 Würzburg, Germany

We study a two-dimensional Su-Schrieffer-Heeger model of electrons coupled to Einstein phonons with auxiliary-field quantum Monte Carlo simulations. By adding a symmetry-allowed interaction, the phonons can be integrated out at the expense of imaginary-time correlations of the discrete Hubbard-Stratonovich fields. Using single spin-flip updates, we investigate the phase diagram at the O(4)-symmetric point as a function of hopping t and phonon frequency  $\omega_0$ . For low phonon frequencies, the C₄ lattice symmetry is broken by valence bond order. Depending on t, the ordering wavevector is either  $(\pi, \pi)$  or  $(\pi, 0)$ , the latter value being accompanied by a dynamically generated  $\pi$ -flux in each plaquette. At larger  $\omega_0$ , the O(4) symmetry is spontaneously broken by long-range antiferromagnetic (AFM) order. In the limit  $t \rightarrow 0$ , the model maps onto an unconstrained Z₂ gauge theory coupled to fermions which is in its confined phase for the parameters considered. Whereas the  $(\pi, 0)$ -VBS to AFM transition is a candidate for a deconfined quantum critical point, the details of the  $(\pi, 0)$ -VBS to  $(\pi, \pi)$ -VBS to AFM transitions are still under investigation.

TT 34.10 Thu 17:30 H23

Splitting of topological charge pumping in an interacting two-component fermionic Rice-Mele Hubbard model — •ERIC BERTOK¹, FABIAN HEIDRICH-MEISNER¹, and ARMANDO A. ALIGIA² — ¹Institute for Theoretical Physics, Georg-August-Universität Göttingen — ²Centro Atómico Bariloche and Instituto Balseiro, Bariloche, Argentina

A Thouless pump transports an integer amount of charge when pumping adiabatically around a singularity. We study the splitting of such a critical point into two separate critical points by adding a Hubbard interaction. Furthermore, we consider extensions to a spinful Rice-Mele model, namely a staggered magnetic field or an Ising-type spin coupling, further reducing the spin symmetry. The resulting models additionally allow for the transport of a single charge in a twocomponent system of spinful fermions, whereas in the absence of interactions, zero or two charges are pumped. In the SU(2)-symmetric case, the ionic Hubbard model is visited once along pump cycles that enclose a single singularity. Adding a staggered magnetic field additionally transports an integer amount of spin while the Ising term realizes a pure charge pump. We employ real-time simulations in finite and infinite systems to calculate the adiabatic charge and spin transport, complemented by the analysis of gaps and the many-body polarization to confirm the adiabatic nature of the pump. The resulting charge pumps are expected to be measurable in finite-pumping speed experiments in ultra-cold atomic gases. We discuss the implications of our results for a related quantumgas experiment by Walter et al. [arXiv:2204.06561].

Thermodynamics of the metal-insulator transition in the extended Hubbard model from determinantal quantum Monte Carlo — •ALEXANDER SUSHCHYEV and STEFAN WESSEL — RWTH Aachen University

We use finite-temperature determinantal quantum Monte Carlo simulations to study the thermodynamic properties of the extended Hubbard model on the square lattice at half-filling. In particular, we consider the effect of a nearestneighbor and a long-range Coulomb repulsion on the thermal metal-insulator transition in the Slater regime at intermediate coupling. Within the parameter

regime accessible to sign-free quantum Monte Carlo simulations we explore in detail the temperature dependence of the double occupancy and entropy. Notably, we probe for signatures of a first-order metal-insulator transition driven by the suppression of correlation effects by the non-local interactions, as proposed in [1].

TT 34.12 Thu 18:00 H23 Surrogate models for quantum spin systems based on reduced order mod- $\textbf{elling} - \textbf{•} Stefan Wessel^1, Michael Herbst^1, Benjamin Stamm^1, and Mat-$ TEO RIZZI² - ¹RWTH Aachen University - ²University of Cologne and FZ Iülich

We present a methodology to investigate phase-diagrams of quantum spin models based on the principle of the reduced basis method. It is based on constructing a low-dimensional basis built from solutions of snapshots, i.e., ground states corresponding to particular and well-chosen parameter values. We propose to use a greedy-strategy to assemble the reduced basis and thus to select the parameter points where the full model is solved. Once the reduced basis is computed, observables required for the computation of phase-diagrams can be computed with a computational complexity independent of the underlying Hilbert space for any parameter value. We illustrate the accuracy of this approach for a geometrically frustrated antiferromagnetic two-dimensional lattice model and quantum spin model that describes a chain of excited Rydberg atoms.

**Bound by three-body interactions** — •GARY FERKINGHOFF¹, LEANNA Müller¹, Umesh Kumar², Götz S. Uhrig¹, and Benedikt Fauseweh³ — ¹Condensed Matter Theory, Technische Universitat Dortmund, Otto-Hahn-Straße 4, 44227 Dortmund, Germany — ²Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA - ³Institute for Software Technology, German Aerospace Center (DLR), Linder Hohe, 51147 Cologne, Germany

Stable bound quantum states are ubiquitous in nature. Mostly, they result from the interaction of only pairs of particles, so called two-body interactions, even when complex many-particle structures are formed. We show that three-quasiparticle bound states occur in a generic, experimentally accessible solid state system: antiferromagnetic spin ladders, related to high-temperature superconductors. Strikingly, this binding is induced by genuine three-quasi-particle interactions; without them there is no bound state. We compute the dynamic exchange structure factor required for the experimental detection of the predicted state by resonant inelastic x-ray scattering for realistic material parameters. Our work enables us to quantify these elusive interactions and unambiguously establishes their effect on the dynamics of the quantum many-particle state. In this talk we will present the main results of our study, briefly explain the theoretical tools that we used and present an experimental setting for verifying our theoretical results.

Non-linear response functions and disorder: The case of the photo galvanic effect — •Konstantinos Ladovrechis and Tobias Meng — Institute for Theoretical Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, Technische Universität Dresden, Germany

The circular photogalvanic effect (CPGE) is a non-linear photocurrent which is generated in materials with broken inversion symmetry when they are shed with circularly polarised light. In Weyl semi-metals, the CPGE is quantized in terms of fundamental constants and the Chern numbers associated with the Weyl nodes. In this work, we investigate the effect of pointlike disorder onto the quantization of CPGE. Implementing 1st-order and self-consistent Born approximations, we identify that the quantization of CPGE is broken and perturbative corrections in the scattering strength emerge, which we further classify in terms of self-energy and vertex corrections.

## TT 36: Focus Session: Ultrafast Spin, Lattice and Charge Dynamics of Solids

This focus session deals with a current and interdisciplinary topic, which is of interest to many researchers in solid state physics. The focus is on the generation and manipulation of new effects such as switching the macroscopic magnetic order, the driving of metal-insulator transitions, and the observation of purely quantum mechanical phenomena in excited states (e.g., the squeezing of phonons) on the femtosecond time scale using laser pulses. The long-term goal is the coherent control of degrees of freedom in solids. The relevant issues are light-matter interaction on the ultrashort time scale, non-equilibrium dynamics of magnetic, phononic and electronic degrees of freedom, many-particle physics and strong correlations.

Coherent electronic control of an insulator-to-metal transition - •CLAUDIO GIANNETTI, PAOLO FRANCESCHINI, and ALESSANDRA MILLOCH — Università Cattolica del Sacro Cuore, Brescia (Italy)

Managing light-matter interaction on timescales faster than the loss of electronic coherence is key for achieving the full quantum control of final products in solidsolid transformations. Here, we demonstrate coherent electronic control of the photoinduced insulator-to-metal transition in the prototypical Mott insulator V₂O₃. Selective excitation of a specific interband transition with two phaselocked light pulses manipulates the orbital occupation of the correlated bands in a way that depends on the coherent evolution of the photoinduced superposition of states.

Comparison between experimental results and numerical solutions of the optical Bloch equations indicates an electronic coherence time on the order of 5 fs. Temperature dependent experiments suggest that the electronic coherence time is enhanced in the vicinity of the insulator-to-metal transition critical temperature, thus highlighting the role of fluctuations in determining the electronic coherence. These results open new routes to selectively switch functionalities of quantum materials and store quantum information in solid-solid transformations.

TT 36.4 Fri 11:15 H10 Nanoscale transient magnetization dynamics: A comprehensive EUV TG study — •LAURA FOGLIA — Elettra Sincrotrone Trieste, Trieste, Italy

The advent of X-ray free electron lasers (FELs) has allowed to overcome the wavelength limitations of optical radiation to manipulate and study magnetic phenomena on nanometer length- and femtosecond time-scale, which is paramount for light-controlled ultrafast magnetic data processing and storage applications. In this talk, we review the most recent advances on the EUV TG-based investigation of nanoscale transient magnetization dynamics, a technique pioneered at the FERMI FEL in Trieste, Italy. First, we show how EUV-TG is capable of inducing transient magnetization gratings which decay within tens of picoseconds

via thermal diffusion. Building upon this first demonstration, we investigate the transition from ultrafast demagnetization to all-optical switching (AOS) by looking at the ratio between the first and the second order of diffraction as a function of excitation fluence. Indeed, the non-linear fluence dependence of AOS induces a non-uniform spacing of the magnetization pattern that results in the appearance of even diffraction orders. Finally, we compare the magnetization dynamics induced by intensity gratings with those launched by polarization gratings, obtained when the two excitation beams have orthogonal polarization. Here, the intensity distribution on the sample is uniform and ultrafast the formation of transient magnetization gratings has to be associated to the coupling of majority and minority spins with the electric field polarization.

TT 36.5 Fri 11:45 H10

Ultrafast magnetism of antiferromagnets — •ALEXEY KIMEL — Radboud University, Nijmegen, The Netherlands

Antiferromagnets are ideal candidates to reach the THz landmark in data storage with no additional energy costs. However, the lack of a net magnetization in the antiferromagnetic ground state requires exceedingly high magnetic fields to manipulate the spins, hindering even fundamental studies on the control and switching of antiferromagnets. Here we propose an approach to empower THz control of antiferromagnetic order by pushing antiferromagnet out of equilibrium through a generation of coherent magnonic states. We will show that an antiferromagnet out of equilibrium is practically a different material. Generation of coherent magnonic states in antiferromagnets substantially modifies the susceptibility of antiferromagnetic spins to THz magnetic fields and facilitates energy transfer between otherwise noninteracting phononic and magnonic modes [1,2]. In this case, the generated impact on spins goes far beyond trivial superposition of excitations and can facilitate conceptually new ways for controlling antiferromagnetism. The proposed theoretical description suggests that spin dynamics in antiferromagnets is intrinsically non-linear and once coherent magnonic state is induced, additional channels of energy transfer between otherwise orthogonal modes open up.

## TT 37: Superconducting Electronics: SQUIDs, Qubits, Circuit QED

Time: Friday 9:30-13:15

#### TT 37.1 Fri 9:30 H22

Nb constriction Josephson junctions and nanoSQUIDs patterned by He and **Ne focused ion beams** — •SIMON PFANDER¹, TIMUR GRIENER¹, JULIAN LINEK¹, THOMAS WEIMANN², UTE DRECHSLER³, REINHOLD KLEINER¹, ARMIN KNOLL³, OLIVER KIELER², and DIETER KOELLE¹ — ¹Physikalisches Institut, Center for Quantum Science (CQ) and LISA⁺, Universität Tübingen, 72076 Tübingen, Germany — ²Department Quantum Electronics, Physikalisch-Technische Bundesanstalt (PTB), 38116 Braunschweig, Germany — ³IBM Research Europe – Zürich, 8803 Rüschlikon, Switzerland

Nanopatterning of superconducting thin film structures with focused He or Ne ion beams (He/Ne-FIB) offers a flexible tool for creating constriction-type Josephson junctions (cJJs) and strongly miniaturized superconducting quantum interference devices (nanoSQUIDs) for magnetic sensing on the nanoscale. We present our attempts to use He/Ne-FIB for fabricating Nb cJJs and nanoSQUIDs which shall provide ultra-low noise and high spatial resolution for their application in scanning SQUID microscopy (SSM). The nanoSQUIDs are designed as sensors for magnetic flux and dissipation. They shall be integrated on custommade Si cantilevers, which will provide the possibility of simultaneous conventional topographic imaging by atomic force microscopy (AFM). We will discuss the status of this project and challenges that have to be met on the way to combine SSM and AFM on the nanoscale.

We acknowledge the European Commission under H2020 FET Open grant FIBsuperProbes (number 892427).

#### TT 37.2 Fri 9:45 H22

Development of a three-wave-mixing Josephson traveling-wave parametric amplifier — •Victor Gaydamachenko¹, Christoph Kissling^{1,2}, Lukas GRÜNHAUPT¹, RALF DOLATA¹, and ALEXANDER B. ZORIN¹ — ¹Physikalisch-Technische Bundesanstalt, Braunschweig, Germany — ²Technische Universität Ilmenau, Germany

Modern quantum experiments profit from wideband amplification of small microwave signals with noise approaching the quantum-limit. A promising approach to design an amplifier having a bandwidth of several GHz, power gain of 20 dB, and quantum-limited noise are traveling-wave parametric amplifiers (TWPAs). We develop a Josephson traveling-wave parametric amplifier (JTWPA), based on a series array of 1500 rf-SQUIDs, and utilising the threewave mixing regime. One of the main challenges of TWPAs is power leakage to unwanted processes like the generation of higher harmonics and mixing products, which significantly limit the gain. To solve this obstacle, we apply a dispersion engineering technique. Here, we present numerically optimised parameter sets for practical realisation of our concept. Simulations of the device operation show a signal gain of 20 dB in the frequency range from 3 GHz to 9 GHz.

#### TT 37.3 Fri 10:00 H22

Location: H22

**Charge-mediated quantum phase slip interference** — •JAN NICOLAS VOSS¹, MICHA WILDERMUTH¹, MAX KRISTEN^{1,2}, HANNES ROTZINGER^{1,2}, and ALEXEY V. USTINOV 1,2  — ¹Physikalisches Institut, Karlsruher Institut für Technologie, Karlsruhe, Germany — ²Institut für Quantenmaterialien und Technologien (IQMT), Karlrsruher Institut für Technologie, Karlsruhe, Germany

The duality between quantum phase slip junctions and Josephson junctions has triggered a variety of theoretical and experimental works and set the basis for a new type of quantum device based on coherent quantum phase slips. We present a realization of a quantum phase slip interferometer based on two strongly coupled superconducting nanowires. The interference is controlled by a gate voltage and visible as a periodic modulation of the critical Coulomb blockade voltage. The strength of the modulation strongly depends on the homogeneity of the wires, as the phase slip rates exponentially depend on the normal state resistances of the wires. We use the intrinsic electromigration technique ([1]) to adjust and homogenize the resistances of the wires in-situ and therefore are able to study a large range of wire impedances for single devices.

#### TT 37.4 Fri 10:15 H22

RF superconducting arbitrary waveform generator for Qubit control -•HAO TIAN, OLIVER KIELER, ALEXANDER FERNANDEZ SCARIONI, SILKE WOLTER, ROLF-WERNER GERDAU, JOHANNES KOHLMANN, and MARK BIELER - Physikalisch Technische Bundesanstalt

The Josephson Arbitrary Waveform Synthesizer (JAWS) allows for the quantumaccurate-generation of spectrally-pure, arbitrary waveforms. It consists of a series array of Josephson junctions and is driven by GHz bit sequences (current pulses). So far, JAWS circuits are mainly used at National Metrology Institutes for metrological purposes with output frequencies in the kHz to MHz frequency range. Within the scope of the national QuMIC project, PTB and other partners are currently further developing JAWS circuits with the aim to realize a compact and robust module, which is suitable for control and readout of superconducting qubits. In this talk, we will present the work, which is currently undertaken at PTB to reach this goal. Here, the main focus lies on the design and the fabrication of novel JAWS circuits and complex waveguide filters, capable of synthesizing arbitrary waveforms at GHz frequencies. This work was partly supported by German Federal Ministry of Education and Research (contract number: 13N15934).

#### TT 37.5 Fri 10:30 H22

Gate-tunable kinetic inductance in proximitized nanowires — •LUKAS JO-HANNES SPLITTHOFF¹, ARNO BARGERBOS¹, LUKAS GRÜNHAUPT¹, MARTA PITA-VIDAL¹, JAAP JOACHIM WESDORP¹, YU LIU², ANGELA KOU³, CHRISTIAN KRAGLUND ANDERSEN¹, and BERNARD VAN HECK⁴ — ¹Delft University of Technology, Delft University of Technology, Delft, The Netherlands — ²Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, Copenhagen, Denmark — ³Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois Urbana-Champaign, Urbana, USA — ⁴Leiden Institute of Physics, Leiden University, Leiden, The Netherlands

Superconducting-semiconducting nanowires combine two frontiers of condensed matter in a hybrid state, which offers formidable possibilities for quantum computing and quantum sensing devices. In this talk, we study a quarter-wave coplanar waveguide resonator shunted by a hybrid InAs/Al nanowire. We show a gate voltage controllable resonance frequency and demonstrate a frequency shift of up to 8MHz. We relate the frequency shift to the change in kinetic inductance of the hybrid nanowire which arises from the gate-tunable hybridization of the superconductor to semiconductor interface. From our measurement results we extract the normal state conductivity and the superconducting gap of the hybrid nanowire. The measurement technique demonstrated in this work complements existing characterization methods for hybrid nanowires and forms a promising path towards gate-controlled superconducting electronics.

#### TT 37.6 Fri 10:45 H22

Microwave photonics in high kinetic inductance microstrip networks —  $\cdot$ NIKLAS GAISER¹, SAMUEL GOLDSTEIN², GUY PARDO², NAFTALI KIRSH², CIPRIAN PADURARIU¹, BJÖRN KUBALA^{1,3}, NADAV KATZ², and JOACHIM ANKERHOLD¹ — ¹ICQ and IQST, University of Ulm, Ulm, Germany — ²The Racah Institute of Physics, The Hebrew University of Jerusalem, Israel — ³Institute of Quantum Technologies, German Aerospace Center (DLR), Ulm, Germany

Microwave photonics based on superconducting circuits is a promising candidate for many quantum-technological applications. Progress towards compact integrated photonics devices in the microwave regime, however, is constrained by their long wavelengths.

Here, we discuss a solution to these difficulties via compact networks of highkinetic inductance microstrip waveguides with strongly reduced phase velocities experimentally realized in [1]. We describe, how the Kirchhoff equations of a periodic network map to a tight-binding model, which allows a description in term of Bloch waves and band structures, to explain experimental features. The ability to employ band-structure design techniques together with the unique properties of compactness, reduced speed of light, and strong non-linear features allows the design of highly versatile on-chip microwave networks. Furthermore utilizing this platform, we present first theoretical device proposals of linear and non-linear functional units, such as beamsplitters, filters, resonators and diodes exploiting non-reciprocity.

#### TT 37.7 Fri 11:00 H22

**Emission of photon multiplets by a dc-biased superconducting circuit** — •Björn Kubala^{1,2}, Gerbold Menard³, Ambroise Peugeot³, Ciprian Padurariu², Chloe Rolland³, Yuri Mukharsky³, Zubair Iftikhar³, Carles Altimiras³, Patrice Roche³, Helene Le Sueur³, Philippe Joyez³, Denis Vion³, Daniel Esteve³, Joachim Ankerhold², and Fabien Portier³ — ¹Institute of Quantum Technologies, German Aerospace Center (DLR), Ulm, Germany — ²ICQ and IQST, Ulm University, Germany — ³SPEC, CEA Paris Saclay, France

We show experimentally that a dc-biased Josephson junction in series with a high-impedance microwave resonator can emit up to k = 6 photons simultaneously for each Cooper pair tunneling through the junction [1]. Our resonator is made of a simple micro-fabricated spiral coil that resonates at 4.4 GHz and reaches a 1.97 k $\Omega$  characteristic impedance, corresponding to an effective finestructure constant,  $\alpha \sim 1$ . Measuring the second order correlation function of the emission from the resonator allows computing the Fano factor *F* of the emitted photons, found to coincide with the naive prediction F = k in the weak driving regime. At larger Josephson coupling  $E_J$ , a more complex behavior is observed in quantitative agreement with numerical simulations. This simple scheme highlights the ability of superconducting devices operating in the microwave domain to reach strong-coupling regimes of matter-light coupling in-accessible to conventional quantum optics experiments in the visible domain. [1] G. C. Menard, et al., Phys. Rev. X **12**, 021006 (2022).

TT 37.8 Fri 11:15 H22 Waveguide quantum electrodynamics in high impedance networks -•MIRIAM RESCH¹, CIPRIAN PADURARIU¹, BJÖRN KUBALA^{1,2}, and JOACHIM ANKERHOLD¹ - ¹ICQ and IQST, Ulm University, Ulm, Germany - ²Institute of Quantum Technologies, German Aerospace Center (DLR), Ulm, Germany The emerging field of high impedance quantum circuits aims to exploit the extraordinary properties of high kinetic inductance materials, such as granular superconductors. The low propagation speed of electromagnetic excitations in such devices enables to strongly couple sub-units of quantum information devices, namely various types of qubits or resonators and waveguides. Theoretical description of such strongly coupled systems is challenging as the localized modes of the sub-unit typically couples to many waveguide modes simultaneously so that many common approximation schemes break down. While strongcoupling effects in closed systems have been widely investigated, showing, e.g. the breakdown of the Jaynes-Cummings model, our project aims at describing strongly coupled open quantum systems and photon emission. With experimental collaborators, we ultimately want to identify strong-coupling signatures in observables of the emitted radiation. Here, we present as preliminary steps towards the description of more complicated systems first investigations based on an ansatz, where the wave function of the complete system (unit + waveguide) is described by superposition of coherent states as proposed in [1], which allows to solve the system dynamics in a numerically efficient way.

TT 37.9 Fri 11:45 H22 Fano interference in microwave resonator measurements - •SIMON GÜNZLER^{1,2}, DENNIS RIEGER², MARTIN SPIECKER^{1,2}, WOLFGANG WERNSDORFER^{1,2}, and IOAN POP^{1,2} — ¹IQMT, Karlsruhe Institute of Tech-Martin Spiecker^{1,2}, Wolfgang nology, Germany — ²PHI, Karlsruhe Institute of Technology, Germany Resonator measurements are a simple but powerful tool to characterize a material's microwave response. The losses of a resonant mode are quantified by its internal quality factor Q_i, which can be extracted from the scattering coefficient in a microwave reflection or transmission measurement. Here we show that a systematic error on Q_i arises from Fano interference of the signal with a background path. Limited knowledge of the interfering paths and their relative amplitudes in a given setup translates into a range of uncertainty for  $Q_i$ , which increases with the coupling coefficient. We experimentally illustrate the relevance of Fano interference in typical microwave resonator measurements and the associated pitfalls encountered in extracting Q_i. On the other hand, we show how to characterize and utilize the Fano interference to eliminate the systematic error.

#### TT 37.10 Fri 12:00 H22

Direct observation of microscopic tow-level systems in granular aluminum films — •MAXIMILLIAN KRISTEN^{1,2}, JAN N. VOSS², MICHA WILDERMUTH², ANDRE SCHNEIDER², HANNES ROTZINGER^{1,2}, and ALEXEY V. USTINOV^{1,2} — ¹Institut für QuantenMaterialien und Technologien (IQMT), Karlsruher Institut für Technologie — ²Physikalisches Institut, Karlsruher Institut für Technologie Thin films of disordered superconductors are extensively studied due to their applicability in quantum circuits and detectors, where they can provide kinetic inductances orders of magnitude higher than their geometric inductance. While these films generally show very high quality factors in microwave measurements, their disordered microscopic structure favors the presence of numerous material defects behaving as two-level systems (TLS). TLS have been shown to be a major source of dielectric loss in microwave circuits and are limiting the coherence properties of modern superconducting qubits.

We present microwave spectroscopy measurements of resonators made from highly resistive granular aluminum films. By applying mechanical strain and electric fields, we observe several TLS strongly interacting with the resonator modes. We compare the measured data to an analytical model for the singlephoton interaction with TLS and estimate relevant physical properties.

#### TT 37.11 Fri 12:15 H22

Magnetic 1/f noise in superconducting microstructures and the fluctuationdissipation theorem — •M. HERBST, A. FLEISCHMANN, L. GASTALDO, D. HENGSTLER, L. MÜNCH, A. REIFENBERGER, C. STÄNDER, and C. ENSS — Uni Heidelberg

The performance of superconducting devices like SQUIDs and qubits is often limited by 1/f-noise and finite coherence times. Various types of slow fluctuators in the Josephson-junctions and in the passive parts of these superconducting circuits can cause such noise, and devices most likely suffer from a combination of different noise sources, which are hard to disentangle and therefore hard to eliminate. Magnetic flux noise caused by fluctuating magnetic moments of magnetic impurities or dangling bonds in superconducting inductances, surface oxides, insulating oxide layers and adsorbates should be a very likely contribution in many cases. We present an experimental setup to measure at Millikelvin temperatures both, the complex impedance of superconducting micro-structures as well as the magnetic flux noise that is picked-up by these structures. This allows for very important sanity checks by connecting both quantities via the fluctuationdissipation-theorem. In order to allow for state-of-the-art sensitivity in both experiments, the structures under investigation are part of a Wheatstone-like bridge, read-out by two cross-correlated independent dc-SQUID readout chains. We present measurements of the insulating SiO2 layers of our devices, the superconducting structures themselves, and magnetically doped noble-metal layers in the vicinity of the pickup coils at T = 20-800mK and f=100mHz-100kHz.

#### TT 37.12 Fri 12:30 H22

A quantum Szilard engine for two-level systems coupled to a qubit — •Martin Spiecker¹, Patrick Paluch¹, Niv Drucker², Shlomi Matityahu¹, Daria Gusenkova¹, Nicolas Gosling¹, Simon Günzler¹, Dennis Rieger¹, Ivan Takmakov¹, Francesco Valenti¹, Patrick Winkel¹, Richard Gebauer¹, Oliver Sander¹, Gianluigi Catelani³, Alexander Shnirman¹, Alexey V. Ustinov¹, Wolfgang Wernsdorfer¹, Yonatan Cohen², and Ioan M. Pop¹ — ¹Karlsruher Institut für Technologie, Karlsruhe, Germany — ²Quantum Machines, Tel Aviv-Yafo, Israel — ³Forschungszentrum Jülich, Jülich, Germany

The innate complexity of solid state physics exposes superconducting quantum circuits to interactions with uncontrolled degrees of freedom degrading their coherence. By using a simple stabilization sequence we show that a superconducting fluxonium qubit is coupled to a two-level system (TLS) environment of unknown origin, with a relatively long energy relaxation time exceeding 50ms. Implementing a quantum Szilard engine with an active feedback control loop allows us to decide whether the qubit heats or cools its TLS environment. The TLSs can be cooled down resulting in a four times lower qubit population, or they can be heated to manifest themselves as a negative temperature environment corresponding to a qubit population of 80%. We show that the TLSs and the qubit are each other's dominant loss mechanism and that the qubit relaxation is independent of the TLS populations. Mitigating TLS environments is therefore not only crucial to improve qubit lifetimes but also to avoid non-Markovian qubit dynamics.

TT 37.13 Fri 12:45 H22 Green's function approach to modelling finite size systems for applications in superconducting waveguide QED — •PRADEEPKUMAR NANDAKUMAR¹, ANDRES ROSARIO HAMANN^{1,2}, ROHIT NAVARATHNA¹, MAXIMILIAN ZANNER³, MIKHAIL PLETYUKHOV⁴, and ARKADY FEDOROV¹ — ¹ARC Centre of Excellence for Engineered Quantum Systems, School of Mathematics and Physics, The University of Queensland, Saint Lucia, Queensland 4072, Australia — ²Department of Physics, ETH Zurich, CH-8093 Zurich, Switzerland — ³Center for Quantum Physics, and Institute for Experimental Physics, University of Innsbruck, A-6020 Innsbruck, Austria — ⁴Institute for Theory of Statistical Physics, RWTH Aachen University, 52056 Aachen, Germany

In superconducting waveguide QED, artificial atoms are coupled to a 1D radiation channel that consists of continuum of electromagnetic modes. Waveguides are often modelled as infinite in size with open boundary conditions for the ease of understanding. However, while modelling waveguides employed in experiments, one should consider both the finite size of the waveguide as well as its coupling to measurement apparatus. To this end, we have developed a general method to realistically model any waveguide QED system using the Green's function methods that is often employed in studying electronic transport. We apply our formalism and experimentally study the formation of Atom-Photon Bound States (APBS) using two transmon qubits coupled to a 3D rectangular waveguide. Our results identify the prospects for using APBS for studying bosonic impurity models.

#### TT 37.14 Fri 13:00 H22

Dirac physics and charge localization due to quasiperiodic nonlinear capacitances — •TOBIAS HERRIG¹, JEDEDIAH PIXELEY², ELIO KÖNIG³, and ROMAN-PASCAL RIWAR¹ — ¹Forschungszentrum Jülich, Germany — ²Rutgers University, Piscataway, New Jersey, USA — ³Max-Planck Institute, Stuttgart, Germany Superconducting circuits are an extremely versatile platform to realize quantum information hardware, and, as was recently realized, to emulate topological materials, such as Weyl semimetals or Chern insulators. We here show how a simple arrangement of capacitors and conventional SIS junctions can realize a nonlinear capacitive element with a suprising property: it can be quasiperiodic with respect to the quantized Cooper-pair charge. Integrating this element into a larger circuit opens the door towards the engineering of an even broader class of systems. First, we use it to simulate a protected Dirac material defined in the transport degrees of freedom. The presence of the Dirac point leads to a suppression of the classical part of the finite-frequency noise. Second, we are able to exploit the quasiperiodicity to implement the Aubry-André model, and therebey to emulate Anderson localization in charge space. Our setup implements a truly non-interacting version of the model, in which the macroscopic quantum mechanics of the circuit already incorporates microscopic interaction effects. This should be contrasted to conventional solid state and cold atomic realizations, where competition between interaction and localization are a common side effect. We predict that quantum charge fluctuations directly probe the localization effect.

