Award Ceremony

Max Planck Medal 2022 Prof. Dr. Annette Zippelius University of Göttingen

Stern Gerlach Medal 2022 Dr. Frank Eisenhauer Max Planck Institute for Extraterrestrial Physics (MPE), Garching

> Stern Gerlach Medal 2020 Prof. Dr. Joachim Ullrich Deutsche Physikalische Gesellschaft e.V.

Badge of Honour of the DPG 2019 Prof. Dr. Harald Lesch

Ludwig-Maximilians-University of Munich

Walter Schottky Prize 2022 Dr. Felix Büttner

Helmholtz-Zentrum Berlin

Max Born Prize 2022 Prof. Dr. Claudia Felser MPI für Chemische Physik, Dresden

SKM Dissertation Prize 2022 (The Laureate will be announced after the SKM-Dissertation Prize Symposium)

> **Ceremonial Lecture** "Quantum Dots for Green Quantum Technologies"

> > Prof. Dr. Dieter Bimberg Technical University of Berlin

Tuesday, 6 September 2022, 14:30 - 17:30 H1 (Audimax)

Deutsche Physikalische Gesellschaft DPG

Dear conference guests,

As President of the German Physical Society, I would like to welcome you to this meeting of the Condensed Matter Section (SKM) with the participating divisions and working groups involved on the campus of the University of Regensburg.

With around 55,000 members, the DPG is the world's largest physics society. It is also one of the most important international communication platforms for research and education in the field of physics and promotes the exchange of knowledge in physics, especially with its conferences.

It is therefore invaluable that this DPG conference once again enables direct encounters. After all, motivation for physics, inspiration and creativity thrive on personal dialogue, on a culture of discourse that must always be cultivated and promoted. This culture is at the same time indispensable for physics with the primacy of basic research, whose findings are not only important for physics, but also for our society.

At the same time, this conference promotes the public visibility of basic research in a special way. In this year, UNESCO's "International Year of Basic Research for Sustainable Development", the conference is an important contribution by the DPG to draw attention to the importance of basic research, which is often underestimated, at least by the general public - especially as an important component and for the further development of our society, our culture! It is the results of fundamental research that serve as the basis for social decisions and innovations and help to overcome the great challenges facing humanity.

I would like to express my sincere thanks to all those involved for the success of this DPG Conference. First of all, I would like to thank the participating DPG divisions and working groups for organising the scientific programme. My special appreciation also goes to the local organising committee at the University of Regensburg, Prof. Dieter Weiss, Faculty of the Institute of Experimental and Applied Physics. I would like to thank the University of Regensburg for its support and the Wilhelm and Else Heraeus Foundation for once again generously supporting all DPG conferences. I would like to thank the DPG Head Office for its support of all DPG (Spring) Meetings.

Jodin M

Programme

The scientific programme consists of 3.640 contributions:

- 11 Plenary talks
- 1 Evening talk
- 1 Ceremonial talk
- 9 Prize talks
- 4 Lunch talks
- 49 Topical talks
- 11 Tutorials
- 186 Invited talks
- 2.245 Contributed talks
- 1.121 Posters
 - 2 Discussions

Information for Participants

The conference will be held September 4 – 9, 2022.

Conference Information

Conference Venue

University of Regensburg Universitätsstraße 31 93053 Regensburg

The central activities like registration etc. will take place in the Main Lecture Hall (Audimax) of the University of Regensburg (Universitätsstraße 31). For a detailed map of the campus and the buildings please see the end of this booklet.

Parking at Universität Regensburg

Please note: The underground car parks are closed due to renovation. Please use the new parking garages near BioPark and the parking lots between UR and OTH. There are no parking fees.

Please do not park in areas set aside for special users ("reservierte Stellplätze") or in handicapped parking areas without a special parking permit. If you do, you may be towed away (with costs). Towed vehicles will be taken to the alternative car park near the building of Chemistry and Pharmacy. It can be reached through the street "Am BioPark". To reclaim your towed vehicle, please telephone the towing service on +49 (0) 172 8128601. You will be provided with a lock code so you can retrieve your car.

Transportation

Regensburg offers a very good transportation infrastructure. The conference ticket printed on your conference name tag will authorize you to use all buses of the public transport system (RVV) in Regensburg from September 4 to 9 in the fare zone 1 for free.

You can reach the **bus stop "Universität"** by the bus lines 2, 4, 6 and 11. Please note: Line 4 takes a different route and does not stop at the main station.

Conference Office – Information Desk

The conference office and the information desk are located in the foyer of the Main Lecture Hall (Audimax H1). The opening hours are:

		Registration	Information Desk
Sunday	September 4	15:00 - 19:00	12:00 - 20:00
Monday	September 5	07:30 - 18:00	07:30 - 22:00
Tuesday	September 6	08:00 - 16:00	08:00 - 22:00
Wednesday	September 7	08:00 - 16:00	08:00 - 22:00
Thursday	September 8	08:00 - 16:00	08:00 - 22:00
Friday	September 9	08:00 - 12:00	08:00 - 15:00

To contact the information desk during the opening hours call +49 (0)941-943 2530.

You will receive the printed short programme and your name tag at the conference office. **The name tag must be worn visibly during the entire conference.** With your name tag you will receive a receipt for your conference fee, the conference ticket for public transport and free coffee at our coffee corners.

The organisers, staff of the conference desk, and the student assistants will be identifiable by coloured name tags and Φ -T-shirts. Please contact them if you have any questions. Do not hesitate to inquire about all necessary information concerning the conference, orientation in Regensburg, accommodation, restaurants, going out, and cultural events at the information desk located in the foyer of the Main Lecture Hall.

Lost and found property

You can bring found items to the information desk in the foyer of the Audimax. There you can also get your lost property back.

Cloakroom

Participants are asked to look carefully after their wardrobe, valuables, laptops, and other belongings. The organisers

decline any liability. You will find a cloakroom in the basement of the Main Lecture Hall (Audimax). The opening hours will be announced. Please note that there is no possibility to store luggage!

Allocation of the Lecture Halls

H1-H10, H22, H23	Main Lecture Hall
H11-H17	Law and Economy Building
H18-H21	Multi-purpose Building
H31, H32	Mathematics Building
H33-H36	Physics Building
H37-H39	Pre-clinical Medicine Building
H43-H48	Chemistry & Pharmacy Building
S051-S054	Ostbayer. Techn. Hochschule (OTH) / University of Applied Sciences (OTH)
Plenary talks, joint Symposia	H1 (Audimax), H2
Lunch Talks	H2
Prize Ceremony, Evening Talks	H1 (Audimax)
Job Market	Kunsthalle (Foyer Audimax, 1 st floor)
Registration Desk	Foyer Audimax (Main Lecture Hall)
Information Desk	Foyer Audimax (Main Lecture Hall)
EinsteinSlam	H1 (Audimax)

With the DPG-App through the DPG Meeting!

The updated DPG-App is ready-to-use and contains additional functions/features: In addition to the option of target groups, the electronical programme booklets for DPG Conferences (E-VERHANDLUNGEN) are accessible and it is possible to compile a "favorite list" regarding events one wants to attend. Just download the DPG-App for Android or iOS now and utilize the supplemental offerings. You will find more information under *https://www.dpg-physik.de/service/dpg-app. html.*

WIFI

The University of Regensburg is member of the eduroam-network. Users from eduroam institutions, who have registered for eduroam, can use WIFI at the University of Regensburg without local registration in Regensburg. Please ask the computer center/network administration of your home institution for eduroam-registration. Eduroam in Regensburg is possible with WLAN SSID eduroam.

In addition to eduroam WIFI BayernWLAN is offered without prior registration. Furthermore you will have access with StudiWLAN (not at the OTH Regensburg!).

Login required: "RZ Account": dpg2022 "RZ Password": dpg2022

LAN

A few workstations for guests are available in the central library for emergencies. Please sign up directly at the information desk of the central library at th UR! Opening hours: Mo-Fr 10:00 - 14:00.

Printing service "Copy & Paper"

The copyshop at the Forum (Monday to Thursday 08:00-16:00, Friday 08:00-13:00) offers office supplies and printing service up to DIN A0 paper size. You are welcome to print out data from your USB stick or send the copyshop the data in pdf format with the exact details by email: **uni@copyandpaper.de**. Please note: It is not possible to print posters in DIN A0 format directly at the shop - the printing service needs one day in advance!

Presentation

Scientific presentations will be held either orally or by poster. Presentations with a German abstract will be given in German.

Oral Presentation

Lecturers are requested to provide their presentations electronically. All lecture rooms are equipped with projectors ("beamers"). The projectors mainly display in the 4:3 format. However they are compatible with the 16:9, limited to the display width. Some newer systems also work directly with 16:9. A majority of lecture halls offers radio microphone

amplifiers as well. OHPs are not available.

PCs/laptops will be available in all lecture halls. Therefore, the presentation should be recorded onto an USB stick as back-up in PDF and power point format. Of course, you can also use your own laptop – please consider to bring your own adapter if required.

Contributed talks should take 12 minutes with 3 minutes for discussions; Topical and Invited Talks must not exceed 30 or 45 minutes as specified in the programme. Presentations can be held in German language or in English language (conference language). For further information please contact the division in which you have submitted the lecture or the poster.

All lecture rooms will be opened, at the latest, 30 minutes prior to the lecture. Speakers are requested to be in the lecture room at least 20 minutes prior to the start of the session, to report to the chairperson of the session as well as the technical staff, to receive a brief introduction to the equipment in the lecture room.

Poster Presentation

Sites for poster sessions are named and located as follows:

Poster area 1	Sammelgebäude (Multi-purpose Building)
Poster area 2	Physik (Physics)
Poster area 3	Exhibition tent in front of the Physics Building
Poster area 4	Chemie (Chemistry and Pharmacy)

The poster boards will be marked with the number according to the scientific programme. As there will be several different poster sessions at the poster sites every day, authors are asked to mount their poster max. 2-3 hours before their session. Each poster should display the number according to the scientific programme. Each poster should be no larger than 85 cm x 120 cm (A0 portrait format).

Printing Service: "Copy & Paper". It is not possible to print posters in DIN A0 format directly at the shop – the printing service needs 1 day in advance!

For the mounting of the poster please use the prepared "power strip" at the poster frame. Please make sure to use only power strips for mounting the poster (residue-free removing).

Authors are requested to be available at their poster for at least half of the length of their poster session. Please provide the information when you will be available.

The posters will normally be removed after the session or in the next morning. Any posters remaining on display walls will be removed without requesting your permission before the next poster session. You can get your poster back at the Info Desk. The conference management accepts no liability for the posters.

Notice Board

The programme stated in this document corresponds to the status of the programme publication 12 July 2022 and will not be updated!

All changes to the conference programme (i.e. cancellation of presentations, change of rooms, etc.) will be continuously updated on the notice board of the conference website. The information is identical to the programme updates of the scientific programme and is also available there in other formats (sorted by publication date, filterable by conference parts and as an rss-feed). Please use the form *https://regensburg22.dpg-tagungen.de/programm/notice-board-form* to notify changes or cancellations.

Wilhelm and Else Heraeus Communication Programme

Important notes for participants who apply for a grant of the Wilhelm and Else Heraeus Foundation:

At the beginning of the conference you will receive an identification form at the conference office. The participation in the conference must be certified by the conference desk. You have the possibility to leave this certificate by the staff members of the DPG (recommended!) in the conference office or submit it to the DPG Head Office (DPG-Geschäftsstelle, Hauptstr. 5, 53604 Bad Honnef, Germany) by **September 26, 2022 at the latest**.

For more detailed information refer to http://regensburg22.dpg-tagungen.de

The Deutsche Physikalische Gesellschaft thanks the Wilhelm and Else Heraeus Foundation for the generous financial support of young academic talents. We hope that young physicists will continue to seize the offered opportunity for active scientific communication at scientific conferences. A total of about 37,800 young academics were supported by this programme so far.

Catering

Coffee

Free coffee, tea and water will be provided to all registered participants of the conference at DPG-coffee corners located near all exhibition areas and poster areas. All locations are displayed in the map of the campus at the end of this booklet. Please wear your name tag visibly during the entire conference.

In addition you can get refreshments and snacks at the cafeterias in the Multi-purpose Building and in the Buildings of Chemistry, Physics, Philosophy and Law (Monday-Friday). Please pay by your EC- oder credit card. Cash Payment is not possible!

Lunch

Mensa:

Lunch will be supplied in the Mensa of the University (Monday-Friday: 11:00 – 14:00). Prices: about 12.00 € including the meal, one drink and one dessert. Please pay by your EC- oder credit card. Cash Payment is not possible!

Food-Truck:

In addition to the Mensa and the cafeterias a Food truck ("Tommy's Mutzbraten") will offer hearty food in front of the Physics Building (outside).

Uni-Pizzeria:

The Pizzeria UNIKAT offers freshly made Italian food. Reservation recommended!

Campus' Grocery Store

The Campus' Grocery Store "Hechtbauer" at the Forum offers food, beverages and convenience goods (Monday-Friday: 08:00 – 18:00).

Events

Tutorials

On Sunday, September 4, 16:00 – 18:15, there will be tutorial workshops on current scientific topics for interested conference participants, in particular for students and young scientists. All conference participants are welcome.

Topics:

- Careers in science: "To boldly go where no one has gone before"
- · Discovering, Creating, and Exploring Novel Atomically-Thin Materials and Heterostructures
- Non-identical moire twins in bilayer graphene
- Introduction to 2D superconducting spintronics

Welcome Evening

Sunday, September 4, 18:30 - 21:30, Mensa

On Sunday evening, a Bavarian Welcome Evening will be held in the Mensa of the University of Regensburg to which all registered participants are kindly invited. Snacks and drinks will be served. "Vieraloa" (Bavarian Brass Music) will entertain you with music.

Do not miss the opportunity to register in the conference office (15:00 – 19:00) before the Welcome Evening as well as the official beginning of the conference. When registering for the conference you will receive your badge and **food and drink vouchers** for the Welcome Evening. Please note that the cloakroom in the lecture hall basement closes on Sunday at 20:00!

Opening of the Conference

The chair of the Condensed Matter Section (SKM) will give a short opening address on Monday, September 5 from 8:25 until 8:30.

Special Plenary Session with Award Ceremony (in German language)

On Tuesday, September 6 at 14:30, the special plenary session with award ceremony and ceremonial lecture will take place in the Audimax (H1).

Am Dienstag, den 6. September um 14:30 Uhr findet im H1 (Audimax) die Festsitzung mit Preisverleihung und anschließendem Festvortrag statt:

Musik

Begrüßung

durch den Örtlichen Tagungsleiter Prof. Dr. Dieter Weiss, Universität Regensburg

Grußbotschaft (per Video)

des Präsidenten der Universität Regensburg Prof. Dr. Udo Hebel

Rede

des Präsidenten der Deutschen Physikalischen Gesellschaft Prof. Dr. Joachim Ullrich

Musik

Preisverleihung

Vergabe der Max-Planck-Medaille 2022

an Prof. Dr. Annette Zippelius, Universität Göttingen

Vergabe der Stern-Gerlach-Medaille 2022

an Dr. Frank Eisenhauer, MPI Garching

Vergabe der Stern-Gerlach-Medaille 2021 an Prof. Dr. Joachim Ullrich, Deutsche Physikalische Gesellschaft e.V.

Vergabe der Ehrennadel 2019 an Prof. Dr. Harald Lesch, LMU München

Vergabe des Walter-Schottky-Preises 2022

an Dr. Felix Büttner, Helmholtz-Zentrum Berlin

Vergabe des Max-Born-Preises 2022

an Prof. Dr. Claudia Felser, MPI für Chemische Physik, Dresden

Vergabe des Dissertationspreises der Sektion Kondensierte Materie (SKM)

(Der Preisträger bzw. die Preisträgerin wird nach dem SKM-Dissertationspreissymposium ernannt)

Musik

Festvortrag (in English Language) Prof. Dr. Dieter Bimberg, Technische Universität Berlin "Quantum Dots for Green Quantum Technologies"

Public Evening Lecture (in German language)

Tuesday, September 6, 19:00 to 20:00, Audimax (H1) Professor Harald Lesch from the Ludwig-Maximilians-Universität München will speak about: *"Grundlagenforschung für Nachhaltigkeit"*.

The Evening Lecture is open for all conference participants and interested public. The entrance is free.

EinsteinSlam

Wednesday, September 7, 20:00, Audimax (H1)

Keen to hit the stage and fascinate the audience? The EinsteinSlam is yours! Be smart, take part, let science rock EinsteinSlam is the competitive art of making complex science accessible to a broad audience. There are just 10 minutes for every attendee to present his/her self-made performance. The event will finish with a public poll in order to evaluate if a particular contribution was either instructive and amusing or rather should have never been performed. All presentations will be given in English. For more information please see www.einstein-slam.de.

Job Market

During the conference various companies and organisations will present their working fields and career opportunities to all interested participants. The presentations will take place from Tuesday, September 6 to Friday, September 9 in the Kunsthalle (Foyer Audimax, 1st floor). The presentations will last for about 30 minutes plus discussion.

Programme:

Tuesday, Sep 6

14:00 – 15:00 Carl Zeiss AG: "ZEISS Semiconductor Manufacturing Technology: Kleinste Strukturen brauchen großartige Köpfe – Wir entwickeln die EUV-Technologien von morgen."

Wednesday, Sep 7

- 12:45 13:45 Ritzenhoefer GmbH: "Transformation Consulting Von der Physik zur Sinngebungs-Maschine fürs Topmanagement"
- 14:00 15:00 d-fine: "Auswirkungen von Krisen auf Energieversorger Einblick in die analytisch-technologische Beratung bei d-fine."

Thursday, Sep 8

- 12:45 13:45 Basycon Unternehmensberatung GmbH: "Was hat Beratung mit Forschung zu tun?"
- 14:00 15:00 Trumpf GmbH & Co. KG: "Lasersystems for EUV Lithography"

Friday, Sep 9

11:30 – 12:30 Horn & Company: "Horn & Company – Gewinne Einblicke in unsere Projekte zu Data Analytics, Big Data und Künstlicher Intelligenz und lerne unseren Beratungsansatz kennen!"

Exhibition of Scientific Instruments and Literature

From Tuesday to Thursday there will be an exhibition of scientific instruments and literature in the Main Lecture Hall Foyer (Foyer Audimax), Law and Economics Building ("Wirtschaft und Recht"), H6 area and one tent (in front of the Physics Building). Almost 100 companies (see list of exhibitors at the end of this booklet) will present their products. Opening hours are from 09:00 a.m. to 18:00 p.m.. All conference participants are welcome to attend the exhibition. The entrance is free.

City Tours "Regensburg – Experience a Historic City"

Walking Tour in German: Daily 10:30 & 14:30 Costs: 10,00 EUR/person Meeting Point: in front of the Tourist Information in the Old Town Hall of Regensburg Please register online or via e-mail tourismus[@]regensburg.de

<u>Walking Tour in English:</u> Tuesday, September 6, 15:30 – 17:00 Costs: 10.00 EUR/person Meeting point: in front of the Tourist Information in the Old Town Hall of Regensburg Please register via phone +49 941 507-4410 or via e-mail tourismus[@]regensburg.de

Bus trip "City Tour" Information and booking at: https://www.city-tour.info/en/regensburg/tour

SAY CHEESE!

The DPG conferences are basically public to the press. Please note: On behalf of DPG, photos and videos will be recorded during the conferences. In the context of public relations, these recordings (as the case may be) will be published on our website, in social media or within prints of the DPG for example.

CO₂ compensation for the DPG conferences

By \bar{d} ecision of the Executive Board, the DPG will compensate for fossil CO₂ emissions resulting from mobility for DPG conferences and committee meetings.

Acknowledgement

The Deutsche Physikalische Gesellschaft (DPG) and the Local Organisers want to thank the following institutions for supporting the conference:

- Wilhelm and Else Heraeus Foundation, Hanau
- University of Regensburg
- all industrial sponsors (see page 8 in this booklet)
- and all staff who make this conference possible.

Disclaimer of liability

All participants are asked to take care of their wardrobe and valuables. We assume no liability.

TUT

Tutorials

16:00 16:00	H1 H1	TUT 1 TUT 1.1	Sessions Careers in Science Careers in science: "To boldly go where no one has gone before" •Manfred Fiebig
16:00 16:00	H2 H2	TUT 2 TUT 2.1	2D Quantum Materials and Heterostructures: From Fabrication to Applications Discovering, Creating, and Exploring Novel Atomically-Thin Materials and Het- erostructures •Joshua Robinson
16:35	H2	TUT 2.2	Non-identical moire twins in bilayer graphene •Rebeca Ribeiro-Palau
17:10	H2	TUT 2.3	Single-photon emitters in 2D materials •Steffen Michaelis de Vasconcellos
17:45	H2	TUT 2.4	Introduction to 2D superconducting spintronics •Elke Scheer
16:00	H3	TUT 3	Functional Ferroics
16:00	H3	TUT 3.1	Domains and domain walls in functional ferroics •Dennis Meier
16:45	H3	TUT 3.2	Theory and simulations of ferroelectrics and related materials •Jorge Iniguez
17:30	H3	TUT 3.3	Atomic scale analysis of ferroic domain walls •Shelly Conroy
16:00	H4	TUT 4	Stochastic Processes from Financial Risk to Genetics
16:00	H4	TUT 4.1	Diffusion approximations for particles in turbulence •Bernhard Mehlig
16:50	H4	TUT 4.2	Probabilities in physics, paradoxes and populations •Tobias Galla
17:40	H4	TUT 4.3	Risk Revealed: Cautionary Tales, Understanding and Communication •Paul Embrechts

18:30 Mensa

Welcome Evening (for registered participants)

08:25	H1		Opening
08:30	H1	PLV I	Plenary Talks Intrinsic Josephson junctions in Bi ₂ Sr ₂ CaCu ₂ O ₈ : Generation of Terahertz radia- tion and beyond
14:00	H1	PLV II	•Reinhold Kleiner Topology and Chirality
14:00	H2	PLV III	 Claudia Felser (Laureate of the Max-Born-Prize 2022) Controlling and exploiting defects in diamond for Quantum Technologies Mark Newton
13:15	H1	PRV I	Prize Talk Ultrafast topological switching of magnetic skyrmions •Felix Büttner (Laureate of the Walter-Schottky-Prize 2022)
13:15	H2	PSV I	Lunch Talk Berufsbild: Wissenschaftsmanagement in der deutschen Raumfahrtagentur •Tobias Saltzmann
			SYNM
15:00	H1	SYNM 1.1	Invited Talks How to tackle the "I" in FAIR? •Claudia Draxl
15:30	H1	SYNM 1.2	Beyond the average error: machine learning for the discovery of novel materials •Mario Boley
16:00	H1	SYNM 1.3	The Phase Diagram of All Inorganic Materials •Chris Wolverton
16:45	H1	SYNM 1.4	Automated data-driven upscaling of transport properties in materials •Danny Perez
17:15	H1	SYNM 1.5	•Data-driven understanding of concentrated electrolytes •Alpha Lee
15:00	H1	SYNM 1	Session From Physics and Big Data to the Design of Novel Materials
			SYOP
09:30	H1	SYOP 1.1	Invited Talks Orbital degeneracy in transition metal compounds: Jahn-Teller effect, spin-orbit coupling and quantum effects
10:00	H1	SYOP 1.2	•Daniel Khomskii Orbital magnetism out of equilibrium: driving orbital motion with fluctuations, fields and currents
10:30	H1	SYOP 1.3	•Yuriy Mokrousov Orbitronics: new torques and magnetoresistance effects
11:15	H1	SYOP 1.4	 Mathias Kläui Orbital and total angular momenta dichroism of the THz vortex beams at the antiferromagnetic resonances Andrei Sirenko
11:45	H1	SYOP 1.5	•Gyung-Min Choi
09:30	H1	SYOP 1	Session Frontiers of Orbital Physics: Statics, Dynamics, and Transport of Orbital Angular Momentum

SYSD

			Invited Talks
10:15	H2	SYSD 1.1	Charge localisation in halide perovskites from bulk to nano for efficient opto- electronic applications
10:45	H2	SYSD 1.2	•Sascha Feldmann Nonequilibrium Transport and Dynamics in Conventional and Topological Su- perconducting Junctions
11.1 -	110		•Raffael L. Klees
11:15	H2	SYSD 1.3	Probing magnetostatic and magnetotransport properties of the antiferromag- netic iron oxide hematite •Andrew Ross
11:45	H2	SYSD 1.4	Quantum dot optomechanics with surface acoustic waves •Matthias Weiss
			Session
10:15	H2	SYSD 1	SKM Dissertation Prize
			BP
			Prize Talk, Invited Talks
10:15	H13	BP 2.4	Integrative modeling of dynamic biomolecular structures Holger Gohlke
09:30	H15	BP 3.1	•Bolger Golike Basal tension in the wing disc epithelium - what's collagen got to do with it •Elisabeth Fischer-Friedrich (Laureate of the Hertha-Sponer-Prize 2022)
10:30	H16	BP 4.1	Computer simulations of self-motile active droplets and colloid-active gels composites
15:00	H15	BP 5.1	 Davide Davide Marenduzzo The functional nano-architecture of axonal actin
16.15	1116		•Christophe Leterrier
16:15	H16	BP 6.5	From active bacterial microcolonies to biofilms as model tissues •Vasily Zaburdaev
			Sessions
09:30	H13	BP 2	Computational Biophysics and Neuroscience
09:30	H15	BP 3	Cell Mechanics 1
10:30 15:00	H16 H15	BP 4 BP 5	Active Matter 1 Focus Session: Super Resolution Microscopy and Dynamics of Supramolecular Complexes
15:00	H16	BP 6	Statistical Physics of Biological Systems 1
18:00	P1	BP 7	Poster 1
			CPP
			Invited Talks
09:30	H38	CPP 1.1	Ternary blend approach for boosting performance and stability of organic solar cells
15:00	H38	CPP 8.1	 Tayebeh Ameri Stimuli-Responsive Opal Films based on Core-Shell Particle Self-Assembly Markus Gallei
15:45	H38	CPP 8.3	Self-assembled photonic pigments from bottlebrush block copolymers •Richard Parker
16:45	H38	CPP 8.5	Hierarchically structured mechanochromic deformation-sensing pigments •Jessica Clough
			Sessions
09:30	H38	CPP 1	Organic Electronics and Photovoltaics 1
09:30	H39	CPP 2	Polymer Networks and Elastomers
09:30 09:30	H34 H36	CPP 3 CPP 4	Perovskite and Photovoltaics 1 2D Materials 1
10:00	H19	CPP 5	Wetting, Droplets and Microfluidics

			CPP
10:30 10:45 15:00 15:00	H16 H39 H38 H39	CPP 6 CPP 7 CPP 8 CPP 9	Active Matter 1 Wetting, Fluidics and Liquids at Interfaces and Surfaces Focus Session: Photonic Structures from Polymer and Colloidal Self-Assembly Modeling and Simulation of Soft Matter
15:00	H36	CPP 10	2D Materials 2
17:15	H38	CPP 11	2D Materials 3
18:00	P1	CPP 12	Poster 1
			DS
			Invited Talks
09:30	H17	DS 2.1	GaN-based power converters enabling talktive power •Marco Liserre
10:00	H17	DS 2.2	Energy-efficient power electronics based on Gallium Nitride •Oliver Ambacher
10:45	H17	DS 2.4	Potential of Aluminum Nitride for Vertical Power Electronics •Andreas Waag
15:00	H17	DS 6.1	Novel high power device structures: Enabling compact and integrated power ICs •Elison Matioli
15:30	H17	DS 6.2	Ab-initio investigations of V-pits and nanopipes in GaN •Liverios Lymperakis
16:15	H17	DS 6.4	Lateral and Vertical β-Ga ₂ O ₃ Power Transistors for High-Voltage Applications •Kornelius Tetzner
09:30	H14	DS 1	Sessions Thin Film Properties: Structure, Morphology and Composition (XRD, TEM, XPS, SIMS, RBS, AFM,) 1
09:30	H17	DS 2	Focus Session: Innovative GaN-based High-power Devices: Growth, Characteri- zation, Simulation, Application 1
09:30 11:00	H36 H14	DS 3 DS 4	2D Materials 1 Thin Film Properties: Structure, Morphology and Composition (XRD, TEM, XPS,
11.00	1117		SIMS, RBS, AFM,) 2
11:30 15:00	H17 H17	DS 5 DS 6	Organic Thin Films, Organic-Inorganic Interfaces Focus Session: Innovative GaN-based High-power Devices: Growth, Characteri- zation, Simulation, Application 2
15:00 17:15	H36 H38	DS 7 DS 8	2D Materials 2 2D Materials 3
			DY
			Invited Talks
09:30	H18	DY 2.1	Roughness growth modes in thin film growth •Martin Oettel
15:00	H19	DY 9.1	Granular matter composed of non-convex grains •Ralf Stannarius
15:30	H20	DY 12.1	A phononic frequency comb from a single resonantly driven nanomechanical mode •Eva Weig
16:30	H20	DY 12.4	From period-doubling bifurcations to time crystals and coherent Ising machines •Oded Zilberberg
17:15	H20	DY 12.6	2D membranes in motion •Herre van der Zant
			Sessions
09:30	H18	DY 2	Invited Talk Martin Oettel
10:00	H18	DY 3	Statistical Physics far from Thermal Equilibrium
10:00	H19	DY 4	Wetting, Droplets and Microfluidics
10:00	H20	DY 5	Many-Body Quantum Dynamics 1