## TT 38: Superconductivity: Theory

Time: Friday 9:30-11:00

#### TT 38.1 Fri 9:30 H23

Unconventional superconductivity in the Hubbard model on the pyrochlore lattice — Shingo Kobayashi¹, Ankita Bhattacharya², •Carsten Timm², and Philip M. R. Brydon³ — ¹RIKEN Center for Emergent Matter Science, Saitama, Japan — ²TU Dresden, Germany — ³University of Otago, Dunedin, New Zealand

The Hubbard model on the pyrochlore lattice is studied close to half filling. In the normal state, the band structure realizes a j = 3/2 semimetal. Remarkably, the repulsive Hubbard interaction leads to an *attractive* superconducting pairing interaction in the  $E_g$  channel, which allows a two-component order parameter, whereas the interaction is repulsive in the trivial  $A_{1g}$  channel. The attractive interaction relies on the fact that the  $E_g$  pairing avoids the detrimental on-site repulsion. The solution of the BCS gap equation shows that a time-reversal-symmetry-breaking superconducting phase is favored, which displays Bogoliubov Fermi surfaces.

#### TT 38.2 Fri 9:45 H23

**Pairing instabilities of the Yukawa-SYK models with controlled fermion incoherence** • WONJUNE CHOI^{1,2}, OMID TAVAKOL³, and YONG BAEK KIM³ — ¹Department of Physics, Technical University of Munich, 85748 Garching, Germany — ²Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799 München, Germany — ³Department of Physics, University of Toronto, Toronto, Ontario M5S 1A7, Canada

As a solvable platform of the strongly correlated superconductors, we study the pairing instabilities of the Yukawa-Sachdev-Ye-Kitaev (Yukawa-SYK) model, which describes spin-1/2 fermions coupled to bosons by the random, all-to-all Yukawa interactions. In contrast to the previously studied models, the random Yukawa couplings are sampled from a collection of Gaussian ensembles whose variances follow a continuous distribution rather than being fixed to a constant. By tuning the analytic behaviour of the distribution, we control the fermion incoherence to systematically examine various normal states ranging from the Fermi liquid to non-Fermi liquids that are different from the conformal solution of the Location: H23

SYK model with a constant variance. Using the linearised Eliashberg theory, we show that the onset of the unconventional spin-triplet pairing is preferred with the spin-dependent interactions. Although the interactions shorten the lifetime of the fermions in the non-Fermi liquid, the same interactions also dress the bosons to strengthen the tendency to pair the incoherent fermions. As a consequence, the onset temperature of the pairing is enhanced in the non-Fermi liquid compared to the case of the Fermi liquid.

#### TT 38.3 Fri 10:00 H23

**Superconducting pairing from repulsive interactions of fermions in a flatband system** — IMAN MAHYAEH¹, •THOMAS KÖHLER¹, ANNICA M. BLACK-SCHAFFER¹, and ADRIAN KANTIAN^{1,2} — ¹Department of Physics and Astronomy, Uppsala University, Sweden — ²SUPA, Institute of Photonics and Quantum Sciences, Heriot-Watt University, Edinburgh EH14 4AS, United Kingdom

Many-body quantum systems of fermions with flat bands at the Fermi level are intensely studied for their potential to boost superconductivity by enhancement of the density of states. We use quasiexact numerical methods to show that repulsive interactions between spinless fermions in a model one-dimensional flat band system, the Creutz ladder, lead to a finite pairing energy that increases with repulsion. Pure repulsion however leaves charge-order as the dominant quasiorder over the superconductivity. Adding an additional attractive component to the interaction shifts the balance fully in favor of superconductivity. In this regime we find that the interactions of two flat bands further yields a remarkable enhancement to superconductivity far above and outside the known paradigms for one-dimensional fermions.

#### TT 38.4 Fri 10:15 H23

**Degenerate plaquette physics as key ingredient of high-temperature superconductivity in cuprates** — MIKHAIL DANILOV¹, VAN LOON ERIK G. C. P.², •BRENER SERGEY^{1,3}, ISKAKOV SERGEY⁴, KATSNELSON MIKHAIL⁵, and LICHTEN-STEIN ALEXANDER^{1,3} — ¹Institute of Theoretical Physics, University of Hamburg — ²Department of Physics, Lund University — ³The Hamburg Centre for Ultra-

634

fast Imaging —  $^4 \rm Department$  of Physics, University of Michigan —  $^5 \rm Radboud$  University, Institute for Molecules and Materials

A major pathway towards understanding complex systems is given by exactly solvable reference systems that contain the essential physics of the system. For the t - t' - U Hubbard model, the four-site plaquette is known to have a point in the  $U - \mu$  space where states with electron occupations N = 2, 3, 4 per plaquette are degenerate. Such a degenerate point causes strong fluctuations when a lattice of plaquettes is constructed. The next-nearest-neighbour hopping is shown to play a crucial role in the formation of strongly bound electronic bipolarons whose coherence at lower temperature could be the explanation for superconductivity. A complementary approach to the lattice of plaquettes is given by dual fermion perturbation theory starting from a single degenerate plaquette as a reference system. This perturbation theory already contains the relevant shortranged fluctuations from the beginning via the two-particle correlations of the plaquette. We find that d-wave superconductivity remains a leading instability channel under a reasonably broad range of parameters.

TT 38.5 Fri 10:30 H23

**Charge 4e skyrmion superconductivity?** — •GABRIEL REIN^{1,2}, MARCIN RACZKOWSKI¹, and FAKHER F. ASSAAD^{1,2} — ¹Institut für Theoretische Physik und Astrophysik Universität Würzburg, 97074 Würzburg, Germany — ²Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, 97074 Würzburg, Germany

We consider a dynamically generated quantum spin Hall (QSH) state which has as characteristic that skyrmion excitations of the SO(3) order parameter carry charge 2e. In Refs. [1,2] a model was defined with a single parameter  $\lambda$  that drives a continuous transition akin to deconfined quantum criticality from a QSH insulator to an s-wave superconductor via the condensation of charge 2e skyrmions.

# Our aim here is to modify this Hamiltonian by adding flavor degrees of freedom $N_f$ , such that the charge of the skyrmion reads $N_f 2e$ . In this talk we will map out the phase diagram of the model at $N_f = 2$ . Although, to date charge 4e skyrmion superconductivity remains elusive, the phase diagram in the $N_f$ versus $\lambda$ plane is very rich with additional Kekule ordered phases.

#### TT 38.6 Fri 10:45 H23

**Groundstate phase diagrams of variants of the two-leg** *t-J* **ladder at low fillings** — •STEFFEN BOLLMANN^{1,2}, ALEXANDER OSTERKORN², ELIO KÖNIG¹, and SALVATORE R. MANMANA² — ¹Max-Planck Institute for Solid State Research, 70569 Stuttgart, Germany — ²Institut for Theoretical Physics, Georg-August-University Göttingen, 37077 Göttingen, Germany

We study variants of the two-leg t-J ladder at low fillings using matrix product states (MPS) and perturbative approaches. While the groundstate phase diagram for the usual t-J ladder with spatially isotropic couplings at fillings n > 0.5 has been studied in detail, relatively little is known at low fillings. We address the phase diagram at these low fillings and investigate the influence of nearest-neighbor Coulomb interactions V and asymmetries in the spinexchange  $J_z \neq J_x = J_y$  on the size and nature of superconducting phases. For V = 0 the superconducting phase is enhanced, and we find a crossover within this phase from *s*-wave pairing to *d*-wave pairing when increasing the filling. For  $J_z = 0$ , the size of the superconducting region is reduced. In this talk, I will present the phase diagrams, discuss the physics, briefly introduce the methods used to classify the different phases, and give an outlook to possible realizations in experiments.

TT 39.1 Fri 11:15 H23

Stripe discommensuration and spin dynamics of charge and spin stripe ordered  $Pr_{3/2}Sr_{1/2}NiO_4$  — •AVISHEK MAITY¹, RAJESH DUTTA^{2,3}, and WERNER PAULUS⁴ — ¹Heinz Maier-Leibnitz Zentrum (MLZ), Technische Universität München, 85747 Garching, Germany — ²Institut für Kristallographie, RWTH Aachen Universität, 52066 Aachen, Germany — ³Jülich Centre for Neutron Science (JCNS) at Heinz Maier-Leibnitz Zentrum (MLZ), 85747 Garching, Germany — ⁴Institut Charles Gerhardt Montpellier, Université de Montpellier, 34095 Montpellier, France

Magnetic excitations in the charge and spin stripe ordered phases of La-based 214-nickelates have been vigorously explored using inelastic neutron scattering (INS) studies. In view of so far reported two-dimensional antiferromagnetic nature, out-of-plane interaction is not generally expected in 214-nickelates. Here we will present our results on the magnetic excitations of  $Pr_{3/2}Sr_{1/2}NiO_4$ , with stripe incommensurability  $\epsilon = 0.4$ , showing a very compelling evidence for the presence of a sizable out-of-plane interaction ( $J_{\perp} \sim 2.2$  meV) manifesting a symmetrical outward shift of the spin wave dispersion from the antiferromagnetic zone center. Our linear spin wave calculation using an unconventional three-dimensional model of discommensurated spin stripe (DCSS) unit for  $\epsilon = 0.4$  could explicitly show such outward shift results from the overlap of a mode originating exclusively from the out-of-plane interaction. Our study suggests that a careful consideration of the out-of-plane interaction is necessary in the stripe discommensurated 214-nickelates.

**Quantum oscillations in the Kagome superconductor**  $CsV_3Sb_5 - \bullet$ ANMOL SHUKLA¹, LIRAN WANG¹, FRÉDÉRIC HARDY¹, AMIR-ABBAS HAGHIGHIRAD¹, MINGQUAN HE², WEI XIA³, YANFENG GUO³, and CHRISTOPH MEINGAST¹ - ¹Institute for Quantum Materials and Technologies, Karlsruhe Institute of Technology, 76021 Karlsruhe, Germany - ²Low Temperature Physics Lab, College of Physics & Center of Quantum Materials and Devices, Chongqing University, Chongqing 401331, China - ³School of Physical Science and Technology, ShanghaiTech University, Shanghai 201210, China

The recently discovered layered Kagome metals  $AV_3Sb_5$  (A = K, Rb, Cs) exhibit a unique combination of nontrivial band topology, competing for the chargeand superconducting orders with clear signatures of electron correlations. Using magnetization, resistivity, thermal expansion, magnetostriction and heat capacity, we have investigated the normal- and superconducting-state properties of single crystals of the kagome superconductor CsV₃Sb₅. The magnetization and magnetostriction data show clear signatures of quantum oscillations with at least two distinct frequencies. These are much less evident in the heat capacity. Combining the results from these thermodynamic probes and transport meaLocation: H23

surement, we discuss the nature of the Fermi surface and the interplay between the charge order and superconductivity.

#### TT 39.3 Fri 11:45 H23

Statistical learning of engineered topological phases in the Kagome superlattice of AV₃Sb₅ — Thomas Mertz, •Paul Wunderlich, Shinibali Bhattacharyya, Francesco Ferrari, and Roser Valentí — Institut für Theoretische Physik, Goethe-Universität, 60438 Frankfurt am Main, Germany

Recently, the kagome metals  $AV_3Sb_5$  (A = K,Rb,Cs) have gained intense research interest, as they display a wide spectrum of exotic topological properties, in addition to superconductivity, charge, orbital momentum and spin density waves. Motivated by a plethora of experimental evidence for unconventional charge orders in the enlarged  $(2 \times 2)$  unit-cell of the vanadium based kagome metals, we investigate the type of topological phases that can manifest within the electronic parameter space of such kagome superlattices. Unlike conventional theoretical approaches, we employ a recently introduced statistical method capable of constructing topological models for any generic lattice, in an unbiased way without prior knowledge of its phase diagram. By extracting physically meaningful information from large datasets of randomized hopping parameters for the kagome superlattice, we find possible real-space manifestations of charge and bond modulations and associated flux patterns for different topological classes. Our results agree with contemporary theoretical propositions and experimental observations for the AV₃Sb₅ family. Simultaneously, we predict new higherorder topological phases that may be realized by appropriately manipulating the currently known systems.

#### TT 39.4 Fri 12:00 H23

High-pressure IR investigations unveil modifications in the electronic structure of the superconducting Kagome metal CsV₃Sb₅ — •MAXIM WENZEL¹, YUK T. CHAN¹, BRENDEN R. ORTIZ^{2,3}, STEPHEN D. WILSON³, MARTIN DRESSEL¹, ALEXANDER A. TSIRLIN⁴, and ECE UYKUR¹ — ¹1. Physikalisches Institut, Universität Stuttgart, 70569 Stuttgart, Germany — ²California Nanosystems Institute, University of California Santa Barbara, Santa Barbara, CA, 93106, United States — ³Materials Department, University of California Santa Barbara, Santa Barbara, CA, 93106, United States — ⁴Experimental Physics VI, Center for Electronic Correlations and Magnetism, University of Augsburg, 86159 Augsburg, Germany

The non-magnetic Kagome metal series  $AV_3Sb_5$  with A = K, Cs, or Rb is known for the coexistence of charge-density-wave and superconducting orders at low temperatures. Previously, the tunability of both orders has been investigated extensively via high-pressure transport studies; however, the pressure-induced modifications of the electronic band structure, especially the position of the saddle points, remain the subject of current research. While theoretical studies present conflicting suggestions regarding the pressure effects on the band structure, it has been shown that the interband optical transitions are highly sensitive to the position of the saddle points and hence, can probe them experimentally. Therefore, we performed high-pressure infrared studies on the model compound  $CsV_3Sb_5$  at room temperature to trace the behavior of the interband optical transitions up to 17 GPa.

#### TT 39.5 Fri 12:15 H23

Charge-density waves in Kagome-lattice extended Hubbard models at the van Hove filling — •FRANCESCO FERRARI¹, FEDERICO BECCA², and ROSER VALENTÍ¹ — ¹Goethe University, Frankfurt am Main, Germany — ²University of Trieste, Italy

The Hubbard model on the kagome lattice is presently often considered as a minimal model to describe the rich low-temperature behavior of AV₃Sb₅ compounds (with A=K, Rb, Cs), including charge-density waves (CDWs), superconductivity, and possibly broken time-reversal symmetry. We investigate, via variational Jastrow-Slater wave functions, the properties of its ground state when both onsite U and nearest-neighbor V Coulomb repulsions are considered at the van Hove filling. Our calculations reveal the presence of different interaction-driven CDWs and, contrary to previous renormalization-group studies, the absence of ferromagnetism and charge- or spin-bond order. No signatures of chiral phases are detected. Remarkably, the CDWs triggered by the nearest-neighbor repulsion possess charge isproportionations that are not compatible with the ones observed in AV₃Sb₅. As an alternative mechanism to stabilize charge-bond order, we consider the electron-phonon interaction, modeled by coupling the hopping amplitudes to quantum phonons, as in the Su-Schrieffer-Heeger model. Our results show the instability towards a tri-hexagonal distortion with 2x2 periodicity, in a closer agreement with experimental findings.

#### TT 39.6 Fri 12:30 H23

**Chalcogenic orbital density waves in the weak- and strong-coupling limit** — •ADAM KLOSINSKI¹, ANDRZEJ M. OLES^{2,3}, CLIO EFTHIMIA AGRAPIDIS¹, JASPER VAN WEZEL⁴, and KRZYSZTOF WOHLFELD¹ — ¹University of Warsaw, Warsaw, Poland — ²Jagiellonian University, Krakow, Poland — ³Max Planck Institute for Solid State Research, Stuttgart, Germany — ⁴University of Amsterdam, Amsterdam, The Netherlands

Stimulated by recent works highlighting the indispensable role of Coulomb interactions in the formation of helical chains and chiral electronic order in the elemental chalcogens, we explore the p-orbital Hubbard model on a one-dimensional helical chain. By solving it in the Hartree approximation we find a stable ground state with a period-3 orbital density wave. We establish that the precise form of the emerging order strongly depends on the Hubbard interaction strength. In the strong-coupling limit, the Coulomb interactions support an orbital density wave that is qualitatively different from that in the weak-coupling regime. We identify the phase transition separating these two orbital ordered phases and show that realistic values for the interorbital Coulomb repulsion in

elemental chalcogens place them in the weak-coupling phase, in agreement with observations of the order in the elemental chalcogens.

#### TT 39.7 Fri 12:45 H23

Understanding the transition from metal to Hund's insulator in  ${\rm CaFeO_3}-{\rm \bullet}{\rm Maximilian}$  Merkel and Claude Ederer — Materials Theory Group, ETH Zürich, Switzerland

Materials where strong correlations are caused by the Hund's interaction have recently attracted a lot of attention. In some cases, a dominant Hund's interaction can even lead to the emergence of a charge-disproportionated insulating (CDI) or "Hund's insulating" state. One example is the perovskite transition-metal oxide CaFeO₃ (CFO), which exhibits a transition from metal to Hund's insulator around room temperature. This transition couples to a structural distortion that creates alternating large and small FeO₆ octahedra, leading to two inequivalent Fe sites with nominal Fe⁵⁺ and Fe³⁺ charge states. We study CFO using density functional theory (DFT) and dynamical mean-field theory (DMFT). To characterize the CDI state, we first apply DMFT to a five-orbital Hubbard model applicable to CFO and demonstrate the emergence of the CDI phase here [1]. We then investigate the energetics of the transition using fully self-consistent DFT+DMFT calculations. We discuss the ligand-hole character of the charge disproportionation due to the zero or even negative charge-transfer energy. Our calculations show that both structural and electronic properties of the CDI state are well described within DFT+DMFT but also that the subtle interplay of several effects represents a big challenge for any quantitative, predictive theory. [1] M. E. Merkel and C. Ederer, Phys. Rev. B 104, 165135 (2021)

#### TT 39.8 Fri 13:00 H23

**Reinvestigating the metallic region of the half-filled Hubbard Holstein model** — SAM MARDAZAD¹, MARTIN GRUNDNER¹, ULRICH SCHOLLWÖCK¹, ADRIAN KANTIAN², THOMAS KÖHLER³, and •SEBASTIAN PAECKEL¹ — ¹Department of Physics, Arnold Sommerfeld Center of Theoretical Physics, University of Munich, Germany — ²Institute of Photonics and Quantum Sciences, Heriot-Watt University, Edinburgh, UK — ³Department of Physics and Astronomy, Uppsala University, Sweden

The one-dimensional Hubbard-Holstein model is the paradigmatic system to study the interplay between strongly correlated electrons and dispersionless lattice vibrations. Particularly, the intermediate regime of competing interactions has been heavily debated and only with the advent of powerful numerical techniques such as density-matrix renormalization group (DMRG) or advanced quantum Monte Carlo (QMC), the realization of an intermediate metallic phase has been established. However, these early studies are characterized by significant truncations of the phononic Hilbert spaces. Here, we exploit recent advances in the efficient representation of large local Hilbert spaces to re-examine the phase diagram by large-scale DMRG calculations, focussing on the regime of competing, strong interactions. This allows us to systematically study the complex competition between correlations, overcoming previous limitations.

## VA 1.1 Mon 9:30 H12

**Direct Simulation Monte Carlo of diffusion pumps for the application in fusion reactors** — •TIM TEICHMANN, THOMAS GIEGERICH, and CHRISTIAN DAY — Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany Active R&D is performed on developing of a continuously working pumping train for the future European demonstration fusion power plant (DEMO). Diffusion pumps operated with mercury have been identified as candidates for the high vacuum pumps. The numerical simulation of these pumps is challenging because they operate in a wide gas rarefaction range. A simulation framework based on the Direct Simulation Monte Carlo (DSMC) method has been established over the last years. The present talk aims to give an update on the present

#### VA 1.2 Mon 10:10 H12

**Transient modeling of the gas flows in the gas injection systems of fusion reactors** — •CHRISTOS TANTOS, STYLIANOS VAROUTIS, and CHRISTIAN DAY — Karlsruhe Institute of Technology, Karlsruhe, Germany

state of the simulations and their projected impact on the diffusion pump design

This work presents an assessment of the flow evolution inside the gas pipes of the gas injection system (GIS) of fusion reactors during a control action. A successful gas injection system design requires on the one hand the ability to meet the technical requirements under steady state conditions that are in line with the operating requirements of the reactor and on the other hand the appropriate prediction of the dynamic change of the system response times. In this framework, in the present work a state-of-the-art methodology has been utilized analyzing the transient behavior of the argon and deuterium-tritium gas flows in the GIS of DEMO (DEMOnstration Power Plant) fusion reactor. The applied methodology allows for an accurate description of the gas flow in the whole range of the gas rarefaction and compared to other widely applied particle-based approaches it requires low computational effort using an ordinary workstation. The main output of the present work, namely the delay time, representing the time it takes the flow to reach the outlet as well as the time needed to recover steady state conditions, is estimated in a wide range of the operating conditions and ratios length-to-diameter of the GIS tubes. The obtained data show that the response times of the GIS are unfeasibly high and this may have a strong impact on the design of the piping of the DEMO gas injection system.

#### VA 1.3 Mon 10:50 H12

The Regularized 13-Moment Equations for Rarefied Gas Simulations — •MANUEL TORRILHON — RWTH Aachen University

The Regularized 13-Moment-Equations (R13) are using moment approximations for the Boltzmann equation in kinetic gas theory to describe gas flows when the Knudsen number - the ratio between mean free path and observation scale becomes significant. Classical fluid theories like the constitutive laws of Navier-Stokes and Fourier are valid only close to equilibrium and fail for processes at Knudsen numbers as low as 0.05 because there are not sufficient particle collisions within the gas to maintain equilibrium.

The derivation of the R13-equations relies on the combination of moment approximations and asymptotic expansions in kinetic gas theory. The system has been shown to be stable and of high asymptotic accuracy yet using only a relatively small set of variables, namely density, velocity, temperature, stress deviator and heat flux - in total 13 fields. It has been demonstrated to succeed on the prediction of various non-equilibrium processes like shock waves or channel flows with Knudsen layers. The system of equations also exhibits desirable mathematical features like an entropy and is easy to use in numerical simulations. An overview of the equations and their features can be found in the review in Ann. Rev. Fluid Mech. 48, (2016), 429-458.

This talk will introduce the model and discuss recent developments like the efficient implementation in finite element frameworks, polyatomic collision models, and nonlinear extensions.

## VA 2: Vacuum technology: New developments and applications

Time: Monday 12:30-15:10

#### VA 2.1 Mon 12:30 H12

Experimental characterisation of a NEG pump of novel size - a major step to its application in neutral beam injectors of future fusion devices — •STEFAN HANKE¹, CHRISTIAN DAY¹, THOMAS GIEGERICH¹, XUELI LUO¹, FAB-RIZIO SIVIERO², MICHELE MURA², ENRICO MACCALLINI², PAOLO MANINI², EMANUELE SARTORI³, MARCO SIRAGUSA³, and PIERGIORGIO SONATO³ — ¹KIT, Karlsruhe, Germany — ²SAES Getters, Lainate, Italy — ³Consorzio RFX, Padova, Italy

Future fusion plants require plasma heating including neutral beam injectors (NBI), demanding pumping speeds of several 1000 m3/s. A concept to replace the currently used customized cryopumps is based on the high capacity getter ZAO. In a 6 years systematic technology development, the concept of a NBI NEG pump was derived, starting with comprehensive material characterisation, expanded to pumping and regeneration characteristics of ZAO and to heating and thermal management of larger arrangements for scalability and control. The recent step was design, manufacturing and operation of a large NEG pump for demonstration and to confirm scalability. The resulting pump with 15 kg of ZAO was tested in the TIMO facility at KIT. The achieved experimental results, regarding sorption characteristics (depending on pressure, gas flux, getter temperature, loading of the getter with gas, isotope) and regeneration behaviour are described. Subsequently the entire setup was replicated in detail in the TPMC code ProVak3D to find the real sticking factor. With this, the performance of any advanced future arrangement of NEG cartridges can be predicted now.

#### VA 2.2 Mon 13:10 H12

**Design process of the DTT divertor cryopump** – •VOLKER HAUER and CHRIS-TIAN DAY — Karlsruhe Institute of Technology, Institute for Technical Physics, Karlsruhe, Germany

DTT is a planned, superconducting tokamak, which is to be built in Italy in the next few years. It will provide enough flexibility to test different divertor concepts and find the best concept for a subsequent demonstration power plant.

The plasma chamber in the center of the tokamak is actively pumped during operation. Nine cryopumps are used for this purpose due to the high pumping speed required.

The presentation shows the design process of the cryopumps starting from the boundary conditions, the calculation of pumping speeds by means of Test Particle Monte Carlo Simulation (TPMC), the selection of the optimal design and the necessary calculations for mechanical stability to the planned design of the cryopumps.

#### VA 2.3 Mon 13:50 H12

Location: H12

Outgassing rate studies and Monte Carlo simulations for the design of the cryogenic vacuum system of the Einstein Telescope — •KATHARINA BATTES, STEFAN HANKE, XUELI LUO, and CHRISTIAN DAY — Karlsruhe Institute of Technology, Eggenstein-Leopoldshafen, Germany

The Einstein Telescope (ET) is a third-generation underground gravitational wave observatory, currently under development in Europe. It is designed as an equilateral triangle with 10 km long arms and detectors in each corner. Two interferometers will be used to detect both low-frequency (LF) and high-frequency gravitational wave signals.

In order to reduce thermal noise, the main optics will partly be cooled to cryogenic temperatures below 20 K for ET-LF. The integral ET vacuum system requires high to ultra-high vacuum conditions and comprises three different parts: (i) the beamline vacuum characterised by outgassing from the pipe walls, (ii) the tower vacuum characterised by outgassing from the suspension arrangement, and (iii) the cryogenic vacuum systems around the LF mirror.

In this paper, the outgassing behavior of potential materials such as mild steel is studied at the Outgassing Measurement Apparatus OMA. Using this input, a Test Particle Monte Carlo model has been established with the KIT in-house code ProVac3D, to allow for a system analysis of the cryogenic vacuum area. It assesses the impinging rate of residual gas on the cryogenic mirror, depending on the particle sources. With that, the expected speed of frost formation is estimated, which is critical due to degradations of the optical performance.

## VA 2.4 Mon 14:30 H12

**Prevention of Carbon Contamination in Transmission Electron Microscopy by Sample-Specific Preparation** – •JULIA MENTEN¹, DANIELA RAMERMANN¹, ROBERT SCHLÖGL^{1,2}, and WALID HETABA¹ – ¹Max Planck Institute for Chemical Energy Conversion, Mülheim an der Ruhr, Germany – ²Fritz Haber Institute of the Max Planck Society, Berlin, Germany

Transmission electron microscopy (TEM) offers a powerful tool for the analysis of specimens down to an atomic scale. In order to achieve the best possible image resolution and quality of obtained data, sample preparation is a crucial step. Many samples contain a high carbon content, e.g. as organic ligands or solvents.

Electron beam exposure can lead to the deposition of carbon on the specimen surface and limit the quality of the measurements.

In our work we focus on the removal of undesirable carbon species before the sample is inserted in the microscope. Our sample cleaning setup allows for investigation of the influence of different preparation parameters, e.g. drying time or temperature, on how long solvents remain in the vacuum system and therefore can have an impact on the TEM analysis. Evaluation of the decrease in pressure while pumping our setup with a TEM sample gives insight in necessary drying times. The effect of our sample treatment can be verified in the TEM by contrast and thickness measurements after electron beam exposure of the sample.

# **Coherence of spin qubits in planar germanium** — •NICO WILLEM HENDRICKX — IBM Research Zurich, Switzerland

The prospect of building quantum circuits using advanced semiconductor manufacturing techniques position quantum dots as an attractive platform for quantum information processing. Initial demonstrations of one and two-qubit logic have been performed in gallium arsenide and later silicon. However, until recently, interconnecting larger spin qubit systems has remained a challenge.

Over the past years, hole states in strained germanium quantum wells have emerged as a host for spin qubits. These states have favourable properties for defining extended spin qubit arrays. The small effective mass relaxes constraints on lithography, the low degree of disorder enables reproducible quantum dots, the lack of a valley degeneracy ensures an well-defined qubit state and the strong spin-orbit coupling allows for local and electrical qubit control.

Over the past years, this platform has rapidly evolved from materials growth to supporting multi-qubit logic. I will first give an overview of the development of this system, starting from material growth to recent results on operating a highly-connected two-dimensional qubit array. Next, we will discuss the impact of noise on the qubit coherence, as well as strategies to mitigate this. We study the magnetic field dependence of various qubit properties in order to find sweet spots for operation. Finally, we will discuss strategies, challenges, and opportunities in scaling these systems up as a step towards the realisation of scalable qubit tiles for fault-tolerant quantum processors.