			DY
10:30	H16	DY 6	Active Matter 1
15:00	H16	DY 7	Statistical Physics of Biological Systems 1
15:00	H18	DY 8	Data Analytics for Complex Systems
15:00	H19	DY 9	Invited Talk Ralf Stannarius
15:00	H39	DY 10	Modeling and Simulation of Soft Matter
15:30 15:30	H19 H20	DY 11 DY 12	Granular Matter and Contact Dynamics Focus Session: Nonlinear Dynamics of Nanomechanic Oscillators
17:45	H18	DY 13	Big Data and Artificial Intelligence
			HL
			Invited Talks
09:30	H31	HL 2.1	Observation of quantum Zeno effects for localized spins
09.30	1151	112 2.1	•Alex Greilich
09:30	H32	HL 3.1	Pushing the limits in real-time meeasurements of quantum dynamics •Eric Kleinherbers
09:30	H36	HL 6.1	g-factors in van der Waals heterostructures: revealing signatures of interlayer
09.00	1100	112 0.1	coupling
15.00	1100	111 0 1	•Paulo E. Faria Junior
15:00	H32	HL 8.1	Crux of Using the Cascaded Emission of a Three-Level Quantum Ladder System to Generate Indistinguishable Photons
			•Eva Schöll
15:00	H33	HL 9.1	Exceptional points in optics: From bulk materials to one-dimensional confined
			systems
15.00	1100		•Chris Sturm
15:30	H33	HL 9.2	Complex Skin Modes in Non-Hermitian Coupled Laser Arrays •Mercedeh Khajavikhan
16:15	H33	HL 9.3	Non-Hermitian effects in exciton polaritons
			•Eliezer Estrecho
16:45	H33	HL 9.4	Nonlinear dynamics and exceptional points in exciton-polariton condensates
			•Stefan Schumacher
			Sessions
09:30	H31	HL 2	Spin Phenomena in Semiconductors
09:30	H32	HL 3	Quantum Dots and Wires 1: Transport and Electronic Properties
09:30	H33	HL 4	Semiconductor Lasers
09:30	H34	HL 5	Perovskite and Photovoltaics 1
09:30	H36	HL 6	2D Materials 1
15:00	H31	HL 7	(Quantum) Transport Properties
15:00	H32	HL 8	Quantum Dots and Wires 2: Optics 1
15:00	H33	HL 9	Focus Session: Exceptional Points and Non-Hermitian Physics in Semiconduc-
15:00	H34	HL 10	tor Systems Nitrides
15:00	H36	HL 11	2D Materials 2
			KFM
			Invited Talks
09:30	H5	KFM 2.1	Domain-wall engineering in multiferroic materials
11:15	H5	KFM 2.5	•Guillaume Nataf Charged Higher Order Topologies in Room Temperature Magnetoelectric Multi-
11.10	110	1011012.0	ferroic Thin Films
			•Shelly Conroy
15:00	H5	KFM 7.1	Multiferroic coupling on the level of domain walls
			•Mads C. Weber
			Sessions
09:30	H5	KFM 2	Focus Session: Defects and Interfaces in Multiferroics 1
09:30	H7	KFM 3	Microscopy and Tomography with X-ray, Photons, Electrons, Ions and Positrons

			K	M
09:30	H34 S053	H34 KFM 4 Perovskite and Photovoltaics 1	Perovskite and Photovoltaics 1	
10:30			New Methods and Developments: Scanning Probe Techniques 1	
11:05	H7	KFM 6	Instrumentation and Methods for Micro- and Nanoanalysis	
15:00	H5	KFM 7	Focus Session: Defects and Interfaces in Multiferroics 2	•
15:00	H7	KFM 8	Crystallography in Materials Science, Microstructure and Dielectric Propertie	S
15:00	S053		New Methods and Developments: Scanning Probe Techniques 2	
			Ν	ΛA
			Invited Talk	
15:00	H47	MA 10.1	Magnetic vortices: into the third dimension •Sebastian Gliga	
			Sessions	
09:30	H37	MA 2	Magnetic Imaging Techniques	
09:30	H43	MA 3	Spin-Dependent Phenomena in 2D	
09:30	H47	MA 4	Disordered Magnetic Materials	
09:30	H48	MA 5	Magnetic Instrumentation and Characterization	
11:00	H37	MA 6	Complex Magnetic Oxides	
11:00	H43	MA 7	Magnetic Relaxation and Gilbert Damping	
15:00	H37	MA 8	Ultrafast Magnetization Effects 1	
15:00	H43	MA 9	INNOMAG e.V. Prizes 2022 (Diplom-/Master and Ph.D. Thesis)	
15:00	H47	MA 10	Non-Skyrmionic Magnetic Textures	
15:00	H48	MA 11	Computational Magnetism 1	
			Ν	IM
			Invited Talk, Topical Talks	
09:30	H44	MM 1.1	A novel mechanism to generate metallic single crystals	
			•Carolin Körner	
15:00	H44	MM 5.1	Vacancy transport in oxides exposed to high electric fields	
			•Reiner Kirchheim	
17:15	H45	MM 9.1	Design of corrosion-free and highly active electrocatalysts and photocatalyst	s
			via combinations of ab initio calculations and electrodynamics	
			•Heechae Choi	
			Sessions	
09:30	H44	MM 1	Invited Talk Carolin Körner	
10:15	H44	MM 2	Computational Materials Modelling: Energy Materials	
10:15	H45	MM 3	Microstructures and Phase Transformations: Metals & Alloys	
10:15	H46	MM 4	Structural Materials	
15:00	H44	MM 5	Non-equilibrium Phenomena in Materials Induced by Electrical and Magnetic	
10.00	11-7-7		Fields 1	
15:45	H44	MM 6	Computational Materials Modelling: Defects / Alloys	
15:45	H45	MM 7	Microstructures and Phase Transformations: Oxides & Perovskites	
15:45	H46	MM 8	Materials for Storage and Conversion of Energy	
17:15	H45	MM 9	Non-equilibrium Phenomena in Materials Induced by Electrical and Magnetic	
			Fields 2	
18:00	P2	MM 10	Poster Session 1	
				0
			Invited Talk, Topical Talks	
09:30	S054	0 1.1	Laser-excited electrons: how hot are they?	
			•Baerbel Rethfeld	
10:30	H4	0 3.1	Rational design of single atom electrocatalysts: handle with care	
		-	•Gianfranco Pacchioni	
10:30	S051	0 5.1	Molecular nanostructures on metals vs. graphene	

•Meike Stöhr

			0
10:30	S053	0 7.1	Identification of active electrocatalytic centers using EC- STM under reaction conditions
10:30	S054	0 8.1	•Aliaksandr Bandarenka Dynamic structure changes of bare and modified Cu(111) during CO and water activation
15:00	H4	0 10.1	•Andrea Auer Atomically-precise design of low-nuclearity catalysts •Sharon Mitchell
16:00	H4	0 10.4	Design of Model Single-Atom Catalysts: Metal Adatoms, Monomeric Oxide Units, and Mixed Surface Layers on Oxide Surfaces •Zdenek Dohnalek
17:00	H4	0 10.7	•Zdenek Domalek Model catalysis of single atoms on ultrathin solid films •Kai Wu
15:00	S054	0 15.1	Hydration Layer Mapping at Solid-Liquid Interfaces •Angelika Kühnle
09:30 10:30 10:30 10:30 10:30 10:30 10:30 10:30 15:00	S054 H3 H4 H6 S051 S052 S053 S054 H3 H4 H6 S051 S052 S053 S054 P4 P4 P4 P4 P4 P4 P4 P4 P4 P4 P4 P4 P4	$\begin{array}{c} 0 \ 1 \\ 0 \ 2 \\ 0 \ 3 \\ 0 \ 4 \\ 0 \ 5 \\ 0 \ 6 \\ 0 \ 7 \\ 0 \ 8 \\ 0 \ 9 \\ 0 \ 10 \\ 0 \ 11 \\ 0 \ 12 \\ 0 \ 13 \\ 0 \ 14 \\ 0 \ 15 \\ 0 \ 16 \\ 0 \ 17 \\ 0 \ 18 \\ 0 \ 19 \\ 0 \ 20 \\ 0 \ 21 \\ 0 \ 22 \\ 0 \ 23 \end{array}$	Sessions Overview Talk Bärbel Rethfeld Ultrafast Electron Dynamics at Surfaces and Interfaces 1 Focus Session: Single Atom Catalysis 1 Topology and Symmetry-Protected Materials Organic Molecules at Surfaces 1: Substrate Effects Nanostructures at Surfaces 1 New Methods and Developments 1: Scanning Probe Techniques 1 Solid-Liquid Interfaces 1: Reactions and Electrochemistry Ultrafast Electron Dynamics at Surfaces and Interfaces 2 Focus Session: Single Atom Catalysis 2 Electronic Structure Theory Organic Molecules at Surfaces 2: Characterization of Organic Monolayers Nanostructures at Surfaces 2 New Methods and Developments 2: Scanning Probe Techniques 2 Solid-Liquid Interfaces 2: Structure and Spectroscopy Poster Monday: Ultrafast Processes 1 Poster Monday: Organic Molecules at Surfaces 1 Poster Monday: 2D Materials 1 Poster Monday: Scanning Probe Techniques 1 Poster Monday: Solid-Liquid Interfaces Poster Monday: Solid-Liquid Interfaces Poster Monday: Solid-Liquid Interfaces Poster Monday: Sufface Structure, Epitaxy, Growth and Tribology Poster Monday: Nanostructures 1
			SOE
09:30	H11	SOE 2.1	Invited Talk Two-armed bandits versus Carnapian truth seekers and epistemic free riders with bounded confidence •Rainer Hegselmann
09:30 10:15 12:00 12:30 15:00 17:45	H11 H11 H11 H11 H18 H18	SOE 2 SOE 3 SOE 4 SOE 5 SOE 6 SOE 7	Sessions Invited Talk Rainer Hegselmann: Opinion Formation Economic Models Financial Risk Social Systems, Opinion and Group Dynamics Data Analytics for Complex Systems Big Data and Artificial Intelligence

TT

09:30	H10	H10 TT 1.1 Stability of Floquet Majorana box qubits •Anne Matthies	Stability of Floquet Majorana box qubits	
15:00	H10	TT 5.1	Dynamics of visons and thermal Hall effect in perturbed Kitaev models •Aprem Joy	
			Sessions	
09:30	H10	TT 1	Topology: Majorana Physics	
09:30	H22	TT 2	Nanotubes, Nanoribbons and Graphene	
09:30 10:00	H23 H20	TT 3 TT 4	Superconductivity: Properties and Electronic Structure Many-Body Quantum Dynamics 1	
15:00	H20 H10	TT 5	Frustrated Magnets – Spin Liquids	
15:00	H22	TT 6	Kondo Physics, f-Electron Systems and Heavy Fermions	
15:00	H23	TT 7	Fluctuations, Noise, Magnetotransport, and Related Topics	
17:15	H10	TT 8	Frustrated Magnets – Strong Spin-Orbit Coupling	
18:00	H23	TT 9	Cold Atomic Gases and Superfluids	
			V	4
			Sessions	
09:30	H12	VA 1	Rarefied gas dynamics and novel numerical approaches	
12:30	H12	VA 2	Vacuum technology: New developments and applications	
			Q	<u> </u>
			Invited Talks	
09:30	H8	QI 1.1	Coherence of spin qubits in planar germanium •Nico Willem Hendrickx	
09:30	H9	QI 2.1	Measuring the thermodynamic cost of timekeeping	
09.00	112	Q1 2.1	•Yelena Guryanova	
11:15	H9	QI 2.6	Finite-size effects in quantum thermodynamics	
			•Kamil Korzekwa	
15:00	H8	QI 3.1	Generalized randomized benchmarking with short random quantum circuits Martin Kliesch 	
			Sessions	
09:30	H8	QI 1	Implementations: Spin Qubits, Atoms, and Photons	
09:30	H9	QI 2	Quantum Thermodynamics and Open Quantum Systems	
15:00	H8	QI 3	Certification and Benchmarking of Quantum Systems	
18:00	P2	QI 4	Poster: Quantum Information	