#### QI 1.2 Mon 10:00 H8

Spin relaxation times of single-electrons in bilayer graphene quantum dots — •KATRIN HECKER^{1,2}, LUCA BANSZERUS^{1,2}, SAMUEL MÖLLER^{1,2}, EIKE ICKING^{1,2}, KENJI WATANABE³, TAKASHI TANIGUCHI³, CHRISTIAN VOLK^{1,2}, and CHRISTOPH STAMPFER^{1,2} — ¹2nd Institute of Physics, RWTH Aachen University, Germany — ²Peter Grünberg Institute (PGI-9), Forschungszentrum Jülich, Germany — ³National Institute for Materials Science, Japan

Thanks to its weak spin-orbit coupling and low nuclear spin density, bilayer graphene (BLG) promises long spin relaxation and coherence times, making this material a potentially interesting platform for spin based solid state quantum computation. Although the electrostatic confinement of single electrons in BLG quantum dot (QD) devices has been demonstrated, and their single particle spectrum has been studied in detail [1], their relaxation dynamics remain so far mostly unexplored [2]. Here, we report on measurements of the spin relaxation times (T1) of single-electron spin states in a BLG QD. Using pulsed gate spectroscopy, we extract T1 times exceeding 0.2ms at out-of-plane magnetic fields below 2T. The measured values for T1 show a strong dependence on the spin splitting and increase by about two orders of magnitude when decreasing the magnetic fields [3].

Microwave spectroscopy of rare earth spin ensembles at zero magnetic field — •ANA STRINIC^{1,2}, KIRILL G. FEDOROV^{1,2}, RUDOLF GROSS^{1,2,3}, and NADEZHDA КИКНАRСНҮК^{1,3} — ¹Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, Garching, Germany — ²Physik-Department, Technische Universität München, Garching, Germany — ³Munich Center for Quantum Science and Technologies, Munich, Germany

Operating at microwave frequencies and in the absence of external magnetic fields, superconducting circuits show exceptional potential for the development of quantum processors. Realizing a quantum memory, which operates in the microwave regime and in the vicinity of zero magnetic field, would allow for a direct interface to such quantum processors. In this regard, rare earth doped crystals are highly attractive, as they exhibit long optical and spin coherence times and possess transitions in the microwave frequency range [1,2]. In order to identify transitions, which form a suitable quantum memory scheme, we have performed microwave spectroscopy on a ¹⁶⁷ Er:⁷ LiYF₄ crystal in a magnetically shielded environment. The experimental findings of the spectroscopy study are then compared to simulations of the spin Hamiltonian. [1] N. Kukharchyk et al. New J. Phys. **20**, 023044 (2018) [2] J.V. Rakonjac et al. **Nuclear Spin Quantum Memory in Silicon Carbide** — •**B**ENEDIKT TISSOT¹, MICHAEL TRUPKE^{2,3}, PHILIPP KOLLER², THOMAS ASTNER², and GUIDO BURKARD¹ — ¹Department of Physics, University of Konstanz, D-78457 Konstanz, Germany — ²Faculty of Physics, University of Vienna, Boltzmanngasse 5, 1090 Vienna, Austria — ³Institute for Quantum Optics and Quantum Information (IQOQI) Vienna, Austrian Academy of Sciences, Boltzmanngasse 3, 1090 Vienna, Austria

Transition metal (TM) defects in silicon carbide (SiC) are a promising platform for applications in quantum technology. Some TM defects, e.g. vanadium, emit in one of the telecom bands, but the large ground state hyperfine manifold poses a problem for applications which require pure quantum states. We develop a driven, dissipative protocol to polarize the nuclear spin, based on a rigorous theoretical model of the defect. We further show that nuclear-spin polarization enables the use of well-known methods for initialization and long-time coherent storage of quantum states. The proposed nuclear-spin preparation protocol thus marks the first step towards an all-optically controlled integrated platform for quantum technology with TM defects in SiC.

**Cavity-mediated quantum gates between driven remote spin qubits** — •FLORIAN KAYATZ, JONAS MIELKE, and GUIDO BURKARD — University of Konstanz, Konstanz D-78457, Germany

The implementation of two-qubit gates between distant qubits is of fundamental importance for quantum computing architectures involving many qubits. Considering cold ions confined in a linear trap, the Cirac-Zoller gate (CZ-gate) [1,2] constitutes such a two-qubit gate by exploiting the coupling of the ions through the collective quantized ion motion.

Here, we theoretically demonstrate a CZ-like gate between two spin qubits realized in gate defined semiconductor double quantum dots. In the envisioned system both spin qubits are coupled to a microwave resonator mode that has a similar function as the collective ion motion in the original CZ-gate. Recently, strong spin-photon coupling has been demonstrated [3] and, thus, allows for coherent population exchange between the spin qubit and the resonator mode. Thereby, two of the three main steps in the CZ-gate protocol can be realized. We describe in detail how the remaining step that requires the generation of a phase depending on the state of the second qubit and the resonator photon number can be implemented by driving the second DQD-system.

**Coherence improvements at a higher-order sweet spot in double quantum dots** — •MORTEN I. K.  $MUNK^{1,2}$ , MARTIN LEIJNSE¹, and PETER SAMUELSSON² — ¹NanoLund and Division of Solid State Physics, Lund University, Lund, Sweden — ²NanoLund and Division of Mathematical Physics, Lund University, Lund, Sweden

One of the main limiting factors for designing a useful qubit is its dephasing time. In order to improve this, qubits are often operated at optimal points, or so-called "sweet spots", but in recent years, several systems have been proposed which can be tuned to higher-order sweet spots. These qubits often fail in practice, due for example to coupling to leakage states or a lack of protection against other relevant noise sources. In this work we propose a straightforward way of achieving a third-order sweet spot in a double quantum dot with two electrons in the singlet sector. This experimentally feasible qubit has the combined advantages of being operated at strong tunneling strengths, where leakage states are well separated from the qubit states, as well as being possible to construct in a way in which there are no relevant unprotected noise channels. We investigate the decoherence rate due to pure dephasing for a broad range of system parameters and for different noise spectral densities. It is found, in general, that higher-order sweet spots allow for substantially increased dephasing times, suggesting a guiding principle in optimizing the coherence properties of charge qubits in double quantum dots and related systems.

Quantum-optical Characterization of Single-photon Sources based on Chlorine-doped ZnSe/ZnMgSe Nanopillars — • CHRISTINE FALTER, YURII KUtovyi, Nils von den Driesch, Thorsten Brazda, Detlev Grützmacher, and ALEXANDER PAWLIS — Peter Grünberg Institute PGI-9, Forschungszentrum Jülich GmbH

The realization of optical quantum computers and secure quantum communication networks requires the development of efficient and scalable sources of single, indistinguishable photons that can be integrated onto photonic chips. Here we report on a novel type of single-photon source (SPS) device based on individual Cl donors in ZnSe/ZnMgSe quantum well nanopillars. On top of each nanopillar a solid immersion lens is fabricated, employing the photoresist previously used to define the nanopillars. For optimized conditions the external quantum efficiency is increased by up to one order of magnitude. Excitation-power-dependent photoluminescence measurements confirm that the emission stems from a true twolevel system and the single photon purity of the source is verified by measuring the second order correlation function. Finally, we investigate the grade of sequential indistinguishability of subsequent single-photons from our devices by Hong-Ou-Mandel type experiments. This work paves the way for efficient generation of polarization entanglement between two sufficiently indistinguishable photons. Consequently, future applications of these SPSs are envisioned in alloptical based quantum cryptography or to interconnect distant nodes in quantum networks.

OI 2.1 Mon 9:30 H9 Measuring the thermodynamic cost of timekeeping — •YELENA GURYANOVA - Institute for Quantum Optics and Quantum Information (IOOOI), Austrian Academy of Sciences, Boltzmanngasse 3, 1090 Vienna, Austria

All clocks, in some form or another, use the evolution towards higher entropy states to quantify the passage of time. Because of the statistical nature of the second law and corresponding entropy flows, fluctuations fundamentally limit the performance of any clock. This suggests a deep relation between the increase in entropy and the quality of clock ticks. Indeed, minimal models for autonomous clocks in the quantum realm revealed that a linear relation can be derived, where for a limited regime entropy linearly increases with the accuracy. Does a linear relation persist as we move toward a more classical system? We answer this in the affirmative by presenting the first experimental investigation of this thermodynamic relation in a nanoscale clock. We stochastically drive a nanometer-thick membrane and read out its displacement with a radio-frequency cavity, allowing us to identify the ticks. We show theoretically that the maximum possible accuracy for this classical clock is proportional to the entropy created per tick, similar to the known limit for a weakly coupled quantum clock but with a difinterval, one can observe the photon arrival times and get a state detection advantage by using the temporal structure in a model such as a Hidden Markov Model. We study what further advantage may be achieved by applying pulses to adaptively transform the state during the observation. We give a three-state example where adaptively chosen transformations yield a clear advantage, and we compare performances on an ion example, where we see improvements in some regimes.

Quantum Information Transfer in a Chain of Trapped Ions - • THEERAPHOT SRIARUNOTHAI, PATRICK BARTHEL, PATRICK HUBER, GOURI S. GIRI, and CHRISTOF WUNDERLICH — Department of Physics, School of Science and Technology, University of Siegen, 57068 Siegen, Germany

We explore a quantum teleportation scheme with four trapped ¹⁷¹Yb⁺ ions in a non-segmented linear Paul trap, each radiofrequency-controlled ion representing one qubit. The  $\sigma_z \sigma_z$  interaction between qubits is mediated by Magnetic Gradient Induced Coupling (MAGIC) [1]. The 4 × 4 interaction matrix of the qubit-system is measured and, taking advantage of all-to-all connectivity, is used to create Bell states between pairs of nearest neighbours and secondnearest neighbours, respectively. Furthermore, it is demonstrated how, while creating an entangled pair, another qubit serves as a decoupled quantum memory. This memory qubit is protected from decoherence with the same dynamical decoupling sequence as the one applied to perform the Bell-state operations. We developed and implemented a blueprint to demonstrate quantum state transfer using a quantum teleportation scheme. First experimental results on teleportation indicate the transfer of a superposition state from one end to another end of a quantum register. The method and techniques developed here can be applied to a larger system, for example, a full quantum byte or across quantum registers. [1] Ch. Piltz et al., Science Advances 2, e1600093 (2016).

ferent proportionality constant. We measure both the accuracy and the entropy. Once non-thermal noise is accounted for, we find that there is also a linear relation between accuracy and entropy.

QI 2.2 Mon 10:00 H9

Thermodynamics of Permutation-Invariant Quantum Many-Body Systems: A Group-Theoretical Framework — •Benjamin Yadin¹, Benjamin Morris^{2,3}, and KAY BRANDNER^{2,3} — ¹Naturwissenschaftlich-Technische Fakultät, Universität Siegen, Walter-Flex-Straße 3, 57068 Siegen, Germany — ²School of Physics and Astronomy, University of Nottingham, Nottingham NG7 2RD, United Kingdom — ³Centre for the Mathematics and Theoretical Physics of Quantum Nonequilibrium Systems, University of Nottingham, Nottingham NG7 2RD, United Kingdom

Classical thermodynamics originally described ensembles of many particles controlled collectively without addressing individual particles. However, quantum phenomena such as entanglement may lead to very different collective behaviour. We study non-identical particles that interact identically with their environment and control systems. Such collective dynamics are generally generated by a Hamiltonian invariant under particle permutations.

We develop a general framework for such systems, finding a quantum state space containing additional non-classical degrees of freedom. While the permutation symmetry prevents full thermalisation, we prove that a sufficiently complex bath interaction enables maximum possible thermalisation. For systems initialised out of equilibrium with the bath, we calculate steady-state properties and determine the performance of a heat engine model. Compared with previous models using SU(2) spin interactions, we show that SU(d)-based couplings for d-dimensional particles can lead to thermodynamical advantages.

Geometric structure of thermal cones — •ALEXSANDRE DE OLIVEIRA JUNIOR, JAKUB CZARKOWSKI, KAROL ZYCZKOWSKI, and KAMIL KORZEKWA — Faculty of Physics, Astronomy and Applied Computer Science, Jagiellonian University, 30-348 Kraków, Poland.

The second law of thermodynamics imposes a fundamental asymmetry in the flow of events. The so-called thermodynamic arrow of time introduces an ordering on the space of states that can be distinguished according to the system's evolution as past, incomparable, and future thermal cones. In this work, we analyse the structure of the thermodynamic arrow of time within a resource-theoretic framework, where one investigates the accessibility of quantum state transformations under thermodynamic constraints. Specifically, for a *d*-dimensional classical state interacting with a heat bath at a fixed temperature T, we found the necessary and sufficient conditions to construct its incomparable and past thermal cones. By introducing a new thermodynamic monotone, the volume of the future thermal cone, we provide a detailed analysis of the behaviour of the thermal cones. In a general context, while the future thermal cone can be seen as a generalisation of the Hardy-Littlewood-Polya theorem, the past and incomparable region can be interpreted as its extensions. Moreover, our results also apply to other majorisation-based resource theories, such as entanglement, since in the limit of infinite temperature, the partial order that emerges is the same (precisely: the opposite) as defined on the set of bipartite pure entangled states by local operations and classical communication

**Continuous measurement feedback for adaptive qubit thermometry** — •JULIA BOEYENS and STEFAN NIMMRICHTER — Naturwissenschaftlich-Technische Fakultät, Universität Siegen, Siegen 57068, Germany

Bayesian estimation was recently applied to quantum thermometry since it allows for better estimation accuracy when data is limited and admits adaptive estimation schemes. Here, we apply the Bayesian framework to the setting of continuous temperature measurement. We model a qubit probe, subject to continuous monitoring interacting with a bosonic bath of unknown temperature. The Kushner-Stratonovich equation from classical filtering theory is simulated to find the posterior distribution. Bayesian estimation is then used to infer the temperature from this probability distribution using. This is compared to the discrete analogue, collisional thermometry . An adaptive strategy for improved accuracy is described where Hamiltonian parameters of the qubit can be changed continuously by measurement feedback.

**Quantum trajectories beyond weak coupling** — •BRECHT DONVIL¹ and PAOLO MURATORE GINANNESCHI² — ¹Institute for Complex Quantum Systems, Albert-Einstein-Allee 11, D-89069, Ulm — ²University of Helsinki, Department of Mathematics and Statistics P.O. Box 68 FIN-00014, Helsinki, Finland

Master equations are one of the main avenues to study open quantum systems. In situations where the interaction between a dedicated system and its environment is weak, the master equation is of the Lindblad form. In this case, the solution of the master equation can be "unraveled in quantum trajectories" i.e. represented as an average over the realizations of a Markov process in the Hilbert space of the system. Quantum trajectories of this type are both an element of quantum measurement theory as well as a numerical tool for systems in large Hilbert spaces.

In this talk, I show that I show how this procedure can be generalized to arbitrary trace-preserving master equations with time-local dissipation rates. In contrast to the conventional setting, these rates can take also negative values, thus mimicking back-flow of information. Such master equations typically arrive from exactly solvable models or time convoluntionless perturbation theory. The crucial ingredient for our unraveling is to weigh averages by a probability pseudo-measure which we call the "influence martingale". The influence martingale satisfies a 1*d* stochastic differential equation enslaved to the ones governing the quantum trajectories. The influence martingale thus extends the existing theory without increasing the computational complexity.

**Finite-size effects in quantum thermodynamics** — •KAMIL KORZEKWA — Jagiellonian University, Kraków, Poland

The necessity to go beyond classical thermodynamics is usually motivated by the fact that at the nanoscale quantum effects, like coherence and entanglement,

start playing an important role. However, in the quantum regime one also deals with systems composed of a finite number n of particles, whereas the theory of thermodynamics is traditionally constrained to the study of macroscopic systems with  $n \to \infty$ , whose energy fluctuations are negligible compared to their average energy. In this talk I will address this problem and describe recent developments allowing one to go beyond the thermodynamic limit and rigorously investigate thermodynamic transformations of finite-size systems. I will explain why such transformations are generally irreversible and consume free energy, and how this affects the performance of thermodynamic protocols. A new version of the famous fluctuation-dissipation theorem will also be presented, linking the minimal amount of free energy dissipated in the process to the amount of free energy fluctuations present in the initial state of the system. Moreover, I will discuss a novel resource resonance phenomenon, which allows one to significantly reduce dissipation for transformations between states whose fluctuations are properly tuned. Finally, I will also explain how quantum coherence may bring states closer to resonance effectively decreasing the dissipation of free energy.

Work fluctuations and entanglement in quantum batteries — •SATOYA IMAI, OTFRIED GÜHNE, and STEFAN NIMMRICHTER — Universität Siegen Department Physik Emmy-Noether-Campus Walter-Flex-Straße 3 57068 Siegen Germany We consider quantum batteries given by composite interacting quantum systems in terms of the thermodynamic work cost of local random unitary processes. We characterize quantum correlations by monitoring the average energy change and its fluctuations in the high-dimensional bipartite systems. We derive a hierarchy of bounds on high-dimensional entanglement (the so-called Schmidt number) from the work fluctuations and thereby show that larger work fluctuations can verify the presence of stronger entanglement in the system. Finally, we develop two-point measurement protocols with noisy detectors that can estimate work fluctuations, showing that the dimensionality of entanglement can be probed in this manner.

#### QI 2.8 Mon 12:00 H9

Large fluctuations of qubit decoherence under 1/f noise of a sparse bath of two-level fluctuators — •MOHAMMAD MEHMANDOOST and VIATCHESLAV DO-BROVITSKI — QuTech and Kavli Institute of Nanoscience, Delft University of Technology, Lorentzweg 1, 2628 CJ Delft, The Netherlands

We theoretically study the qubit decoherence caused by 1/f noise of a sparse bath of Two-Level Fluctuators (TLFs) in the Ramsey and Hahn echo experiments. We focus on the role of bath density d, defined as the ratio of the number of TLFs n to the logarithmic frequency range  $\ln(\gamma_M/\gamma_m),$  on the qubit decoherence. The first spectral density of 1/f noise produced by sparse bath samples, small d, are roughly similar. The qubit decoherence in this regime is, however, not fully characterized by the noise first spectral density. We therefore use the exact expressions describing the qubit decoherence coupled to a sample TLF bath. Using Monte Carlo simulations, we show that the qubit decoherence is subject to large sample-to-sample fluctuations in sparse baths of fixed density d. This highlights the necessity to adopt a statistical approach to characterize the qubit decoherence in this regime. We also found that the qubit decoherence under 1/f noise of sparse TLF baths is governed by only a few TLFs. We show that if these TLFs are removed, the coherence times are substantially improved. We hope the latter finding opens up a way to improve the coherence times of the state-of-the-art qubits affected by 1/f noise.

## QI 2.9 Mon 12:15 H9

**Entanglement Preservation in Open Quantum System** — •MEI YU, STEFAN NIMMRICHTER, and OTFRIED GÜHNE — Universität Siegen, Siegen, Germany It's widely known that the entanglement will decay when system is exposed to the environment. In this paper, we study how to keep the entanglement against destructive effect from environment at different temperatures. Within the spin gases model, we firstly investigate the entangling ability of two-qubit gate in Markovian and non-Markovian dephasing environment. Then, we implement the specific reset operation on two-qubit system at stochastic times in order to keep entanglement in steady state. The steady-state entanglement behavior is analysed in both cases of Markvovian and non-Markovian dephasing noise with different temperatures. Excepting for considerable entanglement value, the difference between Markovian and non-Markovian effect can be observed directly.

#### Invited Talk

QI 3.1 Mon 15:00 H8 Generalized randomized benchmarking with short random quantum circuits — MARKUS HEINRICH¹, •MARTIN KLIESCH¹, and INGOR ROTH² — ¹Heinrich Heine University Düsseldorf, Germany — ²Technology Innovation Institute, Abu Dhabi, United Arab Emirates

The characterization of the quality of quantum gate implementations is among the most important certification tasks in the quantum sciences. State preparation and measurement errors render this task a challenge, in particular for large qubit numbers. Randomized benchmarking (RB) is among the most popular approaches to address this challenge. Rigorous theoretical guarantees for RB methods rely on sequences of unitary operations each of which is drawn uniformly from a group, often the Clifford group. Due to compiling, such RB strategies effectively require the implementation of quantum circuits with an unfavourable scaling of the circuit depth with the number of qubits. In practice, this scaling results in a restriction to a few qubits.

This talk starts with an introduction to RB, a generalized version thereof and a review of the idea of drawing the unitaries from a generating gate set of the group rather than from its uniform distribution in order to reduce the required circuit depths. Then we show analytically how this changes the exponential decay behaviour observed in RB. In particular, shorter circuits can result in decays that are a combination of the usual RB decay plus a decay corresponding to mixing properties (spectral gap of the moment operator) of the gate set. In this way, we shine new light on the important question of how quantum gates can be certified using short circuits.

## QI 3.2 Mon 15:30 H8

**Compressive gate set tomography** — •RAPHAEL BRIEGER¹, INGO ROTH², and MARTIN KLIESCH¹ — ¹Quantum technology, Heinrich Heine University Düsseldorf, Germany – ²Quantum Research Centre, Technology Innovation Institute, Abu Dhabi, UAE

Flexible characterization techniques that identify and quantify experimental imperfections under realistic assumptions are crucial for the development of quantum computers. Gate set tomography is a characterization approach that simultaneously and self-consistently extracts a tomographic description of the implementation of an entire set of quantum gates, as well as the initial state and measurement, from experimental data. Obtaining such a detailed picture of the experimental implementation is associated with high requirements on the number of sequences and their design, making gate set tomography a challenging task even for only two qubits. In this work, we show that low-rank approximations of gate sets can be obtained from significantly fewer gate sequences and that it is sufficient to draw them randomly. To this end, we formulate the data processing problem of gate set tomography as a rank-constrained tensor completion problem. We provide an algorithm to solve this problem while respecting the usual positivity and normalization constraints of quantum mechanics by using second-order geometrical optimization methods on the complex Stiefel manifold. Besides the reduction in sequences, we demonstrate numerically that the algorithm does not rely on structured gate sets or an elaborate circuit design to robustly perform gate set tomography and is therefore more broadly applicable than traditional approaches.

#### QI 3.3 Mon 15:45 H8

Spin squeezing inequalities meet randomized measurements - •JAN LENNART BÖNSEL, SATOYA IMAI, YE-CHAO LIU, and OTFRIED GÜHNE — University of Siegen, Siegen, Germany

Due to the recent advances in quantum control, large quantum systems containing thousands of atoms can nowadays be prepared in the lab. Here, the characterization of quantum correlations is of special interest. For systems where the individual atoms are difficult to address, the measurement of collective angular momentum observables and the evaluation of the corresponding spin squeezing inequalities are a possibility to characterize entanglement and its usefulness for metrology.

In this contribution, we first study the number of quantum state samples that are necessary to verify entanglement with a certain confidence. For this purpose, we compare different estimators of spin squeezing parameters. We characterize the probability that the estimator deviates from its mean using simulations as well as analytical bounds derived from concentration inequalities, like Cantelli's and Hoeffding's inequality. Second, we analyse if it is possible to obtain a good estimate from fewer measurements made only on a randomly chosen subset of the atoms.

Machine learning approaches to Optimal Gate Sequences for Quantum State Tomography under Noise — •Violeta N. Ivanova-Rohling^{1,2,3}, Niklas ROHLING^I, and GUIDO BURKARD¹ - ¹Department of Physics, University of Konstanz, D-78457 Konstanz — ²Zukunftskolleg, University of Konstanz, D-78457 Konstanz — ³Department of Mathematical Foundations of Computer Sciences, IMI, Bulgarian Academy of Sciences

For limited scenarios, depending on projector rank and system size, optimal measurement schemes for efficient quantum state tomography (QST) are known. In the case of errorless non-degenerate measurements, using mutually unbiased bases yields the optimal QST scheme [1]. However, in the general case, the optimal measurement scheme for efficient QST is not known and, may need to be numerically approximated. Here, we investigate the effect of noise on the optimal QST measurement sets using two noise models: the depolarizing channel, and over- and under-rotation in two-qubit gates [2]. Furthermore, we apply reinforcement learning for optimizing the effective times each quantum gate is switched on in a set of gate sequences which - combined with an elementary projective measurement - realizes a QST quorum. We extend the model by including errors from single-qubit gates and allow for longer gate sequences than necessary for realizing arbitrary measurements aiming at higher noise resilience overall.

Verifying arbitrary entangled state with homogeneous local measurements — •YE-CHAO LIU^{1,2}, YINFEI LI², JIANGWEI SHANG², and XIANGDONG ZHANG²

—¹Universität Siegen, Siegen, Germany — ²Beijing Institute of Technology, Beijing, China

Quantum state verification is the task that uses only local measurements to judge whether one unknown state is the pure state that we desire. Recently, with the rapid growth in the size of manipulated quantum systems, such a fundamental task attracts more and more attention due to the weakness of the standard tomography method in the efficiency, and many entangled states can be verified efficiently or even optimally. However, how to design a verification protocol for an arbitrary entangled state is still an open problem. In this paper, we present a systematic framework to solve the problem by considering the locality of what we call choice-independent measurement protocols, whose operators can be achieved directly when it is homogeneous. Taking several kinds of entangled states as examples, we demonstrate the concrete processes and results of the design method under the most common Pauli projections. Moreover, our framework can tackle the local protocol design of other tasks, like entanglement witness, which is also an important problem. Finally, all these tasks can be converted into corresponding parameter estimation tasks, whose local protocols can be always easily achieved by our methods.

Dynamical Uncertainty Propagation with Noisy Quantum Parameters •FELIX MOTZOI¹, MOGENS DALGAARD², and CARRIE WEIDNER³ ¹Forschungszentrum Juelich — ²Aarhus University — ³Bristol University Many quantum technologies rely on high-precision dynamics, which raises the

question of how these are influenced by the experimental uncertainties that are always present in real-life settings. A standard approach in the literature to assess this is Monte Carlo sampling, which suffers from two major drawbacks. First, it is computationally expensive. Second, it does not reveal the effect that each individual uncertainty parameter has on the state of the system. In this talk, we evade both these drawbacks by incorporating propagation of uncertainty directly into simulations of quantum dynamics, thereby obtaining a method that is orders of magnitude faster than Monte Carlo simulations and directly provides information on how each uncertainty parameter influences the system dynamics. Ad-

ditionally, we compare our method to experimental results obtained using the IBM quantum computers.

Error mitigation - handling noisy quantum hardware — • KATHRIN KÖNIG and THOMAS WELLENS — Fraunhofer IAF, Freiburg, Germany

Currently available quantum computing hardware suffers from errors due to environmental influences, nearest-neighbour interactions and imperfect gate operations. To achieve robust quantum computing, there are techniques like error mitigation by zero-noise extrapolation [1]. To reduce the impact of gate errors on observable expectation values, arbitrary noise can also be converted into stochastic Pauli errors by so called noise tailoring [2]. We elaborate on the implementation of error mitigation on a superconducting quantum computer and its impact on the computation of expectation values.

QI 3.8 Mon 17:15 H8 Break-even point of the quantum repetition code — ÁRON ROZGONYI and •GÁBOR SZÉCHENYI — Eötvös University, Budapest

Repetition code is not a real quantum error correction code in the sense, that it cannot protect the logical information against any Pauli error. However, for simplicity repetition code is widely investigated theoretically and used for benchmarking state-of-the-art quantum devices. In our work, we analyze the efficiency of the phase-flip code as a quantum memory in presence of relaxation and dephasing. We take into account noisy two-qubit gates suffering from depolarizing and coherent error. We determine the parameter regime, where the repetition code performs better than an idle qubit.

QI 3.9 Mon 17:30 H8

Benchmarking quantum error correcting codes on near-term devices •REGINA FINSTERHOELZL and GUIDO BURKARD — Department of Physics, University of Konstanz

We evaluate the performance of small error-correcting codes which we implement on hardware platforms of very different connectivity and coherence: On a superconducting processor and on a spintronic quantum register consisting of a color center in diamond. Taking the hardware-specific errors and connectivity into account, we investigate the dependence of the resulting logical error rate on the platform features such as the native gates, the native connectivity, gate times, and coherence times. Using a standard error model parametrized for the given hardware, we simulate the performance and benchmark these predictions with experimental results when running the code on a real quantum device. The results indicate that for small codes, the hexagonal layout of the superconducting processor proves advantageous, yet for larger codes with multi-qubit controlled operations, the star-like connectivity of the color centers enables lower error rates.

QI 3.10 Mon 17:45 H8 Quantum Lifelong Learning — •Lukas Sigl^{1,2}, Tatjana Wilk², Anna Donhauser^{3,2}, Stefan Küchemann^{3,2}, Bernhard Kraus¹, Jan von Delfr^{3,2}, Jochen Kuhn^{3,2}, and Alexander Holleitner^{1,2} — ¹TU Munich, Cormany – ²MCOCT Commun – ³TUULL is 1 = 2 Germany — ²MCQST, Germany — ³LMU Munich, Germany

Quantum technologies comprise rapidly growing scientific fields with great potential for applications in industry. The current challenge for Germany and Europe is to educate a sufficiently large number of students in quantum technologies and to transfer knowledge as well as technological expertise from the research laboratories to the industrial sector.¹ A key role is played by the specialists and executives of the high-tech industry, who have to recognize and implement the specific potential of quantum technologies for the respective company. We present our Munich project Quantum LifeLong Learning (QL3), a targeted education and training program of the Munich universities in the field of quantum technologies according to a university certificate and ECTS system with the target group of specialists and executives in industry. We acknowledge financial support by the Bundesministerium für Bildung und Forschung (BMBF) of Germany.