			Plenary Talk
08:30	H1	PLV IV	Insights from Atomic-Scale Studies on Surfaces •Ulrike Diebold
			Prize Talk
13:15	H1	PRV II	Water flows in carbon nanochannels: from quantum friction to carbon memo-
			ries •Lydéric Bocquet (Laureate of the Gentner Kastler Prize 2022)
			Lunch Talk, Ceremonial Talk
13:15	H2	PSV II	Wissenschaftkommunikation – für wen eigentlich?
16:30	H1	PSV III	•Nicolas Wöhrl Quantum Dots for Green Quantum Technologies
10.00			•Dieter Bimberg
			SYPQ
			Invited Talks
09:30	H1	SYPQ 1.1	Designing driving protocols for high-fidelity quantum devices using numerically
			exact predictions •Moritz Cygorek
10:00	H1	SYPQ 1.2	Challenges towards high efficiency quantum dot single photon sources
10:30	H1	SYPQ 1.3	•Arne Ludwig Organic Molecules in photonic quantum technologies
			•Costanza Toninelli
11:15	H1	SYPQ 1.4	Quantum-dot single-photon sources for quantum photonic networks •Peter Michler
11:45	H1	SYPQ 1.5	Quantum light sources: entanglement generation in semiconductor nanostruc-
			tures •Ana Predojevic
			Session
09:30	H1	SYPQ 1	High Yield Devices for Photonic Quantum Implementations
			BP
~~~~			Prize Talk, Invited Talk
09:30	H15	BP 8.1	Phase separation in cells: gene localization and noise buffering •Samuel Safran
12:30	H16	BP 9.11	Super-resolution STED and MINFLUX Nanoscopes by Abberior Instruments
			•Gerald Donnert (Laureate of the DPG-Technologietransferpreis 2022)
09:30	H15	BP 8	<b>Sessions</b> Focus Session: Phase Separation in Biochemical Systems
09:30	H16	BP 9	Bioimaging
10:00	H13	BP 10	Cell Adhesion and Multicellular Systems
10:00	H18	BP 11	Active Matter 2
17:30	P4	BP 12	Poster 2
			CPP
			Invited Talks
09:30	H38	CPP 13.1	Insights into degradation mechanisms in Li-based batteries and advantages of
			polymer coatings
11:30	H38	CPP 18.1	•Neelima Paul How X-rays can reveal waters mysteries
11.30	пэо	UFF 10.1	•Katrin Amann-Winkel

## CPP

			Sessions
09:30	H38	CPP 13	Charged Soft Matter, Polyelectrolytes and Ionic Liquid
09:30	H39	CPP 14	Emerging Topics in Chemical and Polymer Physics, New Instruments and Meth-
00.20	1106		ods 2D Materiala 4
09:30 10:00	H36 H18	CPP 15 CPP 16	2D Materials 4 Active Matter 2
11:00	P2	CPP 17	Poster 2
11:30	H38	CPP 18	Complex Fluids and Colloids, Micelles and Vesicles
			DS
			Prize Talks
09:40	H17	DS 10.1	Atomic-Scale Optical Spectroscopy at Surfaces
			•Takashi Kumagai (Laureate of the Gaede-Prize 2020)
10:20	H17	DS 10.2	Slow highly charged ions as a tool for monolayer sensitive nano-engineering
11:00	H17	DS 10.3	<ul> <li>Richard Wilhelm (Laureate of the Gaede-Prize 2021)</li> <li>Quantum Science with Single Atoms and Molecules on Surfaces</li> </ul>
11.00	1117	03 10.5	•Philip Willke (Laureate of the Gaede-Prize 2022)
			Sessions
09:30	H14	DS 9	Thin Film Properties: Structure, Morphology and Composition (XRD, TEM, XPS,
09.30	П1 <del>4</del>	D3 9	SIMS, RBS, AFM,) 3
09:30	H17	DS 10	Gaede Prize Talks
09:30	H34	DS 11	Focus Session: Quantum Properties at Functional Oxide Interfaces 1
09:30	H36	DS 12	2D Materials 4
			DY
			Df
			Invited Talks
09:30	H18	DY 14.1	Non-Markovian Brownian systems: from single-particle thermodynamics to
			collective behavior •Sabine Klapp
10:30	H19	DY 17.1	Caustics in turbulent aerosols
10.00		DIT	•Bernhard Mehlig
			Sessions
09:30	H18	DY 14	Invited Talk Sabine Klapp
09:30	H19	DY 15	Delay and Feedback Dynamics
10:00	H18	DY 16	Active Matter 2
10:30	H19	DY 17	Invited Talk Bernhard Mehlig
11:15	H19	DY 18	Nonlinear Dynamics 1: Synchronization and Chaos
11:30 11:30	H20 H38	DY 19 DY 20	Many-Body Quantum Dynamics 2 Complex Fluids and Colloids, Micelles and Vesicles
11.50	1150	0120	complex huids and conolds, inicelies and vesicles
			HL
			Invited Talks
09:30	H32	HL 12.1	Wafer-Scale Epitaxial Modulation of Quantum Dot Densitiy
			•Nikolai Bart
09:30	H34	HL 14.1	Materials and Device Engineering for Gallium Oxide-based Electronics
10.00	1104		•Siddharth Rajan
10:00	H34	HL 14.2	Ferroelectric two-dimensional electron gases for oxide spin-orbitronics •Julien Bréhin
12:15	H34	HL 14.8	Strain-driven dissociation of water on (incipient) ferroelectrics
			•Chiara Gattinoni
09:30	H36	HL 15.1	Ultrafast all-optical modulation and frequency conversion in 2D materials
			•Sebastian Klimmer

HL

			Sessions
09:30	H32	HL 12	Quantum Dots and Wires 3: Growth
09:30	H33	HL 13	Ultra-Fast Phenomena
09:30 09:30	H34 H36	HL 14	Focus Session: Quantum Properties at Functional Oxide Interfaces 2D Materials 3
09.30	H30	HL 15	2D Materials 5
			KFM
			Prize Talk, Invited Talks, Topical Talk
09:30	H5	KFM 10.1	Einfluss des Sauerstoffgehalts auf das Koerzitivfeld für die Polarisationsum-
01.00			schaltung in HfO, aus der Dichtefunktionaltheorie
			<ul> <li>Luis Azevedo Antunes (Laureate of the Georg-Simon-Ohm-Prize 2022)</li> </ul>
10:00	H5	KFM 10.2	Negative capacitance and voltage amplification in ferroelectric heterostructures
10:30	H5	KFM 10.3	<ul> <li>Jorge Iniguez</li> <li>Advanced Phase-field Simulation of Ferroelectrics and Antiferroelectrics</li> </ul>
10.50	115	KI WI 10.5	•Bai-Xiang Xu
11:15	H5	KFM 10.4	Magnetization processes in SmFeO ₃
			•Thomas Schrefl
			Sessions
09:30	H5	KFM 10	Focus session: Polar Materials Meet Energy demands
09:30	H7	KFM 11	Crystal Structure Defects / Real Structure / Microstructure
09:30	H37	KFM 12	Skyrmions 1 Materials for Storege and Conversion of Energy
10:15	H46	KFM 13	Materials for Storage and Conversion of Energy
			MA
			Invited Talks
09:30	H37	MA 12.1	Topological spin structures at surfaces
00.20	1147		•Stefan Heinze
09:30	H47	MA 14.1	Overriding universality of ferromagnetic phase transitions through nano-scale materials design
			•Andreas Berger
15:00	H43	MA 17.1	Ultimately fast, small and energy-efficient magnetism: fundamentals and pros-
			pects
15.00	1140	MA 17.0	•Johan Mentink
15:30	H43	MA 17.2	From spintronics at limiting temporal and spatial scales in antiferromagnets to an emerging altermagnetic phase
			•Tomas Jungwirth
16:00	H43	MA 17.3	An electronic structure viewpoint on candidate van der Waals ferromagnets
			•Phil King
16:30	H43	MA 17.4	Nano-scale skyrmions and atomic-scale spin textures studied with STM
			•Kirsten von Bergmann
00.00	1107	NAA 10	Sessions

PLV I Mon 8:30 H1

 $Intrinsic \, Josephson \, junctions \, in \, Bi_2 Sr_2 CaCu_2 O_8 : \, Generation \, of \, Terahertz \, radius and the second state of the second state$ diation and beyond — •REINHOLD KLEINER — Physikalisches Institut, Center for Quantum Science (CQ) and LISA⁺, Universität Tübingen

The layered superconductor Bi2Sr2CaCu2O8(BSCCO) is known to intrinsically form a stack of Josephson tunnel junctions (IJJs). Each junction is formed by adjacent superconducting CuO₂ layers and the insulating BiO and SrO layers in between. Due to the fact that the BiO layers are coupled by van der Waals forces, stacks of consisting of only a few IJJs up to several thousands of IJJs can be created by using exfoliation methods combined with lithography. After an initial phase of investigations on small-sized stacks, in recent years the focus was on the generation of terahertz (THz) radiation, making use of stacks consisting of a large number of IJJs. The stacks mainly radiate in the frequency range between 0.5 THz and 2 THz, which inside the so-called THz gap. Beyond THz generation BSCCO received attention in the context of 2D materials and it was also shown recently that IJJ stacks can host electromagnetic modes acting as a discrete classical space-time crystal, developing periodic order both in space and time. In the talk, after some introduction, I will present the recent status on the field of THz generation. I will then turn to the possible realization of a discrete space-time crystal based on BSCCO IJJ stacks.

#### Plenary Talk

PLV II Mon 14:00 H1 Topology and Chirality — • CLAUDIA FELSER — Max Planck Institute for Chemical Physics of Solids, Dresden, Germany - Laureate of the Max-Born-Prize 2022

Topology, a well-established concept in mathematics, has nowadays become essential to describe condensed matter. At its core are chiral electron states on the bulk, surfaces and edges of the condensed matter systems, in which spin and momentum of the electrons are locked parallel or anti-parallel to each other. Magnetic and non-magnetic Weyl semimetals, for example, exhibit chiral bulk states that have enabled the realization of predictions from high energy and astrophysics involving the chiral quantum number, such as the chiral anomaly, the mixed axial-gravitational anomaly and axions. The potential for connecting chirality as a quantum number to other chiral phenomena across different areas of science, including the asymmetry of matter and antimatter and the homochirality of life, brings topological materials to the fore.

#### PLV III Mon 14:00 H2 Plenary Talk Controlling and exploiting defects in diamond for Quantum Technologies -

•Mark Newton, Ben Green, Chloe Newsom, Imogen Gullick, and Gloria ZHAO — Department of Physics, University of Warwick, Coventry UK

Point defects in diamond have great potential for use in a range of quantum technologies. For example as single photon sources and quantum bits that can be exploited in quantum information processing and as the heart of sensors that will transform the way we do analytical science and medical imaging. The negatively charged nitrogen-vacancy centre is an amazing defect in diamond that possesses properties highly suited to many of these applications. However, it does have some challenging weaknesses and full exploitation of the optical and spin properties of this and other defects necessitates that we control their position, orientation and environment to optimise all of the desirable properties simultaneously, especially near the surface of the diamond. I will review our understanding of the production of intrinsic defects and present new data on the creation of defect complexes by doping, electron irradiation, short pulse laser irradiation, ion implantation and annealing. The success and failure of different combinations of processing steps to control and optimise the local defect environment will be discussed and the ongoing search for alternate colour centres with comparable spin properties and superior optical properties will be reviewed.

#### Plenary Talk

PLV IV Tue 8:30 H1

Insights from Atomic-Scale Studies on Surfaces — • ULRIKE DIEBOLD — Institute of Applied Physics, TU Wien, Vienna, Austria

The arrangement of the top layer of atoms on a solid and the resulting electronic and chemical properties affect and sometimes even dominate its functionality. In the talk, I will showcase how we can use basic physical phenomena - tunneling, diffraction, and change in resonance frequencies - to measure surface properties in an atom-by-atom fashion. Such experiments can be interlinked tightly with theoretical computations by investigating well-defined samples in a controlled environment. Examples include assessing the acidity of individual surface atoms, pushing the size of catalytically-active nanoclusters to their physical limit, and extending ultrahigh-vacuum experiments to the liquid phase.

PLV V Wed 8:30 H1 Towards useful quantum computing with superconducting qubits -•RAMI BARENDS - Institute for Functional Quantum Systems (PGI-13), Forschungszentrum Jülich

One of the outstanding scientific challenges of this decade is the construction of an architecture and development of a methodology that can enable useful quantum computing. Superconducting quantum circuits have demonstrated unparalleled performance, by outperforming the world's most powerful supercomputers on a specific sampling task. Yet, applying quantum computing to real-world problems has remained elusive. The performance of current systems is limited, and the development of algorithms that make efficient use of present-day hardware is only starting. I will discuss the challenges in going from the current exploratory phase towards one where addressing real-world problems could be accomplished.

PLV VI Wed 14:00 H1 **Plenary Talk** Disordered Solids — • ANNETTE ZIPPELIUS — Institut für Theoretische Physik, Universität Göttingen, 37077, Germany - Laureate of the Max-Planck-Medal 2022

We discuss a phase of matter which is characterized by 1) random localization of the atoms or molecules and 2) a finite restoring force for static shear deformations. The following questions will be addressed: What is an appropriate order parameter for the amorphous solid state? How can we characterize its random structure? How do long range elastic correlations develop at the glass transition? These questions will be discussed by means of a statistical mechanical theory of disordered system as well as generalized hydrodynamics.

**Plenary Talk** PLV VII Wed 14:00 H2 Topological insulator lasers — • MORDECHAI SEGEV — Technion - Israel Institute of Technology

Topological Insulator Lasers are arrays of semiconductor lasers arranged on a photonic chip in a way that endows them with topological features. We utilize the topological features of robustness and nonzero group velocity, both associated with the topological edge states, to force injection locking of tens of semiconductor lasers, eventually giving rise to many lasers working together as a single high order radiation source. The concepts of topological insulator lasers will be reviewed, while current challenges and recent progress will be described.

#### PLV VIII Thu 8:30 H1 **Plenary Talk** Physics of Structure Formation in Living Systems — • STEPHAN GRILL — MPI-CBG. Dresden

One of the most remarkable examples of self-organized structure formation is the development of a complex organism from a single fertilized egg. With the identification of many molecules that participate in this process of morphogenesis, attention has now turned to capturing the physical principles that govern the emergence of biological form. What are the physical laws that govern the dynamics and the formation of structure in living matter? Much of the force generation that drives morphogenesis stems from the actomyosin cortical layer inside cells, which endows the surface of the cell with the ability to generate active forces and stresses that can drive reshaping. We combine theory and experiment and investigate how the actomyosin cell cortex self contracts, reshapes and deforms, and how these physical activities couple to regulatory biochemical pathways to give rise to the emergence of shape in living systems.

PLV IX Thu 14:00 H1

Evolutionary transitions: universality, complexity and predictability -•RICARD SOLE — Universitat Pompeu Fabra, Barcelona, Spain — Santa Fe Institute, Santa Fe, USA

The evolution of life in our biosphere has been marked by several major innovations. Such major complexity shifts include the origin of cells, genetic codes or multicellularity to the emergence of language, cognition or even consciousness. Understanding the nature and conditions for evolutionary innovation is a major challenge for evolutionary biology. Along with data analysis, phylogenetic studies and dedicated experimental work, theoretical and computational studies are an essential part of this exploration. With the rise of synthetic biology, evolutionary robotics, artificial life and advanced simulations, novel perspectives to these problems have led to an emerging new synthesis, where evolutionary innovations can be understood in terms of phase transitions, as defined in physics. Such mapping (if correct) would help in defining a general framework to establish a theory of evolutionary change and the role played by chance and constraints in shaping living complexity.

#### PLV X Thu 14:00 H2

Semiconductor quantum optics: from artificial atoms to atomically thin materials — •JONATHAN FINLEY — Walter Schottky Institut, Am Coulombwall 4, 85748 Garching, Germany

Optically active confined spins in solids such as III-V semiconductor quantum dots (QDs), colour centres in diamond and atomic-scale defects in 2D-semiconductors are of interest for a wide range of applications in quantum science and technology. For example, in the context of photon-based quantum communication and computation electron and hole spins localized in single QDs can be used for the high rate (~ GHz) on-demand generation of single photons with excellent Hong-Ou-Mandel (HOM) quantum indistinguishability, as well as entangled multi-photon cluster states. We will explore the factors currently limiting the performance of QD based non-classical light sources and discuss how methods derived from the quantum optical toolbox, such as incoherent spin pumping and coherent quantum state preparation can be used to both suppress unwanted re-excitation processes, that lead to multi-photon errors, while precisely timed stimulation pulses reduce the timing jitter of emit-

ted photons, leading to much improved HOM indistinguishability. For few-spin systems hosted by electrically tunable QD-molecules, we will show how selective optical-charge generation can be used to suppress coupling of S-T spin states to electric and magnetic field fluctuations. Finally, we will explore how spin states in 2D-semiconductors are highly sensitive to lattice and macroscopic vibrational modes, providing interesting perspectives in quantum sensing and metrology.

#### **Plenary Talk**

## Spinwaves as experimental probes — •CHRISTIAN BACK — Physik-Department, TU München, Garching, Germany

PLV XI Fri 8:30 H1

Spin waves - the dynamic eigenmodes of magnetically ordered systems - are suitable as potential information carriers in future nanoscale microwave devices with frequencies ranging from a few GHz to several THz. It has been shown that their frequency, amplitude and phase can be relatively easily controlled. In this talk, I will revisit some of the fundamental properties of spin waves in thin magnetic films, show how we can image them with high resolution, and give examples of how they can also be used to detect fundamental properties such as spin-orbit fields.

## PRV I Mon 13:15 H1

**Ultrafast topological switching of magnetic skyrmions** — •FELIX BÜTTNER — Helmholtz-Zentrum Berlin, Berlin, Germany — Laureate of the Walter-Schottky-Prize 2022

Magnetic skyrmions are non-collinear arrangements of spins, characterized by a defining non-trivial topology and a quasi-particle character. Skyrmions can be of nanometer-scale size, even at room temperature and - upon suitable stimulation - they can move coherently within their hosting material. Both, the stability and the emergent quasi-particle dynamics of skyrmions, can be linked to their topology, and these exotic properties have widely inspired research in fundamental and applied physics alike. In this talk, I will first give an overview of the field of skyrmionics before discussing one particularly fascinating aspect in greater depth: the possibility to switch, i.e., nucleate or annihilate, magnetic skyrmions despite their topological protection. I will show that the topological nucleation energy barrier of skyrmions, which can be understood from a simple product of magnetic exchange energy and film thickness, can surprisingly be lifted by heating the system into a newly discovered fluctuation state. This allows the simultaneous nucleation of an extended array of skyrmions, even on a picosecond time scale, as we could evidence by direct experimental observation. I will discuss this mechanism in the context of topological phase transitions and conclude with a perspective on technological applications.

 Water flows in carbon nanochannels: from quantum friction to carbon memories — •LYDÉRIC BOCQUET — Laboratoire de Physique, Ecole Normale Supérieure and CNRS, Paris — Laureate of the Gentner-Kastler-Prize 2022

In this talk, I will discuss various experimental and theoretical results that we obtained recently on the transport of water and ions in ultra-confinement. I will in particular focus on the odd properties of the water-carbon couple, which highlights a variety of strange transport properties. I will first discuss the ultra-fast, and radius dependent, flows of water in carbon nano-structures [1]. We demonstrate that this phenomenon is a consequence of an unconventional quantum friction at the water-carbon interface, taking its root in the coupling between water collective modes with electronic excitations [2]. I will then explore far from equilibrium transport of ions across quasi two-dimensional slits. We predict that under an electric field, ions assemble into elongated clusters - as a consequence of a 2D Wien effect -, whose slow dynamics results in the emergence of long-term memory [3]. This phenomenon, known as the memristor effect, can be harnessed to build an elementary neuron. Experimental demonstrations of this effect in the 2D nanochannels allow for the development of elementary ion-based computing, with basic forms of Hebbian learning [4].

PRV III Wed 13:15 H1

Learning the stochastic dynamics of living systems across scales: from single cells to tissues — •DAVID BRÜCKNER — Institute of Science and Technology, Am Campus 1, 3400 Klosterneuburg, Austria — Laureate of the Gustav-Hertz-Prize 2022

Many biological phenomena, including embryo development, immune response, and cancer, rely on the coordinated movement of cells in complex environments. In all these processes, cells face a dual physical challenge: they navigate confining extra-cellular environments, in which they squeeze through thin constrictions; and they communicate with close-by cells to organize their collective behaviour. The motion of cells is powered by a complex machinery whose molecular basis is increasingly well understood. However, a quantitative understanding of the functional cell behaviours that emerge at the cellular scale remains elusive. This raises a central question: are there simple dynamical 'laws' that describe the dynamics of confined cell migration and cell-cell interactions? In this talk, I will discuss how we can use stochastic inference methods to learn the dynamics of migrating cells directly from observed experimental trajectories. I will show how these approaches give insight into the non-linear dynamics governing confined single cell migration, the pair-wise collisions of cancerous and healthy cell types, as well as collective cell migration at the tissue level.

Lunch Talk PSV I Mon 13:15 H2 Berufsbild: Wissenschaftsmanagement in der deutschen Raumfahrtagentur — • ТОВІАЅ SALTZMANN — Deutsches Zentrum für Luft- und Raumfahrt (DLR), Bonn

It's no rocket science - Forschungsförderung im Spannungsfeld zwischen Industrie, Wissenschaft und Politik.

Lunch Talk PSV II Tue 13:15 H2 Wissenschaftkommunikation - für wen eigentlich? — •NICOLAS WÖHRL, PE-TER KOHL und AXEL LORKE — Fakultät für Physik und SFB 1242, Universität Duisburg-Essen, 47048 Duisburg

Auch Physiker:innen sind gefragt, wenn es um Wissenschaftskommunikation geht, z.B. bei Themen wie Quantenkryptographie, alten und neuen Energietechniken oder dem Klimawandel. Wie notwendig (und manchmal schwierig) gelungene Kommunikation ist, wurde uns während der Corona-Krise eindrücklich vor Augen geführt. Forschende übernahmen eine wichtige Rolle als Mittler zwischen Fachliteratur und populärer Darstellung. So wurde Fehlinformationen und Verschwörungs"theorien" überzeugend entgegengetreten. Und zwar erfolgreich: Das "Wissenschaftsbarometer 2021" zeigt, dass während der Pandemie das Vertrauen in die Wissenschaft stieg. Systeme und Probleme werden komplexer, und wir brauchen eine informierte Öffentlichkeit, um wissenschaftsbasierte Entscheidungen zu treffen und umzusetzen. Dabei geht es nicht nur um Forschungsergebnisse, sondern auch darum, Prozesse und Methoden von wissenschaftlicher Arbeit transparent abzubilden - eine Aufgabe, die prinzipiell alle Forschenden übernehmen können. Im Vortrag diskutieren wir u. a.: Wie kann Öffentlichkeitsarbeit neben allen anderen Aufgaben in Forschung und Lehre gelingen? Welchen Stellenwert hat sie in der Ausbildung? Warum brauchen wir neben Pressestellen und Journalismus auch kommunikative Wissenschaftler:innen? Wie sollte Unterstützung für Forschende in Zukunft aussehen? Und welchen Nutzen hat die Kommunikation mit der Öffentlichkeit für die Wissenschaftler:innen selbst?

PSV III H1

Quantum Dots for Green Quantum Technologies — •DIETER BIMBERG TU Berlin and CIOMP of CAS Changchun - Laureate of the Stern-Gerlach-Medal 2020

Universal self-organization at surfaces of semiconductors leads to the formation of self-similar quantum dots (QDs). Their electronic and optical properties are close to those of atoms in a dielectric cage. All their energy levels are however only twofold degenerate [1]. The few particle states like excitons are strongly Coulomb-correlated due to the carrier localisation. Their energies depend on shape and size of the dots, such that positive, zero or negative biexciton binding energies and fine-structure splitting appear [2].

Applications of single, few and millions of QDs for novel Quantum Technologies will be elucidated.

a. Single QDs can be emitters of Q-bits on demand or entangled photons for future quantum cryptography systems. In electrically pumped RCLED structures, emission of q-bits at rates beyond 1 Gbit/s were shown [3, 4].

b. Hybridization of Flash and DRAMs, bringing together the advantages of both types of memories, is the "Holy Grail" of memories and ensures future memory development after the end of Moore's law. The goal of non-volatility (i.e. storage time > 10 years) can be achieved for the storage of holes in type I I (InGa)Sb QDs embedded in a (AlGa)P matrix [5].

c. The demand for higher data rates in optical networks, requires novel ultrahigh bit rate, energy efficient sources. QD Lasers based on GaAs emit up to the

#### **Evening Talk**

München Deutschland

PSV IV Tue 19:00 H1+H2 Grundlagenforschung für Nachhaltigkeit — •HARALD LESCH — LMU Physik,

Grundlagen der Physik sind meist weit weg von den direkten Anwendungen. Aber bei dem Thema Nachhaltigkeit haben wir keine Zeit mehr. Hier gilt es schnell und mutig darüber zu sprechen und auch zu handeln. Klimawandel und Energiewende sind beides Themen, deren Lösung unter Zeitdruck entwickelt werden muss. So zeigt sich die Thermodynamik als Mutter aller Theorien als wichtige Begrenzung unserer Möglichkeiten auch bei den erneuerbaren Energien. Die Forschung an komplexen Systemen liefert uns wichtige Hinweise über deren resiliente Eigenschaften. Und währenddessen müssen wir ständig versuchen im Land der physikalischen Optionen neue Möglichkeiten zu entdecken.

Mit anderen Worten, es geht um Physik unter Druck, unter Zeitdruck.

#### Lunch Talk

PSV V Wed 13:15 H2

The German Research Foundation - Funding Opportunities for International Collaborations — • MICHAEL MÖSSLE, MARIO BOMERS, and JOANNA KOWALSKA — Deutsche Forschungsgemeinschaft, Bonn

The German Research Foundation (DFG) is the central funding organization for basic research in Germany. As a self-governing organization for science and research it offers a broad spectrum of funding opportunities from individual grants to larger coordinated programs. The talk will be focused on the DFG funding opportunities for international collaborations. In particular, we will cover the possibilities to include international partners in regular DFG funding schemes, O-band at 1.3  $\mu$ m, showing record low jth and complete temperature stability up to 80°C. Passive mode-locking generates pulses in the sub-ps range at repetition rates up to 90 GHz. The hat spectrum of one single laser of several tens of closely spaced narrow lines is thus a potential pulse source for bit rates up to  $\approx$  6 TBit/s using higher order modulation formats like DQPSK [6]

### **Tutorials**

### TUT 1: Careers in Science (joint session MA/TUT)

Time: Sunday 16:00-17:30

#### Tutorial

TUT 1.1 Sun 16:00 H1 Careers in science: "To boldly go where no one has gone before" - • MANFRED FIEBIG — Department of Materials, ETH Zurich

What does it take to do a career in science and become a university professor? An obvious answer is: you have to do outstanding research. But just doing great science plays a surprisingly small part — and what defines scientific work as outstanding anyway? Then, you also need to communicate your findings well. The best result is worth little if you present it in an awful talk or manuscript. You also need to be "good with people", may these be your students or your colleagues. Even luck can play an important role in a successful scientific career, but is very important to distinguish luck from "luck". I will refer to all these points and analyze what "being lucky" has actually to do with luck. I will present a list of points that I consider essential for a prosperous start into a scientific career. Some of these points are surprisingly unnoticed, so following them may put you ahead of the crowd.

Questions and discussion

### TUT 2: 2D Quantum Materials and Heterostructures: From Fabrication to Applications (joint session HL/TUT)

Due to the atomic thickness of 2D materials, stacking of different monolayers has opened the door for artificial van der Waals heterostructures. By exploiting the strongly different nature of the individual layers (semiconducting, metallic, magnetic, superconducting, etc.) and rotating them from layer to layer, heterostructures with unique physical properties and functionalities can be envisioned for novel electronic or optical devices. The tutorial will cover the fabrication of these heterostructures and their potential use in applications ranging from electronic to optical devices, operating at the quantum level.

Time: Sunday 16:00-18:20

#### Tutorial

TUT 2.1 Sun 16:00 H2 Discovering, Creating, and Exploring Novel Atomically-Thin Materials and Heterostructures — • JOSHUA ROBINSON — The Pennsylvania State University, University Park, PA, USA

The last decade has seen an exponential growth in the science and technology of two-dimensional materials. Beyond graphene, there is a huge variety of layered materials that range in properties from insulating to superconducting. Furthermore, heterogeneous stacking of 2D materials also allows for additional dimensionality for band structure engineering. In this talk, I will discuss recent breakthroughs in two-dimensional atomic layer synthesis and properties, including novel 2D heterostructures and realization of unique 2D allotropes of 3D materials (e.g. 2D metals and oxides). Our recent works demonstrate that the properties and doping of 2D materials, especially synthetic 2D materials, are extremely sensitive to the substrate choice. I will discuss substrate impact on 2D layer growth and properties, doping of 2D materials, selective area synthesis of 2D materials, and creating 2D allotropes from traditionally 3D materials for photonic and quantum applications. Our work and the work of our collaborators has lead to a better understanding of how substrate not only impacts 2D crystal quality, but also doping efficiency in 2D materials, and stabilization of 3D materials at their quantum limit.

#### Tutorial

TUT 2.2 Sun 16:35 H2

Non-identical moire twins in bilayer graphene — •REBECA RIBEIRO-Palau¹, Everton Arrighi¹, Viet-Hung Nguyen², Mario Di Luca¹, Gaia MAFFIONE¹, KENJI WATANABE³, TAKASHI TANIGUCHI³, DOMINIQUE MAILLY¹, and JEAN-CHRISTOPHE  $CHARLIER^2 - {}^1$ Universite Paris-Saclay, CNRS, Centre de Nanosciences et de Nanotechnologies (C2N), 91120 Palaiseau, France -²Institute of Condensed Matter and Nanosciences, Universite catholique de Louvain (UCLouvain), 1348 Louvain-la-Neuve, Belgium —  3 National Institute for Materials Science, 1-1 Namiki, Tsukuba, Japan

I will present recent results which demonstrate that the moire superlattice formed by a bilayer graphene aligned with BN, is present every 60 deg, but the symmetry is broken between the 0 deg and 60 deg alignments, creating nonidentical "moire twins" with different electronic properties. In particular, electron transport measurements display a fully developed valley Hall effect at 0 deg while on the contrary, it is completely absent at 60 deg. We explain this effect by performing numerical simulations, which highlight the central role of the atomic-scale structural relaxation of the second graphene layer. This in-plane atomic relaxation, different for the two alignments, impacts on the electronic band structure of our system. Our results demonstrate that in situ control of the rotational order provides a unique insight on the interplay between mechanical and electronic properties, and increases the posibilities for band-structure engineering on van der Waals heterostructures.

Tutorial TUT 2.3 Sun 17:10 H2 Single-photon emitters in 2D materials - • STEFFEN MICHAELIS DE VASCON-CELLOS - University of Münster, Institute of Physics and Center for Nanotechnology, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany

Single-photon sources are key components for quantum technologies, such as communications, cryptography, computation, and metrology. Recently, the family of solid-state quantum light emitters was joined by single-photon sources in atomically thin materials [1]. Compared to 3D bulk materials, the 2D host crystals with their high structural flexibility allow for a high photon extraction efficiency, new methods for the deterministic creation, and convenient integration with photonic circuits.

In this tutorial, I will introduce the basic properties of single-photon emitters in different 2D van der Waals material systems and discuss present experimental methods for their creation, control, and coupling to photonic nanostructures.

[1] S. Michaelis de Vasconcellos et al., "Single-Photon Emitters in Layered Van der Waals Materials," Phys. Status Solidi B 2022, 259, 2100566

Tutorial TUT 2.4 Sun 17:45 H2  $Introduction \ to \ 2D \ superconducting \ spintronics - \bullet {\tt Elke \ Scheer} - {\tt Depart}$ ment of Physics, University of Konstanz, Konstanz

The proximity effect between a conventional (s-wave) 3D superconductor (S) and a ferromagnet (F) can lead to the formation of Cooper pairs with parallelspin (spin-triplet) alignment instead of the conventional antiparallel-spin (spinsinglet) state. The demonstration of spin-triplet generation in S/F systems [1,2] has inaugurated the field of superconducting spintronics aiming at developing energy-efficient spintronic devices [3]. Both superconductivity and ferromagnetism depend on the dimensionality of the system, but have been shown to exist in 2D or quasi-2D systems [4,5]. The possibility to exfoliate layered van der Waals (vdW) materials down to the few-layer limit [6] in combination with the existence of S and of F vdW materials makes this material basis in particular promising to explore triplet S in 2DS/2DF heterostructures. In this tutorial talk I will briefly recall the physics of SF spintronics in 3D, before I will describe the particular properties and challenges in the investigation of 2D-SF hybrid systems and give an overview over the so far best-studied material combinations and target devices.

### TUT 3: Functional Ferroics (joint session KFM/TUT)

Chair: Dr. Jan Schultheiß (Augsburg University / NTNU Trondheim)

Time: Sunday 16:00-18:15

#### Tutorial

TUT 3.1 Sun 16:00 H3

Domains and domain walls in functional ferroics — • DENNIS MEIER — Department of Materials Science and Engineering, Norwegian University of Science and Technology - Center for Quantum Spintronics, Department of Physics, Norwegian University of Science and Technology, Trondheim, Norway

Ferroic materials with spontaneous magnetic or electric long-range order are a rich source for functional phenomena. Ferromagnets, for example, are used in hard discs and read heads, whereas ferroelectrics find application as capacitors, energy harvesters, and in tunnel junctions. The rich functionality of ferroic materials is closely linked to their domain structures and the responses of the domains to external stimuli.

In this tutorial, I will give an introduction to the fundamentals that underpin the domain formation in ferroics and discuss different microscopy techniques that allow for imaging electric and magnetic domains. Furthermore, we will talk about more exotic systems, such as improper ferroelectrics and multiferroics, where the interplay of coexisting order parameters gives rise to completely new domain and domain wall properties at the nanoscale. Open experimental challenges will be addressed, as well as future application and research opportunities.