Toward Digital-Analog Simulations using Superconducting Qubits and Res**onators** — •RICCARDO ROMA¹, FRANK WILHELM-MAUCH^{1,2}, and DMITRY BAGRETS^{2,3} — ¹Theoretical Physics, Universität des Saarlandes, 66123 Saarbrücken, Germany — ²Forschungszentrum Jülich GmbH, Germany — ³Institut für Theoretische Physik, Universität zu Köln, Zülpicher Straße 77, 50937 Köln, Germany

We propose a novel architecture for processors based on superconducting qubits coupled to resonators for digital-analog simulations of bosonic-fermionic systems. More in detail we present some preliminary results of the numerical analysis of a system composed of a pair of superconducting qubits, each coupled to an ancillary qubit via a resonator, interacting with a cross-resonance gate.

#### QI 4.2 Mon 18:00 P2

Electronic Structure Simulations for Batteries and Fuel Cells Using a Quantum Computer — •KONSTANTIN LAMP^{1,2}, ALEJANDRO D. SOMOZA¹, FELIX RUPPRECHT¹, MARINA WALT³, NICOLAS VOGT³, GIORGIO SILVI³, and BIRGER HORSTMANN^{1,2} – ¹German Aerospace Center, Wilhelm-Runge Straße 10, 89081 Ulm —  2 Helmholtz Institute Ulm, Helmholtzstraße 11, 89081 Ulm -³HQS Quantum Simulations GmbH, Haid-und-Neu-Strasse 7, 76131 Karlsruhe In the context of modern energy devices like batteries and fuel cells a description of challenging molecular structures is vital for the advancement of these technologies. However, classical algorithms for the simulation of such systems suffer from an exponential growth in required resources, which may be avoided by exploiting the correspondence between chemical orbitals and qubits of a quantum computer.

In this work, we show a variety of hybrid quantum algorithms for electronic structure calculations performed on the IBM System One quantum computer with state-of-the-art techniques of error mitigation and noise characterization. In particular, we focus on a class of hybrid algorithms that leverage additional measurements on the quantum processor without an increase in the complexity of the quantum circuits, like VQSE [Phys.Rev.X 10, 011004] and an extension of the QEOM method [Phys.Rev.Res. 2, 043140]. Furthermore, we investigate techniques like Entanglement Forging [arXiv:2104.10220] that exploit partitions of the initial problem into strongly correlated sectors in order to achieve efficient quantum simulations of larger systems.

Quantum simulation of the transverse field Ising models — •SUMEET SUMEET and KAI PHILLIP SCHMIDT - Friedrich-Alexander-Universität Erlangen-Nürnberg, Department of Physics, Staudtstraße 7, 91058 Erlangen, Germany With the advancements in quantum technologies, it has become inevitable to investigate the potential existence of quantum advantages for quantum many-body systems. One of the most paradigmatic model is the transverse field Ising model (TFIM) that can be simulated on a quantum computer to compute properties such as the ground-state energy. This problem, when tackled on a classical computer, leads to an exponential surge in the cost of computation with increasing system size. Classical-quantum hybrid algorithms such as the Variational Quantum Eigensolver (VQE) algorithm, is considered reasonably good for obtaining the ground-state energy of quantum many-body systems in the current NISQ era. Here we explore various ansaetze, focusing mainly on the Hamiltonian variational ansatz, for calculating the ground-state energy of one-dimensional TFIMs. We devise strategies to compute the ground-state energy for relatively large spin systems leveraging the power of quantum computers. In addition to that, we explore the quantum advantage and access the resource requirement for a quantum computer to evaluate the properties of systems in difficult regions around the quantum phase transition, which is a computationally difficult problem for a classical computer. Further, we extend our considerations to explore geometrically frustrated TFIMs using quantum simulation.

#### QI 4.4 Mon 18:00 P2

Estimating the entangling power of a two-qubit gate from measurement data: artificial neural networks and randomized measurements versus standard tomography methods — •SALWA SHAGLEL — Universität Siegen, Siegen, Germany Quantum logic gates are the building blocks of quantum circuits and algorithms, where the generation of entanglement is essential to perform quantum computations. The amount of entanglement that a unitary quantum gate can produce from product states can be quantified by the so-called entangling power, which is a function of the gate's unitary or Choi matrix representation.

I introduce two efficient approaches to the practical problem of estimating the entangling power of an unknown two-qubit gate from measurement data. The first approach is using a deep neural network trained with noisy data simulating the outcomes of prepare-and-measure experiments on random gates. The training data is restricted to 48 measurement settings, which is significantly less than the 256 dimensions of the ambient space of 16x16 Choi matrices and very close to the minimum number of settings that guarantees the recovery of a two-qubit unitary gate using the compressed sensing technique at an acceptable error rate. The second approach to determine the entangling power is based on the second moments of correlation functions obtained from locally randomized measurements. The two approaches do not make any prior assumptions about the quantum gate, and they also avoid the need for standard reconstruction tools based on full quantum process tomography, which is prone to systematic errors.

#### QI 4.5 Mon 18:00 P2

**Frequency-degenerate Josephson mixer for quantum illumination** — •FABIAN KRONOWETTER^{1,2,3}, FLORIAN FESQUET^{1,2}, MARIA-TERESA HANDSCHUH^{1,2}, KEDAR HONASOGE^{1,2}, YUKI NOJIRI^{1,2}, MICHAEL RENGER^{1,2}, ACHIM MARX¹, FRANK DEPPE^{1,2,4}, RUDOLF GROSS^{1,2,4}, and KIRILL G. FEDOROV^{1,2} — ¹Walther-Meißner-Institut, BAdW, 85748 Garching, Germany — ²Physik-Department, TUM, 85748 Garching, Germany — ³Rohde & Schwarz GmbH, 81671 Munich, Germany — ⁴Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany

In quantum illumination, the joint measurement of the signal and idler beams enables a quantum advantage in target detection, as compared to the ideal classical radar. This advantage is predicted to exist for the case of weak quantum signals propagating in a bright thermal background, where the latter potentially contains a weakly reflecting target. The joint measurement exploits non-classical correlations between the signal and idler modes. A promising detector concept allowing for a theoretical 3 dB quantum advantage implements this joint measurement by exploiting a frequency-degenerate Josephson mixer (JM). The circuit of this JM consists of two 180° hybrid ring beam splitters and two flux-driven Josephson parametric amplifiers. We present the first successful operation of the frequency-degenerate JM with Gaussian states and, thus, demonstrate an important milestone for the realization of the microwave quantum radar.

QI 4.6 Mon 18:00 P2

**Fabrication of low-loss Josephson parametric circuits** — •KEDAR E. HONASOGE^{1,2}, YUKI NOJIRI^{1,2}, DANIIL E. BAZULIN^{1,2}, LEON KOCH^{1,2}, THOMAS LUSCHMANN^{1,2}, NIKLAS BRUCKMOSER^{1,2}, MARIA-TERESA HANDSCHUH¹, FLO-RIAN FESQUET^{1,2}, MICHAEL RENGER^{1,2}, FABIAN KRONOWETTER^{1,2,4}, ACHIM MARX¹, STEFAN FILIPP^{1,2,3}, RUDOLF GROSS^{1,2,3}, and KIRILL G. FEDOROV^{1,2} — ¹Walther-Meißner-Institut, 85748 Garching, Germany — ²Physik-Department, Technische Universität München, 85748 Garching, Germany — ³Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany — ⁴Rohde & Schwarz GmbH, Munich, Germany

Interest in quantum-limited amplification based on Josephson superconducting circuits has increased drastically in the past decade due to the rapidly advancing field of quantum information processing. In this context, a key challenge lies in realizing low-loss superconducting devices by minimizing energy dissipation. We achieve this goal by employing various cleaning steps during fabrication of superconducting circuits. Respectively, we fabricate Josephson parametric amplifiers with internal quality factors in excess of 10⁴. We characterize bandwidth, gain, noise, dynamic range, and other properties of the realized devices. Based on these investigations, we derive useful criteria for development of more intricate Josephson parametric circuits, such as Josephson parametric converters.

#### QI 4.7 Mon 18:00 P2

**Perspectives of microwave quantum key distribution** – •FLORIAN FESQUET^{1,2}, FABIAN KRONOWETTER^{1,2,4}, MICHAEL RENGER^{1,2}, KEDAR HONASOGE^{1,2}, YUKI NOJIRI^{1,2}, MARIA-TERESA HANDSCHUH^{1,2}, ACHIM MARX^{1,2}, RUDOLF GROSS^{1,2,3}, and KIRILL. G. FEDOROV^{1,2} – ¹Walther- Meißner-Institut, 85748 Garching, Germany – ²Physik-Department, TUM, 85748 Garching, Germany – ³Munich Center for Quantum Science and Technology (MCQST), 80799 Munich, Germany – ⁴Rohde & Schwarz GmbH, 81671 Munich, Germany

One of the cornerstones of quantum communication is an unconditionally secure distribution of classical keys between remote parties. This can be achieved by exploiting quantum features of electromagnetic waves, such as entanglement or the no-cloning theorem. However, these quantum resources are known to be susceptible to noise and losses, which are omnipresent in open-air communication scenarios. Here, we theoretically investigate the perspectives of continuousvariable open-air quantum key distribution (QKD) at microwave frequencies. We demonstrate that continuous-variable QKD with propagating microwaves can be unconditionally secure at room temperatures at distances up to 200 meters. Furthermore, we show that microwave QKD provides the potential to outperform conventional QKD protocols at telecom wavelengths for certain weather conditions

#### QI 4.8 Mon 18:00 P2

Simulating quantum repeaters with experimentally relevant parameters — •JULIUS WALLNÖFER¹, FABIAN WIESNER¹, FREDERIK HAHN¹, NATHAN WALK¹, and JENS EISERT^{1,2} — ¹Dahlem Center for Complex Quantum Systems, Freie Universität Berlin, 14195 Berlin, Germany — ²Helmholtz-Zentrum Berlin für Materialien und Energie, 14109 Berlin, Germany

The quantum repeater protocol is a well established standard for distributing entanglement over long distances. However, there are a number of open questions when considering setups that go beyond the standard scenarios and error models. We have developed a numerical simulation platform for quantum repeaters to explore in multiple directions:

(i) With experiments of small scale quantum repeaters becoming a reality, it is of high interest to explore detailed error models that are close the real situations found in the experiment. Our simulation allows us to not only compare setups with different parameters, but also to assess the effect of improving certain aspects has on e.g. the achievable key rate.

(ii) We explore conceptual questions in larger scale quantum repeaters outside of standard situations - especially in asymmetric setups where e.g. the length or quality of quantum channels is not identical. Furthermore, we investigate strategies for quantum repeaters when considering entanglement purification and multi-mode memories.

**Rare earth ion materials in micro-cavities as optically addressable qubits for quantum information** — •JANNIS HESSENAUER¹, CHRISTINA IOANNOU¹, KUMAR SENTHIL KUPPUSAMY¹, MARIO RUBEN¹, DIANA SERRANO², PHILIPPE GOLDNER², and DAVID HUNGER¹ — ¹Karlsruher Institut für Technologie, Karlsruhe, Germany — ²Université PSL, Chimie ParisTech, CNRS, Paris, France Rare earth ions retain long optical and spin coherence times in solid state hosts and are therefore a promising realization of optically addressable spin qubits. Due to the dipole forbidden nature of the optical transitions, an efficient spinphoton interface for quantum information technology requires the coupling of single ions to an optical cavity to enhance the transitions via the Purcell effect. Recently, rare earth ions in molecular crystals have demonstrated outstanding coherence properties, while also promising a large parameter space for optimization by chemically engineering of the host molecule. We characterize the optical properties of molecular materials at low temperature using techniques such as photoluminescence spectroscopy, absorption spectroscopy and spectral hole burning. Furthermore, we present our progress towards integrating Yb³⁺-doped materials into stable high finesse fiber-based Fabry-Pérot cavities.

#### QI 4.10 Mon 18:00 P2

**Circular Bragg gratings for Integrated Enhancement of Quantum Emitters** — •DARIO MEKLE, JONAS GRAMMEL, and DAVID HUNGER — Physikalisches Institut, Karlsruher Institut für Technologie

Surface-emitting center-disk cavities, composed of circular Bragg gratings have been successfully employed for distributed feedback lasers and quantum emitter applications based on nitrogen vacancy centers and semiconductor quantum dots.

We aim to transfer this approach to achieve greater collection efficiencies of rare earth ion based emitters in the form of nanocrystals and molecules. The collection efficiency is improved through the use of cavity induced Purcell enhancement and by utilizing directional field emission patterns. A finite element analysis is used to perform geometric parameter optimizations of circular Bragg cavities consisting of PMMA (or similar polymers) and air layers.

The simulation predicts a Purcell factor of more than 140, significantly higher than previously published results. We report on progress in fabricating the simulated structures using electron beam lithography on gold substrates.

#### QI 4.11 Mon 18:00 P2

Enhancing the optical emission of erbium dopants in silicon with photonic crystals — •FLORIAN BURGER^{1,2}, LORENZ WEISS^{1,2}, ANDREAS GRITSCH^{1,2}, STEPHAN RINNER^{1,2}, JOHANNES FRÜH^{1,2}, and ANDREAS REISERER^{1,2} — ¹Max Planck Institute of Quantum Optics, Garching bei München, Germany — ²Munich Center for Quantum Science and Technology (MCQST), LMU Munich, Germany

Silicon photonics has developed into a mature technology platform that allows for rapid development cycles using standardized tools. Integrating coherent optical emitters into silicon chips would pave the way towards large-scale quantum networks. In this context, we explore the use of erbium dopants which feature both long spin coherence times and coherent optical transitions in the telecom C band, where the loss in optical fibers is minimal. Using low-loss nanowire waveguides, we performed resonant spectroscopy and were able to confirm the integration of erbium dopants at well-defined lattice sites, with narrow inhomogeneous linewidths of approximately 1 GHz and homogeneous linewidths of less than 20 kHz at temperatures below 8 K. As the practical use of the investigated transitions is hampered by their long excited-state lifetime, we plan to enhance the emission with tailored photonic nanostructures. To this end, we have designed and fabricated nanophotonic cavities, offering strong narrow-band Purcell enhancement, as well as photonic-crystal waveguides with moderate broadband Purcell enhancement. We will present details about the design and fabrication of these structures, and give an outlook on the control of single erbium dopants in silicon.

#### QI 4.12 Mon 18:00 P2

**Cavity-enhanced spectroscopy of molecular quantum emitters** — •Evgenij Vasilenko, Weizhe Li, Nicholas Jobbitt, Senthil Kuppusamy, Mario Ruben, and David Hunger — Kalrsruhe Institute of Technology (KIT)

Rare earth ions in solid-state hosts are a promising candidate for optically addressable spin qubits, owing to their excellent optical and spin coherence times. Recently, also rare earth ion-based molecular complexes have shown excellent optical coherence properties [1]. Due to the long optical lifetime of the optical transition  ${}^{5}D_{0}$ - ${}^{7}F_{0}$ , an efficient spin-photon interface for quantum information processing requires the coupling of single ions to a microcavity. Open-access Fabry-Pérot fiber cavities have been demonstrated to achieve high quality factors and low mode volumes, while simultaneously offering large tunability and efficient collection of the cavity mode [2]. Since the used molecular quantum emitters require a cryogenic environment, the demands on mechanical stability of the cavity setup have a high priority. To tackle these challenges, we report on the development of a monolithic type of cavity assembly, sacrificing some lateral scanning ability for the purpose of significantly increasing the passive stability. We integrate molecules into the cavity in the form of a crystalline thin film on a macroscopic mirror and identify a sub-nanometer local surface roughness, sufficient to avoid excessive scattering loss. We report on first studies of cavityenhanced emission spectroscopy.

QI 4.13 Mon 18:00 P2 **Finite-range multiplexing in tripartite quantum networks** — •JULIA ALINA KUNZELMANN, HERMANN KAMPERMANN, and DAGMAR BRUSS — Institut für Theoretische Physik III, Heinrich-Heine-Universität Düsseldorf

Due to the interaction between qubits and their environment, long-distance communication still poses a challenge. To overcome this problem, quantum repeaters are used, in which the repeater rate can be maximized by utilizing multiplexing. In previous work (Abruzzo et al. (2014)), a finite-range multiplexing protocol for two parties was investigated. We extend this protocol to three parties and it turns out that also in the tripartite network, full-range multiplexing does not provide substantial advantages over finite-range multiplexing. We also analyze decoherence of quantum memories and various strategies to lower the experimental requirements. To achieve this, different three-dimensional matching strategies are analyzed.

#### QI 4.14 Mon 18:00 P2

Integrated Photonic Information Processing for Quantum Networks – •JELDRIK HUSTER¹, SIMON ABDANI¹, JONAS ZATSCH¹, CHRISTIAN SCHWEIKERT², ROUVEN KLENK², and STEFANIE BARZ¹ – ¹Institute for Functional Matter and Quantum Technologies & IQST, University of Stuttgart, 70569 Stuttgart, Germany – ²Institute of Electrical and Optical Communications Engineering, University of Stuttgart, 70569 Stuttgart, Germany

The steady progression of photonic quantum systems allows the realisation of quantum computation, communication and networked applications. Key in pursuit of scalable photonic quantum technology are integrated devices operating in the telecom regime, due to their small footprint, high phase stability and low loss connectivity. Particularly, the generation of multipartite entangled states is of special interest. These states are the basis for measurement-based quantum computing and multiparty key exchange. Here, we present our recent progress on silicon-photonic quantum circuits operating at the single-photon level. The circuits consist of tuneable beam splitters, phase shifters and highly efficient grating couplers. They are powered by spontaneous parametric down conversion sources and used in combination with superconducting single-photon detectors. We show the characterisation of integrated devices and a pathway to generate complex entangled sates in an integrated manner.

#### QI 4.15 Mon 18:00 P2

Entanglement distribution over a cryogenic microwave link — •SIMON GANDORFER^{1,2}, MICHAEL RENGER^{1,2}, WUN KWAN YAM^{1,2}, FLORIAN FESQUET^{1,2}, KEDAR HONASOGE^{1,2}, FABIAN KRONOWETTER^{1,2,3}, YUKI NOJIRI^{1,2}, MARIA-TERESA HANDSCHUH^{1,2}, ACHIM MARX¹, RUDOLF GROSs^{1,2,4}, and KIRILL G. FEDOROV^{1,2} — ¹Walther-Meißner-Institut, 85748 Garching, Germany — ²Physik-Department, TUM, 85748 Garching, Germany — ³Rohde & Schwarz GmbH & Co. KG, 81671 Munich, Germany — ⁴Munich Center for Quantum Science and Technology, 80799 Munich, Germany

In the context of rapid progress in quantum technologies, the realization of hardware platforms for quantum communication networks is of utmost importance. Quantum local area networks connecting remote superconducting quantum nodes are crucial for the implementation of distributed quantum computing architectures. In this regard, we demonstrate a 6.5 m cryogenic link connecting two dilution cryostats via a cold network node. The respective microwave quantum communication channel is realized with superconducting microwave coaxial cables cooled to temperatures below 100 mK. By using this system, we demonstrate a successful distribution of squeezed states and two-mode entanglement between the remote dilution fridges and validate robustness of the quantum state transfer up to channel temperatures of 1 K.

QI 4.16 Mon 18:00 P2

Efficient spin-photon interface for NV centers in diamond — •JEREMIAS RESCH¹, KERIM KÖSTER¹, MAXIMILLIAN PALLMANN¹, JULIA HEUPEL², CYRIL POPOV², and DAVID HUNGER¹ — ¹Karlsruher Institut für Technologie (KIT) — ²Universität Kassel

In order to achieve spin-photon-based quantum computers, we require excellent control of the qubit spin states, in addition to long coherence times of the nuclear spin states. By combining several computing nodes, and linking them to a global register via optical networks, scalability is achieved. A crucial component of this optical network is an efficient, coherent single-photon source. Coupling colour centers in diamond, such as the nitrogen-vacancy or tin-vacancy centers, to a microcavity is a promising approach in order to achieve efficient single-photon sources. In our experiment, we integrate a diamond membrane into an open access fiber-based Fabry-Perot microcavity to attain emission enhancement into a single well-defined mode. We present our fully tunable, cryogenic cavity platform operating in a closed-cycle cryostat, and we achieve a sub-picometer mechanical stability during quiet periods. We observe cavity-enhanced fluorescence spectra of an ensemble of shallow-implanted nitrogen-vacancy centers in diamond, showing Purcell-enhancement of the zero-phonon line.

#### QI 4.17 Mon 18:00 P2

**Designing a microwave antenna for spectroscopy of nitrogen vacancy centers in a fiber-based cavity** — •MATTHIAS KLAUSMANN, MAXIMILIAN PALLMANN, JEREMIAS RESCH, and DAVID HUNGER — Karlsruher Institut für Technologie Overcoming losses in long distance fiber-based quantum networks is one of the big challenges in the field of quantum communication, which requires the development of a quantum repeater. Color centers in diamond are a promising platform for realizing the needed spin-photon interfaces due to the possibility of optical readout and initialization. The optical readout of coherent photons can be enhanced by integrating the diamond in a cavity by exploiting the Purcell-effect. In addition, the coherent control of the electron spin of the color center and nearby nuclear spins is necessary for such a device.

In our experiment, we look for different designs of microwave antennas to manipulate the electron spin of nitrogen vacancy centers in a fiber-based Fabry-Pérot micro-cavity with regard that this can also be used under cryogenic conditions. Testing the antenna designs is performed in a room-temperature confocal microscope setup. We observe large ensembles of shallow implanted nitrogenvacancy centers but also single centers at a depth of a few micrometers below the diamond surface. With our antennas we are able to perform pulsed optically detected magnetic resonance, Rabi and Echo measurements. Using this measurement protocols, the hyperfine interaction between the electron spin and the nuclear spin of the hosting nitrogen atom as well as the interaction with a nearby 13C nuclear spin can be resolved.

#### QI 4.18 Mon 18:00 P2

**Microwave quantum teleportation over thermal channels** — •WUN KWAN YAM^{1,2}, MICHAEL RENGER^{1,2}, SIMON GANDORFER^{1,2}, FLORIAN FESQUET^{1,2}, KEDAR HONASOGE^{1,2}, FABIAN KRONOWETTER^{1,2,3}, YUKI NOJIRI^{1,2}, MARIA-TERESA HANDSCHUH^{1,2}, ACHIM MARX¹, RUDOLF GROSS^{1,2,4}, and KIRILL G. FEDOROV^{1,2} — ¹Walther-Meißner-Institut, BAdW, 85748 Garching, Germany — ²Physik-Department, TUM, 85748 Garching, Germany — ³Rohde & Schwarz GmbH & Co. KG, 81671 Munich, Germany — ⁴Munich Center for Quantum Science and Technology, 80799 Munich, Germany

Microwave quantum communication enables quantum local area networks between superconducting quantum processors and, thereby, paves the way towards distributed quantum computing. Quantum teleportation belongs to the most relevant quantum communication protocols. It permits efficient and unconditionally secure transfer of quantum states. Recent experimental demonstration of quantum teleportation with propagating microwaves [1] motivates the investigation of its resilience against experimental imperfections. To this end, we analyze the effect of thermal noise in the analog feedforward channel. We show that quantum teleportation implements an error correction scheme for loss and noise in the feedforward signal. Furthermore, we consider realistic operating parameters and find that the teleportation fidelity can exceed the no-cloning threshold for finite energy codebooks.

**Quantum Polyspectra - Grand Unified Theory of Continuous Quantum Mea**surements — •MARKUS SIFFT and DANIEL HÄGELE — Ruhr University Bochum, Faculty of Physics and Astronomy, Experimental Physics VI (AG), Germany The evaluation of continuous quantum measurements is a challenge in research areas like circuit quantum electrodynamics, spin noise spectroscopy, and quantum sensing. Measurement records can exhibit as diverse results as quantum jumps, mainly Gaussian noise, or even stochastic peaks from detectors with single photon resolution. Until now, specialized theories were used to model and eventually evaluate such measurement records. The poster reports on our recent progress in unifying all continuous measurement schemes into one theory. The theory is based on the measurement record, its power spectrum, and its third and fourth order generalizations, so-called polyspectra. Expressions for quantum polyspectra can be derived without approximation from the stochastic master equation [1]. System parameters follow from fitting quantum polyspectra to measured spectra [2]. This approach allows for a systematic evaluation of quantum measurements including coherent quantum dynamics, environmental damping, and measurement backaction at arbitrary measurement strength (Zeno-physics). We present and interpret quantum polyspectra of conventional spin noise spectroscopy, quantum transport through quantum dots, and spin noise spectroscopy in the single-photon regime.

**Multipartite High-dimensional Quantum Steering** – •SOPHIE EGELHAAF and ROOPE UOLA — Department of Applied Physics, University of Geneva, 1211 Geneva, Switzerland

Bipartite low dimensional entanglement has been studied extensively. However, many findings cannot be extrapolated to multiple parties and moreover, increasing the dimensions of the systems adds complexity to the entanglement structure.

We are interested in characterising the degree of high-dimensional entanglement, specifically focusing on various multipartite quantum steering scenarios. One such example is a triangle network with only one trusted party, or more generally a line network with some trusted parties. We investigate what can be deduced about the strength of entanglement between the different nodes of the network in such scenarios. We are especially interested in entanglement dimensionality, i.e. the question of how many degrees of freedom can be certified to be entangled, for which we provide analytical bounds.

## QI 4.21 Mon 18:00 P2

**Gate-error characterization via long-sequence quantum process tomography** — •ANDREAS KETTERER and THOMAS WELLENS — Fraunhofer Institut für Angewandte Festkörperphysik (IAF), Tullastr. 72, 79108 Freiburg, Germany

Currently available quantum computing hardware realizes networks of tens of super-conducting qubits with the possibility of controlled nearest-neighbor interactions. However, the inherent noise and decoherence effects of such quantum chips considerably alter basic gate operations and lead to imperfect outputs of the targeted quantum computation. We show how to characterize such quantum gate errors in detail using a combination of quantum process and gate set tomography in order to estimate a complete set of single- and two-qubit gate operations. Key ingredients of our approach are the efficient characterization of a universal single qubit gate set via gate-set tomography and the subsequent reconstruction of one additional two-qubit entangling gate using a long-sequence version of quantum process tomography. The latter involves repeated applications of the respective target gate in combination with appropriately chosen single-qubit operations in order to assure a precise estimation of all involved error parameters. Lastly, we demonstrate the devised protocol by implementing it on IBMQ hardware and briefly discuss the impact of crosstalk effects on near-term quantum algorithms.

#### QI 4.22 Mon 18:00 P2

**Solvable projected entangled pair states for ternary unitary quantum gates** — •RICHARD MAXIMILIAN MILBRADT¹, CHRISTOPHER ASSMUS¹, and CHRISTIAN BERNHARD MENDL^{1,2} — ¹Technical University of Munich, Department of Informatics, Boltzmannstraße 3, 85748 Garching, Germany — ²Technical University of Munich, Institute for Advanced Study, Lichtenbergstraße 2a, 85748 Garching, Germany

Recently we introduced the so-called ternary unitary quantum gates. These are four-particle gates acting in 2 + 1-dimensions and are unitary in time and both spatial dimensions. Now we generalise the concept of solvable MPS[Phys. Rev. B 101, 094304 (2020)] to two spatial dimensions with cylindrical boundary conditions. We show that such *solvable PEPS* can be identified with matrix product unitaries. In the resulting tensor network for evaluating equal-time correlation functions, the bulk ternary unitary gates cancel out, and we delineate and implement a numerical algorithm for computing such correlations.

Towards digital-analog quantum computing with superconducting qubits — Julia Lamprich¹, Nicola Wurz¹, •Stefan Pogorzalek¹, Manish Thapa¹, Vicente Pina-Canelles¹, Antti Vepsäläinen², Miha Papič¹, Jayshankar Nath¹, Florian Vigneau¹, Daria Gusenkova¹, Ping Yang¹, Hermanni Heimonen², Hsiang-Sheng Ku¹, Adrian Auer¹, Johannes Heinsoo², Frank Deppe¹, and Inés de Vega¹ — ¹IQM Quantum Computers, Nymphenburgerstr. 86, 80636 Munich, Germany — ²IQM Quantum Computers, Keilaranta 19, FI-02150 Espoo, Finland

Digital-Analog Quantum Computing (DAQC) is a novel approach to quantum computing. Here, one variant is banged DAQC where single qubit gates are applied on top of an analog (entangling) evolution. We have investigated the experimental and fundamental challenges in realizing banged DAQC for the example of preparing a Bell state. The main challenge in banged DAQC is the correct execution of single qubit gates under simultaneous qubit-qubit interaction. The latter is induced by a flux-tunable coupler element, which allows for the accumulation of conditional phase during the analog block. In addition, banged DAQC is compared to an alternative approach called stepwise DAQC, where the single qubit gates are executed only when the qubits do not interact. For both approaches, the relevant error sources are identified and fidelities are compared to the purely digital case.

We acknowledge support from the German Federal Ministry of Education and Research via the projects DAQC (13N15686) and Q-Exa (13N16062).