#### Tutorial

TUT 3.2 Sun 16:45 H3

Theory and simulations of ferroelectrics and related materials - •JORGE INIGUEZ - Luxembourg Institute of Science and Technology - University of Luxembourg

In this tutorial I will introduce the theoretical and simulation methods most frequently employed to investigate ferroelectrics and related materials (antiferroelectrics, multiferroics). I will start from the general electronic-structure methods that permit predictive calculations at the atomic scale, and introduce successive simplifications to eventually reach continuum field schemes that give us access to the mesoscale. I will illustrate the specificity and usefulness of the different approaches by presenting, for each of them, one or two classic examples of application. In passing, this will allow me to emphasize the key role that simulation has played in our field, and to touch upon interesting possibilities for application in energy-related problems.

Jorge Íñiguez's work on ferroelectrics and related materials is mainly funded by the Luxembourg National Research Fund, currently through projects FNR/C18/MS/12705883/REFOX/Gonzalez, INTER/NWO/20/15079143, and C21/MS/15799044.

#### Tutorial

TUT 3.3 Sun 17:30 H3 Atomic scale analysis of ferroic domain walls — •SHELLY CONROY — Depart-

ment of Materials, London Centre of Nanotechnology, Imperial College London, United Kingdom

The dynamic interfaces of ferroic materials known as domain walls by-pass the static limitations of traditional nano-device designs. In contrast to heterointerfaces between different materials, domain walls can be created, moved and removed via an applied stimulus. By combining multiple ferroic properties such as electricity and magnetism, new multi-functional interactive device applications are possible. As these mobile walls can be atomically sharp, it is essential to have physical characterisation at this scale spatially and time-resolved. In this tutorial, I will give an introduction to electron microscopy techniques starting with how to identify domain patterns in the bulk samples, and the most appropriate electron microscopy techniques to use with increasing magnification, leading to pico-meter characterisation. We will discuss some of the most recent advances in electron microscopy characterisation methods for ferroelectrics such as visualising electric charge density at sub-angstrom resolution, and the benefits of coupling polarisation characterisation with electron energy loss spectroscopy band structure analysis. We will then talk about how one can probe multiferroic properties such as magnetic field, strain and phonon modes. As one of the most exciting aspects of ferroic domain walls is their mobility, the various in situ options to investigate their dynamics will be detailed.

### TUT 4: Stochastic Processes from Financial Risk to Genetics (joint session SOE/TUT/BP/DY)

Macroscopic and microscopic models from Economy to Biology must account for stochasticity on various levels. While classical physics strives for deterministic descriptions through differential equations from fundamental level to thermodynamics, many physics-based models on higher level explicitely include stochasticity from various sources. Discrete and continuous stochastic processes then become the mathematical foundation of these models. This tutorial highlights classical as well as current methods and approaches of probabilistic models and stochastic processes in physics, biology as well as socio-economic systems, thereby bridging the risk to extinction in genetics with its economic counterpart. (Session organized by Jens Christian Claussen.)

Time: Sunday 16:00-18:30

#### Tutorial

TUT 4.1 Sun 16:00 H4 Diffusion approximations for particles in turbulence - •BERNHARD MEHLIG - University of Gothenburg, Gothenburg, Sweden

The subject of this tutorial is the dynamics of particles in turbulence, such as micron-sized water droplets in the turbulent air of a cumulus cloud. The particles respond in intricate ways to the turbulent fluctuations. Non-interacting particles may cluster together to form spatial patterns - even though the turbulent fluid is incompressible [1]. In this tutorial I explain how to understand spatial clustering using diffusion approximations, highlighting an analogy with Kramers' escape problem [2]. I introduce/review the necessary elements of diffusion theory. My goal is to give a pedagogical introduction to diffusion approximations in non-equilibrium statistical physics, using particles in turbulence as an example.

[1] K. Gustavsson and B. Mehlig, Statistical models for spatial patterns of heavy particles in turbulence, Adv. Phys. 65 (2016) 57 (read Sections 1, 3.1, and 6.1).

[2] H. A. Kramers, Brownian motion in a field of force and the diffusion model of chemical reactions, Physica 7 (1940) 284 (read up to eq. (17)).

TUT 4.2 Sun 16:50 H4 Tutorial Probabilities in physics, paradoxes and populations - • TOBIAS GALLA - Instituto de Física Interdisciplinary Sistemas Complejos, IFISC (CSIC-UIB), Campus Universitat Illes Balears, E-07122 Palma de Mallorca, Spain

It is notoriously hard for humans to develop a good intuition for probabilities and stochastic processes. Our brains are not able to do this naturally, and there are numerous mistakes which are easy to make. These mistakes are in fact made regularly in the press (sometimes perhaps deliberately). More worrisome, decision makers such as judges, doctors or politicians are also prone to mishandling probabilities. In this tutorial I will outline a few of these traps, and how to avoid them. I will also discuss the nature of probabilistic models of physical processes - is there genuine randomness in the world around us? I will then present a number of instances in which physics approaches combined with stochastic modelling can make a difference. As one example, I will outline experimental and theoretical results which highlight the importance of stochastic processes in population dynamics. Other examples will include stochastic processes in genetics, the evolution of cancer and in game theory.

#### Tutorial

TUT 4.3 Sun 17:40 H4

Location: H4

Risk Revealed: Cautionary Tales, Understanding and Communication •PAUL EMBRECHTS — Department of Mathematics, ETH Zürich

The title of the tutorial refers to a forthcoming book, to be published by Cambridge University Press, co-authored with Valérie Chavez-Demoulin (Lausanne) and Marius Hofert (Waterloo). Extreme Value Theory (EVT) offers a mathematical tool for the modeling of so-called What-If events, or stress scenarios. I will present several examples of risk-based decision-making and show how EVT can be used as part of the solution. The current pandemic has clearly shown that the communication of scientific evidence has a difficult stand in the ubiquitous environment of social media. I will discuss some examples of this struggle.

### **Entanglement Distribution in Quantum Networks (SYED)**

jointly organised by the Quantum Information Division (QI) and the Semiconductor Physics Division (HL)

Christoph Becher,
Universität des Saarlandes

saarland.de

Sven Höfling, Julius-Maximilians-Universität, 97074 Würzburg sven.hoefling@physik.uniwuerzburg.de Peter van Loock, Johannes Gutenberg-Universität, 55128 Mainz, loock@uni-mainz.de

Scalable quantum networks, i.e., links between quantum nodes that are capable of storing and processing quantum information, promise advantages in many applications such as secure quantum communication, networks of distributed quantum sensors and connecting quantum computers. A common prerequisite is the ability to create and distribute entangled states as resource for establishing such a network. This symposium reviews some recent developments in the field of entanglement generation and distribution in quantum networks with solid state and photonic qubit systems, both from an experimental and conceptual perspective.

### SYED 1: Entanglement Distribution in Quantum Networks

Time: Wednesday 9:30-12:15

#### Invited Talk

SYED 1.1 Wed 9:30 H1

A multi-node quantum network of remote solid-state qubits —  $\bullet$ RONALD HANSON — QuTech and Kavli Institute of Nanoscience Delft, Delft University of Technology, The Netherlands

Future quantum networks may harness the unique features of entanglement in a range of exciting applications, such as quantum computation and simulation, secure communication, enhanced metrology for astronomy and time-keeping as well as fundamental investigations. To fulfill these promises, a strong worldwide effort is ongoing to gain precise control over the full quantum dynamics of multi-particle nodes and to wire them up using quantum-photonic channels.

We report on the realization of a three-node entanglement-based quantum network based on diamond NV centers and demonstrate several quantum network protocols without post-selection: the distribution of genuine multipartite entangled states across the three nodes, entanglement swapping through an intermediary node [1], and qubit teleportation between non-neighbouring nodes [2]. Moreover, we will discuss future challenges and prospects for quantum networks, including increasing the distance between nodes to metropolitan scales [3] and the role of next-generation integrated devices.

Invited Talk SYED 1.2 Wed 10:00 H1 Quantum key distribution with highly entangled photons from GaAs quantum dots — •ARMANDO RASTELLI, SANTANU MANNA, SAIMON COVRE DA SILVA,

GABRIEL UNDEUTSCH, and CHRISTIAN SCHIMPF — Institute of Semiconductor and Solid State Physics, Johannes Kepler Universität Linz, Linz, Austria

Entanglement is one of the most peculiar phenomena in quantum science and a key resource for quantum technologies. More than two decades after the initial proposal [1], semiconductor quantum dots (QDs) are now beginning to outperform other sources for the generation of entangled photon pairs. Among different material systems, QDs in the (Al)GaAs platform have demonstrated the highest degree of polarization entanglement to date together with other appealing features for quantum science and technology [2]. In this talk, we will discuss the properties of GaAs QDs obtained by the droplet etching method and present recent results relevant to their application in quantum communication, i.e. entanglement-based quantum key distribution [3,4], quantum teleportation and entanglement swapping.

SYED 1.3 Wed 10:30 H1

**Entanglement distribution with minimal memory requirements using timebin photonic qudits** — •JOHANNES BORREGAARD — QuTech and Kavli Institute of Nanoscience, Delft University of Technology, 2628 CJ, Delft, The Netherlands Generating multiple entangled qubit pairs between distributed nodes is a prerequisite for a future quantum internet. To achieve a practicable generation rate, standard protocols based on photonic qubits require multi-qubit quantum memories with long coherence times, which remains a significant experimental challenge. In this talk, I will discuss a novel protocol based on time-bin photonic qudits that allow for the simultaneous generation of multiple entangled pairs between two distributed qubit registers. By adopting the qudit protocol, the required memory time is independent of the transmission loss between the nodes in contrast to standard qubit approaches. Consequently, a significant boost of the capabilities of near-term quantum communication hardware can be achieved paving the way for a practical quantum internet.

#### 15 min. break

Invited TalkSYED 1.4Wed 11:15H1Quantum photonics: interference beyond HOM and quantum networks —•STEFANIE BARZ — Institute for Functional Matter and Quantum Technologies,<br/>University of Stuttgart, Germany — Center for Integrated Quantum Science and<br/>Technology (IQST), University of Stuttgart, Germany

In the first part of my talk, I will talk about recent experiments on quantum interference. I will show the impact of distinguishability and mixedness - two fundamental properties of quantum states - on quantum interference. I will demonstrate that these two properties can influence the interference of multiple particles in very different ways, leading to effects that cannot be observed in the interference of two particles alone. In the second part of my talk, I will report on our recent work in quantum networks. I will talk about a crucial component of a photonic quantum network: Bell-state measurements and report on an experimental demonstration of a scheme that allows obtaining a success probability of more than 50%. Finally, I will show the implementation of a novel protocol for networked key exchange using cluster states as a resource.

#### Invited Talk

#### SYED 1.5 Wed 11:45 H1

Photonic cluster-state generation for memory-free quantum repeaters — •TOBIAS HUBER — Lehrstuhl für Technische Physik, University of Würzburg, Würzburg, Germany

Many different hardware implementations show very promising results towards implementing quantum repeater nodes based on local memories [1]. While defects in diamond are currently the frontrunners, due to already demonstrated 3-node networks [2] and the possibility to enter the quantum repeater advantage regime (when comparing to direct links, considering losses at the given wavelength) [3], semiconductor quantum dots offer an intriguing alternative. Semiconductor quantum dots have the advantages of easy fabrication which leads to high device efficiencies. Furthermore, protocols for deterministic generation of linear photonic-cluster states do exist and have been already demonstrated experimentally [4]. With only moderate resource overhead a quantum repeater graph state can be fused from linear cluster states, opening the pathway towards memory-less 3rd generation quantum repeaters.

In this talk I will present our recent advances in device design and cluster-state generation with semiconductor quantum dots.

Michele Ceriotti EPFL COSMO MXG 337 - Station 12 CH-1015 Lausanne michele.ceriotti@epfl.ch Georg Kresse University of Vienna Sensengasse 8/12 A-1090 Wien georg.kresse@univie.ac.at

Mariana Rossi MPI for the Structure and Dynamics of Matter Luruper Chaussee 149, Geb. 99 22761 Hamburg mariana.rossi@mpsd.mpg.de

Machine learning methods have gained a prominent spot in the research of materials and molecules, especially in the context of the atomic-scale modeling of their properties. The growing understanding of how machine-learning methods should be adapted to the specific requirements of the field is making them progressively more effective and easy to use. Machine-learning techniques use the predictions of electronic-structure theory to train surrogate models that can compute the same properties with similar accuracy at much reduced cost. The combination of physics-based and data-driven paradigms is extending dramatically the reach of electronic-structure theory, as its predictive accuracy can now be applied to more complex, larger-scale problems and longer timescales. The field has been evolving so fast that in the past years we have witnessed considerable breakthroughs enabled by this combination: first-principles accuracy assessment of finite-temperature thermodynamics, including also subtle effects such as quantum nuclear fluctuations, has become commonplace; predictions of microscopic quantities beyond the interatomic potential energy are making it possible to incorporate functional properties into a fully-predictive machine-learning framework; inverse design and generative models are simplifying the search of configurational and composition spaces for compounds with optimal performance; including information and training data calculated from methods that go beyond density functional theory allows to make predictions systematically improvable.

#### Invited Talk

SYES 1.1 Thu 15:00 H1 Machine-learning-driven advances in modelling inorganic materials -•VOLKER L. DERINGER — University of Oxford, Oxford, UK

Understanding the links between structures and properties of materials is an important research challenge. Computer simulations based on quantummechanical methods give access to small-scale models, but quickly reach their limits when structurally complex systems are to be studied. Here, I will showcase recent advances in modelling inorganic functional materials that have been enabled by machine learning (ML) based interatomic potentials. Specifically, I will demonstrate the power of ML-driven simulations in exploring the structures of amorphous elemental systems, at ambient and high pressure, and I will discuss future perspectives for modelling compositionally more complex materials.

#### SYES 1.2 Thu 15:30 H1 Invited Talk Machine-Learning Discovery of Descriptors for Square-Net Topological

Semimetals — •EUN-AH KIM — Cornell University, Ithaca, NY, USA The accumulation of massive amounts of materials data motivates data-based machine learning(ML) approaches. However, an extensive database of materials relying on high-throughput density functional theory (DFT) can be unreliable for emergent properties. Much needed is an approach that can articulate and build on expert human researchers' insights. The tolerance factor introduced in Refs [1-2] articulates a chemical insight for identifying topological semimetals among square-net materials and presents an opportunity to develop such a human-machine synergy. Hence, we developed a supervised-unsupervised hybrid approach combining non-linear Gaussian Process(GP) regression [3] with supervised metric learning to discover descriptors for topological semimetals. Simultaneously, we curated a database containing 1279 square-net materials featuring different physical and chemical attributes and the binary label for the topological property associated with each material. Application of the GP model to the database rediscovers the tolerance factor and offers new theoretical insight.

#### SYES 1.3 Thu 16:00 H1 Invited Talk Four Generations of Neural Network Potentials - • JÖRG BEHLER - Universität Göttingen, Germany

A lot of progress has been made in recent years in the development of machine learning potentials for atomistic simulations, with neural network potentials (NNPs) being an important example. While the first generation of NNPs has been restricted to small systems, the second generation extended the applicability of ML potentials to high-dimensional systems containing thousands of atoms by constructing the total energy as a sum of environment-dependent atomic energies. Long-range electrostatic interactions can be included in third-generation NNPs employing environment-dependent charges, but only recently limitations of this locality approximation could be overcome by the introduction of fourthgeneration NNPs, which are able to describe non-local charge transfer using a global charge equilibration step. In this talk an overview about the historical evolution of high-dimensional neural network potentials will be given along with an overview of typical applications in large-scale atomistic simulations.

SYES 1.4 Thu 16:30 H1 Invited Talk Using machine learning to find density functionals — •KIERON BURKE — University of California, Irvine, USA

Over the past decade, advances in machine learning have led to the creation of new approximate density functionals. I will review this area, with an emphasis on very recent developments. How do such functionals compare to those of human design? What are their advantages and their limitations? For example, can they work for strongly correlated systems? I will consider both the exchangecorrelation energy used in Kohn-Sham DFT and the non-interacting kinetic energy functional, needed to bypass the KS equations.

Invited Talk SYES 1.5 Thu 17:00 H1 Coarse graining for classical and quantum systems — •CECILIA CLEMENTI — Freie Universität Berlin, Germany

The last years have seen an immense increase in high-throughput and high-resolution technologies for experimental observation as well as highperformance techniques to simulate molecular systems at a microscopic level, resulting in vast and ever-increasing amounts of high-dimensional data. However, experiments provide only a partial view of the molecular processes and are limited in their temporal and spatial resolution. On the other hand, simulations are still not able to completely characterize large and/or complex molecular processes over long timescales, thus leaving significant gaps in our ability to study these processes at a physically relevant scale. We present our efforts to bridge these gaps, by combining statistical physics with state-of-the-art machinelearning methods to design optimal coarse models for complex macromolecular systems. We derive simplified molecular models to reproduce the essential information contained both in microscopic simulation and experimental measurements.

Eisenforschung	Max-Planck-Gesellschaft	Polymerforschung
Düsseldorf	Berlin	Mainz
neugebauer@mpie.de	scheffler@fhi-berlin.mpg.de	kremer@mpip-mainz.mpg.de

Combining concepts from big data analytics with experimental and theoretical techniques in solid state physics has opened exciting new routes to designing materials with superior mechanical, electronic or optical properties as well as to enhance resolution and performance of established experimental techniques as e.g. electron microscopy, x-ray diffraction, or atom probe tomography. The symposium will bring together leading experts who pioneer the application of these techniques for their respective fields. The intention is to show success stories but also to critically discuss present limitations as well as emerging areas. A critical aspect that will be in the focus of the symposium is that big data analytics alone, i.e. without a deep understanding of the underlying physics, turns out to be insufficient in successfully addressing experiment or materials related challenges.

#### **Invited Talk**

SYNM 1.1 Mon 15:00 H1 How to tackle the "I" in FAIR? — •CLAUDIA DRAXL — Physics Department,

Humboldt-Universität Berlin, Germany Veracity, one of the 4V challenges of Big Data, is an issue for the FAIRness of materials-science results. This concerns in particular, the interoperability. On the computational side, the precision of different DFT codes was thoroughly investigated [1]. Later, it was demonstrated how ultimate precision for molecules and solids can been reached [2] and how different methodology impacts the results [3]. Also code-specific uncertainties coming from numerical settings were assessed [4]. More recently, we demonstrated [5] how a spectral fingerprint, combined with a similarity metric, can be used for establishing quantitative relationships between materials data. Besides the identification of electronically similar materials, this approach can be used for assessing uncertainty in data that potentially come from different sources. Various examples highlight how to quantify differences between measured optical spectra or the impact of methodology and computational parameters on calculated spectral properties. Moreover, combining our fingerprint with a clustering approach allows us to explore materials spaces in view of finding (un)expected trends or patterns [6].

#### Invited Talk

SYNM 1.2 Mon 15:30 H1 Beyond the average error: machine learning for the discovery of novel materials — •Mario Boley¹, Simon Teshuva¹, Felix Luong¹, Lucas Foppa², and Matthias Scheffler² — ¹Monash University — ²Fritz Haber Institute of the Max Planck Society

Machine learning models promise to radically accelerate the discovery of novel functional materials by rapidly screening huge candidate spaces for materials with rare combinations of properties. While current models allow for accurate property prediction on average, e.g., indicated by the root mean squared error, such measures are only loosely connected to materials discovery. They do not capture that discovery is a process, where models are repeatedly retrained with new data. Moreover, they depend on some fixed sampling distribution, which is irrelevant when actively exploring candidates and distorted by the overwhelming mass of mediocre materials. Finally, they do not reflect model uncertainty, which is a crucial parameter for effective active learning strategies. Here, based on the example of searching for stable and stress resistant double perovskites under a bandgap constraint, we evaluate models in terms of their optimisation regret-a function of consecutive improvements of the target property by newly discovered materials. In particular, we employ non-parametric regression models (Gaussian processes and random forests) within the "expected improvement" search strategy. Starting from an initial dataset of 815 computed double perovskite properties, we are able to discover materials with improved target values already within the first 20 newly acquired data points.

#### Invited Talk SYNM 1.3 Mon 16:00 H1 The Phase Diagram of All Inorganic Materials - •CHRIS WOLVERTON -Northwestern University, Evanston, IL USA

One of the holy grails of materials science, unlocking structure-property relationships, has largely been pursued via bottom-up investigations of how the arrangement of atoms and interatomic bonding in a material determine its macroLocation: H1

scopic behavior. Here we consider a complementary approach, a top-down study of the organizational structure of networks of materials, based on the interaction between materials themselves. We demonstrate the utility of applying network theory to materials science in two applications: First, we unravel the complete *phase stability network of all inorganic materials* as a densely-connected complex network of 21,000 thermodynamically stable compounds (nodes) interlinked by 41 million tie-lines (edges) defining their two-phase equilibria, as computed by high-throughput density functional theory. Using the connectivity of nodes in this phase stability network, we derive a rational, data-driven metric for material reactivity, the *nobility index*, and quantitatively identify the noblest materials in nature. Second, we apply network theory to the problem of synthesizability of inorganic materials, a grand challenge for accelerating their discovery using computations. We use machine-learning of our network to predict the likelihood that hypothetical, computer generated materials will be amenable to successful experimental synthesis.

#### 15 min. break

Invited Talk SYNM 1.4 Mon 16:45 H1 Automated data-driven upscaling of transport properties in materials -•DANNY PEREZ¹ and THOMAS SWINBURNE² – ¹Los Alamos National Laboratory, Los Alamos, USA — ²CRNS/CINaM, Marseille, France

Transport properties of complex defects are crucial factors that control the performance of many material systems, e.g., the radiation tolerance of materials for nuclear fusion or fission applications. Characterizing the transport of complex defects is however notoriously tedious and time-consuming, especially as the defects grow, leading to a combinatorial explosion in the number of possible conformations and local transition pathways. I will present a large-scale datadriven approach to automatically obtain reduced-order models of defect evolution, transport coefficients, as well as effective continuum transport equations, from large number of short molecular dynamics (MD) simulations. The optimal MD simulations to carry out are identified on-the-fly using a Bayesian uncertainty quantification framework and automatically executed on a massivelyparallel task-execution infrastructure. We show how this microscopic information can be systematically and efficiently upscaled into meso and macro-scale representations that can inform microstructure evolution models.

#### Invited Talk

SYNM 1.5 Mon 17:15 H1 Data-driven understanding of concentrated electrolytes — •ALPHA LEE — Department of Physics, University of Cambridge, Cambridge, UK

Electrolytes play an important role in a plethora of applications ranging from energy storage to biomaterials. Notwithstanding this, the structure and dynamics of concentrated electrolytes remain enigmatic. In this talk, I will show how machine learning can unravel hidden patterns in simulations of electrolytes, helping us understand the structure of concentrated electrolytes and mechanisms of ion transport. In the first part of my talk, I will illustrate how debates such as extent of "ion pairing" in concentrated electrolytes can be addressed using methods in unsupervised machine learning and Bayesian hypothesis testing. In the second part of my talk, I will discuss how machine learning help relate local ionic structure to molar ionic conductivity. This furnishes microscopic insights on what are the drivers of conductivity as a function of ion concentrations. More broadly, I will discuss the role that machine learning can play in not only delivering predictive models, but also serving as an "intuition pump" to understand complex soft matter systems.

### Frontiers of Orbital Physics: Statics, Dynamics, and Transport of Orbital Angular Momentum (SYOP)

jointly organised by the Magnetism Division (MA), the Surface Science Division (O), the Crystalline Solids and their Microstructure Division (KFM), the Thin Films Division (DS), the Semiconductor Physics Division (HL) and the Low Temperature Physics Division (TT)

> Ingrid Mertig Martin-Luther-Universität Halle-Wittenberg 06099 Halle ingrid.mertig@physik.uni-halle.de

The interplay of orbital, spin, and lattice leads to not only exotic phases of matter such as orbital ordering in multiferroic materials and orbital Chern insulator states in twisted bilayer graphene but also dynamic phenomena including orbital Hall effect, orbital torque, and topological orbital magnetoelectric response. While so far the focus has been on spin currents, orbital currents, the flow of the electrons with finite orbital angular momentum, is found to be extremely efficient in many materials and can outperform conventional spin current effects. As recently demonstrated, orbital currents can additionally play a pivotal role in generating spin currents thus leading to torques with unprecedented amplitude to manipulate magnetization. On the other hand, optical means including vortex beams provide a potentially outstanding means of generating and manipulating orbital order and orbital transport. So far these effects have been observed in metallic heterostructures where light metals and their oxides generate strong orbital currents as well as oxidic 2DEG heterostructures that show efficient orbital to charge conversion thus showing that orbital currents can play a role in many systems. Developing methods and materials for harnessing orbital currents can thus potentially have significant impact and open a new direction in spintronics research. This session brings experts on the orbital physics from different areas of condensed matter physics in one place to promote collaborations beyond the boundaries of each community, share knowledge on cutting edge theoretical and experimental methods, and discuss challenges and future directions of the orbital physics. The invited speakers include not only experts on oxide multiferroic materials and spintronic devices but also on new experimental techniques that can unambiguously detect the orbital ordering and dynamics in solids and optical methods.

SYOP 1.1 Mon 9:30 H1 Orbital degeneracy in transition metal compounds: Jahn-Teller effect, spinorbit coupling and quantum effects — • DANIEL KHOMSKII — II Physikalisches Institut Universitaet zu Koeln Zuelpicher Str. 77 50937 Koeln, Germany Transition metal compounds with orbital degeneracy display a number of spe-

cific interesting properties [1, 2]. Among them there are first of all the cooperative Jahn-Teller (JT) effect and corresponding orbital ordering. For t2g electrons also spin-orbit coupling (SOC) may play crucial role: for these states orbital moment is not quenched by crystal field. There may be a very nontrivial effects connected with the mutual influence of Jahn-Teller effect and SOC. In most cases SOC suppresses JT effect, but there are situation in which it can instead promote, activate it. Also very nontrivial quantum effects can occur in this case. In my talk, after a short general introduction, I will discuss in particular this mutual interplay of JT effect and SOC for different situations [3, 4]. [1] Daniel I. Khomskii and Sergey V. #### SYOP 1.2 Mon 10:00 H1 Invited Talk Orbital magnetism out of equilibrium: driving orbital motion with fluctuations, fields and currents — • YURIY MOKROUSOV — Forschungszentrum Jülich GmbH, Jülich, Germany - Johannes Gutenberg-University Mainz, Mainz, Germanv

In modern spintronics properties of non-equilibrium orbital polarization and orbital currents start to attract significant attention. In this talk we will review the theory of orbital magnetism in low-symmetric crystals and corresponding current-induced orbital magnetization. We will in particular show that applied electrical currents and optical pulses can drive non-equilibrium orbital magnetism and currents of orbital angular momentum. These orbital currents can be used to transmit angular momentum over large distances in solids, and can be utilized to exert sizeable orbital torques on magnetization thus enabling magnetic switching even in light materials with weak spin-orbit interaction. Moreover, we will underline that in fluctuating magnets spin excitations can mediate a significant orbital response which can be coupled to temperature gradients so as to ignite thermal orbital currents. We will thus attempt to promote a paradigm that unleashing non-equilibrium orbital physics and entanglement of spin and orbital degrees of freedom in diverse classes of materials can lead to much richer physics than previously expected, and might provide a key to realization of novel properties of matter out of equilibrium as well as energy-efficient applications.

#### Invited Talk SYOP 1.3 Mon 10:30 H1 Orbitronics: new torques and magnetoresistance effects — •MATHIAS KLÄUI - Institute of Physics, Johannes Gutenberg University Mainz, 55099 Mainz, Ger-

many Experimentally, orbital currents for efficient manipulation of magnetization have only recently started to be explored. We studied spin orbit torques generated in TmIG/Pt/(Cu(O)x) heterostructures. Varying the CuOx and Pt layer thicknesses, we realized a 16x increase of the spin orbit torques exerted on the TmIG compared to conventional TmIG/Pt [1]. Such an enhancement is extremely surprising if one considers only conventional spin-charge interconversion based on spin orbit coupling effects and given the low spin-orbitcoupling of Cu and Cu(O)x one does not expect large torques. However, the results can be naturally explained as Cu(O)x can generate large orbital currents that are then converted to spin currents in the Pt layer, which then manipulate the TmIG extremely efficiently. In addition, we found in Py/Cu(O)x a Orbital Rashba-Edelstein Magnetoresistance effect related to the conventional spin Hall magnetoresistance [2]. In particular in this work, the length scale of the orbital to spincurrent conversion in Py could be identified as a key step to harnessing orbital currents efficiently even without a heavy metal-based orbital to spin conversion layer [3]. Invited Talk SYOP 1.4 Mon 11:15 H1 Orbital and total angular momenta dichroism of the THz vortex beams at the antiferromagnetic resonances — • ANDREI SIRENKO — Department of Physics, New Jersey Institute of Technology, Newark, New Jersey 07102, USA

Light beams with orbital angular momentum (OAM), or vortex beams, can couple to magnetism exhibiting dichroisms in a magnetized medium. Terahertz (THz) vortex beams with various combinations of the orbital angular momentum L=+/-1, +/-2, +/-3, and +/-4 and spin angular momentum S = +/-1, or conventional circular polarization, were used for studies of the magnon spectra at the antiferromagnetic resonance conditions in TbFe3(BO3)4 and Ni3TeO6 single crystals. In both materials we observed strong vortex beam dichroism for the magnon doublet, which is split in an external magnetic field applied along the spin ordering direction. The absorption conditions at the magnon frequencies depend on the total angular momentum of light J that is determined by the combination of the spin and orbital angular momenta: J=S+L. For the higher orders of l, the selection rules for AFM resonances dictated by l completely dominate over that for conventional circular polarization. Our results demonstrate the high potential of the vortex beams with OAM as a new spectroscopic probe of magnetism in matter. This work was performed in collaboration with T. N. Stanislavchuk, P. Marsik, L. Bugnon, M. Soulier, C. Bernhard, V. Kiryukhin, and S.-W. Cheong.

SYOP 1.5 Mon 11:45 H1 Observation of the orbital Hall effect in a light metal Ti — • GYUNG-MIN CHOI - Sungkyunkwan University, Suwon, Korea

The orbital angular momentum is a core ingredient of orbital magnetism, spin Hall effect, giant Rashba spin splitting, orbital Edelstein effect, and spin-orbit torque. However, its experimental detection is tricky. In particular, direct detection of the orbital Hall effect remains elusive despite its importance for the electrical control of magnetic nanodevices. Here we report the direct observation of the orbital Hall effect in a light metal Ti1. The Kerr rotation by the accumulated orbital magnetic moment is measured at Ti surfaces, whose result agrees with theoretical calculations semi-quantitatively. As another evidence, we measured the orbital torque in the Ti/ferromagnet heterostructures, from which we determine the orbital Hall angle >0.21. Our experimental results confirm the orbital Hall effect in a light metal Ti and hint at opportunities in the emerging field of orbitronics.

### High Yield Devices for Photonic Quantum Implementations (SYPQ)

jointly organised by the Semiconductor Physics Division (HL) and the Working Group young Leaders in Physics (AGyouLeaP)

Simone Portalupi	Doris Reiter	Stephan Götzinger
University of Stuttgart	TU Dortmund	MPI Erlangen
s.portalupi@ihfg.uni-stuttgart.de	doris.reiter@tu-dortmund.de	stephan.goetzinger@mpl.mpg.de

The symposium aims at discussing the challenges and achievements in realizing photonic devices for quantum applications. This will cover growth, fabrication, quantum optical measurements, and theoretical modelling. Platforms like semicoductors, organic molecules, and transparent materials will be examples of the discussed topics. Particular attention will be posed in discussing and selecting results which have a clear impact in transferring quantum technologies to real world implementations. Focus will be given as well to all techniques that allows boosting not only the device performances but also the fabrication yield (ideally to mass production), like deterministic technologies, lithography and 3D printed approaches.

SYPQ 1.1 Tue 9:30 H1 Designing driving protocols for high-fidelity quantum devices using numerically exact predictions — • MORITZ CYGOREK and ERIK M. GAUGER — Heriot-

Watt University, Edinburgh, UK Improving the quality of quantum devices, such as solid state quantum dots as emitters of non-classical light, is not only a matter of device fabrication. Engineering operation protocols by combining coherent driving, adiabatic rapid passage, Stark tuning, and phonon-assisted state preparation is key to enhancing devices robustness and fidelity. This turns a hardware problem into the software problem of predicting the dynamics of quantum devices. The challenge for solid state devices is the simultaneously strong coupling to phonon environments, strong time-dependent driving, and possibly strong interactions with structured photonic environments. After a series of conceptual developments in less than a decade, it has become possible to describe the dynamics of such devices numerically exactly, i.e., to fully account for all effects described by the microscopic Hamiltonians to arbitrary precision. While prior numerically exact methods had been practicable only for very small idealised quantum systems, now, easy-to-use computational tools are publicly available that provide numerically exact results even for the multi-scale dynamics of small quantum networks strongly coupled to multiple environments with long memory times. Here, I summarise these developments and discuss their impact for the design of driving protocols for realworld quantum device. Furthermore, I discuss the prospects and challenges for a universal solver of arbitrary open quantum systems.

#### SYPQ 1.2 Tue 10:00 H1 Invited Talk

Challenges towards high efficiency quantum dot single photon sources -•ARNE LUDWIG — Ruhr-Universität Bochum, Germany

A key component for photonic quantum devices is a source of high-fidelity photonic qubits, a single photon source (SPS) [1]. A promising route to create such a device employs semiconductor quantum dots (QDs) in photonic cavities. These approaches exploit the exquisite toolbox of semiconductors, in particular scalable manufacturing.

However, noise processes hampering these [2]. A main contributor to decoherence and low efficiency is random charge rearrangements in the semiconductor environment or the QD itself. A random change of the QD charge state from e.g. Auger processes [3] or photoionization [4] can switch the emitter temporarily off [3,5].

Noise from a fluctuating electrostatic environment is called charge noise. One way to efficiently suppress this, is to embed the QDs in the high purity material undoped region of a p-i-n-diode [6,7]. This approach combined with a tuneable cavity has been pursued to realize a highly efficient fiber-coupled SPS with an end-to-end efficiency of 57% [8].

Quantum-dot single-photon sources for quantum photonic networks -•PETER MICHLER — University of Stuttgart, Institute for semiconductor optics and functional interfaces, Stuttgart, Germany

In many foreseen implementations of quantum photonic networks, photons must be able to propagate over long distances in silica fibers with limited absorption and wave packet dispersion. When propagating into silica fibers, photons in the so-called telecom C-band (1530-1565 nm) will experience the absolute minimum of absorption whereas in the O-band (1260-1360 nm) they can travel with vanishing dispersion together with limited absorption.

In this talk, we report about recent highlights achieved with quantum dots emitting in the telecom O- and C-band [1,2]. This includes bright Purcell enhanced single-photon sources based on quantum dots in circular Bragg gratings [2] and the study of resonance fluorescence of single In(Ga)As QDs emitting in the telecom C-band [3]. Moreover, we present an efficient and stable fiberto-chip coupling, which enables the injection of single photons from telecom quantum dots into a silicon-on-insulator chip [4].

SYPQ 1.5 Tue 11:45 H1

SYPQ 1.4 Tue 11:15 H1

Quantum light sources: entanglement generation in semiconductor nanostructures — •ANA PREDOJEVIC — Stockholm University, Stockholm, Sweden Single quantum dots are established emitters of single photons and entangled photon pairs. By means of resonant excitation they generate photon pairs with high efficiency, low multi-photon contribution, and suitable for entangling schemes such as time-bin entanglement. The entanglement of photons generated by quantum dots can be employed in free-space and fibre-based quantum communication. In addition to this, some applications of entanglement are more versatile if the photons are entangled simultaneously in more than one degree of freedom - hyperentangled, which we also demonstrated using quantum dots. However, the achievable degree of entanglement and the source readiness to be deployed in quantum communication protocols depend on additional functionalities, including high photon collection efficiency. I will present engineered photonic systems that allow for entangled photon pair sources to be more efficient. Also, I will introduce novel methods to characterize sources of entangled photons.

### Complexity and Topology in Quantum Matter (SYQM)

jointly organised by the Semiconductor Physics Division (HL), the Low Temperature Physics Division (TT), the Dynamics and Statistical Physics Division (DY), and the Thin Films Division (DS)

Matthias Vojta Technische Universität Dresden matthias.vojta@tu-dresden.de Ralph Claessen Julius-Maximilians-Universität Würzburg claessen@physik.uni-wuerzburg.de

Over the past two decades the mathematical concept of topology has emerged into a powerful tool for understanding and classifying quantum matter. The existence of global invariants in a physical system not only gives rise to novel types of quantum phases beyond Landau's concept of broken symmetries and local order parameters, but may also lead to "topological protection" of otherwise rather delicate quantum states with respect to external perturbations, with obvious application potential for future quantum technologies. Topological physics is, in fact, ubiquitous. This symposium is dedicated to giving an overview of its unifying relevance in widely differing areas of condensed matter physics, ranging from electronic band structures to quantum magnetism to photonics devices. The talks will also cover the impact of topology in out-of-equilibrium systems.

SYQM 1.1 Fri 9:30 H1

The role of crystalline symmetries in topological materials: the topological materials database - • MAIA VERGNIORY - Max Planck for Chemical Physics of Solids, Nöthnitzer Str. 40, 01187 Dresden, Germany

Quantum materials are a collection of atoms with interacting electrons and nuclei displaying emergent behaviour and topological properties. The past two decades has witnessed an explosion in the field of topological materials: from weak interacting electrons to strongly correlated ones, topological materials represent one of the most exciting application for future technologies. High performance electronics, quantum information or ultrafast spintronics are just a few of the possible technologies that can be developed based on these materials. In this talk I will discuss the route to go from pure mathematical prediction of topological properties, through high through-put materials search to device fabrication. I will discuss both topological insulators, in non magnetic and magnetic phases as well as topological (chiral) semimetals using the the modern theory of topological band structure. Topological Quantum Chemistry built upon symmetrybased considerations and complemented with chemical theories of bonding, ionization, and covalence. Consequently, it describes the universal global properties of all possible band structures and materials. Beyond the single particle picture, I will present our formalism based on Green's functions aiming to discover topological correlated phases in materials displaying electronic entanglement.

Invited Talk SYQM 1.2 Fri 10:00 H1 **Microwave Bulk and Edge Transport in HgTe-Based 2D Topological Insu-lators** — •Erwann Bocquillon^{1,2}, Matthieu C. Research on the helical edge states of 2D topological insulators is motivated by exotic fundamental physics, robust topological quantum computation and novel spinorbitronics. In this talk, we report on the use of microwave methods to investigate dynamical transport in HgTe-based 2D topological insulators. More specifically, capacitance spectroscopy highlights the response of the edges which host very mobile carriers, while bulk carriers are drastically slowed down in the gap. Charge relaxation timescales are shorter on the edges, which suggests that edge states can be selectively addressed on timescales over which bulk carriers are frozen. Additionally, we also propose edge resonator geometries to characterize Coulomb interaction by via high-frequency measurements.

Topological photonics and topological lasers with coupled vertical resonators - •SEBASTIAN KLEMBT — Chair for Applied Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, Am Hubland, D-97074 Würzburg, Germany.

Topological Photonics is an emerging and novel field of research, adapting concepts from condensed matter physics to photonic systems adding new degrees of freedom. After the first demonstations of topological photonic insulators, the field has moved on to study and exploit the inherent non-hermiticity of photonic systems and the interplay with their topological nature. In my talk I will discuss novel photonic lattice devices resulting from the coupling of individual vertical III-V semiconductor microresonators. So-called exciton-polaritons (hybrid states of light and matter) can emerge in the strong coupling regime. By chosing precise lattice geometries we are able to taylor optical band structures realizing novel photonic lattice. Here, the specific geometry as well as the hybrid light-matter nature allow for ways to break time-reversal symmetry and implement topologically non-trivial systems. Thus we were able to experimentally demonstrate the first exciton-polariton topological insulator, manifesting in chiral, topologically protected edge modes. In order to study topological effects in combination with optical non-linearities, topological lasers have been envisaged and realized. They exploit topological effects to efficiently couple and phase-lock extended arrays of lasers to behave as one single coherent laser. Here, I report on the first experimental demonstration of a topological insulator vertical cavity laser array.

#### Invited Talk

SYQM 1.5 Fri 11:45 H1 Spectroscopic Studies of the Topological Magnon Band Structure in a

Skyrmion Lattice — • MARKUS GARST — Karlsruhe Institute of Technology When magnons propagate across a non-collinear magnetic texture, they collect a Berry phase that can be interpreted as the flux of a synthetic orbital magnetic field. The magnon thus experiences a synthetic Lorentz force that bends the quasi-classical trajectories of the magnons. For a magnetic skyrmion lattice, the average synthetic field is finite such that the magnons are confined to cyclotron orbits of the corresponding magnon Landau levels. This is reflected in a magnon band structure with finite Chern numbers. Here, we report on a series of spectroscopic studies of this band structure using various techniques that allow to probe different regimes in energy-momentum space: magnetic resonance spectroscopy [1], spin-wave spectroscopy [2], inelastic neutron scattering [3] and Brillouin light scattering [4,5]. These techniques have been applied to various cubic chiral magnets like MnSi, FeCoSi and Cu2OSeO3, that are well described by a universal effective continuum theory parametrized by a few parameters only. The combined data from all techniques are found to be in quantitative agreement with theory.

#### Invited Talk SYSD 1.1 Mon 10:15 H2 Charge localisation in halide perovskites from bulk to nano for efficient optoelectronic applications — •SASCHA FELDMANN — Cavendish Laboratory, University of Cambridge, Cambridge, UK - Rowland Institute, Harvard University, Cambridge, USA

Halide perovskites have emerged as high-performance semiconductors for efficient optoelectronic devices like solar cells or LEDs. Yet, we still do not fully understand why these materials work so efficiently, given that we can process them crudely from solution, likely introducing many defects detrimental to devices based on conventional crystalline semiconductors like silicon. In this talk, I will give an overview of our recent work on understanding the high luminescence yields observed in i) bulk mixed-halide thin films and ii) atomically doped nanocrystals. We show that spatially varying energetic disorder in the electronic states of mixed-halide films causes local charge accumulation, which unearths a strategy for efficient charge extraction at low-light conditions for solar cells and for efficient light emission in LEDs operating at low currents. In doped perovskite nanocrystals, we find that the dopant-induced lattice periodicity breaking results in the transient localisation of charges with an increased overlap of electron and hole wavefunctions. This leads to increased radiative rates - a property that is typically intrinsic to a semiconductor and hard to change - together with reduced non-radiative losses, paving the way to highly efficient LEDs and quantum applications. Overall, these findings hint at energetic disorder in these materials not only being tolerated but potentially helpful in explaining their high performance.

#### Invited Talk

SYSD 1.2 Mon 10:45 H2 Nonequilibrium Transport and Dynamics in Conventional and Topological Superconducting Junctions — • RAFFAEL L. KLEES — University of Konstanz, D-78457 Konstanz, Germany

In this talk, I will give a brief overview about the main content of my dissertation. Recently, it has been shown that multiterminal superconducting junctions (MSJs) provide an ideal platform to mimic topological systems in a controlled manner [1]. In the first part, we will construct deterministic model systems of MSJs based on quantum dots that show nontrivial Andreev bound states in terms of a nonzero first and second Chern number. We will also see how the underlying object of quantum geometry and topology, the quantum geometric tensor [2], can be accessed with the help of polarized microwave spectroscopy [3]. In the second part, I will report on the theory behind recent scanning tunneling microscope (STM) experiments between single superconducting Yu-Shiba-Rusinov (YSR) bound states that form in localized magnetic impuritites on superconducting substrates [4]. Motivated by these experiments, we study YSR-functionalized STM tips and present a detailed analysis of multiple Andreev reflection processes mediated by YSR states giving rise to a very complex subgap structure in the current-voltage characteristics [5]. SYSD 1.3 Mon 11:15 H2 Invited Talk Probing magnetostatic and magnetotransport properties of the antiferromagnetic iron oxide hematite - •ANDREW Ross - Johannes Gutenberg Universität-Mainz, Mainz, Germany

With spin dynamics in the THz regime, a lack of stray fields and a high stability in external magnetic fields, antiferromagnets have several benefits over ferromagnets for spintronics applications. In this talk I will discuss two key steps towards functionalising antiferromagnetic insulators, focussing on the antiferromagnetic iron oxide, hematite, the main component of rust.

First, I will demonstrate how spin Hall magnetoresistance measurements can be used to extract the strengths of key antiferromagnetic anisotropies for both bulk and thin film samples responsible for the equilibrium orientation of the magnetic ordering.

Then, I will show how we can use antiferromagnetic insulators for information transport via quantised magnetic excitations, magnons. Polarised magnons are electrically excited by an interfacial spin-bias and carried over micrometres by the antiferromagnetic Neel order, facilitated by the relative orientation of the antiferromagnetic Neel vector and the low damping of hematite. By performing direct magnetic imaging of the domain structure, the strong attenuation of the magnon transport by a multi-domain structure is elucidated. Overall, the results I will present demonstrate the feasibility and promise of the prototypical antiferromagnet hematite for antiferromagnetic spintronic devices.

SYSD 1.4 Mon 11:45 H2

Quantum dot optomechanics with surface acoustic waves - •MATTHIAS WEISS - Institut für Physik, Universität Augsburg - Physikalisches Institut, WWU Münster

Phonons, the quanta of mechanical vibrations, represent fundamental excitation in solid state materials and interact strongly with literally any other system. This universal coupling and their low susceptibility to dissipation makes phonons ideally suited to manipulate dissimilar systems and interface them in hybrid technologies.

In this talk, I show experiments of the interaction between the coherent phonon field of a surface acoustic wave and a single quantum emitter, a semiconductor quantum dot, employing resonant light scattering. This approach provides an ideal testbed to study electron-phonon interactions and to implement optomechanical control schemes. I show that the dynamic strain field of the acoustic wave modulates the dot's sharp optical transition at gigahertz frequencies enabling precisely triggered single photon emission and the generation of phononic sidebands in the optical spectrum. When combining two acoustic waves of different frequencies, spectral components are programmed by coherent wave mixing of photons and phonons by the quantum dot. I will discuss the experimental observations using a simple model of coupled phonon emission and absorption processes obeying well-defined phase matching conditions.

Location: H2

### Interplay of Substrate Adaptivity and Wetting Dynamics from Soft Matter to Biology (SYSM)

jointly organised by the Chemical and Polymer Physics Division (CPP), the Biological Physics Division (BP), and the Dynamics and Statistical Physics Devision (DY)

Uwe Thiele Institut für Theoretische Physik Westfälische Wilhelms-Universität Münster u.thiele@uni-muenster.de Karin John Laboratoire Interdisciplinaire de Physique Université Grenoble Alpes, CNRS karin.john@univ-grenoble-alpes.fr

Stefan Karpitschka AG Grenzflächen komplexer Flüssigkeiten Max-Planck-Institut für Dynamik & Selbstorganisation Göttingen stefan.karpitschka@ds.mpg.de Ralf Seemann AG Geometrie fluider Grenzflächen, Experimentalphysik Universität des Saarlandes Saarbrücken ralf.seemann@ds.mpg.de

The basic understanding and practical application of the coupled dynamics of a (de)wetting liquid and adaptive soft substrates is attracting increasing interest in fields spanning chemical and biological physics, material science, and hydrodynamics. Examples of substrates include flexible elastomers or hydrogels that form dissipation-rich wetting ridges, polymer brushes that adapt their wettability and mechanical properties by absorbing liquid, or membraneless organelles in a biological cell whose creation and manipulation involves their adhesion to flexible membranes. Wetting interactions may also be manipulated by spatio-temporally structured external fields allowing, for example, wettability-switching triggered by electric fields or light irradiation. In all these systems, capillary and wetting energies interact with elastic properties, possible decomposition and mixing processes as well as absorption, adsorption and desorption processes resulting in feedback mechanism that influence the static and dynamic behaviour of the liquid-substrate system.

In general, one can say that intricate multiscale dynamics results from the coupling of different non-equilibrium processes, that is various mechanisms of energy dissipation may dominate on different time- and length scales, ultimately determining the dynamic behaviour. Furthermore, the interplay of several degrees of freedom offers new possibilities for a targeted control of dynamic wetting processes, but also poses new challenges for experimental investigation and theoretical description: Recent developments in length-scale-bridging experimental techniques allow for in situ (and in vivo) visualisation enabling quantitative analysis while methods from statistical physics to computational fluid and solid dynamics give unprecedented multiscale insight.

### SYSM 1: Interplay of Substrate Adaptivity and Wetting Dynamics from Soft Matter to Biology

Time: Wednesday 15:00-17:45

### Invited Talk SYSM 1.1 Wed 15:00 H1

# **Statics and Dynamics of Soft Wetting** — •BRUNO ANDREOTTI — LPENS, 24 rue Lhomond, 75005 Paris

The laws of wetting are well-known for drops on rigid surfaces, but these change dramatically when the substrate is soft and deformable. The combination of wetting and the intricacies of soft polymeric interfaces has provided many rich examples of fluid-structure interaction, both in terms of phenomenology as well as from the fundamental perspective. In this colloquium, I will discuss experimental and theoretical progress on the statics and dynamics of soft wetting. In this context, I will critically revisit the foundations of capillarity, such as the nature of solid surface tension, the microscopic mechanics near the contact line, and the dissipative mechanisms that lead to unexpected spreading dynamics.

# Invited Talk SYSM 1.2 Wed 15:30 H1 Droplets on elastic substrates and membranes - Numerical simulation of soft wetting — •SEBASTIAN ALAND — TU Freiberg, Germany

Wetting of flexible substrates plays a major role in a broad variety of phenomena. The interaction between droplets and their surrounding is at small length scales dominated by surface tension forces. These forces may lead to significant deformation of the surrounding structure if either very soft or very thin (e.g. a biological membrane). The interplay between wetting dynamics and structure mechanics leads to a range of fascinating phenomena from stick-slip motion to droplet-mediated remodeling of membranes.

In this talk, we present a computational model which is capable to shed some light on such elastocapillary phenomena. The model captures the interaction between two immiscible fluids and a soft structure or membrane. The discretization is based on a combination of a phase-field model with a moving finite-element grid. In numerical tests we demonstrate that this novel method is robust, flexible and accurate. We confirm analytical theory of droplet surfing on Kelvin-Voigt substrates and find an explanation for the experimentally observed stick-slip phenomenon. Finally, we present first simulations of droplet-mediated membrane remodeling.

SYSM 1.3 Wed 16:00 H1

Wetting of Polymer Brushes in Air — LARS VELDSCHOLTE, GUIDO RITSEMA VAN ECK, LIZ MENSINK, JACCO SNOEIJER, and •SISSI DE BEER — Sustainable Polymer Chemistry Group, Department of Molecules & Materials, MESA+ Institute for Nanotechnology, University of Twente, P.O. Box 217, 7500 AE Enschede, The Netherlands

For the development of brush-based functional surface-coatings, it is critical to understand their properties, because they will determine their performance and user-experience. Polymer brush wetting is a key parameter in this. In this presentation we will show that brushes can display counter-intuitive wetting properties. We aim to unravel those by combining molecular dynamics simulations, contact angle goniometry and ellipsometry laboratory experiments.

Location: H1

**Elastocapillary phenomena in cells** — •ROLAND L. KNORR — Interfacial Cell Biology Lab, Integrative Research Institute for the Life Sciences, Humboldt-Universität zu Berlin, Germany — Graduate School and Faculty of Medicine, The University of Tokyo, Japan

Compartmentalisation is essential for eukaryotic cell function, allowing the division of processes into membrane-bound, specialised compartments, such as organelles. In recent years, intracellular phase separation has garnered much attention as a non-membrane means of organising components through the formation of droplet-like compartments, which are functionally implicated in both health and disease. Evidence suggests that droplet clearance involves autophagy, a highly-conserved cellular recycling system in which membrane sheets expand and bend to isolate and degrade portions of the cell interior.

Here, we investigate the mechanisms of droplet sequestration by membrane sheets in both living and synthetic cells. A minimal theoretical model shows that the surface tension of wetting droplets determines whether membrane sheets isolate the droplet phase in a whole or piecemeal fashion. We also find that wetting droplet induce local membrane spontaneous curvature changes, resulting in the reversal of the bending direction of membrane sheets and, thus, in cytosol sequestration [Nature 2020, 2021]. Further, we demonstrate that the morphogenesis of protein storage vacuoles in plants underlies similar physical principles [PNAS, JCB 2021]. I propose that droplet-mediated autophagy and vacuole remodelling represent a novel class of cellular processes driven by elastocapillary.

#### SYSM 1.5 Wed 17:15 H1

Active contact line depinning by micro-organisms spreading on hydrogels — MARC HENNES^{1,2}, JULIEN TAILLEUR^{1,3}, GAËLLE CHARRON¹, and •ADRIAN DAERR¹ — ¹Université Paris Cité, UMR 7057 Matière et Systèmes Complexes, Frankreich — ²Universität zu Köln, Institut für Biologische Physik — ³CNRS, Frankreich

Capillary forces, capable of pinning millimetre-sized water droplets on inclined surfaces, become enormous at the bacterial scale, exceeding typical propulsion forces of microbes by several orders of magnitude. It is thus fascinating to explore the tricks that micro-organisms have evolved to overcome contact line pinning and spread across substrates. I will discuss specifically the spreading of bacteria (*Bacillus subtilis*) across agar hydrogels.

Recently we discovered a mode of collective bacterial motility in humid environment through the depinning of bacterial droplets[1]. Bacteria harness a variety of phenomena, drawing both on the porosity and the softness of the substrate, that result in unpinning the contact line, hence inducing a collective slipping of the colony across surfaces at slopes that can be as small as 0.5°. The exploited microscopic mechanisms could play a role in other contexts, including biofilm formation and flagella dependent migration modes like swarming, and highlight the possibilities of tuning the wetting dynamics on soft porous substrates.

Collective opinion formation, emergence of hierarchies and collective dynamics on markets are typical phenomena both of bacterial and animal as well as of socio-ecomomic communities. Statistical physics concepts widely contributed to the understanding of such nonlinear collective phenomena. Collective movement of humans in public space have been an early studied dynamics of active Brownian motion. This symposium integrates individual modeling of human and animal behaviour, movement and mobility, opinion formation, information processing and group interations towards an understanding of the self-organizing dynamics in societies.

Capturing group interactions: The next frontier of modeling social and biological systems — •FRANK SCHWEITZER — Chair of Systems Design, ETH Zürich, Switzerland

Complex social and biological systems comprised of many interacting agents are often represented as networks. This implies to decompose interactions between many agents into concurrent dyadic interactions of pairs of agents. Such a reduction is recently challenged with different approaches, which are addressed in this talk: (i) temporal network models reflect the causal relation between interactions occuring at different time steps, (ii) hyperedge network models capture group interactions by constructing higher-order networks, (iii) inference network models reveal information hidden behind observed interaction patterns. Combined, we obtain a very rich picture of social structures that emerge and adapt at different time scales and at different size levels (dyads, groups, communities, networks). Two examples of real-world social organizations (Bechstein bats, software developers) are used to illustrate our insights.

# Invited TalkSYSO 1.2Thu 10:00H1Modelling Individual Mobility Behavior• LAURA MARIA ALESSANDRETTI— Technical University of Denmark, Copenhagen, Denmark

From choosing a restaurant for dinner, to deciding whether to cycle or drive, spatial decisions are ubiquitous in human day-to-day lives. Taken together, these choices underlie critical societal phenomena, including the spread of epidemics, traffic congestion, and the emergence of urban segregation. In this talk, I will present recent empirical findings on the mechanisms underlying individual mobility behaviour, made possible by the study of comprehensive, high-resolution mobility data, and modelling approaches. The talk will touch upon key aspects in mobility, such as the interplay between exploration and exploitation, the effect of cognitive constraints, the relation between social and spatial behavior, and the effect of spatial scales. I will conclude with a perspective on open questions and future directions.

#### Invited Talk SYSO 1.3 Thu 10:30 H1 Validating argument-based opinion dynamics with survey experiments —

•SVEN BANISCH — Karlsruhe Institute of Technology, Institute of Technology Futures, Germany

We combine experimental research on the biased processing of arguments with a computational theory of collective opinion dynamics. While the biased processing of arguments has been frequently reported in social-psychological literature, its integration into argument-based models of opinion dynamics has been missing. In this paper we operationalize the argument communication process employed in these models in conjunction with an experimental design developed to measure biased processing and the resulting attitude changes in the context of energy production technologies. This allows us to analytically compute the expected attitude change through exposure to an unbiased set of arguments for different strengths of biased processing. Calibrating the microlevel assumptions with the experimental data shows a clear signature of moderate biased processing. We further extend the model by incorporating an unbiased external information source providing random arguments at a certain rate (as opposed to receiving arguments from others). The macroscopic opinion distributions emerging from this at the collective level are one-sided clearly in favor

# (green) or against (coal) a technology and match the surveyed attitudes if we control for the impact of social influence. Sociological model-building reveals that the relationship between biased processing and attitude polarization is not as direct as typical assumed in the psychological literature.

SYSO 1.4 Thu 11:15 H1

Self-organization, Criticality and Collective Information Processing in Animal Groups — •PAWEL ROMANCZUK — Insitute for Theoretical Biology, Department of Biology, Humboldt Universität zu Berlin, Germany — Bernstein Center for Computational Neuroscience, Berlin — Research Cluster of Excellence "Science of Intelligence", Berlin

Collective behavior of animals is a fascinating example of self-organization in biology. In contrast to non-living physical systems, collective animal behavior and the underlying social interactions are the result of evolutionary adaptations. Being and acting in a group is believed to confer fitness benefits to individuals, for example by promoting exchange of social information, accurate collective decisions, or protection from predators. In this context, it has been argued that animal collectives should operate in a special parameter region close to critical points, i.e. close to phase transitions between different collective states, where various aspects of collective information processing become optimal. Here, we will investigate the *criticality hypothesis* for animal collective behavior from different angles by combining model simulations together with laboratory and field experiments on collective predator response in fish.

#### Invited Talk

SYSO 1.5 Thu 11:45 H1

**Collective dynamics and physiological interactions in bird colonies** — •HANJA BRANDL — University of Konstanz, Konstanz, Germany — Max Planck Institute of Animal Behavior, Konstanz, Germany — University of Zurich, Zurich, Switzerland

Social behaviours can help animals survive in harsh and unpredictable environments by giving them access to information about where resources are or the presence of predators. To reap these benefits requires individuals to form and maintain social bonds with others, then enabling them to coordinate key activities such as foraging together or to synchronise reproduction. However, the social networks that form among individuals promote not only benefits. Social connectivity can also have negative consequences, such as the transmission of physiological stress from one individual to another. As humans, we have all experienced situations where interacting with stressed friends or family members has made us feel stressed ourselves. As the stress response is highly conserved across vertebrates, it is highly likely that stress transmission is common in other animal societies and could amplify the effects of stress exposure in animal collectives; yet, its consequences remain almost completely unexplored.

In this talk, I present findings from my research on avian societies in the wild and the laboratory, using behavioural experiments and fine-scale tracking to unravel the mechanisms, functions, and consequences of birds' social bonds. I discuss methods, frameworks, and limitations in studying animal social networks using examples from my work on zebra finches, but will also give an outlook into other study systems.