Thermo-optical properties of superconducting thin films for waveguideintegrated single-photon detectors. — •ANTHONY CHUKWUNONSO OGBUEHI^{1,2}, PIERRE PIEL^{1,2}, MARTIN WOLFF^{1,2}, MATTHIAS HÄUSSLER^{1,2}, CARSTEN SCHUCK^{1,2}, and URSULA WURSTBAUER^{1,2} — ¹Institute of Physics, Münster University, Germany — ²Center for Soft Nanoscience SoN, Münster University, Germany

Integrated quantum photonics relies on the generation, manipulation, and measurement of single quantum states of light. The latter can be achieved with superconducting nanowire single-photon detectors (SNSPD) embedded into photonic integrated circuits [1]. While SNSPDs show attractive detection efficiency and high timing accuracy [2], it remains largely unknown how detector performance characteristics are connected to superconducting material properties. Here we study the temperature-dependent dielectric function of niobium-titanium nitride (NbTiN) thin films above and below the critical temperature by means of spectroscopic ellipsometry by varying a number of parameters. Material optimization guided by spectroscopic ellipsometry provides a novel approach for both getting new insight into key parameters of the detection process and improving single-photon detector benchmarks, benefitting a wide range of integrated quantum technology applications.

**Quantum Possibilistic Paradoxes and Logical Contextuality** — •LEONARDO SANTOS — Universität Siegen, Siegen, Germany

Contextuality and nonlocality are nonclassical properties exhibited by quantum statistics whose implications profoundly impact both the foundations and applications of quantum theory. In this contribution we provide some insights into logical contextuality and inequality-free proofs. The former concept can be understood as the possibility version of contextuality, while the latter refers to proofs of quantum contextuality or nonlocality that are not based on violations of some noncontextuality (or Bell) inequality. By *possibilistic* we mean a description in terms of possibilities for the outcomes, which are Boolean variables assuming value 1 when the corresponding probability is strictly larger than zero and 0 otherwise. In this work we built a bridge between these two concepts from what we call possibilistic paradoxes, which are sets of possibilistic conditions whose occurrence implies contextuality and nonlocality. As the main result, we demonstrate the existence of possibilistic paradoxes whose occurrence is a necessary and sufficient condition for logical contextuality in a very important class of scenarios. Finally, we discuss some interesting consequences arising from the completeness of these possibilistic paradoxes.

**Generating Entangled States on IBM Quantum** — SEBASTIAN BRANDHOFER¹, JELENA MACKEPRANG², •DANIEL BHATTI², ILIA POLIAN¹, and STEFANIE BARZ² — ¹Institute of Computer Architecture and Computer Engineering & IQST, University of Stuttgart, Germany — ²Institute for Functional Matter and Quantum Technologies & IQST, University of Stuttgart, Germany

Commercially available quantum computers have reached the NISQ era and already can be employed to run basic quantum algorithms. One of the most important resources for quantum computations are entangled multi-qubit quantum states. Therefore, it is necessary to produce these states deterministically and with a high fidelity. Based on the specific physical architectures of different IBM quantum computers we produce graph states and GHZ states with the help of CPHASE and CNOT gates, respectively, and assess the quality of the state preparation. To optimize the resulting state fidelities, we develop and implement a classical optimization algorithm that considers various error characteristics of the qubits and the two-qubit gates.

## QI 4.27 Mon 18:00 P2

Quantum circuits for the preparation of spin eigenfunctions on quantum computers — •ALESSANDRO CARBONE^{1,2}, DAVIDE EMILIO GALLI², MARIO MOTTA³, and BARBARA JONES³ — ¹Theory and Simulations of Materials (THEOS), and National Centre for Computational Design and Discovery of Novel Materials (MARVEL), École Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland — ²Dipartimento di Fisica, Università degli Studi di Milano, via Celoria 16, 20133 Milano, Italy — ³IBM Quantum, IBM Research Almaden, 650 Harry Road, San Jose, CA 95120, USA

The preparation of accurate and efficient approximations for Hamiltonian eigenstates on quantum computers is a crucial step for building the quantum advantage when studying many-body quantum systems. If we can describe molecules or materials with a coarse-grained spin Hamiltonian, spin eigenfunctions can be a useful starting point for simulations which aim to understand their electronic structure. In particular the purpose of this work is to delve into the description of the quantum circuits which prepare total spin eigenfunctions in the case of spin-1/2 systems. We investigate the balance between generality, accuracy, and computational cost in the encoding of spin eigenfunctions by quantum circuits without ancillary qubits, by pursuing two approaches: an exact recursive construction of spin eigenstates, and a heuristic variational construction of approximate spin eigenstates. We have tested the described quantum circuits on the available IBM (classical) simulators and quantum devices in the cases of 3-spin and 5-spin systems.

#### QI 4.28 Mon 18:00 P2

**Performances and limitations of variational quantum algorithms under realistic noise models** — •MARCO SCHUMANN, FRANK WILHELM-MAUCH, and ALESSANDRO CIANI — Institute for Quantum Computing Analytics (PGI-12), Forschungszentrum Jülich, 52425 Jülich, Germany

As the field of quantum computing progresses, an intriguing question is if the currently available NISQ devices can deliver a quantum advantage for practical applications, like Variational Quantum Algorithms (VQAs). Due to the lack of error correction, noise limits the performance of these algorithms. Recently it was shown that a quantum state undergoing a variational quantum circuit with general Pauli noise approaches the completely mixed state with increasing circuit depth. In this ongoing project, we study the question of how variational quantum circuits behave under more realistic noise models, like dephasing or amplitude damping noise. We use the Quantum Approximate Optimization Algorithm (QAOA), which is a specific VQA, to solve combinatorial optimization problems. Considering the problem of MaxCut on different d-regular graphs with different qubit numbers, we run the circuit for many instances of randomly chosen circuit parameters. We find that for weak amplitude damping or dephasing noise the average purity of the output state of the circuit approaches the purity of the completely mixed state while the variance of the purity approaches zero with increasing circuit depth. The decrease of the average purity is well described by an exponential decay, where the decay rate is approximately linear in the noise strength.

#### QI 4.29 Mon 18:00 P2

A multi-qubit Bloch vector representation of density matrices in Julia — •QUNSHENG HUANG and CHRISTIAN MENDL — Technische Universität München. Fakultät für Informatik. Boltzmannstraße 3. 85748 Garching

In the Bloch sphere picture, one finds the coefficients for expanding a singlequbit density operator in terms of the identity and Pauli matrices. A generalization to n qubits via tensor products represents a density operator by a real vector of length  $4^n$ , conceptually similar to a statevector.

The tensor structure leads to computationally efficient algorithms for applying circuit gates and performing few-qubit quantum operations. In view of variational circuit optimization, we study backpropagation through a quantum circuit and gradient computation based on this representation, and generalize our analysis to the Lindblad equation for modeling the (non-unitary) time evolution of a density operator.

#### QI 4.30 Mon 18:00 P2

Efficient energy estimation for variational quantum algorithms using ShadowGrouping — •ALEXANDER GRESCH and MARTIN KLIESCH — Quantum Technology Research Group, Heinrich Heine University, Düsseldorf

Hybrid variational quantum algorithms (VQAs) are one of the main candidates for relevant applications of quantum computation in the near future. However, due to the hybrid quantum-classical nature of VQAs, a large number of repeated energy measurements for various trial states is needed. Each of these states requires an estimate  $\hat{E}$  of the target energy *E*.

In our work, we aim to find the optimal strategy with single-qubit measurements that yields the highest provable accuracy given a total measurement budget. To this end, we derive a new upper bound to the failure probability  $\mathbb{P}[|\tilde{E} - E] > \epsilon]$  for a given tolerable accuracy  $\epsilon$ , which improves upon previous bounds obtained in the context of derandomized classical shadows. Moreover, we combine strategies that measure groups of commuting Hamiltonian terms with that framework. This combination results in a measurement allocation

scheme which we call *ShadowGrouping*. Numerically, we demonstrate that ShadowGrouping outperforms state-of-the-art methods in estimating the electronic ground-state energies of various small molecules. Hence, this work provides a promising way to approach the measurement bottleneck of VQAs.

Single Photon Sources at Telecom Wavelengths — •JONAS GRAMMEL¹, DARIO MEKLE¹, ANDRÁS LAUKÓ¹, THOMAS HERZOG², SIMONE LUCA PORTALUPI², PETER MICHLER², and DAVID HUNGER¹ — ¹Physikalisches Institut, Karlsruher Institut für Technologie — ²Institut für Halbleiteroptik und Funktionelle Grenzflächen, Universität Stuttgart

Semiconductor single photon sources are fundamental building blocks for quantum information applications. The current limitations of such quantum dot sources are the emitting wavelength and insufficient collection efficiency in fiberbased implementations. In the project *Telecom Single Photon Sources* we aim to realize high brightness, fiber coupled sources of single and indistinguishable photons at the telecom wavelength for the upcoming realization of fiber-based quantum networks. We employ open cavities realized with fiber-based mirrors, in combination with InGaAs quantum dots emitting in the telecom O-band and C-band. To achieve Fourier-limited photons we utilize the lifetime reduction of the emitters via the Purcell effect. We optimize the mode matching between the cavity mode and the guided fiber mode by introducing a fiber-integrated modematching optics that can basically reach near-unity collection efficiency. Fundamentally new is also the combination of Fabry-Perot micro-cavity modes with lateral micro and nano structures to reduce the cavity mode volume and thereby boost the emission enhancement and efficiency of the single photon emitters.

#### QI 4.32 Mon 18:00 P2

Towards downscaling of inter-electode spacing in PDMR for quantum sensing applications — •JAN HEIDEN, MARCEL SCHRODIN, and WOLFGANG WERNS-DORFER — KIT, Karlsruhe, Germany

Photoelectric Detection of Magnetic Resonances (PDMR) states a novel technique for the detection of electronic spin-states in nitrogen vacancy centers (NV centers). Contrary to the currently established optical detection (ODMR), which measures the spin-dependent fluorescence of the negatively charged NV- center, the new method relies on the selectivity of the photocurrent induced by the ionizing conversion between NV0 and NV-. Therefore, gold electrodes are deposited directly onto the diamond surface with current inter-electrode distances of down to 2 um.

Besides improved selectivity, PDMR promises enhanced spatial resolution, purely dependent on the process of micro-fabrication. Further advantages arise from the separation of excitation and signal processing paths towards integration of optical systems into on-chip electronic environments.

The work presented focuses on proceeding the down-scaling of the interelectrode spacing towards the nanometer regime for diamond-spin based quantum information applications at milikelvin temperatures.

Addressing of superconducting qubit in rectangular waveguide. — -ROMAIN ALBERT¹, MAXIMILIAN ZANNER¹, ERIC ROSENTHAL², SILVIA CASULLERAS¹, MATHIEU L. JUAN³, KONRAD LEHNERT², ORIOL ROMERO-ISART¹, and GERHARD KIRCHMAIR¹ — ¹University of Innsbruck, Innsbruck, Austria — ²JILA - University of Colorado, Boulder, United States — ³Université de Sherbrooke, Sherbrooke, Canada

Superconducting qubits embedded into microwave waveguides have shown great potential for analog quantum simulation. Such systems present a unique combination of short-range direct qubit interactions and long-range waveguide mediated interactions which make it possible to model a wide variety of Hamiltonians. However, it is challenging to address individual qubits in such systems, as they are often separated by less than the wavelength of their control field. One possible solution is to use the non-linear dispersion of the waveguide to focus frequency chirped pulses to a specific location and it was shown theoretically that such a pulse can be used to selectively control a qubit[1]. We experimentally demonstrate this control using transmon qubits embedded in a rectangular waveguide.

Realizing a fault-tolerant quantum computer is the goal of an ever-growing number of publicly funded and commercial research and development activities. Amongst many potential platforms, quantum computers based on superconducting quantum circuits with Josephson junctions are a promising candidate. However, the fidelity of superconducting qubits is limited by decoherence due to noise arising from various sources, in particular the local environment of the qubit. Driven by the development of partially noise-protected qubit designs, related lifetimes increased significantly from several nanoseconds to a few hundred microseconds. Nonetheless, it is crucial to gain an even better understanding of the origin of loss channels to further improve the qubit coherence by tailored design and fabrication processes. Here, we demonstrate a process for fabricating coplanar waveguide resonators and qubits based on niobium thin films sputtered on silicon substrates. We achieve qubit lifetimes up to 150 µs by systematically analyzing fabrication steps, such as surface treatment and thin film deposition.

## QI 4.36 Mon 18:00 P2

**Optimizing Fabrication Parameters for Superconducting Coplanar Waveguide Resonators** – •DAVID BUNCH^{1,2,3}, LEON KOCH^{1,2,3}, NIKLAS BRUCKMOSER^{1,2,3}, KEDAR E. HONASOGE^{1,2}, YUKI NOJIRI^{1,2,3}, THOMAS LUSCHMANN^{1,2,3}, TAMMO SIEVERS^{1,2,3}, KIRLL G. FEDOROV^{1,2}, and STEFAN FILIPP^{1,2,3} – ¹Physik-Department, Technische Universität München, 85748 Garching, Germany – ²Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, Germany – ³Munich Center for Quantum Science and Technology (MCQST)

Superconducting circuits are a promising platform for the implementation of a universal quantum computer. However, the coherence times of superconducting qubits that make up such systems are limited by material losses, leading to errors in quantum gates. In particular, the coherence time is predominantly limited by coupling to unwanted two level systems (TLS) located at material interfaces. Identifying fabrication techniques, materials, and thin-film dielectrics that reduce losses is essential to achieve scalable architectures for superconducting quantum computing. To evaluate the efficacy of different fabrication techniques we measure the quality factor of superconducting microwave resonators. We present results on optimal sputtering parameters for enhancing the internal quality factor of superconducting methods, and surface treatments on these resonators. We validate our results by fabricating qubits with high coherence times.

QI 4.38 Mon 18:00 P2 Nb/AlOx/Nb-trilayer based Dimer Josephson Junction Array Amplifiers — FABIAN KAAP¹, SERGEY LOTHKOV¹, CHRISTOPH KISSLING¹, VIC-TOR GAYDAMACHENKO¹, MARAT KHABIPOV¹, MARK BIELER¹, and •LUKAS GRÜNHAUPT^{1,2} — ¹Physikalisch-Technische Bundesanstalt, Department Quantum Electronics, 38116 Braunschweig, Germany — ²Physikalisch-Technische Bundesanstalt, Quantum Technology Competence Center, 38116 Braunschweig, Germany

Josephson parametric amplifiers are crucial components for superconducting quantum circuits as they enable high fidelity readout of qubits by improving the signal-to-noise ratio. Among them, Dimer Josephson Junction Array Amplifiers (DJJAA) [1] have shown promise as user-friendly devices with gain on the order of 20 dB, low added noise, saturation powers larger than approximately - 110 dBm, and non-degenerate amplification over a bandwidth of up to ~10 MHz. Due to the use of dc-SQUIDS and multiple dimer modes the operating frequency can be tuned in the range of 2-10 GHz. Using results obtained on DJJAAs with Al/AlOx/Al Josephson junctions as a baseline, we present our progress towards realizing DJJAAs with Nb/AlOx/Nb-trilayer Josephson junctions. We will discuss the circuit design, our fabrication processes, and show preliminary cryogenic measurements of the device.

QI 4.39 Mon 18:00 P2

High-fidelity gates and readout for scalable multi-qubit superconducting quantum processors — •FLORIAN WALLNER^{1,2}, MALAY SINGH^{1,2}, GLEB KRYLOV^{1,2}, IVAN TSITSILIN^{1,2}, GERHARD HUBER^{1,2}, NIKLAS BRUCKMOSER^{1,2}, LEON KOCH^{1,2}, NIKLAS GLASER^{1,2}, CHRISTIAN SCHWEIZER^{1,2}, and STEFAN FILIPP^{1,2,3} — ¹Physik- Department, Technische Universität München, 85748 Garching, Germany — ²Walther-Meißner-Institut, Bayerische Akademie der Wissenschaften, 85748 Garching, German — ³Munich Center for Quantum Science and Technology (MCQST)

To reach the goal of implementing an error-corrected quantum computer, qubits with long coherence times need to be manipulated in real time with high fidelity, followed by a fast and accurate readout. Currently, the main challenge for all hardware platforms is to scale up the number of qubits while at the same time maintain high quality gate operations.

Here, we report on our recent advances to build superconducting multi-qubit devices. Through a dedicated fabrication process we reach coherence times of up to 150  $\mu$ s. We show single-qubit characterization measurements of gates and high fidelity dispersive readout. By applying this method to multi-qubit systems, we achieve simultaneous multiplexed readout of several qubits coupled to the same feed line. Furthermore, we demonstrate first randomized benchmarking results for single- and two-qubit gates. In addition we give an outlook on our efforts to build multi-qubit devices and qubits on alternative architectures that promise substantial longer coherence times.

## QI 4.40 Mon 18:00 P2

Improving the Sørensen-Mølmer gate using analytical optimal control — •SUSANNA KIRCHHOFF^{1,2}, FRANK K. WILHELM^{1,2}, and FELIX MOTZOI³ — ¹Forschungszentrum Jülich, Quantum Computing Analytics (PGI 12), D-52425 Jülich, Germany — ²Theoretical Physics, Saarland University, 66123 Saarbrücken, Germany — ³Forschungszentrum Jülich, Institute of Quantum Control (PGI-8), D-52425 Jülich, Germany

The Sørensen-Mølmer gate is an entangling gate for ion qubits [1]. The entangled state is obtained by the application of a bichromatic light beam which collectively drives the ions. This leads to an entangling gate if certain conditions on gate time, drive frequency and amplitude are fulfilled. These conditions can be derived from the propagator. However, the gate is not perfect. In [1] the authors apply the Lamb-Dicke approximation and neglect some fast rotating terms as well as the single qubit rotation before calculating the propagator. This leads to gate errors. We investigate how the approximations affect the gate fidelity and explore methods to avoid those errors and make the gate more robust against heating.

Probing the quantum noise of metals and spin liquids with NV center **spin qubits** — JUN YONG KHOO^{1,5}, FALKO PIENTKA^{2,5}, PATRICK A. LEE³, and •INTI SODEMANN VILLADIEGO^{4,5} — ¹Institute of High Performance Computing, Agency for Science, Technology, and Research, Singapore – ²Institut fur Theoretische Physik, Goethe-Universitat Frankfurt a.M. - ³Department of Physics, Massachusetts Institute of Technology, Cambridge Massachusetts, USA ⁴Institut fur Theoretische Physik, Universitat Leipzig — ⁵Max-Planck-Institut fur Physik komplexer Systeme

Finding tailored probes that allow to identify the presence of exotic fractionalized states in quantum materials is a major open challenge. Recently, spin qubits based on NV centers are emerging as a new tool to investigate the magnetic noise emanating from complex correlated materials.

Here we study the magnetic noise emerging from a U(1) spin liquid state with a spinon Fermi surface. We show that at low frequencies the noise from this state has the same distance and frequency dependence as a metal but is reduced by a dimensionless pre-factor controlled by the diamagnetic susceptibilities of emergent fractionalized particles in this state. We estimate that the regime to detect this behavior can be comfortably accessed by the typical NV center splittings of a few GHz and estimate that the expected T1 times for an NV center placed above candidate materials, such as the organic dmit and ET salts, monolayer 1T-TaS2/Se2, would range from several tens to a few hundred milliseconds.

Nitrogen vacancy centers in diamond membranes coupled to an optical mi**crocavity** — •MAXIMILIAN PALLMANN¹, KERIM KÖSTER¹, JONATHAN KÖRBER³, Julia Heupel², Rainer Stöhr³, Timon Eichhorn¹, Larissa Kohler¹, Cyril Popov², and David Hunger¹ – ¹Karlsruher Institut für Technologie – ²Universität Kassel — ³Universität Stuttgart

Color centers in diamond centers are very promising candidates for applications in quantum communication and metrology. The nitrogen vacancy center (NV) stands out due to its exceptional spin coherence properties. On the other hand, it suffers from rather bad optical properties due to significant phonon coupling, and only 3% of the emitted light belongs to the Zero phonon line (ZPL). This can be overcome by coupling the emitters to optical cavities, making use of the Purcell effect.

In our experiment, we integrate a diamond membrane to an open access fiberbased Fabry-Perot microcavity [1] to attain emission enhancement into a single well-collectable mode as well as spectral filtering. We investigate the influence of the diamond membrane on the optical properties of the cavity.

We present Purcell-enhanced ensemble-fluorescence of shallow-implanted NV centers and observe cavity-induced collective effects that lead to a bunching behavior in the emission.

QI 5.6 Tue 11:15 H8

Jülich, D-52425 Jülich, Germany – ²Institute for Theoretical Physics, University of Cologne, D-50937 Cologne, Germany

Deriving effective Hamiltonian models plays an essential role in quantum theory, with particular emphasis in recent years on control and engineering problems. To develop fast, high-fidelity operations on cQED devices, there are also increasing demands on modelling tools that go beyond the strong perturbative regime and accurately capture the dynamics.

To this goal, we present two symbolic methods for computing effective Hamiltonian models. The first method makes use of the Jacobi iteration and works without the assumptions of perturbation theory while retaining convergence. In the perturbation regime, it reduces to a variant of the Schrieffer-Wolff method, which takes advantage of a recursive structure and exponentially decreases the number of terms in the high-order expansion. Both methods consist of algebraic expressions and can be easily automated for symbolic computation.

Based on these methods, we perform (semi-)analytical calculations that compute the effective Hamiltonian. We investigate both the ZZ and the crossresonance interaction in the quasi-dispersive regimes. By choosing a proper frame transformation, we show that one can develop control pulses to suppress noises such as leakage and dynamical ZZ crosstalk, improving upon the conventional perturbative calculation.

Demonstration of an integrated optomechanical microcavity with a suspended frequency-dependent photonic crystal reflector — •SUSHANTH KINI  $M^1$ , ANASTASIIA CIERS¹, JULIETTE MONSEL¹, CINDY PERALLE², SHU MIN WANG¹, PHILIPPE TASSIN², and WITLEF WIECZOREK¹ — ¹Dept of Microtechnology and Nanoscience, Chalmers University, Göteborg, Sweden — ²Dept of Physics, Chalmers University, Göteborg, Sweden

Optical microcavities confine the light field on sub-wavelength length scales leading to stronger light-matter interactions. Using microcavities in cavity optomechanics, which explores the interaction between an optical cavity and mechanical motion, one drastically increases the optomechanical interaction. In our work, we use this concept in on-chip optomechanical microcavities fabricated from AlGaAs heterostructures. In our realization, the mechanicallycompliant element is a suspended photonic crystal (PhC) reflector slab, whose distance to a distributed Bragg reflector (DBR) mirror is less than the optical wavelength. We demonstrate a precise control over the microcavity resonance wavelength by varying the PhC hole radius, notably keeping cavity length constant. Importantly, we demonstrate that the frequency dependence of the optical reflectivity of the PhC slab modifies the optomechanical effects compared to a conventional optomechanical system. In the future, this integrated optomechanical microcavity platform offers novel capabilities in manipulating mechanical motion, such as offering more efficient cooling schemes or the capability to generate mechanical squeezing in the ultra-strong coupling regime.

Quantum reservoir computing with coupled cavity arrays — •FREDERIK LO-HOF, NICLAS GÖTTING, and CHRISTOPHER GIES — Institute for Theoretical Physics, University of Bremen, Bremen

Arrays of coupled cavities with embedded semiconducting quantum dots are a

potential platform for the realization of a photonic quantum reservoir computer. The quantum reservoir paradigm is intriguing as it can be realized with preexisting technology and does not rely on fine-tuning of the system parameters as it is the case with gate-based quantum computing. Crucially, the performance of a quantum reservoir relies on a sampling of the exponentially increasing phasespace dimension. We provide theoretical benchmarks on how the topology of a quantum reservoir influences the reservoir's performance and discuss prospects for implementing quantum reservoir computing on a platform of arrays of semiconducting microcavities.

#### QI 5.9 Tue 12:00 H8

Ultra-stable open micro-cavity platform for closed cycle cryostats — •MICHAEL FÖRG^{1,2}, JONATHAN NOÉ^{1,2}, MANUEL NUTZ^{1,2}, THEODOR W. HÄNSCH^{1,3}, and THOMAS HÜMMER^{1,2,3} — ¹Fakultät für Physik, Ludwig-Maximilians-Universität Munich, Germany — ²Qlibri GmbH, Munich, Germany — ³Max-Planck-Institut für Quantenoptik, Garching, Germany

High-finesse, open-access, mechanical tunable, optical micro-cavities offer a compelling system to enhance light matter interaction in numerous systems, e.g. for quantum repeaters, single-photon sources, quantum computation and spectroscopy of nanoscale solid-state systems. Combining a scannable micro-scopic fiber-based mirror and a macroscopic planar mirror creates a versatile experimental platform. A large variety of solid-state quantum systems can be brought onto the planar mirror, analyzed, addressed individually, and (strongly) coupled to the cavity. We present a fully 3D-scannable, yet highly stable micro-cavity setup, which features a stability on the sub-pm scale under ambient conditions and unprecedented stability inside closed-cycle cryostats. An optimized mechanical geometry, custom built stiff micro-positioning, vibration isolation and fast active locking enables quantum optics experiments even in the strongly vibrating environment of closed-cycle cryostats.

# Invited TalkQI 6.1Tue 9:30H9Towards an Artificial Muse for new Ideas in Quantum Physics — •MARIOKRENN — Max Planck Institute for the Science of Light (MPL), Erlangen, Germany

Artificial intelligence (AI) is a potentially disruptive tool for physics and science in general. One crucial question is how this technology can contribute at a conceptual level to help acquire new scientific understanding or inspire new surprising ideas. I will talk about how AI can be used as an artificial muse in quantum physics, which suggests surprising and unconventional ideas and techniques that the human scientist can interpret, understand and generalize.

**Learning variable quantum processes** — MARCO FANIZZA¹, YIHUI QUEK², and •MATTEO ROSATI³ — ¹FT: IFQ, Universitat Autonoma de Barcelona, 08193 Bellaterra (Barcelona) Spain — ²Dahlem Center for Complex Quantum Systems, Freie Universität Berlin, 14195 Berlin, Germany — ³Electrical Engineering and Computer Science, Technische Universität Berlin, 10587 Berlin, Germany

Much of the current research on characterizing quantum processes via statistical learning theory assumes a highly controlled learning setting. Typically, the learner is allowed to use the unknown process as a black-box that may be applied to well-crafted inputs. In this work, we relax this assumption. How hard is it to learn a quantum process observed 'in-the-wild', without control over the inputs? This is the case, for instance, in learning astronomical processes induced by random celestial events, Hamiltonians at variable temperature and biological processes triggered by mechanisms which we can observe but not control. We reformulate this problem as one where a learner has access to a source that outputs classical-quantum states  $\sum_{x} p(x)|x\rangle \langle x| \otimes \psi(x)$  where  $\psi$  is the unknown process mapping an input classical random variable x to an output quantum state. The goal is to learn  $\psi$ . When  $\psi$  is drawn from a class of functions C, we show that the complexity of this task scales polynomially in a combinatorial dimension of C (a measure of its effective size) that we define, and further give algorithms that achieve this complexity. We show, for the first time to our knowledge, that quantum states and processes can be learned efficiently even when identical repetitions of the same experiment are not possible.

Shortening Quantum Convolutional Neural Networks to Constant Depth — •NATHAN MCMAHON, PETR ZAPLETAL, and MICHAEL HARTMANN — Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany

The quantum convolutional neural network (QCNN) is a quantum circuit that detects symmetry protected topological (SPT) phases, with its construction drawing from ideas of renormalisation theory. In this talk I will discuss a special class of these circuits that are equivalent to constant depth quantum circuits, local measurements, and classical post-processing, including an earlier example from Cong et al for a Z2 x Z2 SPT phase detection circuit. We modify this circuit and demonstrate how to shorten it to constant depth, while improving both the time complexity and signal fidelity.

Surprisingly, while the quantum component circuit is constant depth on Nqubits, we still observe a provably exponential (in N) sample complexity speed up compared to only local Pauli measurements and post-processing of the input state. To understand how this happens we demonstrate that a reduced complexity of the input state leads to a guaranteed reduction in the sample complexity speedup.

We finally consider how to explain the effectiveness of the QCNN as a phase recognition algorithm through quantum fidelity approaches to phase transitions. We do this by deriving a sufficient condition for the layers of the QCNN for its output to perform phase recognition. In the process, also making a tantalising connection between the renormalisation group and optimisation.

## QI 6.4 Tue 10:30 H9

Quantum Convolutional Neural Network as a Phase Detection Circuit on the Toric Code — •LEON SANDER, NATHAN MCMAHON, and MICHAEL HART-MANN — Chair of Theoretical Physics, Friedrich-Alexander-Universität Erlangen Nürnberg, Germany

Understanding macroscopic behaviour of quantum materials is an interesting challenge in the field of quantum technologies. This macroscopic behaviour can be evaluated by the examination of quantum phases. Consequently, recognising the phase of a given input state is an important problem, which is often solved by measuring the corresponding order parameter. However, previous work by Cong et al. and Hermann et al. suggests quantum convolutional neural networks (QCNN) are an alternative method of phase detection that can also improve sampling efficiency near the phase boundary compared to direct measurements.

We construct a QCNN designed to act as a phase recognition circuit that determines whether certain magnetic/Ising type perturbations are sufficient to induce a phase transition in the toric code. The choice to study this quantum error correcting code can be motivated as it promises to reveal connections between quantum information and quantum phase transitions.