### Symposium United Kingdom as a Guest of Honor (SYUK)

organised by the DPG Condensed Matter Section (SKM)

Martin Wolf Fritz Haber Institute of the Max Planck Society Faradayweg 4-6 14195 Berlin wolf@fhi-berlin.mpg.de

The "Guest of Honor" symposia celebrates the European physics community in general and the links in science across Europe. Thereby, the German Physical Society aims to foster collaborations between individual scientists, research groups and institutions.

This year's "Guest of Honor" symposium honors the numerous ties between United Kingdom and Germany (beyond Brexit) by highlighting five fields of common interest. Each is represented by a pair of Invited Talks from distinguished scientist from UK and Germany.

Structure and Dynamics of Interfacial Water — •ANGELOS MICHAELIDES — University of Cambridge, Cambridge, UK

There are few molecules, if any, more important than water. However, remarkably little is known about how it interacts with surfaces, particularly at the molecular level. In this talk I will discuss some of our recent work on the application and development of a variety of state of the art computer simulation methods to better understand the structure and dynamics of water at surfaces and under confinement. Specific topics discussed will include work carried out in collaboration with experimentalists to understand the growth and diffusion of ice clusters at metal surfaces, heterogenous ice nucleation, and water confined within 1and 2-dimensional membranes. Methodological developments aimed at providing more accurate treatments of adsorption on and bonding within solids will also be covered, as well as an efficient machine learning strategy for simulating complex aqueous interfaces.

#### Invited Talk

SYUK 1.2 Wed 10:00 H2 A molecular view of the water interface — •MISCHA BONN — Max Planck, Mainz, Germany

Water surfaces and interfaces are ubiquitous, not just in nature, but also in many technological applications. Water is a rather unique liquid, owing to its strong intermolecular interactions: strong hydrogen bonds hold water molecules together. At the surface of water, the water hydrogen-bonded network is abruptly interrupted, conferring distinct properties on the interface, compared to bulk. I will present some challenges and progress in the study of interfacial water. Specifically, I will address how to study the ~1 monolayer of water molecules that is in direct contact with the other phase, and distinguish this ~Angstromthin layer from the bulk. The question rises how large the interface is. And can we describe the interfacial region as a modified dielectric continuum, or do we need to consider molecular structure?

#### Invited Talk

SYUK 1.3 Wed 10:30 H2

Motile cilia waves: creating and responding to flow - •PIETRO CICUTA -

University of Cambridge, Cambridge, UK Motile cilia are active filaments present on the surface of various human organs, where they perform crucial functions by driving surface flows. Structurally, they are conserved across the eukaryotes. Cilia can affect each other, for example leading to phase locking of their beating, by the forces they exert on each other through the fluid and in some cases through the cell cytoskeleton.

Some beautiful physics has been developed by various teams in the last decade to understand how the details of beating on each cilium can lead to specific phase locking, and to the emergence of collective waves. In recent work we have explored the role of external flows, both oscillatory and constant. Analogies can be drawn between these flows and the effect of external magnetic fields in magnetic systems.

We present both experimental results, and numerical explorations of a simple class of "rower" models of motile cilia.

SYUK 2.1 Wed 15:00 H2 Hysteresis Design of Magnetic Materials for Efficient Energy Conversion -•OLIVER GUTFLEISCH — TU Darmstadt, Material Science

High performance permanent magnets are key components of energy-related technologies, such as direct drive wind turbines and e-mobility. They are also important in robotics and automatization, sensors, actuators, and information technology. The magnetocaloric effect is the key for new and disruptive solid state-based refrigeration. Magnetic hysteresis and its inherent energy product - characterises the performance of all magnetic materials. Despite considerable progress in the modelling, characterisation and synthesis of magnetic materials, hysteresis is a long-studied phenomenon that is still far from being completely understood. Discrepancies between intrinsic and extrinsic magnetic properties remain an open challenge and magnets do not operate yet at their physical limits. Basic material requirements, figure of merits, demand and supply, criticality of strategic elements are explained for both permanent magnets and magne**Invited Talk** 

SYUK 1.4 Wed 11:00 H2

Location: H2

Cilia and flagella: Building blocks of life and a physicist's playground -•OLIVER BÄUMCHEN — Chair of Experimental Physics V, University of Bayreuth, Bavreuth, Germany

Flagella and cilia are actively beating, hair-like cellular appendages that represent universal building blocks of life. They inherit various essential functions that range from driving fluid flows in the mammalian brain and transporting mucus in the respiratory tract to realizing microbial motility and navigation through complex environments. While large-scale flows are achieved through the coordination of dense ciliary carpets, only a few isolated flagella are needed in order to propel a single-celled microorganism. These flagella displace the surrounding fluid by means of periodic motions, while precisely timed modulations of their beating enable the cell to steer towards or away from specific locations. In this presentation I will focus on the interactions of flagella with interfaces and elucidate how physical principles advance our understanding of microbial motility and emergent phenomena in microbial suspensions. Microorganisms that are equipped with photoreceptors may adapt their flagella beating and also actively switch their flagella-surface interactions in response to light cues. These skills allow photoactive microorganisms to effectively adapt to variable light conditions in their natural habitats and make flagellated microbes a fascinating playground for physicists.

SYUK 1.5 Wed 11:45 H2 Computational modelling of the physics of rare earth - transition metal permanent magnets from SmCo_5 to  $Nd_2Fe_{14}B - \bullet$ Julie Staunton — University of Warwick, Coventry CV4 7AL, U.K.

Magnetic materials are ubiquitous, technologically indispensable and a deeper understanding of the physics is needed for the design of new permanent magnets. Most strong magnets contain both rare earths (RE) and transition metals (TM) and this talk will describe recently developed ab initio modelling of intrinsic properties. Each RE atom has a magnetic moment, set up by its nearly localised f-electrons, immersed in a glue of septillions of valence electrons coming from all the RE and TM atoms. Local magnetic moments associated with the TM atoms also emerge from this complex electron fluid. The magnetic properties stem from the behaviour of the RE and TM local moments, the atomic arrangements and on the overall response to applied fields. Ab initio Density Functional Theorybased Disordered Local Moment (DLM-DFT) theory provides a parameter-free, accurate account of the electrons and incorporates the effects of the fluctuating local moments by averaging over them to describe temperature dependent effects. After demonstrating the computational modelling with calculations of the light RE-Co₅ permanent magnet class, the rich and complex behaviour associated with the Fe atoms in Nd₂Fe₁₄B will be described together with its role in determining the hard magnetic properties of this champion magnet.

tocalorics referring to the benchmark materials NdFeB and LaFeSi. The search for perfect defects is driving the material design strategy.

Non-equilibrium dynamics of many-body quantum systems versus quantum technologies — •IRENE D'AMICO — University of York, York, UK

Quantum technologies take advantage of properties developed by quantum systems when driven out of equilibrium. For example, quantum computation is based on an accurate, controlled driving of these systems to perform specific dynamics which produce entanglement, compute basic gates, and eventually leads to the completion of a numerical algorithm. Thermal fluctuations are often an enemy which spoils the controlled out-of-equilibrium dynamics. On the other

Location: H2

side, quantum thermodynamics takes advantage of thermal - and quantum fluctuations to create engines and refrigerators of sizes well below the thermodynamic limit and properties still under discussion. In this talk we will first focus on engineering robust properties for distributed quantum computing using spinnetworks [1]: here the twist is not to drive the out-of-equilibrium dynamics, but let the system Hamiltonian do the job. We will then turn up the temperature, and consider a less-explored aspect of quantum thermodynamics, that is the effects and signatures of many-body interactions on few-electrons' quantum machines [2].

SYUK 2.3 Wed 16:00 H2 Quantum computing with trapped ions — •Ferdinand Schmidt-Kaler -QUANTUM, Uni Mainz

Quantum technologies allow for fully novel schemes of hybrid computing. We employ modern segmented ion traps. I will sketch architectures, the required trap technologies and fabrication methods, control electronics for quantum register reconfigurations, and recent improvements of qubit coherence and gate performance. Currently gate fidelities of 99.995% (single bit) and 99.8% (two bit) are reached. We are implementing a reconfigurable qubit register and have realized multi-qubit entanglement [1] and fault-tolerant syndrome readout [2] in view for topological quantum error correction [3], since current aim is to leave the noisy area of quantum computing. Complementary to gate tomography, we employ thermodynamically-inspired methods within the frameworks of global passivity and passivity deformation where system qubits undergoing unitary evolution but may optionally be coupled also to an unobserved environment qubit, resulting in a heat leak [4].

Invited Talk SYUK 2.4 Wed 16:45 H2 Breaking the millikelvin barrier in cooling nanoelectronic devices — •RICHARD HALEY — Physics Department, University of Lancaster, Lancaster LA1 4YB, UK

Over the last several years a number of groups across Europe have been developing techniques to cool the electrons in nano-fabricated devices to sub-

mK temperatures. Cooling device electrons into the microkelvin regime, below the canonical limit of around 10 millikelvin, enhances sensitivity for observing known and new physical phenomena, and improves the performance of quantum technologies, sensors and metrological standards.

There are two main challenges. First, one must provide a technique which will deliver electron temperatures colder than a dilution refrigerator and which is relatively easy to implement. Currently the microkelvin regime is really only accessible in specially dedicated labs. Second, one must understand the thermal links between the microkelvin cooling platform and the electrons in the device of interest, bearing in mind that nanoscale systems are typically also more susceptible to nuisance heating than bulk materials. Progress has been made with three methods and combinations thereof: immersion cooling in liquid helium; demagnetisation cooling of electrical leads and contacts; and the demagnetisation of material deposited directly onto device chips.

Here we review the current state-of-the-art in cooling nanoelectronic devices, and ways to make the techniques easier to adapt and adopt.

SYUK 2.5 Wed 17:15 H2 Invited Talk Superconducting Quantum Interference Devices for applications at mK temperatures — •SEBASTIAN KEMPF — Institute of Micro- and Nanoelectronic Systems, Karlsruhe Institute of Technology, Hertzstraße 16, 76187 Karlsruhe, Germany.

Superconducting quantum interference devices (SQUIDs) are among the most sensitive wideband devices for measuring any quantity that can be naturally converted into magnetic flux. They are intrinsically compatible with Kelvin and sub-Kelvin operation temperatures, offer great sensitivity to even tiniest signals and often show a noise level close to the quantum limit. For this reason, SQUIDs are routinely used for various applications such as investigating magnetic nanoparticles, diagnostics in health care, "non-invasive" mineral deposit exploration, low-field magnetic resonance imaging, quantum information processing or the readout of low-impedance cryogenic particle detectors. However, SQUID based measurements are susceptible to suffer from parasitic Joule heating, often preventing to reach very low sub-K temperatures.

Using the example of cryogenic low-impedance detectors, we discuss strategies to minimize parasitic SQUID Joule heating to ultimately operate singlechannel detectors as well as mid- and large-scale detector arrays at lowest mK temperatures. We particularly show that on-chip thermal decoupling of shunt resistors and sample environment or dispersive SQUID readout allow for performing SQUID based measurements down to very low temperatures. Moreover, we discuss a SQUID based multiplexer allowing for simultaneous readout of hundreds and thousands of signal sources with only several nW of power.

### Sessions

- Invited Talks, Prize Talks, Tutorials, Contributed Talks, and Posters -

### BP 1: Tutorial: Stochastic Processes from Financial Risk to Genetics (joint session SOE/TUT/BP/DY)

Macroscopic and microscopic models from Economy to Biology must account for stochasticity on various levels. While classical physics strives for deterministic descriptions through differential equations from fundamental level to thermodynamics, many physics-based models on higher level explicitely include stochasticity from various sources. Discrete and continuous stochastic processes then become the mathematical foundation of these models. This tutorial highlights classical as well as current methods and approaches of probabilistic models and stochastic processes in physics, biology as well as socio-economic systems, thereby bridging the risk to extinction in genetics with its economic counterpart. (Session organized by Jens Christian Claussen.)

Time: Sunday 16:00-18:30

See SOE 1 for details of this session.

### **BP 2: Computational Biophysics and Neuroscience**

Time: Monday 9:30-12:15

BP 2.1 Mon 9:30 H13 Non-ideality in lipid mixtures, a molecular dynamics study — •LISA BEREZOVSKA¹, FABRICE THALMANN¹, and RAISA KOCIURZYNSKI² — ¹Institut Charles Sadron, CNRS and University of Strasbourg, 23 rue du Loess, F-67034 Strasbourg, France — ²Faculty of Biology, Albert-Ludwigs-University Freiburg, Schänzlestraße 1, 79104 Freiburg, Germany

Biological membranes are complex environments characterized by multicomponent lipid mixtures[1]. We investigate in this work binary lipid bilayers using the SPICA coarse-grained molecular dynamics model.

Adapting the Kirkwood-Buff theory of liquid mixtures [2] to finite wavelegth density fluctuations statistics, we compare various practical approaches for determining the interaction parameters in a theory of regular solution description of these numerical lipid mixtures.

BP 2.2 Mon 9:45 H13

Membrane-mediated interactions between non-spherical elastic particles — •JIARUL MIDYA, THORSTEN AUTH, and GERHARD GOMPPER — Theoretical Physics of Living Matter (IBI-5/IAS-2), Forschungszentrum Jülich, D-52425 Jülich,Germany

Transport of particles across lipid-bilayer membranes is important for biological cells to exchange information and material with the environment. Large particles often get wrapped by membranes [1]. However, many particles in vivo and in vitro are deformable, e.g., vesicles, filamentous viruses, macromolecular condensates, polymer-grafted nanoparticles, and microgels. Vesicles may serve as a generic model system for deformable particles [2]. Using the Helfrich Hamiltonian, triangulated membranes, and energy minimization, we predict the interplay of vesicle shapes and wrapping states. Increasing particle softness enhances the stability of shallow-wrapped and deep-wrapped states over non-wrapped and complete-wrapped vesicles. For the deep-wrapped vesicles, we predict a purely repulsive interaction. For shallow-wrapped states, interaction potential depends on the mutual orientation of the vesicles. Our predictions may guide the design and fabrication of deformable particles for efficient use in medical applications, such as targeted drug delivery.

### BP 2.3 Mon 10:00 H13

**RNA structure prediction via Machine Learning** — •Alexander Schug^{1,2}, Oskar Taubert⁴, Christian Faber¹, Mehari Zerihun¹, Fabrizio Pucci¹, Fabrice von der Lehr³, Philipp Knechtges³, Marie Weiel^{4,5}, Charlotte Debus^{4,5}, Daniel Coquelin^{4,5}, Stefan Kesselheim^{1,5}, Achim Basermann³, Achim Streit⁴, and Markus Götz^{4,5} — ¹Jülich Supercomputing Centre, FZ Jülich, Jülich — ²Faculty of Biology, University of Duisburg/Essen — ³Institute

for Software Technology, German Aerospace Centre (DLR) —  4 Steinbuch Centre for Computing, Karlsruhe Institute of Technology —  5 Helmholtz AI

Knowledge of biomolecular structure is necessary to gain any detailed understanding of their function For proteins, tools rooted in statistical physics such as Direct Coupling Analysis (DCA) or Machine Learning driven approaches (ML) such as Alpha Fold 2 exploit massive sequence databases to trace evolutionary patterns for structure predictions. We demonstrate how additional information, such as low-resolution experimental information (e.g. SAXS or FRET) can integrated. For RNA there are significantly less data available than for proteins, which makes ML more challenging. Still, we demonstrate how contact prediction for RNA can be vastly improved both via simple convolutional neural networks but also by unsupervised deep-learning approaches by combining multiple self-supervised learning tasks. In an empirical evaluation for RNA, we find a strong increase of prediction quality.

### Invited Talk

BP 2.4 Mon 10:15 H13

**Integrative modeling of dynamic biomolecular structures** — •HOLGER GOHLKE — Institute for Pharmaceutical and Medicinal Chemistry, Heinrich Heine University Düsseldorf, 40225 Düsseldorf, Germany — John von Neumann Institute for Computing (NIC), Jülich Supercomputing Centre (JSC), Institute of Biological Information Processing (IBI-7: Structural Biochemistry), and Institute of Bio- and Geosciences (IBG-4: Bioinformatics), Forschungszentrum Jülich GmbH, 52425 Jülich, Germany

Structures of biomacromolecules and their complexes are essential to understand the underlying molecular mechanisms of the biological processes. If biomolecular systems are complex, information from multiple experimental and computational methods is combined by integrative modeling (IM) for generating integrative structure models. We will describe how molecular modeling and simulations contributed to a high-resolution NMR characterization of all apparent states of the prototypic 10*23 DNAzyme and to rationally selecting a single-atom replacement, with which the performance of the DNAzyme could be considerably enhanced. Furthermore, we will address how to overcome the sparsity of FRET experiments to provide state-specific structural information of complex dynamic biomolecular assemblies and probe the robustness of Maximum Entropy Method reconstructions for a flexible system with ordered parts using FRET data as experimental information.

### 15 min. break

### BP 2.5 Mon 11:00 H13

**Mechanical stimulation in stem cell-derived 3D neuronal networks** – •ELIJAH SHELTON¹, KATJA SALBAUM^{1,2}, FILIPPO KIESSLER¹, PAULINA WYSMOLEK³, SELINA SONNTAG¹, and FRIEDHELM SERWANE^{1,2,4} – ¹Faculty of Physics and Center for NanoScience, Ludwig-Maximilians-Universität, Munich, Germany – ²Graduate School of Systemic Neuroscience (GSN), Munich, Germany – ³Max Planck Institute for Medical Research, Heidelberg, Germany – ⁴Munich Cluster for Systems Neurology (SyNergy), Germany

Neurons sense and respond to mechanical factors in their local microenvironment. For example, firing activity is modulated in response to amplitude and location of a mechanical stimulation as single cell in vitro experiments have shown.

Location: H13

Location: H4

However, it is unclear (i) how these observations translate to the scale of neuronal tissues and (ii) how mechanical stimulation informs the formation and function of neurons in 3D networks. To tackle this problem, we combine stem cell-derived neuronal organoids, magnetic droplets as mechanical actuators, and calcium imaging as tool for neuronal characterization. Using 30-50 micron diameter magnetic droplets, we produce controlled and precise mechanical stimulations inside these 3D tissues. We visualize electrophysiological activity within these networks using genetically encoded calcium sensors and confocal fluorescence microscopy. Here, I present recent mechanical and electrophysiological measurements within these neuronal organoids. Such kinds of recordings might provide insights into how mechanical forces can influence both form and function of neuronal networks.

### BP 2.6 Mon 11:15 H13

Characterizing spreading dynamics of subsampled systems with nonstationary external input — JORGE DE HEUVEL¹, JENS WILTING², MORITZ BECKER³, VIOLA PRIESEMANN², and •JOHANNES ZIERENBERG² — ¹University of Bonn, Bonn, Germany — ²Max Planck Institute for Dynamics and Self-Organization, Göttingen Germany — ³University Medical Center Göttingen, Göttingen Germany

Many systems with propagation dynamics, such as spike propagation in neural networks and spreading of infectious diseases, can be approximated by autoregressive models. The estimation of model parameters can be complicated by the experimental limitation that one observes only a fraction of the system (subsampling) and potentially time-dependent parameters, leading to incorrect estimates. We show analytically how to overcome the subsampling bias when estimating the propagation rate for systems with certain nonstationary external input. This approach is readily applicable to trial-based experimental setups and seasonal fluctuations as demonstrated on spike recordings from monkey prefrontal cortex and spreading of norovirus and measles.

BP 2.7 Mon 11:30 H13 Mesoscopic description of metastability and hippocampal replay in neural networks with short-term plasticity — BASTIAN PIETRAS¹, VALENTIN SCHMUTZ², and •TILO SCHWALGER³ — ¹Universität Pompeu Fabra, Barcelona, Spain — ²Brain Mind Institute, School of CÉcole Polytechnique Fédérale de Lausanne (EPFL), Lausanne, Switzerland — ³Technische Universität Berlin

Sequences of metastable states in neuronal population activities have been linked to various sensory and cognitive functions. Two prominent mechanisms of metastable dynamics are noise-induced transitions among attractors and deterministic transitions induced by slow fatigue processes. The dependence of these mechanisms on neural circuit parameters at the microscopic scale are largely unclear. Starting with a network of linear-nonlinear Poisson spiking neurons with synaptic short-term plasticity, we use a bottom-up approach and derive a stochastic neural-mass model at the mesocopic scale that links to the microscopic circuit parameters. We apply the mesoscopic model to investigate hippocampal "replay" events, i.e. spontaneous sequences of metastable activations of place cells. We study a spiking-neural-network for depression-induced metastability of place-cell activity. The corresponding mesoscopic model precisely reproduces the statistics of metastastable events in the microscopic network model. This enables us to efficiently explore the full range of neuron numbers including the thermodynamic limit. We find a novel dynamical regime in finite-size networks where metastable replay events are fluctuation-driven and exhibit biologically plausible irregularity.

### BP 2.8 Mon 11:45 H13

## **Decision-making and dynamics in a small neural network** — •MONIKA SCHOLZ — Max Planck Institute for Neurobiology of Behavior - caesar

The nematode C. elegans feeds on small microbes which it ingests using a pumping action of the pharynx. Its pharyngeal nervous system, which controls feeding, comprises only 20 neurons. We aim to understand how the animal adapts its feeding rate to environmental conditions and metabolic needs, using a combination of theoretical modelling, voltage imaging and behavioral observations. When imaging the animals feeding behavior we identify two modes of regulating food intake: First, we find burst-pause dynamics which we link to a decisionmaking process where the animal attempts to measure the external food concentration. We also find a second mode of action, in which the pumping frequency is smoothly adapted to reflect the quality of the available food. Using a conductance model of the pharyngeal muscle and its key regulatory circuit, we ask which of these modes of regulation are in the muscular excitability and which are driven by phasic inputs by the nervous system. We will discuss the utility of this small nervous system in understanding computational principles connecting neural activity to behavior.

### BP 2.9 Mon 12:00 H13

Available processing time regulates optimal balance between sensitivity and precision — SAHEL AZIZPOUR¹, •JOHANNES ZIERENBERG², VIOLA PRIESEMANN², and ANNA LEVINA³ — ¹Donders Institute for Brain, Cognition and Behavior, Nijmegen, Netherlands — ²Max Planck Institute for Dynamics and Self-Organization, Göttingen Germany — ³Eberhard Karls University of Tübingen, Tübingen, Germany

Solving everyday tasks naturally leads to a trade-off between the time spent on processing some input and the accuracy of the outcome. In particular, fast decisions have to rely on uncertain information about inputs. However, standard estimates of information processing capabilities, such as the dynamic range, are defined based on infinite-time averages that do not incorporate noise effects from finite processing times. Here, we develop estimates of processing capability that explicitly account for noisy outputs. We use these measures to show that limiting the processing time in recurrent neural networks can drastically affect the sensitivity and precision of outcomes. This way, optimal dynamical states shift away from the conventionally expected critical point toward subcritical states for finite processing times. Our results thus highlight the necessity to explicitly account for processing times in future estimates of information processing capabilities.

### **BP 3: Cell Mechanics 1**

Time: Monday 9:30–12:30

### Prize Talk

BP 3.1 Mon 9:30 H15

Basal tension in the wing disc epithelium - what's collagen got to do with it — KARLA YANIN GUERRA SANTIALLAN^{1,3}, CHRISTIAN DAHMANN², and •ELISABETH FISCHER-FRIEDRICH^{1,3,4,5} — ¹Cluster of Excellence Physics of Life, Technische Universität Dresden, Dresden, Germany — ²Institute of Genetics, Technische Universität Dresden, Dresden, Germany — ³Biotechnology Center, Technische Universität Dresden, Dresden, Germany — ⁴Faculty of Physics, Technische Universität Dresden, Dresden, Germany — ⁵Laureate of the Hertha-Sponer-Prize 2022

Healthy tissue morphogenesis is an important prerequisite for organ function. During development, epithelial folding is a major element of tissue morphogenesis. It has been shown that epithelial folding can be driven through a reduction of basal cell tension. However, a comprehensive analysis of the regulating factors of basal tension is still lacking. In this study, we use indentation with the cantilever of an atomic force microscope to estimate mechanical tension at the basal cell boundary in the wing disc epithelium of the 3rd instar larva of *Drosophila melanogaster*. We find that basal tension is not only affected by contractility of the actin cytoskeleton but is strongly influenced by the presence of the basement membrane as well as osmotic pressure. Our data suggest that elastic stresses in the basement membrane induced by basement membrane stretch, e.g. via osmotic swelling, may be a key factor in the adjustment of basal tension.

#### Location: H15

BP 3.2 Mon 10:00 H15

**Viscoelasticity of spherical cellular aggregates** — •ANTOINE GIROT^{1,2}, MARCIN MAKOWSKI¹, MARCO RIVETTI¹, CHRISTIAN KREIS^{1,3}, ALEXANDROS FRAGKOPOULOS^{1,2}, and OLIVER BÄUMCHEN^{1,2} — ¹Max Planck Institute for Dynamics and Self-Organization (MPIDS), 37077 Göttingen, Germany — ²University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany — ³Department of Physical and Environmental Sciences, University of Toronto, ON Toronto, Canada

Understanding the complexity of many biophysical processes such as the dynamics of biological tissues requires a proper mechanical characterization of multicellular aggregates. Current experimental techniques, however, are typically limited to systems that are not larger than an individual cell. We employ *in vivo* micropipette force measurements combined with optical detection to precisely measure the force response and the deformation of living organisms simultaneously. In this presentation, we use this approach to investigate the mechanical behaviour of *Volvox globator*, a multicellular aggregate composed of thousands bi-flagellated cells forming a spherical monolayer filled with mucilage. *Volvox* is considered a model system, *e.g.* to study the evolution from single cells to multicellular life. We show that a model that couples elastic and viscous components is in excellent agreement with the mechanical response of *Volvox* and therefore can be used to extract the viscoelastic properties. We find that the viscous component is rate-dependent and exhibits a shear-thinning behaviour, while the elasticity of the cellular monolayer depends on the size of the colony.

### BP 3.3 Mon 10:15 H15

Phase field model for the mechanics and migration of nucleated cells — •ROBERT CHOJOWSKI, ULRICH S. SCHWARZ, and FALKO ZIEBERT — Institute for Theoretical Physics and BioQuant, Heidelberg University, Germany

Eukaryotic cells are built from many different constituents of varying sizes and properties. Of these organelles, the nucleus is by far the largest one. During recent years, it has become clear that many cellular functions are modulated by the nucleus, including mechanosensing of the environment and cell migration in complex environments. Its stiffness has been determined by AFM and micropipette experiments to be up to 10-fold higher than the stiffness of the surrounding cytoplasm. Despite its physical and biological importance, the nucleus is often neglected in models for cell mechanics and migration. Here we extend our reversible elastic phase field method [1] by a compartment with nuclear elasticity. We validate our numerical implementation by comparing to the analytical solution of a homogeneously adhered disk-like cell. We then simulate the effect of the nucleus for several interesting experimental setups, in particular for cell migration through a narrow channel.

### BP 3.4 Mon 10:30 H15

**Mechanical Properties of the Premature Lung** – •JONAS NAUMANN¹, NICK-LAS KOPPE¹, ULRICH HERBERT THOME², MANDY LAUBE², and MAREIKE ZINK¹ – ¹Research Group Biotechnology and Biomedicine, Peter-Debye-Institute for Soft Matter Physics, Leipzig University, 04103 Leipzig, Germany – ²Center for Pediatric Research Leipzig, Department of Pediatrics, Division of Neonatology, Leipzig University, 04103 Leipzig, Germany

Even though mechanical ventilation is a life-saving therapy for premature infants suffering from respiratory distress syndrome, prolonged ventilation and related mechanical load may cause subsequent pulmonary diseases such as bronchopulmonary dysplasia. To study the effect of mechanical stress on the immature lung, premature rat lungs were subjected to rheology experiments in compression and tension at different velocities. Here, fetal lungs behaved significantly stiffer with increasing deformation velocities as also used during high-frequency ventilation. A higher Young's modulus of fetal rat lungs compared to adult controls clearly pointed towards altered tissue characteristics. Furthermore, influences of hydrostatic pressure differences on the electrophysiology of lung epithelial cells were studied with a pressure-adjustable Ussing chamber. We observed a strong impact of hydrostatic pressure on vectorial sodium transport, important for alveolar fluid clearance. These pressure-dependent cellular alterations might explain clinical observations of ventilation-induced side effects.

**Novel Optofluidic Particle Trap Enables FemtoNewton Force Sensing** — •ILIYA STOEV^{1,2}, BENJAMIN SEELBINDER^{1,2}, ELENA ERBEN^{1,2}, NICOLA MAGHELLI^{1,2}, and MORITZ KREYSING^{1,2,3} — ¹Max Planck Institute of Molecular Cell Biology and Genetics, Pfotenhauerstraße 108, 01307, Dresden, Germany — ²Centre for Systems Biology, Pfotenhauerstraße 108, 01307, Dresden, Germany — ³Cluster of Excellence Physics of Life, TU Dresden, Arnoldstraße 18, 01307, Dresden, Germany

Here we show how thermoviscous expansion phenomena can be used to generate a new contactless particle trap that is characterised by a linear force-extension relationship and can therefore be employed in non-invasively measuring femtoNewton forces with thermally limited sensitivity. Our new method combines optics with microfluidics, lifting prerequisites related to the probe material and resulting in only moderate heating at the position of the micromanipulated object. This offers an appealing alternative to the use of optical tweezers in highly delicate samples and living systems. As a follow-up work, we aim to explore the opportunity of using these thermoviscous flows in a novel phase-sensitive microrheology approach by building on the formalism established in classic bulk rheology. We anticipate that our new method would be of interest to material scientists and mechanobiologists alike as it provides a route towards measuring the mechanics of highly viscous media, tenuous gels and likely even cellular cytoplasm or embryonic ooplasm. Further refinements of the method aim at removing the need for using fluorescent tags and/or external probes.

### BP 3.6 Mon 11:15 H15

Theoretical model reveals significance of microtubules poleward flux in chromosome congression — •Ivan Sigmund, Domagoj Božan, and Nenad Pavin — University of Zagreb, Faculty of Science

At the onset of mitosis, a living cell forms mitotic spindle to ensure proper division of duplicated chromosomes between two daughter cells, whereas malfunctioning spindles can lead to chromosome missegregation. During prometaphase chromosomes are initially randomly distributed and in interaction with microtubules experience forces that congress them in spindle equator. Here we investigate what are the dominant forces that drive chromosome congression. By introducing a theoretical model, we show that length dependent poleward flux generates a net force towards the spindle equator. This poleward flux is generated by motor proteins which accumulate along the region of antiparallel microtubule overlaps. On the other hand, forces exerted by passive crosslinkers, that accumulate within the region of parallel microtubule overlaps, are off-centering, and can impair chromosome congression. Thus, our model reveals the significance of microtubule poleward flux in chromosome congression.

BP 3.7 Mon 11:30 H15

Red blood cell shape transitions and dynamics in time-dependent capillary flow — •KATHARINA GRAESSEL¹, STEFFEN M. RECKTENWALD², FELIX M. MAURER², THOMAS JOHN², CHRISTIAN WAGNER^{2,3}, and STEPHAN GEKLE¹ — ¹Biofluid Simulation and Modeling, Theoretische Physik VI, University of Bayreuth — ²Dynamics of Fluids, Experimental Physics, Saarland University — ³Physics and Materials Science Research Unit, University of Luxembourg

Red blood cells in small microchannels flow in characteristic shapes, mainly symmetric croissants at the channel center and non-symmetric off-centered slippers. While these shapes have been studied for some time, not much is known about the transition dynamics between different states. Here, we use boundaryintegral simulations together with microfluidic experiments in time-dependent flows to observe and understand red blood cell shape transitions. The transition from the croissant to the slipper shape happens much faster than the opposite transition. We find that the center of mass of slipper cells shows lateral oscillations due to the tank-treading movement of the RBC membrane. The oscillation frequency increases with the cell velocity and the viscosity of the surrounding fluid.

BP 3.8 Mon 11:45 H15

Elastic modulus of lipid-loaded platelets investigated with scanning ion conductance microscopy (SICM) — •HENDRIK VON EYSMONDT¹, JOHANNES RHEINLAENDER¹, MADHUMITA CHATTERJEE², and TILMAN E. SCHÄFFER¹ — ¹Institute of Applied Physics, Eberhard-Karls-University Tübingen, Germany — ²Department of Cardiology and Angiology, University Hospital Tübingen, Germany

Platelets are small, anucleate blood cells involved in blood hemostasis, wound healing, and immune response as well as in diseases like atherosclerosis and coronary artery disease. Both low-density lipoprotein (LDL) and its oxidized form (OxLDL) increase the prothrombotic potential of platelets. Recently, it was shown that a chemokine receptor ACKR3/CXCR7 agonist inhibits platelet activation and thrombus formation, offering a new therapeutic choice for hyperlipidemic patients. However, the impacts of LDL, OxLDL, and CXCR7-agonist on platelet morphology and mechanics have not yet been identified.

We therefore investigated the influence of LDL, OxLDL, and CXCR7-agonist on platelet morphology and mechanics using SICM. We showed that CXCR7agonist pre-treatment reduced the initial spreading rate on collagen, the final spreading area on both collagen and fibrinogen, and the elastic modulus on fibrinogen. We also showed that OxLDL, but not LDL, significantly alters the morphology and elastic modulus of lipid-loaded platelets and that CXCR7-agonist pretreatment can reverse some of the effects of OxLDL.

### BP 3.9 Mon 12:00 H15

Measuring the Tension of Droplets and Living Cells with the Scanning Ion Conductance Microscope — •JOHANNES RHEINLAENDER and TILMAN E. SCHÄFFER — Institute of Applied Physics, University Tübingen, Germany

It is well known that surface tension can dominate the mechanics of micro- and nanoscale systems. However, probing the mechanics of elastic interfaces at the micrometer scale can be difficult because of the complex probe-sample interactions or the unknown underlying geometry. Here, were introduce a method to measure the surface tension of interfaces at the micrometer scale in a contactfree manner using the scanning ion conductance microscope (SICM). The SICM is based on recording the ion current through a nanopipette and was recently extended to also measure the mechanical stiffness of soft samples utilizing a microfluidic flow through the nanopipette opening. By measuring the threedimensional shape and mechanical stiffness of oil droplets on various surfaces, we show that we can quantitatively measure their surface tension independently of their shape over more than three orders of magnitude. Applying this concept to living cells, we show that we can quantitatively measure their local stiffness and average (cortical) tension in a contact-free way. Living cells exhibit cortical tensions on the order of few mN/m, which we found to strongly vary with cell type and external conditions. For example, we show that normal and cancer cells strongly differ in their cortical tension, which demonstrates that the SICM is a versatile tool to measure the mechanical properties of living cells.

### BP 3.10 Mon 12:15 H15

The secret life of sarcomeres: stochastic heterogeneity of sarcomeres in beating stem-cell-derived cardiomyocytes — •DANIEL HÄRTTER^{1,2}, LARA HAUKE¹, WOLFRAM-HUBERTUS ZIMMERMANN¹, and CHRISTOPH F. SCHMIDT² — ¹Institute of Pharmacology and Toxicology, Göttingen University Medical Center, Germany — ²Department of Physics and Soft Matter Center, Duke University, Durham, NC, USA

Monday

Location: H16

Sarcomeres are the basic contractile units of cardiac muscles. We tracked single sarcomere motion in individual hiPSC-derived cardiomyocytes at high resolution, using a novel set of experimental and computational tools. While the emergent cell-level motion is smooth, individual sarcomeres are highly motile and behave heterogeneously during beating cycles. In response to rigid mechanical constraints, sarcomeres are forced into a tug-of-war-like competition. Automated, machine-learning-supported analysis of a large data set (>1200 cells) indicates that sarcomere heterogeneity is not caused by static non-uniformity between sarcomeres (e.g., strong/weak), but can be primarily attributed to the stochastic and non-linear nature of sarcomere dynamics and thus occurs intrinsically during cardiomyocyte beating. We show that a simple dynamic model reproduces crucial experimental findings by assuming a non-monotonic forcevelocity relation for single sarcomeres, as previously predicted for ensembles of motor proteins. This led us to a novel, active matter perspective on sarcomere motion, with sarcomeres as interacting, non-linear and stochastic agents, in contrast to the prevailing mechanistic view on muscle contraction.

### BP 4: Active Matter 1 (joint session BP/CPP/DY)

Time: Monday 10:30-12:45

### Invited Talk

BP 4.1 Mon 10:30 H16 Computer simulations of self-motile active droplets and colloid-active gels composites — •DAVIDE DAVIDE MARENDUZZO — School of Physics and Astronomy, University of Edinburgh, Edinburgh, UK

In this talk we will show results from computer simulations probing the behaviour of composite materials based on active gels.

In the first part of the talk we will investigate the behavior of active nematic or cholesteric droplets inside an isotropic fluid. In different regions of parameter space, we find regular motility and chaotic behaviour, and discuss the relevance of these results to biophysical systems such as microbial motility.

In the second part of the talk, we will study the dynamics of a dispersion of passive colloidal particles in an active nematic host. We find that activity induces a dynamic clustering of colloids even in the absence of any preferential anchoring of the active nematic director at the particle surface. When such an anchoring is present, active stresses instead compete with elastic forces and re-disperse the aggregates observed in passive colloid-liquid crystal composites.

### BP 4.2 Mon 11:00 H16

Chloroplasts in dark-adapted plants show active glassy behavior — •NICO SCHRAMMA, CINTIA PERUGACHI ISRAËLS, and MAZI JALAAL - University of Amsterdam, Amsterdam, Netherlands

Photosynthesis in plants is one of the main drivers for the survival of whole ecosystems on earth. To guarantee the efficiency of this process, plants have to actively adapt to ever-changing light conditions. On large time scales plants can grow towards the light. However, this process is too slow to adapt towards transient stimuli. To do this plants can re-arrange the intracellular structure by the active motion of chloroplasts on short timescales. These organelles are confined between the cell membrane and vacuole and can move inside the cytoplasm via actin polymerization forces. Remarkably, the simple - yet elegant - interplay of light-sensing and active forces leads to various modes of collective motion. Here, we show that the chloroplasts under dark conditions are densely packed systems, driven by a-thermal noise and can exhibit active glassy motion. Furthermore, we aim to establish chloroplast motion as a new framework to study the dynamics of light-controlled dense biological systems featuring intriguing dynamic phase transitions.

### BP 4.3 Mon 11:15 H16

Activity-induced polar patterns of filaments gliding on a sphere - •CHIAO-Peng Hsu, Alfredo Sciortino, Yu Alice de la Trobe, and Andreas Bausch — Center for Protein Assemblies and Lehrstuhl für Zellbiophysik E27, Physics Department, Technische Universität München, Garching, Germany

Active matter systems feature the ability to form collective patterns as observed in a plethora of living systems, from schools of fish to swimming bacteria. While many of these systems move in a wide, three-dimensional environment, several biological systems are confined by a curved topology. The role played by a non-Euclidean geometry on the self-organization of active systems is not yet fully understood, and few experimental systems are available to study it. Here, we introduce an experimental setup in which actin filaments glide on the inner surface of a spherical lipid vesicle, thus embedding them in a curved geometry. We show that filaments self-assemble into polar, elongated structures and that, when these match the size of the spherical geometry, both confinement and topological constraints become relevant for the emergent patterns, leading to the formation of polar vortices and jammed states. These results experimentally demonstrate that activity-induced complex patterns can be shaped by spherical confinement and topology.

The effect of chiral flows on pattern formation on active cell surfaces - LUCAS WITTWER², ELOY DE KINKELDER¹, and •SEBASTIAN ALAND^{1,2} — ¹TU Freiberg ²HTW Dresden

Mechanochemical processes play a crucial role during morphogenesis, the formation of complex shapes and tissues out of a single cell. On the cellular level, the actomyosin cortex governs shape and shape changes. This thin layer of active material underneath the cell surface exerts an active contractile tension, the strength of which being controlled by the concentration of force-generating molecules. Advective transport of such molecules leads to a complex interplay of hydrodynamics and molecule concentration which gives rise to pattern formation and self-organized shape dynamics. In this talk, we present a novel numerical model to simulate an active viscoelastic surface immersed in viscous fluids. The resulting patterning, flows and cell shape dynamics are shown for different parameter configurations. It is further demonstrated that adding a chiral (i.e. counter-rotating) force at the cell surface can promote a ring of high molecule concentration and facilitate cell division.

### BP 4.5 Mon 12:00 H16

**Premelting controlled active matter in ice** – •JEREMY VACHIER¹ and JOHN S.  $Wettlaufer^{1,2} - {}^1Nordita$ , KTH Royal Institute of Technology and Stockholm University, Hannes Alfvéns väg 12, SE-106 91 Stockholm, Sweden —  2 Yale University, New Haven, Connecticut 06520-8109, USA

Self-propelled particles can undergo complex dynamics due to a range of bulk and surface interactions. In the case of a foreign particle inside a subfreezing solid, such as a particle in ice, a premelted film can form around it allowing the particle to migrate under the influence of an external temperature gradient, which is a phenomenon called thermal regelation. It has recently been shown that the migration of particles of a biological origin can accelerate melting in a column of ice and thereby migrate faster. We have previously shown that the effect of regelation plays a major role in the migration of inert particles and impurities inside ice, with important environmental implications. In particular, the question of how the activity affects a particle's position over time is essential for paleoclimate dating methods in ice cores. We re-cast this class of regelation phenomena in the stochastic framework of active Ornstein-Uhlenbeck dynamics and make predictions relevant to this and related problems of interest in geophysical and biological problems.

### BP 4.6 Mon 12:15 H16

Emergent collective behavior of active Brownian particles with visual perception — • Rajendra Singh Negi, Roland G. Winker, and Gerhard Gompper - Theoretical Physics of Living Matter, Institute of Biological Information Processing (IBI-5), Forschungszentrum Jülich, 52425 Jülich, Germany

Collective behavior of self-propelled agents emerges from the dynamic response of individuals to various input signals [1,2]. One such input signal is visual perception. We explore the behavior of a model of self-steering active Brownian particles with visual perception in two dimensions [3]. Several non-equilibrium structures like motile worms, worm-aggregate coexistence, aggregates, and a dilute-gas phase are obtained, depending on the system parameters. The strength of the response to the visual signal, vision angle, packing fraction, rotational diffusion, and activity (velocity  $v_0$ ) determine the location and extent of these phases in the phase diagram. The radius-of-gyration tensor is used to distinguish between the worm and the aggregate phase. Our results help to understand the collective behavior of cognitive self-propelled particles, like animal herds and micro-robotic swarms.

#### BP 4.7 Mon 12:30 H16

Diffusiophoretic propulsion of an isotropic active particle near a finite-sized  $disk - \cdot Abdallah Daddi-Moussa-Ider^1$ , Andrej Vilfan^{1,2}, and Ramin GOLESTANIAN^{1,3} — ¹Max Planck Institute for Dynamics and Self-Organization (MPIDS), 37077 Göttingen, Germany — ²Jozef Stefan Institute, 1000 Ljubljana, Slovenia — ³Rudolf Peierls Centre for Theoretical Physics, University of Oxford, Oxford OX1 3PU, United Kingdom

We employ a far-field analytical model to quantify the leading-order contribution to the induced phoretic velocity of an isotropic active colloid near a finite-

sized disk of circular shape resting on an interface separating two immiscible viscous incompressible Newtonian fluids. To this aim, we formulate the solution of the phoretic problem as a mixed-boundary-value problem which we then transform into a system of dual integral equations on the inner and outer domains. Depending on the ratio of different involved viscosities and solute solubilities, the sign of phoretic mobility and chemical activity, as well as the ratio of particleinterface distance to the radius of the disk, we find the isotropic active particle to be repelled from the interface, be attracted to it, or reach a stable hovering state and remain immobile near the interface. Our results may prove useful in controlling and guiding the motion of self-propelled phoretic active particles near aqueous interfaces.

A. Daddi-Moussa-Ider, A. Vilfan, R. Golestanian, J. Fluid Mech. 940 A12 (2022)

### BP 5: Focus Session: Super Resolution Microscopy and Dynamics of Supramolecular Complexes

organized by Jonas Ries (EMBL Heidelberg) and Ulrich Schwarz (Heidelberg University)

### **Invited Talk**

BP 5.1 Mon 15:00 H15 The functional nano-architecture of axonal actin — •CHRISTOPHE LETER-RIER — Aix Marseille Université, CNRS, INP UMR7051, NeuroCyto, Marseille, France

The intricate arborization and molecular identity of axons is maintained for decades, but must also continuously adapt to changes in the environment and modulate the activity of neurons. Axons fulfill these paradoxical demands thanks to a unique cytoskeletal organization that ensures the coordinated transport, anchoring and assembly of axonal components. In our lab, we use super-resolution microscopy to delineate and map the nanoscale architecture of actin-based structures within the axon: the periodic actin/spectrin submembrane scaffold, intraaxonal hotspots and trails, and presynaptic actin assemblies. We are exploring their molecular organization and functions by combining versatile labeling approaches, correlative live-cell/super-resolution/electron microscopy and quantitative analysis that allow for high-content, nanoscale interrogation of the axonal architecture.

### BP 5.2 Mon 15:30 H15

Photon-stream-based aberration correction for STED microscopy •DEBADRITA GHOSH, CLAUDIA GEISLER, and ALEXANDER EGNER — Institute for Nanophotonics, Goettingen, Germany

Stimulated emission depletion (STED) microscopy is the most prominent superresolution fluorescence microscopy method and achieves a resolution far beyond the diffraction limit. However, like all these methods, it is adversely affected by sample-induced aberrations, which can degrade the achievable resolution and image quality significantly. These aberrations are caused by wavefront distortions due to refractive index variations, for example within thick biological specimens. This challenge can be addressed by using adaptive optics (AO) in a feedback-controlled manner such that the wavefront distortions are compensated and the image quality is restored. Typically, the feed-back loop uses image features which necessitates repeated acquisitions of the same field-of-view. This approach, therefore, is slow and prone to unwanted photo-bleaching. Here, we present an AO correction scheme that does not rely on image features, but exploits the dependence of the fluorescence lifetime on the local STED intensity. In principle, our photon-stream-based metric can be evaluated on a single image pixel, which makes it photon-budget-friendly and allows to correct aberrations rapidly in parallel with image acquisition. We successfully utilized this new metric for automated and continuous aberration correction in biological samples, making imaging fast and easy even for users without expert knowledge.

### BP 5.3 Mon 15:45 H15

Cytoskeletal organization of red blood cells during malaria infections investigated with super-resolution microscopy and pair cross-correlation analysis - •PINTU PATRA¹, CECILIA P SANCHEZ², MICHAEL LANZER², and Ulrich S SCHWARZ¹ — ¹Institute for Theoretical Physics & BioQuant, Heidelberg University, Germany – ²Center of Infectious Diseases, Parasitology, University Hospital Heidelberg, Germany

Measuring the distance between molecules is key to understanding the molecular organization of biological systems. The pair cross-correlation (PCC) function computed from two-color super-resolution microscopy images provides a measure of co-localization between differently labeled molecules. Here, we theoretically compute the PCC-function between two molecules by using 2D Gaussian distribution as the effective point spread function for single molecules. By fitting this function to simulated data based on experimentally measured images, one can estimate both small and large separation distances. We apply this method to malaria-infected red blood cells and demonstrate that the knob-associated histidine-rich protein (KAHRP), which is used by the parasite to remodel the spectrin-actin network from a distance, relocalizes from the ankyrin bridges to the actin-based junctional complexes during the 48 hours course of the infection.

### Superresolution microscopy for structural cell biology - •JONAS RIES -EMBL Heidelberg

Superresolution microscopy, such as single-molecule localization microscopy (SMLM), is becoming a key technique for structural cell biology, ideally complementing electron microscopy. I will discuss projects in my group in which we push SMLM towards nanometer resolution in 3D and multicolor with the aim to investigate the structure and dynamics of molecular machines in cells. I will show how these technologies allowed us to gain mechanistic insights into the machinery that drives endocytosis. Endocytosis is an essential cellular function by which cells take up molecules from the environment. We were able to reconstruct the dynamics of this process from thousands of snapshots taken in fixed cells. I will conclude with first results illustrating the potential of MINFLUX to image dynamic structural changes of protein machines in the living cell with nanometer resolution. Specifically, I will show how we resolved the precise stepping motion of the motor protein kinesin in living cells.

#### BP 5.5 Mon 16:45 H15

Spatiotemporal SARS-CoV-2 binding dynamics investigated with 100 Hz ROCS microscopy and thermal fluctuation analysis - • DOMINIK HUBER and ALEXANDER ROHRBACH - Laboratory for Bio- and Nanophotonics, Department of Microsystems Engineering - IMTEK, University of Freiburg, 79110 Freiburg, Germany

The emergence of the new severe acute respiratory syndrome corona virus 2 (SARS-CoV-2) in recent years has caused tremendous interest in investigating the interactions between viruses and cells. Especially the imaging and tracking of viruses are of great importance to see and understand the binding and uptake of viruses into cells and to be able to intervene in these processes. Due to their small size and fast movement imaging virus dynamics is a very challenging task, which has so far been achieved with different fluorescence methods, being limited by photo bleaching and imaging speed.

In our research we apply Rotating Coherent Scattering (ROCS) microscopy in order to visualize the diffusion of SARS-CoV-2 virus like particles (VLPs) close to A549 lung epithelial cells. ROCS microscopy allows for label-free imaging with more than 100 Hz temporal at 150 nm spatial resolution. The high contrast image stacks enable single particle tracking and characterization of the binding process and strength of VLPs with SARS-CoV-2 spike proteins to A549 cells using thermal fluctuation analysis.

### BP 5.6 Mon 17:00 H15

Transient Optoplasmonic Detection of Single Proteins on the Nanosecond Time Scale – •MARTIN D. BAASKE^{1,2}, NASRIN ASGARI¹, DEEP PUNJ¹, and MICHEL ORRIT 1  —  1 Leiden University, Leiden, Netherlands —  2 Johannes Gutenberg-University, Mainz, Germany

Label-free optical detection schemes commonly rely on specific chemical interactions between receptor and target molecule in order to facilitate analyte recognition. Here I present our first steps on a novel pathway to fingerprint proteins via analysis of their motion, i.e., physical properties such as stokes radius and polarizability rather than chemical interactions. We show that via a polarization selective technique and careful optimization of a confocal microscope single gold nanorods, which are commonly used as labels, can be transformed into high-speed nanoscale sensors. We perform photothermal spectroscopy on single gold nanorods and use it as a means to probe their sensitivity to refractive index changes with respect to the experimental parameters * in turn allowing us to optimize the later on a rod-to-rod basis. This enables the detection single protein molecules traversing plasmonic near fields with previously time resolutions on the nanosecond scale.

#### BP 5.7 Mon 17:15 H15

Modeling the assembly and invagination of clathrin lattices at the cell membrane — •FeLIX Frey^{1,2} and ULRICH S. SCHWARZ³ — ¹Department of Bionanoscience, Delft University of Technology, Delft, the Netherlands — ²Institute of Science and Technology Austria, Klosterneuburg, Austria - ³Institute for Theoretical Physics and BioQuant-Center, Heidelberg University, Heidelberg, Germany

BP 5.4 Mon 16:15 H15

Location: H15

Biological cells constantly relay material and information across their plasma membranes. For particles with sizes between 50 and 200 nm, clathrin-mediated endocytosis (CME) is the main uptake route. In CME clathrin triskelia assemble at the cell membrane and form a clathrin lattice. After initially growing flat the lattice starts to curve before it reaches its final size [1]. However, how this flat-to-curved transition proceeds in detail is still elusive, because theoretically several pathways can be envisioned [2]. When confronted with conventional imaging data, a microscopic model for the growth of clathrin lattices indeed suggests

## BP 6: Statistical Physics of Biological Systems 1 (joint session BP/DY)

BP 6.1 Mon 15:00 H16 Dynamics and Fair Risk Sharing in Groups of Intelligent, Egoistic Individuals — SAMUEL MONTER¹, •VEIT-LORENZ HEUTHE¹, EMANUELE PANIZON², and CLEMENS BECHINGER¹ — ¹FB Physik, Universität Konstanz, Konstanz, Germany — ²Department of Quantitative Life Science, ICTP, Trieste, Italy

Many animal species organize in social groups of fascinating complexity. The evolutionary biologist W.D. Hamilton hypothesized that the gregariousness of some animals can be explained solely from the egoistic motivation to decrease the risk of predation [1]. As a quantitative measure of this risk, he considered the Voronoi area around each animal. Many collective behavior studies try to capture this motivation by imposing interaction rules or neglect the driving motive altogether when modeling the dynamics of animals. In this study we train a swarm of individuals in a Multi Agent Reinforcement Learning (MARL) framework according to Hamilton's hypothesis, i.e. to decrease their predation risk. Thus, we gain insights into the dynamics of an ensemble of selfishly motivated individuals unbiased by any a priori assumption about interactions. We find that the individuals learn to cluster into groups which exhibit dynamic steady states resembling the behavior of natural swarms. Additionally, the predation risk is shared evenly within the groups, counterintuitive to the selfish motivation of each individual. Our findings suggest that gregariousness could indeed be driven by selfish motives in accordance with Hamilton's hypothesis.

### BP 6.2 Mon 15:15 H16

Boundary-driven epithelial ordering: from the mouse embryo to topological defects — •PAMELA GURUCIAGA¹, TAKAFUMI ICHIKAWA², TAKASHI HIIRAGI³, and ANNA ERZBERGER¹ — ¹European Molecular Biology Laboratory, Heidelberg, Germany — ²Kyoto University, Kyoto, Japan — ³Hubrecht Institute, Utrecht, The Netherlands

In physical problems boundaries are typically considered to be simple, static and externally fixed. Biological systems however not only interact with their surroundings, but also alter them in ways that feed back on their own dynamics. We address this complex interaction in the context of epithelial development. Motivated by observations of an interplay between apico-basal polarity and boundary geometry in mouse epiblast morphogenesis, we develop a theory for epithelial ordering based on the Landau-de Gennes approach to surface-induced order in liquid crystals. We introduce a vector order parameter to represent the polarity, and model its interaction with the boundaries by a weak anchoring energy. We calculate the alignment fields arising from different boundary curvatures, and compare our predictions with imaging data of the morphogenetic process. Our work highlights the role of extraembryonic tissue in embryogenesis, while identifying interesting physical phenomena, such as boundary-dependent transitions in the structure of topological defects.

### BP 6.3 Mon 15:30 H16

A competitive advantage through fast dead matter elimination in confined cellular aggregates — •YOAV G. POLLACK^{1,2}, PHILIP BITTIHN¹, and RAMIN GOLESTANIAN^{1,3} — ¹Max Planck Institute for Dynamics and Self-Organization (MPI-DS), Göttingen, 37077, Germany. — ²Max Planck Institute for Multidisciplinary Sciences (MPI-NAT), Göttingen, 37077, Germany. — ³Rudolf Peierls Centre for Theoretical Physics, University of Oxford, OX1 3PU, UK.

Competition of different cell types for limited space is relevant in biological processes such as tissue morphogenesis and tumor growth. Predicting the outcome for non-adversarial competition of such growing active matter is non-trivial, as it depends on how processes like growth, proliferation and the degradation of cellular matter are regulated in confinement; regulation that happens even in the absence of competition to achieve homeostasis. We show that passive byproducts of the processes maintaining homeostasis can significantly alter fitness, enabling cell types with lower homeostatic pressure to outcompete those with higher homeostatic pressure. We reveal that interfaces play a critical role for this specific kind of competition: There, growing matter with a higher proportion of active cells can better exploit local growth opportunities that continuously arise as the active processes keep the system out of mechanical equilibrium. Our results show that optimizing the ratio of growing (active) to dead (passive) cells some level of plasticity as required for bending [3]. Recently we have combined mathematical modeling with 3D superresolution microscopy to determine the dynamics of membrane invagination. We find that membrane curvature is generated cooperatively between the triskelia of the clathrin lattice [4].

A biophysical model of DNA methylation ageing — •AIDA HASHTROUD and STEFFEN RULANDS — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

Machine learning models can accurately predict biological age and time of death based on sequencing measurements of DNA methylation marks. The mechanistic basis underlying these methylation clocks is poorly understood. Here, using a combination of tools from statistical physics and sequencing experiments we show that biological age can be predicted as a result of collective processes in the boundaries between genomic regions of different densities of cytosine-guanine pairs (CpGs). Specifically, we define a biophysical model predicting the time evolution of DNA methylation patterns during ageing based on a wave localization mechanism of tilted competition between antagonistic chromatin modifiers. Our work shows that biological age can be predicted from DNA methylation patterns using models with few parameters inspired by statistical physics.

From active bacterial microcolonies to biofilms as model tissues - •VASILY ZABURDAEV — Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany - Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany Bacterial intrinsic activity is evident on all stages of their life cycle. We will start by following how individual cells deploy forces to attach and move on surfaces. We suggest how these active movements may be harnessed to generate work and, for example, cells can power the rotation of micro-turbines. When let to move and interact, however, bacteria will find each other and form microcolonies that consist of several thousands of cells. Microcolonies are often the functional units of the bacterial existence in natural settings and in the context of disease. We will provide theoretical framework describing the bacterial microcolonies as active viscoelastic materials and discuss how this theory might be useful in eukaryotic systems such as organoids, tumour spheroids or clustering immune cells. Microcolonies may further develop into even more complex bacterial communities known as biofilms - there, bacteria embed themselves in the self-secreted extracellular matrix creating an analogue of multicellular tissues. We will outline some future research avenues deepening this analogy and illustrate it with an intriguing example of wound healing in bacterial biofilms.

Playing it safe: information constrains collective betting strategies — •PHILIPP FLEIG^{1,2} and VIJAY BALASUBRAMANIAN² — ¹Max Planck Institute for Medical Research, 69120 Heidelberg, Germany — ²Department of Physics & Astronomy, University of Pennsylvania, Philadelphia, PA 19104, USA

Risk is an inherent part of life and biological functions are partly shaped by the need to reduce risk. Broadly, risk arises from stochastic interactions of an organism with its environment. Every time an organism displays a particular response or behaviour (e.g. expresses a phenotype or exhibits a certain immune response), it is placing a bet with potential impact on its biological fitness. The more precisely the statistics of the environment are known to the organism, the more successfully bets can be placed. However, an organism typically has limited information about the statistics of the environment. This limitation should be accounted for in the adaptation of biological functions to the environment. We develop a theoretical principle where information geometric model complexity guides stochastic biological functions towards less risky betting strategies. In the framework of Bayesian inference, we show that given finite information about the environment, there is an optimally safe adaptation strategy set by the Bayesian prior. Furthermore, in a toy model of stochastic phenotypic switching by bacteria, we demonstrate how the implementation of our principle of "playing it safe" increases the fitness (population growth rate) of the bacterial collective. We suggest that the principle applies broadly to problems of adaptation, learning and evolution.

Assessing biomolecular interactions across scales using optical tweezers — •Roman Renger, Nicholas Luzzietti Luzzietti, and Philipp Rauch — LU-MICKS, Amsterdam, Netherlands

Biological processes involving proteins interacting with nucleic acids, cell membranes or cytoskeletal filaments are key to cell metabolism and hence to life in general. Detailed insights into these processes provide essential information for understanding the molecular basis of physiology and the pathological conditions that develop when such processes go awry. The next scientific breakthrough consists in the direct, real-time observations and measurements of the most fundamental mechanisms involved in biology Single-molecule technologies offer a powerful opportunity to meet these challenges and to study dynamic protein function and activity in real-time and at the single-particle level. Here, we present our efforts for further enabling discoveries in the field of biology and biophysics using the combination of optical tweezers with correlative fluorescence microscopy (widefield, TIRF, confocal and STED) and label-free Interference Reflection Microscopy (IRM). We present several examples in which our technology has enhanced the understanding of basic biological phenomena, ranging from protein structure to intracellular organization. Furthermore, we show that advances in hybrid single-molecule methods can be turned into an easy-to-use and stable instrument that has the ability to open up new avenues in many research areas.

**Transport in complex intracellular environments** — •MOHAMMAD AMIN ES-KANDARI, BART VOS, MATTIAS LUBER, and TIMO BETZ — Third Institute of Physics - Biophysics Georg August University Göttingen

Active transport is vital for targeted delivery of organelles, proteins and signaling molecules in eukaryotic cells and defects in active transport are linked to different diseases such as Alzheimer's disease. Kinesin and dynein are two motor proteins which are responsible to carry the cargoes along the microtubule filaments. Since the cytoplasm is a highly crowded environment, the motion of cargoes can be hindered by some sorts of obstacles and this brings us to the question how these motors can generate a processive motion in such an environment to bypass the roadblocks. In this project, we aim to investigate the possible mechanisms that kinesin and dynein can use to overcome the obstacles.

### BP 7.3 Mon 18:00 P1

Single Particle Tracking of Molecular Motors under Different Physiological Conditions — •ADRIAN LENTZ, PAULINA BLAIR, DANIEL KUCKLA, PHILIPP HAGEMANN, and CORNELIA MONZEL — Experimental Medical Physics, Heinrich-Heine University, Düsseldorf, Germany

Single particle tracking (SPT) is a powerful tool to gain insights into the dynamics of molecular motors. These proteins convert the chemical energy of adenosine triphosphate (ATP) into a forward motion to transport vesicles along the microtubule network. In our study we investigate the linear motion of the kinesin variant Kif5C, which is normally found in neuronal cells. A genetically modified Kif5C with fused green fluorescent protein was monitored with millisecond resolution and analysed with an algorithm that links precisely detected particle positions to trajectories. We establish a point density based classification of trajectories into different molecular gaits and determine diffusion, velocity and processivity of the Kif5c motor. We show a systematic analysis of the influence of different acquisition times on the motor motion determination and compare Kif5C transport in the human cell lines HeLa, MCF-7, HEK, NIH/3T3 and COS-7. Of central interest was then to measure the effect of different physiological conditions, e.g. absence or high concentration of glucose and high amount of ATP, on the Kif5C dynamics. of the constituents of the cellular machinery and the processes taking place in the cell is steadily increasing, little is known about the information flow within the cell. Are pathways conveying only on/off signals, or is there more graded information being transduced?