## QI 6.5 Tue 10:45 H9

**Evaluating the power and performance of sigmoid quantum perceptrons.** — •SAMUEL WILKINSON and MICHAEL HARMAN — Department of Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Staudtstr. 7, 91058 Erlangen, Germa

Quantum neural networks (QNN) have been proposed as a promising architecture for quantum machine learning. There exist a number of different quantum circuit designs being branded as QNNs, however no clear candidate has presented itself as more suitable than the others. Rather, the search for a "quantum perceptron" – the fundamental building block of a QNN – is still underway.

One candidate is quantum perceptrons designed to emulate the nonlinear activation functions of classical perceptrons. Such sigmoid quantum perceptrons (SQPs) inherent the universal approximation property that guarantees that classical neural networks can approximate any continuous function. However, this does not guarantee that QNNs built from SQPs will have any quantum advantage over their classical counterparts. Here we critically investigate both the capabilities and performance of SQP networks by computing general measures of the dimension and capacity of the network, as well as its performance on real learning problems. The results are compared to those obtained for other candidate networks which lack activation functions. It is found that simpler, easier-toimplement parametric quantum circuits actually perform better than SQPs. This indicates that the universal approximation theorem, which a cornerstone of the theory of classical neural networks, is not a relevant criterion for QNNs.

## 15 min. break

QI 6.6 Tue 11:15 H9

An algorithm to factorize quantum walks into shift and coin operations — •CHRISTOPHER CEDZICH¹, TOBIAS GEIB², and REINHARD F. WERNER² — ¹Quantum Technology Group, Heinrich Heine Universität Düsseldorf, Universitätsstr. 1, 40225 Düsseldorf — ²Institut für Theoretische Physik, Leibniz Universität Hannover, Appelstr. 2, 30167 Hannover

Quantum walks provide a basic architecture for implementing quantum information processing and computing. It is therefore important to resolve a given task into available operations, i.e., to "compile" a targeted program. We provide such a method, showing that an arbitrary one-dimensional quantum operation can be resolved into a protocol of two basic operations: A fixed conditional shift that transports particles between cells and suitable coin operators that act locally in each cell. This allows to tailor quantum walk protocols to any experimental setup by rephrasing it on the cell structure determined by the experimental limitations.

QI 6.7 Tue 11:30 H9

**Improved Bell state measurement** — •SIMONE D'AURELIO, MATTHIAS BAYER-BACH, and STEFANIE BARZ — Institute for Functional Matter and Quantum Technologies & IQST, University of Stuttgart, 70569 Stuttgart, Germany

Bell-state measurements play an important role in many quantum tech-nologies, e.g. in quantum repeaters, certain quantum communication protocols and photonic quantum computing. However, using linear- optics only, such a Bell-state measurement has a success probability of 50%. Here, we show the implementation of a novel scheme that allows overcoming this limit.

We give details on the experimental setup. We show how we gen- erate Bellstates in a linear Mach-Zehnder-like scheme as well as how we create ancilliary N00N states from single photons. Both states in- terfere in a linear-optical setup and photon-number measurements at the output allow determining the respective Bell state.

#### QI 6.8 Tue 11:45 H9

Preparation of maximally entangled states with digital-analog quantum computing — •NICOLA WURZ¹, JULIA LAMPRICH¹, MANISH THAPA¹, VI-CENTE PINA CANELLES¹, STEFAN POGORZALEK¹, ANTTI VEPSÄLÄINEN², MIHA PAPIC¹, JAYSHANKAR NATH¹, FLORIAN VIGNEAU¹, DARIA GUSENKOVA¹, PING YANG¹, HERMANNI HEIMONEN², HSIANG-SHENG KU¹, ADRIAN AUER¹, JO-HANNES HEINSOO², FRANK DEPPE¹, and INÉS DE VEGA¹ — ¹IQM Quantum Computers, Munich, Germany — ²IQM Quantum Computers, Espoo, Finland Digital-Analog Quantum Computing (DAQC) is a novel approach, which combines digital single qubit gates with analog multi-qubit blocks. The DAQC concept distinguishes between stepwise and banged DAQC, where the single qubit gates are placed in between analog blocks or applied simultaneously with the analog (entangling) evolution, respectively. We have identified relevant sources of error for both DAQC protocols. When preparing a maximally entangled twoqubit state using either stepwise or banged DAQC, we reach similar fidelities as in the purely digital case. The multi-qubit version of the implemented circuit allows us to create GHZ states by parallelizing several two-qubit interactions. For the case of three qubits, we have investigated infidelities arising due to the multiqubit nature of the interaction, including parasitic and higher order couplings.

We acknowledge support from the German Federal Ministry of Education and Research via the projects DAQC (13N15686) and Q-Exa (13N16062).

#### QI 6.9 Tue 12:00 H9

Momentum-Space Entanlgement and the Wilsonian Effective Action — •Matheus Henrique Martins Costa^{1,2}, Gastao Inacio Krein², Flavio de Souza Nogueira¹, and Jeroen van den Brink¹ — ¹Institute for Theoretical Solid State Physics - IFW Dresden, Dresden, Germany — ²Instituto de Física Teórica - Universidade Estadual Paulista, Sao Paulo, Brazil

The entanglement between momentum modes of a quantum field theory at different scales is not as well studied as its counterpart in real space, despite the natural connection with the Wilsonian idea of integrating out the high-momentum degrees of freedom. Here, we push such connection further by developing a novel method to calculate the Rényi and entanglement entropies between slow and fast modes which is based on the Wilsonian effective action at a given scale and apply it to the perturbative regime of some scalar theories, comparing the lowest-order results with those from the literature and giving them an interpretation in terms of Feynman diagrams. Our results open the way for further work in exploring the relation between renormalization and entanglement and the role of the latter in phase transitions.

## QI 6.10 Tue 12:15 H9

**Holographic code in the laboratory** — •GERARD ANGLÈS MUNNÉ¹, VALENTIN KASPER², and FELIX HUBER¹ — ¹Faculty of Physics, Astronomy and Applied Computer Science, Jagiellonian University, 30-348 Kraków, Poland. — ²Institut de Ciències Fotòniques (ICFO), Mediterranean Technology Park, 08860 Castelldefels, Barcelona, Spain

We propose a method to prepare the holographic pentagon code in the laboratory. The code states can be described by graph states whose interactions patterns are optimized for experimental purposes. Taking a small instance of the holographic code on 12 qubits, we show how to do encoding and decoding. Furthermore, we demonstrate how to test the holographic property - any bulk part is determined by its nearby boundary - through a partial recovery procedure.

Universal ground state entanglement entropy in strongly biased bipartite systems — •OHAD SHPIELBERG — University of Haifa, Haifa, Israel

Consider the AB bipartite system with a single conserved quantity, say a particle number. The particle bias R is defined as the expectation of the particle number in subsystem A over the expectation in subsystem B. At the limit of large R, the ground state entanglement entropy is shown to universally scale like log R/R, independent of the Hamiltonian details. A  $1/\sqrt{R}$  universal power law is obtained for multiple conserved quantities. Moreover, the analysis shows a similar universal structure of the Rényi entropy.

This universal behavior could be exploited to optimize entanglement-assisted control over large many body systems, using systems with a small degree of freedom. Alternatively, one can use the different scaling of the entanglement entropy to detect hidden conserved quantities.

Part of the announced results are available at Phys. Rev. A 105, 042420 (2022).

**Quantum networks and symmetries** — •KIARA HANSENNE¹, ZHEN-PENG XU¹, TRISTAN KRAFT², and OTFRIED GÜHNE¹ — ¹Naturwissenschaftlich-Technische Fakultät, Universität Siegen, Siegen, Germany — ²Institute for Theoretical Physics, University of Innsbruck, Innsbruck, Austria

Quantum networks are promising tools for the implementation of long-range quantum communication. The characterization of quantum correlations in net-

works and their usefulness for information processing is therefore central for the progress of the field, but so far only results for small basic network structures or pure quantum states are known. Here we show that symmetries provide a versatile tool for the analysis of correlations in quantum networks. We provide an analytical approach to characterize correlations in large network structures with arbitrary topologies. As examples, we show that entangled quantum states with a bosonic or fermionic symmetry can not be generated in networks; moreover,

654

cluster and graph states are not accessible. Our methods can be used to design certification methods for the functionality of specific links in a network and have implications for the design of future network structures.

QI 7.2 Wed 15:15 H8

**Secure Anonymous Conferencing in Quantum Networks** — •FEDERICO GRASSELLI¹, GLÁUCIA MURTA¹, JARN DE JONG², FREDERIK HAHN³, DAGMAR BRUSS¹, HERMANN KAMPERMANN¹, and ANNA PAPPA^{2,4} — ¹Heinrich-Heine-Universität Düsseldorf — ²Technische Universität Berlin — ³Freie Universität Berlin — ⁴Fraunhofer Institut for Open Communication Systems

Users of quantum networks can securely exchange classical messages via quantum conference key agreement (CKA), which requires the users' identities to be publicly known. In numerous scenarios, however, communicating users demand anonymity with respect to the other network users, the network manager and even between themselves.

We introduce a security framework for anonymous conference key agreement with different levels of anonymity, generalizing the security of quantum key distribution (QKD). We present efficient and noise-tolerant protocols exploiting multipartite Greenberger-Horne-Zeilinger (GHZ) states and prove their security against general quantum attacks in the finite-key regime. We analyze their performance in noisy and lossy quantum networks and compare with protocols that only use bipartite entanglement to achieve the same functionalities. Our simulations show that GHZ-based protocols can outperform protocols based on bipartite entanglement and that the advantage increases for protocols with stronger anonymity requirements.

Our work advocates the use of multipartite entanglement for cryptographic tasks involving several users and enables the implementation of quantum communication protocols beyond QKD and CKA.

QI 7.3 Wed 15:30 H8

**Prepare-and-measure conference key agreement protocol based on singlephoton interference** — •GIACOMO CARRARA, FEDERICO GRASSELLI, GLÁUCIA MURTA, HERMANN KAMPERMANN, and DAGMAR BRUSS — Institut für Theoretische Physik III, Heinrich-Heine-Universität Düsseldorf, Germany

Quantum Key Distribution (QKD) and its multipartite counterpart, Conference Key Agreement, (CKA) are fundamental cryptographic tasks, where two or more parties try to establish a common, secret key. The so-called Twin-Field Quantum Key Distribution (TF-QKD) setup recently received great attention as it only requires lasers and linear optical devices. TF-QKD has been generalized to many parties, where a CKA protocol based on single-photon interference has been proposed [F. Grasselli *et al*, 2019, New J. Phys., **21** 123002]. This multipartite protocol, however, has a big drawback: it does not have a prepare-and-measure formulation and thus lacks a simple, practical implementation. In this work we propose a CKA protocol that allows for a prepare-and-measure implementation, where the parties are required only to produce weak coherent pulses. We provide for this protocol a security analysis based on the decoy state method and analyze how the protocol performs compared to the well-known repeaterless bound, considering different network architectures.

## QI 7.4 Wed 15:45 H8

**Experimental anonymous conference key agreement using linear cluster states** — •LUKAS RÜCKLE, JAKOB BUDDE, and STEFANIE BARZ — Institute for Functional Matter and Quantum Technologies and IQST, University of Stuttgart, 70569 Stuttgart

Quantum networks allow for secure communication between more than just two parties. One example is the conference key agreement, where multiple parties exchange a secure key. Interestingly, quantum networks can provide another security feature: protecting the identity of the participants. Here, we realize such anonymous quantum conference key agreement in a linear network architecture using photonic cluster states. We show how different parties of the network can exchange a key anonymously by extracting a smaller GHZ state from the cluster state. We further study how noise affects the finite and asymptotic key rate and show that we achieve a positive asymptotic key rate.

## QI 7.5 Wed 16:00 H8

Average waiting times for entanglement links in multiplexed quantum networks — •LISA WEINBRENNER, LINA VANDRÉ, and OTFRIED GÜHNE — Universität Siegen, Deutschland

In quantum communication protocols using noisy channels, the error probability typically scales exponentially with the length of the channel. To reach long-distance entanglement distribution, one can use quantum repeaters. These schemes involve first a generation of elementary bipartite entanglement links between two nodes and then measurements to combine the elementary links to a long-distance link.

Since the generation of an elementary link is probabilistic and quantum memories have a limited storage time, the generation of a long-distance link is probabilistic, too [1]. One possibility to speed up the generation of a long-distance link is a multiplexed system, in which there is more than one elementary link between two nodes [2]. In this contribution, we will present estimates and bounds on waiting times in such a system. Our results rely on an analytical treatment of the underlying stochastic process, as well as numerical investigations using the matrix product state formalism.

Fiber communication with collective quantum measurements: a machine learning perspective with applications — •MATTEO ROSATI¹ and JANIS NÖTZEL² — ¹Electrical Engineering and Computer Science, Technische Universität Berlin, 10587 Berlin, Germany — ²1Emmy-Noether Gruppe Theoretisches Quantensystemdesign Lehrstuhl für Theoretische Informationstechnik Technische Universität München.

The transmission rate of classical bits on optical fiber is ultimately governed by the Holevo capacity. Achieving such rate requires writing information into coherent states of light and then performing a collective quantum measurement on multiple received signals at once, known as quantum joint-detection receiver (QJDR).

We find that the realization of a QJDR would enable two key advantages in current communication networks: (i) an estimated 55% decrease in energy consumption of optical amplifiers; (ii) an unbounded logarithmic growth of the channel capacity with the signal pulse rate, as opposed to the bounded rate attained by conventional detectors.

We then develop a machine learning framework to discover approximate implementations of the QJDR with a state-of-the-art photonic circuit. We compute the theoretical learning complexity of such photonic circuits, showing that it is polynomial in the number of optical modes, and introduce a simple algorithm to optimize them. Finally, we show that our algorithm is able to discover decoder setups that are both realizable at the state of the art and can attain a decoding success rate as high as 93% of the optimal QJDR.

**A Graphical Formalism for Entanglement Purification** — •LINA VANDRÉ and OTFRIED GÜHNE — Universität Siegen, Germany

Hypergraph states form an interesting family of multi-qubit quantum states which are useful for quantum error correction, non-locality and measurementbased quantum computing. They are a generalisation of graph and cluster states. The states can be represented by hypergraphs, where the vertices and hyperedges represent qubits and entangling gates, respectively.

For quantum information processing, one needs high-fidelity entangled states, but in practice most states are noisy. Purification protocols address this problem and provide a method to transform a certain number of copies of a noisy state into single high-fidelity state. There exists a purification protocol for hypergraph states [1]. In my talk, I will first reformulate the purification protocol in a graphical manner, which makes it intuitively understandable. Based on this, I will propose systematic extensions, which naturally arise from the graphical formalism.

Quantum memories for space: from ideas to experimental roadmap — •MUSTAFA GÜNDOĞAN, MARTIN JUTISZ, ELISA DA ROS, and MARKUS KRUTZIK — Humboldt-Universität zu Berlin, Berlin, Germany

Quantum communication is usually limited to around a few hundred kilometers due to the exponential losses in optical fibers. Quantum repeaters (QR) based on the heralded storage of entangled states have been proposed to overcome this direct transmission limit. However, they are still limited to around a few thousand kms. On the other hand, space-based quantum links where channel loss scales mainly polynomially offer another solution to this problem. In this case, however, the communication distance is limited to the line-of-sight distance of the satellite which is around 2000 km for low earth orbit. In order to reach truly global distances, we have recently proposed an architecture that combines the above two approaches [1]: a quantum repeater operating in space. We show that this scheme provides a three orders of magnitude faster entanglement distribution rate across global distances than ground-based and hybrid space-ground architectures.

In this talk, after summarizing our findings and presenting a comparison of our scheme with already existing architectures I will finish with presenting our experimental work towards building space-compatible quantum memories with warm and cold atomic gases.

## Restoring quantum communication efficiency over high loss optical fibres -•FRANCESCO ANNA MELE — Scuola Normale Superiore, Pisa, Italy

In the absence of quantum repeaters, quantum communication proved to be nearly impossible across optical fibres longer than approximately 20 km due to the drop of transmissivity below the critical threshold of 1/2. However, if the signals fed into the fibre are separated by a sufficiently short time interval, memory effects must be taken into account. In this talk we show that by properly accounting for these effects it is possible to devise schemes that enable unassisted quantum communication across arbitrarily long optical fibres at a fixed positive qubit transmission rate. We also demonstrate how to achieve entanglement-assisted communication over arbitrarily long distances at a rate of the same order of the maximum achievable in the unassisted noiseless case.

This talk is based on https://arxiv.org/abs/2204.13128 and https://arxiv.org/ abs/2204.13129.

#### Invited Talk

QI 8.1 Wed 15:00 H9 Exploring Quantum Materials with Quantum Sensors - • URI VOOL - Max Planck Institute for Chemical Physics of Solids, Dresden, Germany

In recent years, improvements in crystal growth and sample fabrication have given us access to an expanding variety of quantum materials which exhibit exotic macroscopic phenomena directly tied to the strong quantum effects in their microscopic structure. These are exciting for basic research and potential technology applications, but there are still fundamental open questions about the structure of such systems, and the ability to control their quantum effects.

Meanwhile, there has been rapid growth in the ability to control coherent quantum effects in various solid state systems, from atomic defects to macroscopic electromagnetic circuits. These quantum systems can be efficiently manipulated and tuned while maintaining high coherence, making them leading quantum computing platforms. These advantages also make them excellent quantum sensors, and their operation at cryogenic temperatures and material compatibility make them especially suited for exploring quantum materials.

This talk will present several recent and ongoing experiments using coherent quantum systems for material exploration. We will focus on two experimental techniques: 1. Nitrogen-vacancy centers as cryogenic scanning probes for imaging hydrodynamic electron flow. 2. Hybrid superconducting circuits as probes of the superconducting structure in novel materials. Finally, we will discuss the prospective of this approach for material exploration and quantum technology.

#### QI 8.2 Wed 15:30 H9

Fractional Josephson effect induced by weak measurement - • MOHAMMAD ATIF JAVED, JAKOB SCHWIBBERT, and ROMAN-PASCAL RIWAR -Forschungszentrum Jülich, Peter Grünberg Institute (PGI-2), 52425, Jülich, Deutschland

The fractional Josephson effect is commonly directly linked to the presence of Majorana- and parafermions, which are important candidates to implement (universally) protected quantum gates in superconducting quantum hardware. However, these exotic particles still seem notoriously challenging to realize in experiment, and difficult to unambiguously identify via transport measurements. Moreover, a proper understanding of the topological transport properties requires a generalization to an open quantum system context.

Here, we study a standard quantum dot in proximity to two conventional superconducting contacts, including a weak transport measurement and a nonequilibrium quasiparticle source. The non-hermitian system dynamics are analysed by means of exceptional points, leading to a braiding of the complex eigenspectrum. Based on this analysis, we show that this system exhibits an open system version of a fractional Josephson effect, in spite of using only conventional materials.

Defects in semi-conductors for Quantum Applications — • SAJID ALI, FABIAN BERTOLDO, SIMONE MANTI, and KRISTIAN THYGESEN - CAMD, Computational Atomic-Scale Materials Design, Department of Physics, Technical University of Denmark, 2800 Kgs. Lyngby Denmark

Discovery of single photon emission (SPE) from 2D materials has opened a new arena of research because of the unique electric, magnetic and optical properties possessed by these SPE*s systems. Based on these superiror properties, such systems provide very attractive platform that can help to realize, control, ma-

nipulate and measure individual quantum states. The defect systems with similar properties must be explored in other 2D materials, as this will broaden the range of materials available for such applications, consequently revolutionising this field. In the present work we have shortlisted/ the defect systems with optimal properties for various quantum applications e.g. qubits, quantum key distribution, brain magnetometers etc., based on our screening study of intrinsic point defects in dynamically and thermodynamically stable and non-magnetic host systems from C2DB database . We study various aspects and properties of these defect systems e.g. photoluminescence (PL) line shape, Transition dipole moment, Radiative recombination rates, Inter-system crossing rates, Hyperfine coupling parameters, Zero field splitting, Spin-Coherence times etc. We identify a set of defect systems, with ideal properties, which can be exploited for various quantum technologies.

Iterative adaptive spectroscopy with a two-level nanomechanical platform •Avishek Chowdhury¹, Ann Tuan Le¹, Hugo Ribeiro³, and Eva M. Weig^{1,2} ¹Department of Electrical and Computer Engineering, Technical University of Munich, 85748 Garching, Germany – ²Munich Center for Quantum Science and Technology (MCQST), Schellingstr. 4, 80799, Munich, Germany -³Department of Physics and Applied Physics, University of Massachusetts Lowell, Lowell, MA 01854, USA

We develop an iterative, adaptive frequency sensing protocol based on Ramsey interferometry of a two-level system. Our scheme allows one to estimate unknown frequencies with a high precision from short, finite signals. It avoids several issues related to processing of decaying signals and reduces the experimental overhead related to sampling. High precision is achieved by enhancing the Ramsey sequence to prepare with high fidelity both the sensing and readout state and by using an iterative procedure built to mitigate systematic errors when estimating frequencies from Fourier transform. Furthermore, we implement the protocol to demonstrate a proof-of-principle study on a classical twolevel nanomechanical platform. We demonstrate that the protocol can detect the coupling between two normal modes with an accuracy higher than their individual dissipation rate. Moreover, the protocol can detect small DC fluctuation of the surrounding electrical field around our nanomechanical oscillator.

## QI 8.5 Wed 16:15 H9

Quantum enhancement of multiphoton absorption signals in nonlinear interferometers – •Shahram Panahiyan^{1,2} and Frank Schlawin^{1,2} –  ${}^{1}Max$ Planck Institute for the Structure and Dynamics of Matter, Center for Free Electron Laser Science, Luruper Chaussee 149, 22761 Hamburg, Germany —  2 The Hamburg Centre for Ultrafast Imaging, Luruper Chaussee 149, 22761 Hamburg, Germany

SU(1,1)-interferometers are novel nonlinear interferometers [1] in which optical parametric amplifiers create quantum states of light by squeezing and antisqueezing the light fields [2]. By taking advantage of these quantum states of light, SU(1,1)-interferometers have been employed for spectroscopy [3], imaging [4], quantum state engineering, and quantum information purposes.

Motivated by these applications, we study the precision of multiphoton absorption measurements in a nonlinear SU(1,1)-interferometer. We analyze multiphoton absorption signals, characterize the absorption as a function of nonlinear order, and derive sensitivity bounds from the Fisher Information. We show

that the precision of multiphoton absorption measurements can be enhanced compared to classical measurement strategies. Finally, we highlight that this enhancement is robust against experimental imperfections in detection devices.

## QI 8.6 Wed 16:45 H9

Multicopy metrology with many-particle quantum states — •RÓBERT TRÉNYI^{1,2,3}, ÁRPÁD LUKÁCS^{1,4,3}, PAWEŁ HORODECKI^{5,6}, RYSZARD HORODECKI⁵, TAMÁS VÉRTESI⁷, and GÉZA TÓTH^{1,2,8,3} — ¹Dept. of Theoretical Physics, U. of the Basque Country UPV/EHU, Bilbao, Spain — ²DIPC, San Sebastián, Spain — ³Wigner Research Centre for Physics, Budapest, Hungary — ⁴Dept. of Mathematical Sciences, Durham University, United Kingdom — ⁵International Centre for Theory of Quantum Technologies, University of Gdansk, Gdansk, Poland — ⁶Faculty of Applied Physics and Mathematics, National Quantum Information Centre, Gdansk University of Technology, Gdansk, Poland — ⁷Institute for Nuclear Research, Debrecen, Hungary — ⁸IKERBASQUE, Bilbao, Spain

We consider quantum metrology with several copies of bipartite and multipartite quantum states. We characterize the metrological usefulness by determining how much the state outperforms separable states. We identify a large class of entangled states that become maximally useful for metrology in the limit of infinite number of copies. The maximally achievable metrological usefulness is attained exponentially fast in the number of copies. We show that, on the other hand, pure entangled states with even a small amount of white noise do not become maximally useful even in the limit of infinite number of copies. We also make general statements about the usefulness of a single copy of pure entangled states. We show that the multiqubit states presented in Hyllus et al. [Phys. Rev. A 82, 012337 (2010)], which are not useful, become useful if we embed the qubits locally in qutrits.

## QI 8.7 Wed 17:00 H9

**Quantum metrology in the non-asymptotic regime** — •JOHANNES JAKOB MEYER¹, SUMEET KHATRI¹, PHILIPPE FAIST¹, DANIEL STILCK-FRANÇA², GI-ACOMO GUARNIERI¹, and JENS EISERT^{1,3,4} — ¹Dahlem Center for Complex Quantum Systems, Freie Universität Berlin, 14195 Berlin, Germany — ²Univ Lyon, ENS Lyon, UCBL, CNRS, Inria, LIP, F-69342, Lyon Cedex 07, France — ³Fraunhofer Heinrich Hertz Institute, 10587 Berlin, Germany — ⁴Helmholtz-Zentrum Berlin für Materialien und Energie, 14109 Berlin, Germany

The main concern of quantum metrology is to determine how we can achieve the best possible precision in estimating parameters of physical processes. One of the main tools used in the field is the Quantum Cramér-Rao bound. However, it is a relation that is only tight and meaningful asymptotically and, conversely, too optimistic for finite numbers of experimental repetitions. We analyze how a change of perspective to an operationally motivated measure of estimation success can be used to achieve more meaningful bounds. We show that the measure can be evaluated using a semidefinite program and detail how it can be used to establish minimax guarantees against any prior distribution of the underlying parameter. We focus on the analysis of group-covariant estimation on pure states, which is relevant because of its relation to phase estimation. We prove that the optimal measurement in this setting is given by the pretty good measurement and exhibit a construction of a probe state that numerically saturates the optimal asymptotic minimax rate.

## QI 8.8 Wed 17:15 H9

**Gradient Magnetometry with Atomic Ensembles** — •IAGOBA APELLANIZ¹, IÑIGO URIZAR-LANZ¹, ZOLTÁN ZIMBORÁS^{1,2,3}, PHILIPP HYLLUS¹, and GÉZA TÓTH^{1,2,4} — ¹Department of Physics, University of the Basque Country UPV/EHU, P. O. Box 644, E-48080 Bilbao, Spain — ²Dahlem Center for Complex Quantum Systems, Freie Universität Berlin, 14195 Berlin, Germany — ³Wigner Research Centre for Physics, Hungarian Academy of Sciences, P.O. Box 49, H-1525 Budapest, Hungary — ⁴IKERBASQUE, Basque Foundation for Science, E-48013 Bilbao, Spain

We study gradient magnetometry with ensembles of atoms with arbitrary spin. We calculate precision bounds for estimating the gradient of the magnetic field based on the quantum Fisher information. For states that are sensitive to homogeneous fields, a simultaneous measurement is needed, as the homogeneous field must also be estimated.

We present a method to calculate precision bounds for gradient estimation with two spatially separated atomic ensembles. We also consider a single atomic ensemble with an arbitrary density profile, where the atoms cannot be addressed individually, and which is a very relevant case for experiments.

Ultra-low perturbation quantum measurements via random-time sampling — •MARKUS SIFFT and DANIEL HÄGELE — Ruhr University Bochum, Faculty of Physics and Astronomy, Experimental Physics VI (AG), Germany

Random-time sampling of a quantum system is introduced as a new approach to continuous quantum measurements with prospects for ultra-low-perturbation measurements [1]. Random sampling is, e.g., naturally realized in an optical spin noise experiment when weak probe-laser light exhibits random single-photon events in the detector [2]. Our theory shows that a direct evaluation of these detector click events yields power spectra that are equivalent but not identical to those of the usual Gaussian continuous measurement regime [3]. Surprisingly, this holds true even for average sampling rates much lower than the typical frequency range of the measured quantum dynamics. The third-order quantum polyspectrum (bispectrum) also contains the same information as its continuous counterpart. System characterization can, therefore, be performed using the analytic form of the quantum polyspectra [4]. Many applications of randomtime sampling are envisioned for high-resolution spectroscopy, circuit quantum electrodynamics, quantum sensing, and quantum measurements in general. ## QI 9: Quantum Correlations

Time: Thursday 9:30–12:15

#### QI 9.1 Thu 9:30 H8

Dimension-free entanglement detection in multipartite Werner states -•Felix Huber¹, Igor Klep², Victor Magron³, and Jurij Volčič⁴ — ¹Institute of Theoretical Physics, Jagiellonian University, 30-348 Kraków, Poland — ²Faculty of Mathematics and Physics, University of Ljubljana, Slovenia — ³LAAS-CNRS & Institute of Mathematics from Toulouse, France -⁴Department of Mathematical Sciences, University of Copenhagen, Denmark Werner states are multipartite quantum states that are invariant under the diagonal conjugate action of the unitary group. We give a complete characterization of their entanglement that is independent of the underlying local Hilbert space: for every entangled Werner state there exists a dimension-free entanglement witness. The construction of such a witness is formulated as an optimization problem. To solve it, two semidefinite programming hierarchies are introduced. The first one is derived using real algebraic geometry applied to positive polynomials in the entries of a Gram matrix, and is complete in the sense that for every entangled Werner state it converges to an entanglement witness. The second one is based on a sum-of-squares certificate for the positivity of trace polynomials in noncommuting variables, and is a relaxation that involves smaller semidefinite constraints.

Location: H8

#### QI 9.2 Thu 9:45 H8

Constructing entanglement witnesses based on the Schmidt decomposition of operators — •SOPHIA DENKER¹, CHENGJIE ZHANG², ALI ASADIAN³, and OTFRIED GÜHNE¹ — ¹Naturwissenschaftlich-Technische Fakultät, Universität Siegen, Walter-Flex-Straße 3, 57068 Siegen, Germany — ²School of Physical Science and Technology, Ningbo University, Ningbo, 315211, China — ³Department of Physics, Institute for Advanced Studies in Basic Sciences (IASBS), Gava Zang, Zanjan 45137-66731, Iran

Characterizing entanglement is an important issue in quantum information, as entanglement is considered to be a resource for quantum key distribution or quantum metrology. One useful tool to detect and quantify entanglement are witness operators. A standard way to design entanglement witnesses for two or more particles is based on the fidelity of a pure quantum state; in mathematical terms this construction relies on the Schmidt decomposition of vectors. In this contribution, we present a method to build entanglement witnesses based on the Schmidt decomposition of operators. Our scheme works for the bipartite and the multipartite case and is found to be strictly stronger than the concept of fidelity-based witnesses. We discuss various examples and demonstrate that our approach can also be used to quantify quantum correlations as well as characterize the dimensionality of entanglement.

Nonlinear Entanglement Detection from Immanant Inequalities — •ALBERT RICO and FELIX HUBER — Faculty of Physics, Astronomy and Applied Computer Science, Jagiellonian University, 30-348 Kraków, Poland

We develop a method for nonlinear entanglement detection which is based on inequalities for immanants. This allows to use multipartite witnesses to detect bipartite states in a non-conventional way. We give examples and compare their effectiveness to the standard usage of witnesses. We show that this type of nonlinear entanglement detection can outperform its linear version, and how the detection can be performed in the laboratory through randomized measurements.

## QI 9.4 Thu 10:15 H8

The shape of higher-dimensional state space: Bloch ball analog for a qutrit — CHRISTOPHER ELTSCHKA¹, MARCUS HUBER^{2,3}, SIMON MORELLI^{2,3}, and •JENS SIEWERT^{4,5} — ¹Institut für Theoretische Physik, Universität Regensburg, Regensburg, Germany — ²IQOQI Vienna, Vienna, Austria — ³Atominstitut TU Wien, Vienna, Austria — ⁴University of the Basque Country UPV/EHU and EHU Quantum Center, Bilbao, Spain — ⁵Ikerbasque, Basque Foundation for Science, Bilbao, Spain

The Bloch ball as a geometric representation of the state space for qubits is an ubiquitous tool to gain deeper insight and intuitive understanding of quantummechanical phenomena. Unfortunately, even for the next more complex system, the qutrit, such a geometric representation (rather than cross sections or projections) is not known. In order to serve as a model for higher-dimensional state space, it should display a number of desirable properties, such as different surface parts corresponding to pure or mixed states, convexity, inner and outer sphere with the corresponding radii, pure states should form a connected set, etc. [1]. We show that, based on the Bloch representation of qutrit states, such a model can be constructed that captures many of the geometric features discussed in Ref. [1].

## QI 9.5 Thu 10:30 H8

Nearly optimal separability certification of quantum states — •TIES-ALBRECHT OHST¹, CHAU NGUYEN¹, OTFRIED GÜHNE¹, and XIAO-DONG YU² — ¹Naturwissenschaftlich-Technische Fakultät, Universität Siegen — ²Department of Physics, Shandong University, Jinan

Entanglement describes the possibility of local parties sharing a joint global system state that cannot be expressed as a probabilistic mixture of locally prepared states. The question on whether some given state is entangled or separable, on the contrary, is generically difficult to answer. We present an algorithm for the quantum separability problem for intermediate dimensions with evidences of being nearly optimal. The basic idea of our considerations can in general be described by a systematic search for separable decompositions of a given state by polytope approximations to a local system. As a benchmark we can compute the separability thresholds for known bound entangled states of two coupled qutrits with an accuracy that has not been achieved before. Also, for bi-partite systems of higher dimension we can certify the separability of states reliably which follows from the comparison with data by known entanglement criteria. For three coupled qubit systems, our ideas allow for an efficient distinction between different separability classes that lie at the heart of the theory of multi-partite entanglement. We developed an algorithm for the search among all fully bi-separable states to find the one whose entanglement robustness is as large as possible. Quite interestingly, the obtained states show a deep connection to the post measurement states in the teleportation protocol.

## QI 9.6 Thu 10:45 H8

<code>Hilbert-Schmidt geometry of two-qubit correlations</code> — •SANTIAGO LLORENS¹ and JENS SIEWERT^{2,3} — ¹Grup d'Informació Quàntica, Universitat Autònoma de Barcelona, Barcelona, Spain — ²University of the Basque Country and EHU Quantum Center, Bilbao, Spain — ³Ikerbasque, Basque Foundation for Science, Bilbao, Spain

The Bloch representation of quantum states endows the state space with a natural Euclidean geometry via the Hilbert-Schmidt scalar product. Based on this, a Bloch ball-type global view of the state space for a qutrit was found recently. This imposes the question whether an analogous method exists for the simplest quantum correlations – those in a system of two qubits. From such a visualization one may expect a better understanding of the links between the algebraic correlation constraints and their geometric background. We show that indeed the 2-sector (aka as the correlation tensor) of two-qubit states allows for a geometric representation of the algebraic constraints to the entries of the Bloch vector. In this context we provide novel insight into the relation between entanglement quantifiers and characteristic parameters of the Bloch representation of bipartite systems.

QI 9.7 Thu 11:15 H8

Schmidt number witnesses for high-dimensional quantum states in photonic temporal mode setups — •NIKOLAI WYDERKA¹, GIOVANNI CHESI², HERMANN KAMPERMANN¹, and DAGMAR BRUSS¹ — ¹Institut für Theoretische Physik III, Heinrich-Heine-Universität Düsseldorf, D-40225 Düsseldorf, Germany — ²Istituto Nazionale di Fisica Nucleare Sezione di Pavia, Via Agostino Bassi 6, I-27100 Pavia, Italy

Photonic temporal modes offer a robust and efficient toolbox for highdimensional quantum information applications. In order to characterize the experimentally generated quantum states, we aim to use witnesses to certify their Schmidt numbers as a robust entanglement measure. To that end, we develop an iterative algorithm that yields Schmidt number witness candidates that require only a few of those measurements inherent to the temporal mode framework using quantum pulse gates. Finally, we use the numerical candidates to derive a proper Schmidt number witness for states close to the maximally entangled state.

## QI 9.8 Thu 11:30 H8

**Complete hierarchy for high-dimensional steering certification** — •CARLOS DE GOIS, MARTIN PLÁVALA, and OTFRIED GÜHNE — Naturwissenschaftlich Technische Fakultät, Universität Siegen

Steerability can be employed as a semi-device independent test of the Schmidt number. As such, it is a promising component in quantum informational protocols that make use of entanglement dimension certification. Recently proposed and experimentally demonstrated for the special case in which the assemblage is prepared from two choices of measurements, high-dimensional steering is so far lacking a general certification procedure. Herein, we provide necessary and, at a limit, sufficient conditions to certify the entanglement dimension of a steering assemblage. These conditions are stated in terms of a hierarchy of semidefinite programs, which can also be used to compute the steering dimension robustness.

#### QI 9.9 Thu 11:45 H8

Distance-based resource quantification for sets of quantum measurements — •LUCAS TENDICK, MARTIN KLIESCH, HERMANN KAMPERMANN, and DAGMAR BRUSS — Institute for Theoretical Physics, Heinrich Heine University Düsseldorf, D-40225 Düsseldorf, Germany

The advantage that quantum systems provide for certain quantum information processing tasks over their classical counterparts can be quantified within the general framework of resource theories. Certain distance functions between quantum states have successfully been used to quantify resources like entanglement and coherence. Perhaps surprisingly, such a distance-based approach has not been adopted to study resources of quantum measurements, where other geometric quantifiers are used instead. Here, we define distance functions between sets of quantum measurements and show that they naturally induce resource monotones for convex resource theories of measurements. By focusing on a distance based on the diamond norm, we establish a hierarchy of measurement resources and derive analytical bounds on the incompatibility of any set of measurements. We show that these bounds are tight for certain projective measurements based on mutually unbiased bases and identify scenarios where different measurement resources attain the same value when quantified by our resource monotone. Our results provide a general framework to compare distance-based resources for sets of measurements and allow us to obtain limitations on Belltype experiments.

Entanglement Transition in the Projective Transverse Field Ising Model — •HANS PETER BÜCHLER — Institut für theoretische Physik III, Universität Stuttgart

Discrete quantum trajectories of systems under random unitary gates and projective measurements have been shown to feature transitions in the entanglement scaling that are not encoded in the density matrix. Here we present the projective transverse field Ising model, a stochastic model with two noncommuting projective measurements and no unitary dynamics, and demonstrate the appearance of an entanglement transition. This transition is connected to quantum error correction, and we demonstrate the most efficient decoding of stored quantum information. Especially, we show that the ability to retrieve stored quantum information can serve as an experimental tool to detect such entanglement phase transitions.

QI 10.2 Thu 10:00 H9

Efficient Quantum Computation of Floquet Hamiltonians — •BENEDIKT FAUSEWEH¹ and JIAN-XIN ZHU^{2,3} — ¹Institute for Software Technology, German Aerospace Center (DLR), Germany — ²Theoretical Division, Los Alamos National Laboratory, USA — ³Center for Integrated Nanotechnologies, Los Alamos National Laboratory, USA

The Floquet formalism describes the control over quantum systems using external periodic fields. With recent advances in ultrafast spectroscopy of solidstate systems, Floquet engineering, that is, a targeted design of quantum systems driven by laser pulse, has led to an increasing interest in computational methods that can simulate light-matter interactions. Although the perturbative regime, in which the fundamental driving frequency is much larger than the energy bandwidth of the quantum system, shows interesting phenomena, it is the non-perturbative regime that presents the most exciting opportunity to study the interplay with strong correlations and which remains largely unexplored. Here we describe hybrid quantum algorithms that make use of quantum computers to tackle this problem. The required quantum resources are within reach for current day NISQ devices and allow the efficient computation of Floquet Hamiltonians. We demonstrate applications of these algorithms and discuss their performance for small scale driven quantum systems.

This work was carried out under the auspices of the U.S. DOE NNSA (Contract No. 89233218CNA000001) and was supported by the LANL LDRD Program.

#### OI 10.3 Thu 10:15 H9

Noise-utilizing quantum simulation of a system coupled to a structured bath — •JUHA LEPPÄKANGAS, NICOLAS VOGT, KIRSTEN BARK, KEITH FRATUS, JAN-MICHAEL REINER, SEBASTIAN ZANKER, and MICHAEL MARTHALER — HQS Quantum Simulations GmbH, Haid-und-Neu-Strasse 7, 76131 Karlsruhe, Germany

We consider noisy gate-based quantum computers for the purpose of simulating the spin-boson model. We establish a bosonic bath by an ensemble of qubits with finite coherence times. The energy-level broadening of qubits is mapped to broadening of the simulated bath spectral function. We study how desired forms of the spectral density can be constructed by optimizing simulated spinbath couplings and bath energies. We study the effect of different gate decompositions and system connectivity on the quality of the mapping to the desired form. In the ideal situation, the spin-bath couplings can be decomposed using only variable angle two-qubit gates, such as a variable Mølmer-Sørensen gate. In other cases, qubit noise can get mapped to two-body noise in the spin-boson model. We show a numeric comparison of the quality of the mapping for various decompositions. Furthermore we compare the full inclusion of the two-body noise terms with an approximate mapping of the effects on the spectral density of the simulated spin-boson problem.

## QI 10.4 Thu 10:30 H9

**Distributed Multipartite Entanglement Generation in Coupled Cavities** — •Marc Bostelmann, Frederik Lohof, and Christopher Gies — Institute for Theoretical Physics, University of Bremen, Germany

The generation of spatially distributed entanglement is important for the realization of quantum information protocols and quantum computing, leading to new fields of research like quantum machine learning. Coupled cavities offer a platform to create this kind of entanglement between spatially separated qubits [1]. By carefully tailoring excitations with external light pulses we theoretically examine the generation of entangled states, such as GHZ or Dicke states. Starting with a system of two qubits for generating bipartite entanglement, we extend the discussion to the multipartite case, exploiting symmetries of the system. Bridging the gap to experimental realizations, we study robustness of the generated entangled states to dissipation and asymmetry in the system. [1] Aron et al., PRA, 90, 062305 (2014).

**Probing confinement in a**  $\mathbb{Z}_2$  **lattice gauge theory on a quantum computer** — •JULIUS MILDENBERGER¹, WOJCIECH MRUCZKIEWICZ², JAD HALIMEH^{3,4}, ZHANG JIANG², and PHILIPP HAUKE¹ — ¹INO-CNR BEC Center and Department of Physics, University of Trento, Italy — ²Google Quantum AI, Venice, CA, USA — ³Department of Physics and ASC, Ludwig-Maximilians-Universität München, Germany — ⁴MCQST, Munich, Germany

Digital quantum simulators provide a table-top platform for addressing salient questions in particle and condensed-matter physics. A particularly rewarding target is given by lattice gauge theories. Their constituents, e.g., charged matter and the electric gauge field, are governed by local gauge constraints, which are highly challenging to engineer and lead to intriguing yet not fully understood features such as confinement of particles. We simulate confinement dynamics in a  $\mathbb{Z}_2$  LGT on a superconducting quantum chip. The charge-gauge-field interaction is synthesized using only 6 native two-qubit gates, enabling us to reach simulation times of up to 25 Trotter steps. We observe how tuning a term that couples only to the electric field confines the charges, a manifestation of the tight bond that the local gauge constraint generates between both. Moreover, we study a different mechanism, where a modification of the gauge constraint from  $\mathbb{Z}_2$  to U(1) symmetry freezes the system dynamics. Our work showcases the strong restriction that the underlying gauge constraint imposes on the dynamics of an LGT, illustrates how gauge constraints can be modified and protected, and paves the way for studying other models with many-body interactions.

QI 10.6 Thu 11:15 H9

Quantum Information Scrambling in Thermalizing Spin Chains with Nonlocal Interactions — •DARVIN WANISCH^{1,2,3} and STEPHAN FRITZSCHE^{1,2,3} — ¹Theoretisch-Physikalisches Institut, Friedrich-Schiller-Universität Jena, Max-Wien-Platz 1, 07743 Jena, Germany — ²Helmholtz-Institut Jena, Fröbelstieg 3, 07743 Jena, Germany — ³GSI Helmholtzzentrum für Schwerionenforschung GmbH, Planckstraße 1, 64291 Darmstadt, Germany

Motivated by recent works on information scrambling in spin systems with nonlocal interactions, and their potential of sharing features of quantum gravity, we study scrambling in different variants of the Ising model. Our results demonstrate that out-of-time-order correlators (OTOCs) might not be sufficient to properly characterize information scrambling in the presence of nonlocal interactions. In particular, two models that exhibit a highly nonlinear lightcone can vary widely in their thermalization timescale. More elaborate measures of operator growth can distinguish these two scenarios and reveal very different operator dynamics. Moreover, we find a distinct analogy between the growth of a local operator under time-evolution and the entanglement entropy following a quantum quench. Our work gives new insights into scrambling properties of systems that are within reach of state-of-the-art experimental platforms and complements results on the possibility of observing features of quantum gravity in the laboratory.

## QI 10.7 Thu 11:30 H9

Quantum simulation of  $\mathbb{Z}_2$  lattice gauge theories with dynamical matter from two-body interactions in  $(2 + 1)\mathbf{D} - \mathbf{L}$ UKAS HOMEIER^{1,2,3}, ANNABELLE BOHRDT^{3,4}, SIMON LINSEL^{1,2}, EUGENE DEMLER⁵, JAD C. HALIMEH^{1,2}, and FABIAN GRUSDT^{1,2} — ¹LMU Munich, Germany — ²MCQST, Munich, Germany — ³Harvard University, Cambridge (MA), USA — ⁴ITAMP, Cambridge (MA), USA — ⁵ETH Zurich, Switzerland

Gauge fields coupled to dynamical matter are a universal framework in many disciplines of physics, ranging from particle to condensed matter physics, but remain poorly understood at strong couplings. Through the steadily increasing control over numerically inaccessible Hilbert spaces, analog quantum simulation platforms have become a powerful tool to study interacting quantum many-body systems. Here we propose a scheme in which a  $\mathbb{Z}_2$  gauge structure emerges from local two-body interactions and one-body terms in two spatial dimensions. The scheme is suitable for Rydberg atom arrays and enables the experimental study of both  $(2 + 1)D \mathbb{Z}_2$  lattice gauge theories coupled to dynamical matter ( $\mathbb{Z}_2$  mL-GTs) and quantum dimer models on the honeycomb lattice, for which we derive effective Hamiltonians. We discuss ground-state phase diagrams of the experimentally relevant effective  $\mathbb{Z}_2$  mLGT for U(1) and quantum- $\mathbb{Z}_2$  matter featuring deconfined phases. Our proposed scheme allows to experimentally study not only longstanding goals of theoretical physics, such as Fradkin and Shenker's [PRD 19, 1979] conjectured phase diagram, but also go beyond regimes accessible with current numerical techniques.

## QI 10.8 Thu 11:45 H9

Digital quantum simulation of the BCS model with a central-spin-like quantum processor — •JANNIS RUH, REGINA FINSTERHOELZL, and GUIDO BURKARD — University of Konstanz, Konstanz, Germany

The simulation of quantum systems is one of the most promising applications of quantum computers. We present a quantum algorithm to perform digital quantum simulations of the Bardeen-Cooper-Schrieffer (BCS) superconductivity model on a quantum register with a star shaped connectivity map, as it is, e.g., featured by color centers in diamond. We show how to effectively translate the problem onto the quantum computer and implement the algorithm using only the native interactions between the qubits. Furthermore, we use the algorithm to simulate the dynamics of the BCS model by subjecting its mean-field ground state to a time-dependent perturbation. The quantum simulation algorithm is studied using a classically simulated quantum computer.

## QI 10.9 Thu 12:00 H9

**Characterizing quantum correlations among magnons in antiferromagnets** — •VAHID AZIMI MOUOSLOU^{1,2}, YUEFEI LIU³, ANDERS BERGMAN¹, ANNA DELIN³, OLLE ERIKSSON^{1,4}, MANUEL PEREIRO¹, DANNY THONIG⁴, and ERIK SJÖQVIST¹ — ¹Uppsala University, Uppsala, Sweden — ²University of Isfahan, Isfahan, Iran — ³KTH Royal Institute of Technology, Stockholm, Sweden — ⁴Örebro University, Örebro, Sweden

Quantum magnonics provides promising hybrid platforms for accessing unique quantum phenomena and using them to realize stable and energy-efficient nanoscale quantum technologies. Clearly, quantum correlations are the major non-classical resources in such quantum systems. Here we discuss how an antiferromagnetic coupling generates experimentally detectable bipartite continuous variable magnon-entanglement [1, 2]. We present feasible experimental setups based on hybrid magnon+X systems to quantify the demonstrated magnon-entanglement through an uncertainty relation.

**Partitioning methods for solving optimization problems on NISQ-devices** — •FEDERICO DOMINGUEZ¹, KAONAN CAMPOS MICADEI¹, CHRISTIAN ERTLER¹, and WOLFGANG LECHNER^{1,2} — ¹Parity QC Germany GmbH, Munich, Germany — ²Institute for Theoretical Physics, LFUI, and Parity QC GmbH, Innsbruck, Austria

Partitioning methods are hybrid quantum-classical algorithms aimed at overcoming the memory limitations of current quantum devices. These methods decompose large problems into smaller pieces suitable for running on small quantum devices. The partial solutions to the problem are recombined using classical algorithms that can deal with both the error from the partition approximation and the intrinsic errors of the NISQ devices.

In this work, we solve optimization problems by developing partitioning methods based on the Parity encoding [1,2] and we benchmark the results using simulated quantum annealing. The Parity transformation is capable of encoding all-to-all graphs, hypergraphs, and side conditions of optimization problems using only local qubit interactions and allowing for a high gate parallelizability and hence scalability [3,4]. The resulting locality property is especially suited for the partitioning approach. The performance of our method shows that large optimization problems can be efficiently run on small quantum devices. [1] Lechner, W. et al. (2015). Science advances,1(9), e1500838. **Calculation of Correlated Electronic States on Noisy Intermediate Scale Quantum Computers** — •JANNIS EHRLICH¹, DANIEL URBAN¹, and CHRISTIAN ELSÄSSER^{1,2} — ¹Fraunhofer-Institut für Werkstoffmechanik IWM, Freiburg, Germany — ²Freiburger Materialforschungszentrum, Universität Freiburg, Germany

The numerical description of correlated electrons on conventional computers is limited to small system sizes. For the exact diagonalization approach, for example, all configurations in the many-particle space have to be considered, and their number grows exponentially with the number of one-particle states. This limitation can be overcome by simulating the correlated electrons with one of the artificial quantum systems that recently became available through the advance in quantum computing technologies. On such systems, each one-particle state can be represented by one qubit, which can be entangled with each other to generate superpositions. Thus, a linear scaling in the number of qubits is sufficient to cover the full many-particle space. Here, we describe strongly correlated systems within the dynamical mean-field theory (DMFT) and investigate its possible realization on a quantum computer. As a proof of concept, we study the simplified version of two-site DMFT both, by using simulators and an IBMQ quantum computer. We show that a solution of this model can be obtained using the quantum-classical variational quantum eigensolver (VQE). As the quality of the

results is limited by the noise level of current quantum computers (NISQ type), we further investigate how different error mitigation strategies can improve the results.

**Optimal gradient estimation for variational quantum algorithms** — •LENNART BITTEL, JENS WATTY, and MARTIN KLIESCH — Heinrich Heine Universität, Düsseldorf

Variational quantum algorithms (VQAs) are a leading approach for achieving a practically relevant near-term quantum advantage. A bottleneck of this approach is the estimation of derivatives of a given energy functional w.r.t. the parameters of the underlying variational quantum circuit. The parameter shift rule and its extensions allow for such and estimation without systematic errors. However, due to the measurement shot noise, they can have a large statistical error. As a consequence, many measurement rounds are required, which result in non-optimal VQA run-times.

In this work, we reduce this measurement overhead by using a Bayesian estimation framework. For this, we use prior knowledge about the circuit to then determine optimal measurement settings that minimize the expected statistical and systematic errors simultaneously. With accurate priors, this approach can significantly outperform traditional methods. We test our estimation algorithm numerically for a common quantum approximate optimization algorithm (QAOA). For a desired estimation accuracy we can reduce the number of measurements by an order of magnitude compared to traditional estimation methods. This also leads to significantly improved convergence times for the gradient descent algorithm.

**Synthesis of and compilation with time-optimal multi-qubit gates** — •PASCAL BASSLER¹, MATTHIAS ZIPPER¹, CHRISTOPHER CEDZICH¹, PATRICK HUBER², MICHAEL JOHANNING², MARKUS HEINRICH¹, and MARTIN KLIESCH¹ — ¹Heinrich Heine University Düsseldorf, Germany — ²University of Siegen, Germany

We develop a method to synthesize a class of entangling multi-qubit gates for a quantum computing platform with fixed Ising-type interaction with all-to-all connectivity. The only requirement on the flexibility of the interaction is that it can be switched on and off for individual qubits. Our method yields a timeoptimal implementation of the multi-qubit gates. We numerically demonstrate that the total multi-qubit gate time scales approximately linear in the number of qubits. Using this gate synthesis as a subroutine, we provide compilation strategies for important use cases: (i) we show that any Clifford circuit on n qubits can be implemented using at most n multi-qubit gates without requiring ancilla qubits, (ii) we decompose the quantum Fourier transform in a similar fashion, (iii) we compile a simulation of molecular dynamics into native gates, and (iv) we propose a method for the compilation of diagonal unitaries with time-optimal multi-qubit gates, as a step towards general unitaries. As motivation, we provide a detailed discussion on a microwave controlled ion trap architecture with magnetic gradient induced coupling (MAGIC) for the generation of the Ising-type interactions.

Estimating molecular forces and other energy gradients efficiently on a quantum computer — •MICHAEL STREIF², THOMAS O'BRIEN¹, NICHOLAS C. RUBIN¹, RAFFAELE SANTAGATI², YUAN SU¹, WILLIAM J. HUGGINS¹, JOSHUA J. GOINGS¹, NIKOLAJ MOLL², ELICA KYOSEVA², MATTHIAS DEGROOTE², CHRISTOFER S. TAUTERMANN³, JOONHO LEE^{1,4}, DOMINIC W. BERRY⁵, NATHAN WIEBE^{6,7}, and RYAN BABBUSH¹ — ¹Google Research, USA — ²Quantum Lab, Boehringer Ingelheim, Germany — ³Boehringer Ingelheim Pharma GmbH & Co KG, Germany — ⁴Department of Chemistry, Columbia University, USA — ⁵Department of Physics and Astronomy, Macquarie University, Australia — ⁶Department of Computer Science, University of Toronto, Canada — ⁷Pacific Northwest National Laboratory, USA

The calculation of energy derivatives underpins many fundamental properties for molecular systems, such as dipole moments or molecular forces. Nevertheless, most methods for quantum chemistry on quantum computers have focused on electronic structure calculations, even though energy derivatives are fundamental for many practical applications. Here, I will introduce quantum algorithms for the calculation of energy derivatives on noisy intermediate scale (NISQ) and fault tolerant (FTQC) quantum computers, with substantially reduced cost compared to previous methods. Our results suggest that the calculation of molecular forces has a similar cost to estimating energies. However, since molecular dynamics (MD) simulations typically require millions of force calculations, current known methods for MD on quantum computers are impractical and new approaches need to be found.

QI 12.6 Thu 16:15 H8 Towards the Simulation of Large Scale Protein-Ligand Interactions on NISQera Quantum Computers — •NIKOLAJ MOLL¹, FIONN D. MALONE², ROBERT M. PARRISH², ALICIA R. WELDEN², THOMAS FOX³, MATTHIAS DEGROOTE¹, ELICA KYOSEVA¹, RAFFAELE SANTAGATI¹, and MICHAEL STREIF¹ — ¹Quantum Lab, Boehringer Ingelheim, 55218 Ingelheim, Germany — ²QC Ware Corporation, Palo Alto, CA, 94301, USA — ³Medicinal Chemistry, Boehringer Ingelheim Pharma GmbH & Co. KG, 88397 Biberach, Germany

Most quantum computing research for quantum chemistry applications has focused on the calculation of ground state energies, while in the pharmaceutical industry, one is often more interested in gaining insight into the interaction of drugs and proteins. The interaction energy together with entropic contributions allows the determination of the efficacy of a potential drug. Here we explore the use of symmetry-adapted perturbation theory (SAPT) as a simple means to compute interaction energies between two molecular systems with a hybrid method combing NISQ-era quantum and classical computers. From the one- and twoparticle reduced density matrices of the monomer wavefunctions obtained by the variational quantum eigensolver (VQE), we compute SAPT contributions to the interaction energy. At first order, this energy yields the electrostatic and exchange contributions for non-covalently bound systems. Ideal statevector simulations show that the SAPT(VQE) interaction energy components display orders of magnitude lower absolute errors than the corresponding VQE total energies which sub kcal/mol accuracy in the SAPT interaction energies.

**Resilience of quantum approximate optimization against correlated errors** — JORIS KATTEMÖLLE and •GUIDO BURKARD — Universität Konstanz, Konstanz, Deutschland

The Quantum Approximate Optimization Algorithm (QAOA) has the potential of providing a quantum advantage in large-scale optimization problems, as well as in finding the ground state of spin glasses. This algorithm is especially suited for Noisy Intermediate Scale Quantum (NISQ) devices because of its noise resilience. So far, this noise resilience has only been studied under the assumption of uncorrelated noise. However, in recent years, it has become increasingly clear that the noise impacting NISQ devices is significantly correlated. In this work, we introduce a model for both spatially and temporally (non-Markovian) correlated errors that allows for the independent variation of the marginalized local error probability and the correlation strength. Using this model, we study the effects of noise correlations on QAOA by full density matrix simulation. We find evidence that the performance of QAOA improves as the strength of noise correlations is increased at fixed marginalised local error probability. This shows that, as opposed to algorithms for fully error-corrected quantum computers, noise correlations need not be detrimental for NISQ algorithms such as QAOA, and may actually improve the performance thereof.

**Exploiting symmetry in variational quantum machine learning** — JOHANNES JAKOB MEYER¹, MARIAN MULARSKI^{1,2}, ELIES GIL-FUSTER^{1,3}, •ANTONIO ANNA MELE¹, FRANCESCO ARZANI¹, ALISSA WILMS^{1,2}, and JENS EISERT^{1,3,4} — ¹Dahlem Center for Complex Quantum Systems, Freie Universität Berlin, 14195 Berlin, Germany — ²Porsche Digital GmbH, 71636 Ludwigsburg, Germany — ³Fraunhofer Heinrich Hertz Institute, 10587 Berlin, Germany — ⁴Helmholtz-Zentrum Berlin für Materialien und Energie, 14109 Berlin, Germany

Variational quantum machine learning is an extensively studied NISQ application. The success of variational quantum learning models crucially depends on finding a suitable parametrization of the model that encodes an inductive bias relevant to the learning task. However, little is known about guiding principles for constructing suitable parametrizations. We explore when and how symmetries of the learning problem can be exploited to construct quantum learning models with outcomes invariant under the symmetry of the learning task. Using tools from representation theory, we show how a standard gateset can be transformed into an equivariant one that respects the symmetries of the problem through a process of symmetrization. We benchmark the proposed methods on two toy problems that feature a non-trivial symmetry and observe a substantial increase in generalization performance. As our tools can also be applied in a straightforward way to other variational problems with symmetric structure, we show how equivariant gatesets can be used in variational quantum eigensolvers.

A single T-gate makes distribution learning hard — MARCEL HINSCHE¹, MAR-IOS IOANNOU¹, •ALEXANDER NIETNER¹, JONAS HAFERKAMP¹, YIHUI QUEK¹, DOMINIK HANGLEITER², JEAN-PIERRE SEIFERT³, JENS EISERT^{1,4,5}, and RYAN SWEKE¹ — ¹FU Berlin, 14195 Berlin, Germany — ²University of Maryland, MD 20742, USA — ³TU Berlin, 10587 Berlin, Germany — ⁴Helmholtz-Zentrum Berlin, 14109 Berlin, Germany — ⁵Fraunhofer Heinrich Hertz Institute, 10587 Berlin, Germany

The task of probabilistic modelling is at the core of many practical applications. As such, the efficient learnability of natural classes of probability distributions is a question of both fundamental and practical interest. The output distributions of local quantum circuits is a particularly interesting class of distributions, of key importance both to quantum advantage proposals and a variety of quantum machine learning algorithms. In this work, we provide an extensive characterization of the learnability of the output distributions of local quantum circuits. We prove that the density modelling problem can be solved efficiently in case of Clifford circuits, while adding a single T gate renders the task computationally hard. Evidently, the simulability of this class does not imply its learnability. Next we show that the generative modelling task is hard for depth  $n^{\Omega(1)}$  universal local quantum circuits for both, classical and quantum algorithms. Finally we obtain a similar hardness result already for depth  $\omega(\log(n))$  local Clifford circuits when restricting to practically relevant learning algorithms, such hybrid-quantum classical algorithms.

Avoiding barren plateaus via transferability of smooth solutions in Hamiltonian Variational Ansatz — ANTONIO ANNA MELE^{1,2}, GLEN BIGAN MBENG³, GIUSEPPE ERNESTO SANTORO², MARIO COLLURA², and •PIETRO TORTA² — ¹Dahlem Center for Complex Quantum Systems, Freie Universität Berlin, 14195 Berlin, Germany — ²SISSA, Via Bonomea 265, I-34136 Trieste, Italy — ³Universität Innsbruck, Technikerstraße 21 a, A-6020 Innsbruck, Austria

A large ongoing research effort focuses on Variational Quantum Algorithms (VQAs), representing leading candidates to achieve computational speed-ups on current quantum devices. The scalability of VQAs to a large number of qubits, beyond the simulation capabilities of classical computers, is still debated. Two major hurdles are the proliferation of low-quality variational local minima, and the exponential vanishing of gradients in the cost function landscape, a phenomenon referred to as barren plateaus. Here we show that, by employing it-

erative search schemes one can effectively prepare the ground state of paradigmatic quantum many-body models, circumventing also the barren plateau phenomenon. This is accomplished by leveraging the transferability to larger system sizes of iterative solutions, displaying an intrinsic smoothness of the variational parameters, a result that does not extend to other solutions found via randomstart local optimization. Our scheme could be directly tested on near-term quantum devices, running a refinement optimization in a favorable local landscape with non-vanishing gradients.

OI 13.1 Fri 9:30 H8 Scalable control of superconducting qubits - • STEFAN FILIPP - Walther-Meissner-Institut, 85748 Garching — TU Munich, Physics-Department, 85748 Garching

The rapid development of quantum technologies in the recent past has led to the realization of first quantum computer prototypes that promise to outperform conventional computers in specific types of problems. However, before practical real-life problems can be solved efficiently on quantum computers we have to still tackle numerous challenges not only to enhance the coherence, but also the control of qubits. To improve the fidelity of single qubit operations we utilize closed-loop optimization methods based on high duty-cycle measurements. With piecewise-constant pulse parameterizations we are able to demonstrate short, 4ns single-qubit pulses with high fidelity and low leakage. We further explore architectures that contain 'hidden' qubits, which are not directly addressable, and experimentally demonstrate full control and measurement capabilities of such a hidden qubit. I will then discuss the impact of such restricted control capabilities on the performance of specific qubit coupling networks. I will further preview promising future directions such as the use of adiabatic gates for quantum feed-forward neural networks and multi-qubit gate operations for the efficient implementation of quantum algorithms as part of the newly formed Munich Quantum Valley, a cross-disciplinary initiative to realize a full-stack quantum computer.

Test and diagnostics speed up for characterizing few-qubit superconducting quantum processors - •Thorsten Last, Garrelt Alberts, Adam LAWRENCE, KELVIN LOH, VIACHESLAV OSTROUKH, and ADRIAAN ROL - Orange Quantum Systems B.V., Lorentzweg 1, 2628 CJ Delft, NL

The combined challenge of increasing the qubit count on a quantum processor and a requirement to further reduce the gubit's error rates require novel approaches in test and qubit diagnostics. An important aspect to improve the situation is an acceleration of the development cycle for quantum processors [1]. Here we present benchmarking and diagnostic tools based on the recently established open-source platform Quantify [2] to perform end-to-end data analytics. Structured (human-assisted) characterization and a gradual enhancement of automation already led to a reduction of time for basic qubit diagnostics from months to days. The diagnostic tools for characterizing small scale superconducting quantum processors are available as software packages or fully integrated into room temperature electronic control racks. They are organized in complexity classes ranging from hardware verification, and basic single-qubit analytics up to the level of algorithmic benchmarking. Besides quantum processor diagnostics these tools are also used for full-stack system verification through experiment. [1] G.J.N. Alberts, et al., EPJ Quantum Technol. 8: 18 (2021). How to correctly account for time-varying fluxes in superconducting circuits — •Ahmed Kenawy¹, Fabian Hassler², David DiVincenzo¹, and ROMAN RIWAR¹ — ¹Peter Grünberg Institute, Theoretical Nanoelectronics, Forschungszentrum Jülich — ²JARA-Institute for Quantum Information, RWTH Aachen University

Time-varying fluxes are a ubiquitous tool to control superconducting hardware. Surprisingly, however, the existing literature has never fully accounted for the electro-motive force induced by the magnetic field. Here, we propose a general recipe to construct a low-energy Hamiltonian, taking as input only the circuit geometry and the solution of the external magnetic fields. We apply this recipe to the example of a dc SQUID and show that the assignment of individual capacitances to each Josephson junction is possible only if we permit those capacitances to be negative, time-dependent, or even momentarily singular. Such anomalous

The vast majority of quantum states and unitaries have circuit complexity exponential in the number of qubits. In a similar vein, most of them also have exponential minimum description length, which makes it difficult to pinpoint examples of exponential complexity. In this work, we construct examples of constant description length but exponential circuit complexity. We provide infinite families such that each element requires an exponential number of two-qubit gates to be generated exactly from a product and where the same is true for the approximate generation of the vast majority of elements in the family. The results are based on sets of large transcendence degree and discussed for tensor networks, diagonal unitaries and maximally coherent states.

capacitances lead, among others, to a strong enhancement of qubit relaxation rates. Then, we tackle the problem of driven topological quantum circuits, focusing on two weakly coupled Kitaev chains and study how the electro-motive

Majorana fermions revealing the true nature of quantum phase slip junctions - •CHRISTINA KOLIOFOTI and ROMAN-PASCAL RIWAR — Forschungszentrum Jülich, Peter Grünberg Institut (PGI-2), 52425 Jülich, Deutschland

force modifies the time-dependent fractional Josephson effect.

Quantum circuit theory is a powerful and ever-evolving tool to predict the dynamics of superconducting circuits. In its language, quantum phase slips are famously considered to be the exact dual to the Josephson effect. However, if taken at face value, this duality stipulates that charge must be continuous. We propose a charge-quantization conserving description of quantum phase slips and show that this seemingly minute change gives rise to some very different predictions. When shunting a quantum phase slip junction with a topological Josephson junction, the new description leads to a complete dissappearance of the Hofstadter butterfly spectrum. For topologically trivial circuits we argue that adhering to charge quantization renders realizations of the Gottesman-Kitaev-Preskill code impossible.

## QI 13.5 Fri 10:45 H8

Tunable-coupler mediated controlled-controlled-phase gate with super**conducting qubits** — •NIKLAS J GLASER^{1,2}, FEDERICO ROY^{1,3}, and STE-FAN FILIPP^{1,2,4} — ¹Walther-Meißner-Institut, Bayerische Akademie der Wis-senschaften, 85748 Garching, Germany — ²Physik-Department, Technische Universität München, 85748 Garching, Germany — ³Theoretical Physics, Saar-land University, 66123 Saarbrücken, Germany — ⁴Munich Center for Quantum Science and Technelow (MCOCT) = 00700 M⁻¹ Science and Technology (MCQST), 80799 München, Germany

Applications for noisy intermediate scale quantum computing devices rely on the efficient entanglement of many qubits to reach a potential quantum advantage. Although entanglement is typically generated using two-qubit gates, direct control of strong multi-qubit interactions can improve the efficiency of the process. We investigate a system of three superconducting transmon-type qubits coupled via a single flux-tunable coupler. Tuning the frequency of the coupler by adiabatic flux pulses enables us to control the conditional energy shifts between the qubits and directly realize multi-qubit interactions. To accurately adjust the resulting controlled relative phases, we describe a gate protocol involving refocusing pulses and adjustable interaction times. This enables the implementation of the full family of pairwise controlled-phase (CPHASE) and controlledcontrolled-phase (CCPHASE) gates. Numerical simulations result in fidelities around 99% and gate times below 300 ns using currently achievable system parameters and decoherence rates.

Coupler-mediated unconditional reset of fixed-frequency superconducting qubits  $- \cdot$  Gerhard Huber^{1,2}, Federico Roy^{1,2}, and Stefan Filipp^{1,2,3} ^{- 1}Walther-Meißner-Institut, Bayrische Akademie der Wissenschaften, 85748 Garching, Germany — ²Physik-Department, Technische Universität München, 85748 Garching, Germany – ³Munich Center for Quantum Science and Technology (MCQST), 80799 München, Germany

Advances in superconducting qubit fabrication procedures have led to energy relaxation times regularly exceeding 100 µs. Therefore, passive reset via relaxation has become unpractical, and an active reset protocol is required to achieve high repetition rate of quantum algorithms. Previous unconditional qubit reset schemes have relied on flux tunable qubits or multiple transitions over higher qubit states. We extend a previous reset scheme using flux tunable qubits to

fixed frequency transmon qubits with tunable couplers. The reset pulse consists of a single parametric flux pulse on the coupler to transfer qubit excitations to a quickly decaying resonator. Our protocol does not rely on additional control lines and can be implemented on current multi-qubit architectures. Further, it can be extended to architectures where a single coupler allows for reset of multiple qubits. We present preliminary numerical and experimental results for this reset protocol demonstrating its potential usefulness.

Analysis of calibration techniques for single-qubit gates on a superconducting quantum computer — •Kathrin König¹, Naoki Kanazawa², and Shota NAKASUJI³ — ¹Fraunhofer IAF, Freiburg, Germany — ²IBM Research, Tokyo, Japan — ³University of Tokyo, Tokyo, Japan

Inexact calibrated gates and environmental influences lead to imperfect outcomes of a quantum computation. We investigate two calibration techniques on an IBM quantum computer. The state-of-the art calibration uses an empirical formula to update the optimal control parameter. The compared new technique can directly estimate the parameter at arbitrary precision. We confirmed that the new technique shows higher precision with comparable accuracy.

# QI 13.8 Fri 11:45 H8

Pulse class meta-optimization of continous quantum gates in transmon systems — •FRANCESCO PRETI — Forschungszentrum Jülich, Jülich, Germany

Reducing the circuit depth of quantum circuits is a crucial bottleneck to enabling quantum technology. This depth is inversely proportional to the number of available quantum gates that have been synthesized. Moreover, quantum gate synthesis and control problems exhibit a vast range of external parameter dependencies, both physical and application-specific. We address the possibility of learning families of optimal control pulses in transmon systems, which depend adaptively on various parameters, in order to obtain a global optimal mapping from the space of potential parameter values to the control space, and hence continuous classes of gates. Our proposed method is tested on different experimentally relevant quantum gates and proves capable of producing high-fidelity pulses even in presence of multiple variables or uncertain parameters with wide ranges.

## QI 13.9 Fri 12:00 H8

Magnetic field dependence of the quasiparticle parity lifetime in 3D transmons with thin-film  $Al - AlO_x - Al$  Josephson junctions — •JONAS KRAUSE¹, Lucas Jannsen¹, Christian Dickel¹, Elmore Vaal¹, Michel Vielmetter¹, JUREK FREY², FELIX MOTZOI³, SHAI MACHNESS², KELVIN LOH⁴, MICHIEL ADRIAAN ROL⁴, GIANLUIGI CATELANI⁵, and YOICHI ANDO¹ — ¹Physics In-stitute II, University of Cologne — ²Quantum Computing Analytics (PGI 12), Forschungszentrum Jülich — ³Institute of Quantum Control (PGI-8), Forschungszentrum Jülich — ⁴Orange Quantum Systems — ⁵JARA Institute for Quantum Information (PGI-11), Forschungszentrum Jülich

Magnetic-field resilient superconducting circuits enable quantum sensing applications, hybrid quantum computing architectures, as well as studying flux noise and quasiparticle loss. Placing a thin-film aluminum transmon in a 3D copper cavity, we can measure its quasiparticle parity lifetime over a large range of magnetic fields, with in-plane fields approaching 1T. The magnetic field reduces

the Josephson Energy  $E_I$ , while the charging energy  $E_C$  is virtually unaffected. The transmon exhibits a parity-dependent frequency splitting. We are working on optimal control techniques for fast parity-selective gates which together with single-shot readout allow measuring the parity lifetime. The magnetic-field dependence of the parity lifetime is of interest for future topological qubits, which rely on combining superconductors with magnetic fields; additionally, it could improve the understanding quasiparticle loss in conventional superconducting qubits.

## OI 13.10 Fri 12:15 H8

Towards cQED experiments with in-situ fabrication of topological insulator Josephson junctions — •LUCAS JANSSEN, JONAS KRAUSE, CHRISTIAN DICKEL, Alexey Taskin, Roozbeh Yazdampanah Ravari, Anjana Uday, Gertjan LIPPERTZ, and YOICHI ANDO - AG Ando, PH2, Universität zu Köln, Germany Circuit quantum electrodynamics experiments with topological insulator (TI) Josephson junctions (JJs) are a promising path towards finding and studying Majorana zero modes. However, the fabrication of TI JJs is challenging. For our topological insulator, we use MBE grown ternary TI (BiSb)_2Te_3. The interface between the proximitising superconductor and the TI film is critically important for the quality of the JJ, which in turn is vital for microwave performance. Hence, we have been fabricating TI JJs with in-situ deposited niobium. However, etching the niobium to define a JJ has proven challenging. We are exploring a combination of titanium and aluminium as an alternative superconductor. An alternative to this etching step is stencil mask technology. We will present our progress in JJ fabrication and possibly first cQED measurements.

#### QI 13.11 Fri 12:30 H8

Mitigation of quasiparticle loss in superconducting qubits by phonon scattering — Arno Bargerbos¹, Lukas J. Splitthoff¹, Marta Pita-Vidal¹, Jaap J. Wesdorp¹, Yu Llu², Peter Krogstrup³, Leo P. Kouwenhoven¹, Christian K. Andersen¹, and •Lukas Grünhaupt^{1,4} — ¹QuTech and Kavli Institute of Nanoscience, Delft University of Technology, Delft, The Netherlands —  2 Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, Copenhagen, Denmark — ³Niels Bohr Institute, University of Copenhagen, Copenhagen, Denmark — ⁴Physikalisch-Technische Bundesanstalt, Braunschweig, Germany

Most error correction schemes for future quantum processors rely on the assumption that errors are uncorrelated. However, in superconducting devices this assumption is drastically violated in the presence of ionizing radiation, which creates bursts of high energy phonons in the substrate. A mitigation technique is to place large volumes of metal on the device, capable of reducing the phonon energy to below the superconducting gap of the qubits. To investigate the effectiveness of this method we fabricate a device with four nominally identical nanowire-based transmon qubits and replace one half of the niobium titanium nitride ground plane with aluminum (Al), which has a much lower superconducting gap. We inject phonons into the substrate by voltage biasing a galvanically isolated Josephson junction and we find protection due to the Al by a factor of 2-4 in terms of qubit lifetime and excited state population. Furthermore, we turn the Al normal with a magnetic field, finding no marked change in the phonon-protection.

## **QI 14: Quantum Foundations**

Time: Friday 9:30-12:30

#### Invited Talk

QI 14.1 Fri 9:30 H9 Testing quantum theory with generalized noncontextuality — •MARKUS P. Müller^{1,2,3} and Andrew J. P.  $Garner^1 - {}^1$ Institute for Quantum Optics and Quantum Information, Austrian Academy of Sciences, Boltzmanngasse 3, A-1090 Vienna, Austria — ²Vienna Center for Quantum Science and Technology (VCQ), Faculty of Physics, University of Vienna, Boltzmanngasse 5, A-1090 Vienna, Austria — ³Perimeter Institute for Theoretical Physics, 31 Caroline Street North, Waterloo, ON N2L 2Y5, Canada

It is a fundamental prediction of quantum theory that states of physical systems are described by complex vectors or density operators on a Hilbert space. However, many experiments admit effective descriptions in terms of other state spaces, such as classical probability distributions or quantum systems with superselection rules. Here, we ask which probabilistic theories could reasonably be found as effective descriptions of physical systems if nature is fundamentally quantum. To this end, we employ a generalized version of noncontextuality: processes that are statistically indistinguishable in an effective theory should not require explanation by multiple distinguishable processes in a more fundamental theory. We formulate this principle in terms of embeddings and simulations of one probabilistic theory by another, show how this concept subsumes standard notions of contextuality, and prove a multitude of fundamental results on approximate embeddings. We show how results on Bell inequalities can be used for the robust certification of generalized contextuality, and use this to propose a novel type of experimental test of quantum theory.

Proposal for demonstrating hidden nonlocality without assumptions -•JONATHAN STEINBERG, H. CHAU NGUYEN, and MATTHIAS KLEINMANN — University of Siegen, Siegen, Germany

A quantum state with hidden nonlocality does not violate any Bell inequality unless its hidden nonlocality is activated using local filters. This phenomenon has been demonstrated in experiments, however only when special Bell inequalities are considered [Kwiat et al., Nature 409, 1014 (2001)], or under the assumption that the quantum state is constrained to a special form which has a known local hidden variable [Opt. Express 28, 13638 (2020)]. Developing a general method for constructing local models for bipartite systems of a qubit and a qudit, we propose a protocol which allows one to conclusively demonstrate hidden nonlocality which is free from assumptions on both, the form of Bell inequalities and the special form of the state. By an optimization over the states and measurement directions we obtain that the required precision is within reach of near future experiments.

QI 14.3 Fri 10:15 H9 Non-locality with overlapping marginals — •Moisés Bermejo Morán —

Jagiellonian University, Krakow, Poland We investigate how non-locality can be shared in multi-partite physical systems. Going beyond the standard scenario with disjoint subsystems, we focus on the case where the subsystems participating in the Bell inequality can have overlap. The analytical methods are limited in generality and the standard numerical tools do not effectively provide good bounds when measurements with overlapping support are involved. We overcome these limitations by considering the Navascués-Pironio-Acín hierarchy for finite-dimensional systems, for a fixed dimension. Finding the optimal value via convex combinations of random states and PVMs. These allow us to find non-trivial monogamy bounds in simple scenarios.

Optimal convergence rate in the quantum Zeno effect for open quantum systems in infinite dimensions — •TIM MÖBUS and CAMBYSE ROUZÉ — Technical University Munich, Germany

In open quantum systems, the quantum Zeno effect consists in frequent applications of a given quantum operation, e.g. a measurement, used to restrict the time evolution (due e.g. to decoherence) to states that are invariant under the quantum operation. In an abstract setting, the Zeno sequence is an alternating concatenation of a contraction operator (quantum operation) and a strongly continuous contraction semigroup (time evolution) on a Banach space. In this paper, we prove the optimal convergence rate of order 1/n of the Zeno sequence by proving explicit error bounds. For that, we derive a new Chernoff-type lemma, which we believe to be of independent interest. Moreover, we generalize the Zeno effect in two directions: We weaken the assumptions on the generator, which induce a Zeno dynamics generated by an unbounded generator and we improve the convergence to the uniform topology. Finally, we provide a large class of examples arising from our assumptions.

## QI 14.5 Fri 10:45 H9

**Gravitational redshift induces quantum interference** – •DAVID EDWARD BRUSCHI¹ and ANDREAS WOLFGANG SCHELL^{2,3} – ¹Institute for Quantum Computing Analytics (PGI-12), Forschungszentrum Jülich, Jülich, Germany – ²Institut für Festkörperphysik, Leibniz Universität Hannover, Hannover, Germany – ³Physikalisch-Technische Bundesanstalt, Braunschweig, Germany

We use quantum field theory in curved spacetime to show that gravitational redshift induces a unitary transformation on the quantum state of propagating photons. This occurs for realistic photons characterized by a finite bandwidth, while ideal photons with sharp frequencies do not transform unitarily. We find that the transformation is a mode-mixing operation, and we devise a protocol that exploits gravity to induce a Hong-Ou-Mandel-like interference effect on the state of two photons. Testing the results of this work can provide a demonstration of quantum field theory in curved spacetime.

QI 14.6 Fri 11:15 H9 Dynamical Theories in Phase-Space: The Almost Hydrogen Atom — •MARTIN PLÁVALA and MATTHIAS KLEINMANN — Universität Siegen, Siegen, Deutschland

We construct a large class of operational theories of hydrogen atom that includes both classical and quantum theory as special cases. We show that one can formulate a well-defined theory of stationary bound states even without uniquely defined time-evolution and we prove that the ground state energy is finite only if the theory exhibits preparation uncertainty relation between position and momentum observables. We perturb the Hamiltonian by including external magnetic field, which leads to breaking of the degeneracy of the energy spectrum; in this setting we show that the magnetic quantum number is bounded by the principal quantum number, similarly as in quantum theory. We also perturb the Hamiltonian by nonstationary electric field and we show that this leads to excitations of the atom. Finally we investigate scattering theory where we show that Rutherford formula for scattering holds in all investigated operational theories.

#### QI 14.7 Fri 11:30 H9

Uncertainty relations with the variance and the quantum Fisher information - •Géza Tóthl^{1,2,3,4} and Florian Fröwis⁵ -  1 Theoretical Physics and EHU Quantum Center, University of the Basque Country UPV/EHU, E-48080 Bilbao, Spain -  2 Donostia International Physics Center (DIPC), E-20080 San Sebastián, Spain -  3 IKERBASQUE, Basque Foundation for Science, E-48011 Bilbao, Spain -  4 Wigner Research Centre for Physics, H-1525 Budapest, Hungary -  5 Group of Applied Physics, University of Geneva, CH-1211 Geneva, Switzerland

We present several inequalities related to the Robertson-Schrödinger uncertainty relation. In all these inequalities, we consider a decomposition of the density matrix into a mixture of states, and use the fact that the Robertson-Schrödinger uncertainty relation is valid for all these components. By considering a convex roof of the bound, we obtain an alternative derivation of the relation in Fröwis et al. [Phys. Rev. A 92, 012102 (2015)], and we can also list a number of conditions that are needed to saturate the relation. We present a formulation of the Cramér-Rao bound involving the convex roof of the variance. By considering a concave roof of the bound in the Robertson-Schrödinger uncertainty relation over decompositions to mixed states, we obtain an improvement of the Robertson-Schrödinger uncertainty relations with three variances. Finally, we present further uncertainty relations that provide lower bounds on the metrological usefulness of bipartite quantum states in two-mode and two-spin systems.

## QI 14.8 Fri 11:45 H9

**Geometry of expectation values of non-commuting observables** — •Konrad Szymanski — Universität Siegen, Siegen, Deutschland

Non-commutativity lies at the heart of quantum theory and provides a rich set of mathematical and physical questions. Here, I address this topic through the concept of the Joint Numerical Range (JNR) – the set of simultaneously attainable expectation values for multiple quantum observables, which in general need not commute. I discuss mathematical and physical implications of the geometry of JNR: classification of the possible shapes of the set, as well as development of novel uncertainty relations, entanglement and Schmidt rank witnesses, and detection of vanishing energy gap.

## QI 14.9 Fri 12:00 H9

# **Measurement-based models of friction and dissipative collapse** — •MICHAEL GAIDA and STEFAN NIMMRICHTER — Universität Siegen

Collapse models are objective modifications of quantum theory that aim to solve the measurement problem. One of the most studied models is the Continuous Spontaneous Localisation (CSL) model and its dissipative extension. We present a protocol based on randomly occurring Gaussian position measurements and unitary feedback operations that reproduces the single particle dynamics of dissipative CSL. Inspired by this protocol, we introduce a class of measurement-based models, implementing classical friction forces. We find that the specific model for linear Stokes friction reproduces the single-particle dissipative CSL master equation, as well.

QI 14.10 Fri 12:15 H9

**Transcendental properties of entropy-constrained sets** — •VJOSA BLAKAJ^{1,2} and MICHAEL WOLF^{1,2} — ¹Technical University of Munich — ²Munich Center for Quantum Science and Technology (MCQST), Munich, Germany

For information-theoretic quantities with an asymptotic operational characterization, the question arises whether an alternative single-shot characterization exists, possibly including an optimization over an ancilla system. If the expressions are algebraic and the ancilla is finite, this leads to semialgebraic level sets. In this work, we provide a criterion for disproving that a set is semialgebraic based on an analytic continuation of the Gauss map. Applied to the von Neumann entropy, this shows that its level sets are nowhere semialgebraic in dimension d > 2, ruling out algebraic single-shot characterizations with finite ancilla (e.g., via catalytic transformations). We show similar results for related quantities, including the relative entropy, and discuss under which conditions entropy values are transcendental, algebraic, or rational.

# AKC 1: Career in Academia

Time: Friday 9:30-12:00

## Invited Talk

AKC 1.1 Fri 9:30 H2

Closing the gender gap: avoid dropout in the postdoc and junior professor phase — • PETRA RUDOLF — Zernike Institute for Advanced Materials, University of Groningen, The Netherlands

The first big drop out from the scientific career for both women and men happens after the postdoc phase. In this talk I shall analyze the reasons why the postdoc phase is the most vulnerable phase in every young researcher's career and discuss what institutions and young researchers can do to better move on to a fulfilling position inside and outside academia. Of course every young scientist has to be good to make it but as a community we have a clear responsibility to foster talent development in physics.

Then I shall concentrate on academic careers and suggest some support actions for junior professor/ tenure track assistant professors to help these young talents to develop their full potential. Proper onboarding and mentoring in addition to practical help to easier reconcile professional and family duties can avoid loosing the young academics at this stage of their career.

#### Discussion

AKC 1.2 Fri 10:00 H2 University career – yes, but how to? — •PETRA RUDOLF¹, DORIS REITER², UL-RICH ECKERN³, and MONIKA MÜHLBAUER⁴ —  1 Zernike Institute for Advanced Materials, University of Groningen, The Netherlands — ²Condensed Matter Theory, TU Dortmund, Germany — ³Professor emeritus, Theoretische Physik II, Universität Augsburg, Germany — ⁴University of Applied Sciences, München, Germany

With the successful defense of the PhD dissertation, many graduates wish to continue their career in academia, aiming to work in a somehow independent position. This initially results in making life in temporary postdoc positions. On the long run, this desire leads to an academic career, with the prospect of later employment as a group leader in research centers of the scientific societies (MPG, HGF, FHG, ...) or as a university professor.

In combination with research-oriented teaching, a professorship is particularly attractive, bridging among generations with its orientation towards future, in largely open-ended and respected positions.

What obstacles are to be met, how to get on track? Comprehensive general information on the framework of preconditions and careful planning are essential for the targeted implementation of the necessary career steps. In particular, the sharing experiences with forerunners allows participation, including genderspecific aspects. All of this enhances the success probabilities of the **candidates**.

We are offering this open format panel discussion in our intention to encourage young women and men to pursue a scientific career in physics.

The AKC is continuously evaluating data from the Federal Statistical Office for physics. We are committed to booster the proportion of female professors (currently 13%), optimally up to their relative population fraction (51%). There is still a long path to go for this goal.

The major concern of this event is hence the link to role models - professionally successful physicists in science-oriented careers. Prof. Petra Rudolf (U Groningen, former first female president of the EPS) will give the introductory lecture and chair the session. Jun. Prof. Doris Reiter, Prof. Ulrike Diebold, Prof. Ulrich Eckern and Prof. Monika Mühlbauer will contribute and share their experiences. Prof. Mühlbauer will also present the "Get to be a professor" campaign that promotes this career choice by specific guidance and support.

The activity shall take place as a lively and informative platform for everyone such as to encourage physicists, in particular females among them, to pursue an academic career. The event will provide information, and it shall support the formation of professional networks by getting acquainted to each other. We aim at active contributions from all participants: questions, comments and reports on own experiences are explicitly invited.