Here, we measure and quantify the information relayed through the MAPK signalling pathway, one of the key signalling pathways in eukaryotic systems. Using a synergy of an optogenetic experimental setup and a data analysis pipeline based on information theory, we quantify the input-output relationships within the MAPK signalling pathway. We show that the capacity of the pathway far exceeds the 1-bit value (on/off), and that collective systems of cell seem to exploit this capacity.

BP 7.4 Mon 18:00 P1

Towards Advanced Single Particle Tracking of Molecular Motors by Quantum Dot Labeling and Monitoring of the Cytoskeletal Environment — •PAULINA BLAIR, ADRIAN LENTZ, XIAOYUE SHANG, DANIEL KUCKLA, PHILIPP HAGEMANN, and CORNELIA MONZEL — Experimental Medical Physics, Heinrich-Heine Universität, Düsseldorf, Germany

The molecular motor Kif5C plays a central role in the intracellular transport and synaptic transmission of neuronal cells. To understand how Kif5C mediated transport depends on its environment, it is essential to track the motor in the cytoplasmic context. We aim to advance the single molecule tracking of Kif5C by Quantum Dot labeling as well as by characterising the cytoskeletal environment. Quantum Dots are nanoscale semiconductors, which in contrast to genetically encoded fluorophores, offer tracking at enhanced spatio-temporal resolution and over long time scales. In this project we express Kif5C genetically fused to a streptavidin molecule in live cells. Quantum Dots functionalised with biotin are added to the cell sample to bind via streptavidin-biotin interaction to Kif5C. Molecular motors are recorded with millisecond resolution and are analysed using a global Linear Assignment Approach. The microtubule is stained using a silicon rhodamine-based fluorophore. We then derive parameters such as network density or intersections to correlate it with the motor protein dynamics.

Our data will provide insights on the benefit of Quantum Dot labeling, on molecular motor gaits such directed, superdiffusive and subdiffusive motion as well as on effects of the cytoskeletal environment.

#### BP 7.5 Mon 18:00 P1

**Quantification of molecule-spanning protein dynamics with fluorescence correlation spectroscopy** — •VERONIKA FRANK¹, JEAN-BENOÎT CLAUDE², JÉRÔME WENGER², and THORSTEN HUGEL^{1,3} — ¹Institute of Physical Chemistry, University of Freiburg, Germany — ²Fresnel Institute, CNRS, Aix Marseille University, France — ³Signaling research centers BIOSS and CIBSS, University of Freiburg, Germany

Protein conformational kinetics and their regulation occur on many time and length scales. Fluorescence methods have mainly focused on the hundreds of microseconds to minutes time scale and NMR on the picosecond time scale. Here we explore the several nanoseconds to microseconds time scale for the multidomain molecular chaperone heat shock protein Hsp90, a homodimer with a molecular weight of 90 kDa per monomer. Hsp90 is a therapeutic target for cancer therapy, but its dynamics and its dynamic interactions with other proteins are not yet fully understood.

Here we use fluorescence correlation spectroscopy and zero-mode waveguide nanoapertures to measure and understand fast molecule-spanning dynamics and how they are affected by interactors.

### BP 7.6 Mon 18:00 P1

**AniMol: A quick interactive web-based molecular trajectory visualiser** — JAMES PANAYIS, JAMES PARTINGTON, and •RUDOLF A. RÖMER — Department of Physics, University of Warwick, Coventry, CV4 7AL, UK

We present software developed to interactively visualise dynamic molecular trajectories in web browsers. This tool allows for quick and efficient interaction with large flexing/moving molecular structures and helps to more easily understand results of in-silico modeling processes, for example protein dynamics simulations. The browser-based software simplifies workflows as no installation is required, and there are very few limitations due to hardware or software compatibilities. We achieve this using a lightweight state-of-the-art graphics engine, and compiling our code to WebAssembly (WASM), a portable compilation target for programming languages supported by all major browsers since 2017. We also present a webserver (animol.warwick.ac.uk) utilising this software offering cloud storage and retrieval of molecular trajectories, to aid collaboration and communication of results.

### BP 7.7 Mon 18:00 P1

**Correlation-based feature selection to identify functional dynamics in proteins** — •GEORG DIEZ, DANIEL NAGEL, and GERHARD STOCK — Physikalisches Institut, Albert-Ludwigs-Universität Freiburg

Molecular dynamic simulations provide an effective tool for a deeper understanding of proteins and their functioning. In order to shed light on the underlying mechanisms of processes, one typically models the dynamics using some key internal coordinates (or features) which capture the most important conformational changes of the protein. However, one often ends up in a high-dimensional feature space which hampers a straightforward interpretation of the typically very complex dynamics. Adopting the Leiden community detection algorithm [1], we present an effective and scalable approach to divide the feature space into subsets which describe collective motion. By applying this approach to the functional dynamics of different protein systems with varying size, we show that it allows to identify and discard uncorrelated motion and noise. Moreover, it provides an effective dimensionality reduction scheme by extracting the key features, and leads to a detailed understanding of the underlying mechanisms.

Reversible protein immobilization and biosensing on liquid-gated GFETs — •MYKOLA FOMIN¹, LARA JORDE², CHANGJIANG YOU², JACOB PIEHLER², and CAROLA MEYER¹ — ¹Department of Physics, Osnabrück University, Germany — ²Department of Biology/Chemistry and CellNanOs Center, Osnabrück University, Germany

Apart from the standard requirements such as selectivity, sensitivity, and biological compatibility, effective electronic biosensors are facing the demand for the fabrication of cost-efficient devices. Cost and resource efficiency would benefit from re-useage of the biosensor after detection, which can be achieved by reversible immobilization of the molecules in question. While multiple biosensors have already been demonstrated to generate a response to a specific analyte molecule and its various concentrations, reversible protein monitoring remains a challenging task. Besides, during such measurements on graphene exists a risk of unspecific attachment to the channel with following protein denaturation. This work aims to demonstrate reversible protein immobilization detected by current changes of a liquid-gated GFET. PEG-tris-NTA on a lipid monolayer is used for site-specific immobilization of histidine-tagged proteins. The lipid layer forms a 2,5 nm hydrophilic cover over the channel that prevents unspecific protein attachment and its denaturation, resulting in enhanced biocompatibility [1]. We track the current changes upon attachment of histidine-tagged GFP to the device and their removal upon imidazole wash.

### BP 7.9 Mon 18:00 P1

Hierarchical dynamics as result of log-periodic oscillations in proteins — •EMANUEL DORBATH, GERHARD STOCK, and STEFFEN WOLF — Albert-Ludwigs-Universität, Freiburg, Germany

Logarithmic oscillations were observed in earthquakes, financial crashes and several biomolecular systems such as proteins. In many protein systems it is generally assumed, that the time scales, ranging from femtoseconds up to microseconds and longer, are in fact not independent but structured hierarchical in the sense that the fast time scales are a prerequisite for the slower ones.

This hierarchy can be well described via the free energy landscape which then gives rise to the logarithmic oscillations and a power-law. From the logarithmic oscillations, multiple relaxation times can be derived extending over several orders of magnitude [Metzler 1999].

Here, an analysis is presented to derive the respective time scales using logarithmic oscillations in non-equilibrium simulations. For this three systems are studied: A 1-dimensional model with an inherent hierarchical energy landscape is used as proof of principle and demonstration of the method. The second one is the simple hierarchical peptide Aib9 with two helical states which has been researched already in the past [Buchenberg 2015]. Finally, the widely studied PDZ2 domain is studied which shows complex conformational folding and restructure mechanisms.

### BP 7.10 Mon 18:00 P1

The effect of  $D_2O$  on the pressure dependent protein-protein interaction in aqueous lysozyme solutions — •MICHELLE DARGASZ, JAQUELINE SAVELKOULS, and MICHAEL PAULUS — Fakultät Physik/DELTA, TU Dortmund, 44221 Dortmund, Germany

In some experimental techniques such as neutron scattering, the substitution of  $H_2O$  with  $D_2O$  is used to obtain a useful signal. It was assumed that the exchange of the solvent does not have a major influence on the protein structure and interactions. However, measurements with lysozyme in  $D_2O$  revealed a larger attractive component of the protein-protein interaction potential [1]. In this study, the pressure-dependent behavior of high concentrated lysozyme solutions with  $H_2O$  and  $D_2O$  was considered using SAXS at the beamline BL2 of the synchrotron radiation source DELTA (Dortmund Germany). In previous mea-

surements a non-linear relationship between the interaction potential and the exerted pressure was observed [2]. This was also visible in this study, as a shift in the correlation peak of the scattering curve occurs as a function of pressure. Up to approx. 2 kbar, a shift to larger q-values occurs, which is reversed with further increasing pressure up to 4 kbar. Since this effect occurs equally in  $H_2O$  as well as  $D_2O$ , it can be assumed that the water structure plays a rather minor role for the nonlinear correlation.

**Coarsening of biomolecular condensates regulate crossover placement in Meiosis I** – •MARCEL ERNST and DAVID ZWICKER – Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany

During meiosis, genetic information from female and male chromosomes is exchanged in a process called crossover. The dynamics that determine the positioning of these crossovers is largely not understood. Experimental observations consistently reveal two key findings: First, the number of crossovers per chromosome is at least one and is usually small, between one and three. Second, there is crossover interference, which prevents nearby crossovers on a single chromosome. We hypothesize that crossovers are determined by biomolecular condensates, which coarsen by exchanging material along chromosomes. We present theoretical and numerical results suggesting scaling laws analogous to Lifshitz-Slyozov-Wagner theory that predict the final number of crossovers, and their spatial structure as a function of coarsening time, chromosome length, and the initial amount of material. These results are consistent with current experimental findings in *Arabidopsis thaliana* and suggest how cells use a fundamental coarsening process to regulate spatial patterns.

**Controlling size, phase transitions, and reactions in microfluidic doubleemulsion droplets** — •PAULA GIRONES PAYA, SEBASTIAN W. KRAUSS, and MATTHIAS WEISS — Experimental Physics I, University of Bayreuth

Double-emulsion based assays have been widely used in a large number of experiments such as in bio-inspired microreactors or in direct evolution assays. Despite the advanced techniques that have been developed to produce picolitersized droplets, a better manipulation of the droplet interior remains a challenge. Here, we demonstrate how hundreds of double emulsion droplets, trapped in a microfluidic sieve, can be grown and shrunk by controlling the salt concentration in the carrier liquid. Alternating the osmotic pressure leads to a rapid and reversible volume change of the aqueous droplet interior, resulting in a reversible phase separation of an enclosed binary fluid. The phase separation is shown to be a versatile tool to control, for example, the dissociation and re-association of double-stranded DNA or to monitor an enzymatic reaction via a pH sensitive fluorescence reporter.

### BP 7.13 Mon 18:00 P1

**Nucleation of chemically active droplets** — •NOAH ZIETHEN and DAVID ZWICKER — Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany

Liquid-liquid phase separation emerged as a crucial organizing principle inside biological cells giving rise to a plethora of intracellular compartments. Unique to the cellular context, these condensates can consist of only a few hundred molecules and are affected by non-equilibrium processes. In particular, active chemical conversion between condensate material and proteins in the surrounding cytoplasm can control their size. Moreover, the significant concentration fluctuations due to the small molecule numbers imply that spontaneous nucleation and dissolution are likely. Yet, it is unclear how the driven reactions affect these stochastic processes. Here, we investigate the influence of chemical reactions on the nucleation behavior of active droplets using a stochastic field theory. We find a decrease in the nucleation rate with the increased strength of the chemical reactions. Using classical nucleation theory, we can reduce the full dynamics to an analytical expression for the free energy, which only depends on the droplet radius and the strength of the chemical reactions. The chemical reactions increase the energy barrier, which the system needs to overcome to form a droplet. Additionally, the binodal and the spinodal line are moved towards the center of the phase diagram. Cells might use these effects to control the nucleation behavior of intracellular droplets or even suppress their formation completely.

### BP 7.14 Mon 18:00 P1

Liquid-liquid phase separation of promoter and gene-body condensates in multi-scale simulations — •ARYA CHANGIARATH SIVADASAN^{1,2} and LUKAS STELZL^{1,2} — ¹Institute of Physics, JGU Mainz — ²Faculty of Biology JGU Mainz and institute of Molecular Biology (IMB), Mainz

Liquid-Liquid phase separation plays an important role in the formation of localized nuclear hubs of RNAPII during the transcription process. Our research is focused on understanding the molecular basis of phase separation of CTD, the largest subunit of RNAPII, using molecular dynamics (MD) simulation methods. We investigated how the CTD phase separation is affected by differences in CTD sequences using coarse-grained MD simulations and the results indicate that deviation from the ideal heptapeptide sequence has less tendency to phase separate, which suggests that these deviations from the ideal heptapeptide repeats are important for responsive regulation of transcription. Moreover, we are looking at how phosphorylation of CTD and the presence of other biomolecules that can influence CTD phase behavior. Hyper-phosphorylation prevents phase separation as the negatively charged phosphate groups repel each other. We show how hyperphosphorylated CTD might co-phase separate in elongation with HRD of Cylin-T1 in accordance with the experiment. To explore more on this, we studied the phase behavior of CTD and phosphorylated CTD in the presence of HRD and the results show that they co phase separate into a large cluster, but do not mix, which may help to physically distinguish between the initiation and elongation stages of transcription.

Mechanical growth and auxin patterning in plant tissues — •MATHIAS HÖFLER¹ and KAREN ALIM^{1,2} — ¹Physics Department and CPA, Technische Universität München — ²Max-Planck-Institut für Dynamik und Selbstorganisation, Göttingen

Individual cell shape and growth underlies a high variance in living organisms. It is puzzling how on a larger scale, the morphogenesis of a tissue can be a reliably stable and efficient process. Theory and experiment show that there is a mechanical and biochemical feedback loop for tissue development and morphogenesis. Mechanical forces in plants have a pronounced effect on the microtubule orientation in cells, thereby changing the cell's mechanical properties, causing an impact on the magnitude and direction, hence anisotropy, of cell growth. Here we study the effect of cell mechanics on the bidirectional, radial growth of tissue in the plant stem. We investigate feedback mechanisms, stress patterns and how these affect tissue and early organ shape and development. For the latter, we furthermore study the role of the growth hormone auxin in the shoot apical meristem (SAM). Here, auxin induces cell wall loosening thus enhancing mechanical growth via biochemical feedback.

### BP 7.16 Mon 18:00 P1

Characterizing flexibility and mobility in the natural mutations of the SARS-CoV-2 spikes — JAMES PANAYIS¹, DOM BELLINI², and •RUDOLF A. RÖMER¹ — ¹Department of Physics, University of Warwick, Coventry, CV4 7AL, UK — ²MRC Laboratory of Molecular Biology, Cambridge CB2 0QH, UK

We perform in-silico modelling of the SARS-CoV-2 spike protein and its mutations, using structures from the Protein Data Bank (PDB), to ascertain their dynamics, flexibility and rigidity. Identifying the precise nature of the dynamics for the spike proteins enables, in principle, the use of further in-silico design methods to quickly screen both existing and novel drugs that may hinder these natural dynamics. We use a recent protein flexibility modelling approach, combining methods for deconstructing a protein structure into a network of rigid and flexible units with a method that explores the elastic modes of motion of this network, and a geometric modelling of flexible motion. We also conduct this analysis on synthetic structures of some newer variants ( $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\delta$ ,  $\lambda$ , o) for some of which structure files are not yet available from the PDB. All proteins are thermalised for at least 1ns with NAMD to human body temperature before the flexibility analysis.

### BP 7.17 Mon 18:00 P1

Effects of CTCF and Cohesin complexes and nucleosome positions on chromatin loops. — •AYMEN ATTOU, TILO ZÜLSKE, and GERO WEDEMANN — University of Applied Sciences Stralsund, Institute for Applied Computer Science, 18435 Stralsund, Germany

The spatial organization of the eukaryotic genome plays an important role in regulating transcriptional activity. In the nucleus, chromatin forms loops that assemble into fundamental units called topologically associating domains, which facilitate or inhibit long range contacts. These loops are formed and held together by a ring-shaped protein complex involving cohesin and CTCF. To analyse the effects of cohesin and CTCF, an established coarse-grained computer model of chromatin with a resolution of single nucleosomes was extended by integrating potentials describing CTCF and cohesin. We performed Monte Carlo simulations combined with replica exchange procedure with regular spaced nucleosomes and experimentally determined nucleosome positions in presence of cohesin-CTCF as well as depleted systems as control. The simulations generated a statistical representative ensemble of configurations in thermal equilibrium. We studied differences in the spatial structure and of contacts probabilities of different domains. That allowed us to understand the impact of cohesin and CTCF on the 3D structure of chromatin and how nucleosome positions can impact the conformations of the chromatin loops during the residence time of the loop anchor, with presumed consequences for transcriptional activity.

### BP 7.18 Mon 18:00 P1

**In Silico Tumor Invasion** — •ERIC BEHLE¹, JULIAN HEROLD², and ALEXANDER SCHUG¹ — ¹JSC, Jülich Research Centre, Wilhelm-Johnen-Straße, 52428 Jülich, Germany — ²Karlsruhe Institute of Technology, Kaiserstraße 12, 76131 Karlsruhe, Germany

To this day, cancer remains an insufficiently understood disease plaguing humanity. In particular, the mechanisms driving tumor invasion still require extensive study. Current investigations address collective cellular behavior within tumors, which leads to solid or fluid tissue dynamics. Furthermore, the extracellular matrix (ECM) has come into focus as a driving force facilitating invasion. To complement the experimental studies, computational models are employed, and advances in computational power within HPC systems have enabled the simulation of macroscopic tissue arrangements. In line with this, we hereby present our work using Cells in Silico (CiS), a high performance framework for largescale tissue simulation developed by us. Combining a cellular potts model and an agent-based layer, CiS is capable of simulating tissues composed of millions of cells, while accurately representing many physical and biological properties. We aim to parameterize CiS via a bottom-up approach, starting with experimental data from small systems. We focused our studies on tumor spheroids, spherical aggregates composed of thousands of individual cells, which are one of the main workhorses of tumor analysis. We investigated the invasion dynamics and their dependence on the ECM density, and further aim to apply our model to the realistic simulation of larger systems.

### BP 7.19 Mon 18:00 P1

Time resolved signal propagation in a photoswitched PDZ3 domain — •AHMED ALI, ADNAN GULZAR, STEFFEN WOLF, and GERHARD STOCK — Institute of Physics, University of Freiburg, Germany

Allostery is one of the most important mechanisms for biomolecular regulation. Generally, it involves a perturbation such as a binding event at one side of a macromolecule to affect another distant functional site. However, how such a perturbation propagates through the protein in detail is still not well understood. To establish a minimal allosteric model system, the third PDZ domain (PDZ3) of the postsynaptic density-95 (PSD-95) protein has been considered. The PDZ3 domain binds to the C-terminus of target proteins and regulates the signal propagation in PSD-95. In addition to the common and conserved central  $\beta$ -sheets and two  $\alpha$ -helices present in all PDZ variants, PDZ3 contains a third C-terminal  $\alpha$ -helix ( $\alpha_3$ -helix) that packs against the  $\beta$ -sheet at a considerable distance to the ligand binding pocket.

In this work, we aim for a detailed understanding of the microscopic dynamics of allosteric communication between  $\alpha_3$  and the ligand binding pocket. In addition, we explicitly aim at finding intraprotein changes appearing on the same time scales as found in recent time-resolved IR spectroscopic experiments. Consequently, we perform direct nonequilibrium molecular dynamics (MD) simulations of PDZ3. We characterize the  $\alpha_3$ -switched response by a combination of principal component analysis, clustering methods, and machine learning and characterize the microscopic mechanism behind the allosteric communication between  $\alpha_3$  and the ligand binding site.

### BP 7.20 Mon 18:00 P1

**Enabling computer simulations of chromatin at physiological density with a resolution of individual nucleosomes** — •TILO ZÜLSKE, AYMEN ATTOU, and GERO WEDEMANN — University of Applied Sciences Stralsund, System Engineering and Information Management, 18435 Stralsund, Germany

The spatial structure of chromatin in the nucleus is important for processes such as the regulation of transcription by facilitating contacts over long distances or by hindering spatial accessibility. Despite extensive research, the spatial structure of chromatin remains enigmatic. Coarse-grained computer simulation models of chromatin help to understand the existing variation of experimental data. Nucleosomes were modelled as spherocylinders connected by elastic segments describing linker DNA. Interactions include stretching, bending, torsion, electrostatic and internucleosomal interactions. Nucleosomes were spaced equidistantly and randomly. Configurations were sampled utilizing Metropolis Monte Carlo and replica exchange algorithms. We studied synthetic fibers of 1.1 Mbp utilizing with periodic boundary conditions that mimic density behavior at different concentrations. The systems comprised 6000 nucleosomes which was more than an order of magnitude larger than the systems computed by us so far. Comparison with experimental results deliver crucial insights how nucleosome positions and density affect the spatial structure and contacts.

### BP 7.21 Mon 18:00 P1

Numerical study of the driving forces behind the slipper formation for RBC cells in rectangular microchannels. — •BERIN BECIC — Biofluid Simulation and Modeling ,Theoretische Physik VI, Universität Bayreuth

Red blood cells in rectangular microchannel flows exhibit two types of motions. At low velocities they tend to migrate towards the center and take symmetric croissant like shapes whereas for high velocities they migrate along the axis with the larger dimension and take an asymmetric slipper shape. Based on these results the behavior of the asymmetric off-centered slipper-movement was studied further via the boundary integral method. There it was observed that surprisingly this motion is only weakly dependant on the cell's elastic properties. Additionally it was found that the flow profile perpendicular to the direction of the displacement of the centered position plays a crucial role in stabilizing the slipper state and surpressing the tumbling motion expected from considering the behavior in a pure shear flow.

BP 7.22 Mon 18:00 P1

Brownian dynamics simulations of deformable cells in ordered polymer networks — •JAN TIMO BACHMANN^{1,2} and ANDREAS  $ZOTTL^2 - {}^1TU$  Darmstadt, Germany —  2 University of Vienna, Austria

Various Cells migrate in different environments and in response to different stimuli. Cell migration may include the navigation and locomotion through complex environments, as in the case of Leukocyte migration where cells have to translocate through small pores in the extracellular matrix (ECM) by squeezing their cell body considerably. To investigate the influence of pores in the ECM on cell velocity and deformation we study a simplified model of an externally driven deformable cell moving through ordered polymer networks by means of Brownian dynamics simulations.

The cell velocity shows oscillatory behaviour with minima before and maxima after each network pore. The speed maxima can exceed the terminal velocity of the respective cell in a network-free fluid, indicating that in the squeezing process elastic interaction energy with the network is utilized to locally enhance the cell speed. The mean velocity through the network as a function of the bending modulus of the cell surface bending potential shows a non-linear unimodal curve. We further show how the interplay of pore size and cell elasticity determines the cell velocity.

BP 7.23 Mon 18:00 P1

**Modelling of cell proliferation in epithelial tissue** – •KEVIN HÖLLRING¹, SARA KALIMAN¹, LOVRO NUIĆ², LUCA ROGIĆ², SIMONE GEHRER¹, MAXIME HUBERT¹, and ANA-SUNČANA SMITH^{1,2} – ¹PULS Group, FAU Erlangen-Nürnberg, Germany – ²Group for Computational Life Sciences, Ruđer Bošković Institute, Zagreb, Croatia

The extracellular microenvironment (ECM) of epithelial cells is known to mechanically govern the properties and behavior of cells and tissues like cell differentiation, size and motility. Yet its effect on the division rate of cells in tissues has not been analyzed in detail to our knowledge. In this work, we use MDCK-II cells grown on glass and 11 kPa PDMS substrates to provide evidence for a local cell density dependent division rate in an ECM stiffness dependent manner but independent of the age of the model- tissue, its internal structure or state.

We provide a theoretical model for microscopic tissue growth in a local microenvironment with well-defined average cell-density in agreement with experimental data and Dissipative Particle Dynamics (DPD) tissue simulations. We also propose an extension to the macroscopic tissue description via the Fisher-Kolmogorov equation (FK) accounting for our new findings that is able to reproduce characteristic edge behavior of tissues that has not been able to be reproduced by the FK formalism alone.

This work therefore sheds a new light on the influence of the ECM stiffness on the maturation of epithelial tissues and the important influences of different time scales for tissue growth and cell division.

### BP 7.24 Mon 18:00 P1

Finding protein-ligand unbinding pathways in dcTMD simulations using distance-based clustering — •VICTOR TÄNZEL — Institute of Physics, Albert Ludwigs University, Freiburg, Germany

The exploration of protein-ligand dynamics by fully atomic simulations is of immense interest, for example in drug design, yet remains unfeasible in unbiased molecular dynamics (MD). To trigger rare events, we employ dissipation-corrected targeted MD (dcTMD) simulations, in which a moving distance constraint biases a prechosen reaction coordinate *x*, here the protein-ligand distance. The method combines a Markovian Langevin equation with a second-order cumulant expansion of the Jarzynski equality. From the required constraint forces, a free energy profile  $\Delta G(x)$  as well as a friction coefficient  $\Gamma(x)$  are extracted.

Transitions often occur along multiple pathways. In order to find these pathways, we study distance-based clustering approaches combining a pairwise ligand RMSD with the Leiden community detection algorithm. Here, we demonstrate the capabilities of this approach with the example of the A2A-ZMA complex and estimate (un-)binding rates.

### BP 7.25 Mon 18:00 P1

**Protein folding as described by different internal coordinates** — •SOFIA SARTORE — Albert-Ludwigs-Universität Freiburg

Proteins reach their final structure (native state) through a process named folding. A powerful tool to investigate such process are molecular dynamics simulations, that can simulate the folding of a protein, giving as output a folding trajectory up to hundreds of microseconds long. This trajectory however needs to be further interpreted and analyzed in order to obtain an understandable model of the process, consisting of states that correspond to metastable conformation of the protein during the folding. To build such states, identifying the main features that are responsible for the folding of the protein is of utmost importance, as well as choosing appropriate coordinates to describe the dynamics under study. Using internal coordinates such as dihedral angles or interatomic distances proves to be convenient, since they disregard the overall motion of the system. In this poster we analyse what influence the choice of different input coordinates has on the resulting picture of the process: we compare an analysis of the fast folding protein HP35 based on dihedral angles as internal coordinates with one based on contacts, a particular set of interatomic distances that satisfy specific requirements. We find that using different input coordinates highlights different dynamics of the system, resulting in different descriptions of the same physical process.

### BP 7.26 Mon 18:00 P1

Machine Learning based parametrization of tumor simulation — •JULIAN HEROLD¹, ERIC BEHLE², and ALEXANDER SCHUG² — ¹Karlsruhe Institute of Technology (KIT), Kaiserstraße 12, 76131 Karlsruhe, Germany — ²JSC, Jülich Research Centre, Wilhelm- Johnen-Straße, 52428 Jülich, Germany

Despite decades of substantial research, cancer remains a ubiquitous scourge in the industrialized world. Effective treatments require a thorough understanding of macroscopic cancerous tumor growth out of individual cells in the tissue and microenvironment context.

Here, we aim to introduce the critical scale-bridging link between clinical imaging and quantitative experiments focusing on small clusters of cancerous cells by applying machine learning to drive model building between them. We deploy Cells in Silico (CiS), a high performance framework for large-scale tissue modeling developed by us. Based on both a cellular potts model and an agent-based layer, CiS is capable of accurately representing many physical and biological properties, such as individual cell shapes, cell division, cell motility etc.

The strong representational capacity of our model comes with the need to adjust a large number of parameters according to experimental findings. We present a generalized approach to optimize these parameters which allows the use of different sources of experimental data.

One major hurdle to achieve this goal is finding appropriate objective functions. To overcome this we implemented a variation of the Particle Swarm Optimization algorithm which learns the objective function during the optimization process.

### BP 7.27 Mon 18:00 P1

**Coarse-Grained Force Fields for Intrinsically Disordered Proteins** — •YANNICK WITZKY, D. JANKA BAUER, ARASH NIKOUBASHMAN, and FRIEDERIKE SCHMID — Inst. für Physik, Universität Mainz, Germany

Simulations of systems containing many long proteins that perform liquidliquid phase separation (LLPS) are usually computed with coarse-grained united residue force fields that allow for feasible runtime. One of these commonly used force fields was developed by Dignon et al.[1], where the proteins are modeled as bead-spring chains in an implicit solvent. As a reference we also used the bottom up coarse-grained UNRES force field [2] that resolves many more protein characteristics and is originally used for folding predictions. The results of simulations of four variants of an intrinsically disordered protein from both force fields are discussed in prospect of their polymer characteristics and the implications for simulations of LLPS-systems.

[1] Dignon et al.(2018) PLoS Comput Biol 14(1): e1005941

### BP 7.28 Mon 18:00 P1

Nano-tribological investigation of the influence of specific synovial fluid components on lubrication of artificial joint materials — •Alex Kreis¹, LUKAS BÖTTCHER¹, REGINA LANGE¹, PAUL HENKE², RAINER BADER², INGO BARKE¹, and SYLVIA SPELLER¹ — ¹Institute of Physics, University of Rostock — ²Biomechanics and Implant Technology Research Laboratory, University Medical Center Rostock

The human synovial fluid in native and endoprosthetic joints enables outstanding lubrication and low wear. The question is how this fluid or its specific components, such as hyaluronic acid and albumin, participate in this performance on a nanoscopic scale. In this work we aim to determine the frictional forces between the force microscope (AFM) tip (Si3N4) and typical materials for articulating components of endoprosthetic implants, such as ceramics, ultra-high molecular weight polyethylene (UHWMPE) and cobalt-chromium (CoCr) based alloy by means of lateral force microscopy (LFM). As reference we use force loops acquired on borosilicate glass surfaces in water. Further we plan to investigate and discuss the influence of the chain length of hyaluronic acid on tribological properties of each of these materials.

#### BP 7.29 Mon 18:00 P1

Microscale resonators for microfluidic based Nuclear Magnetic Resonance spectroscopy — •Alaleh Mirhajivarzaneh¹, Piotr Lepucki¹, Adam P. Dioguardi¹, Aleksandr I. Egunov¹, Marco Rosenkranz¹, Renato HUBER¹, DANIIL KARNAUSHENKO¹, DMITRY D. KARNAUSHENKO¹, OLIVER G. SCHMIDT^{3,4}, BERND BÜCHNER^{1,2}, and HANS-JOACHIM GRAFE¹ — ¹Leibniz Institute for Solid State and Materials Research (IFW) Dresden — ²Dresden University of Technology, Faculty of Physics — ³Research Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Chemnitz — ⁴Chemnitz University of Technology, Material Systems for Nanoelectronics

Over the past few decades efforts to miniaturize Nuclear Magnetic Resonance (NMR) spectroscopy have resulted in the down-scaling of the core of an NMR system to microscale detectors. This achievement has unfolded a new era of NMR spectroscopy, with applications particularly in biological studies, where the sample size can scale down to micro- or nanoliters (nL), typical of microorganism and cell cultures. Our novel microcoil is a 3D microscale resonator with an integrated microfluidic system that offers high sensitivity and resolution (8ppb) for analyte volumes as small as 1.5nL, one of the smallest reported detection volumes in the field of NMR spectroscopy. Additionally, the integrated microfluidic system optimizes the filling factor of the device to reach almost 100%. The rolled-up microcoil can potentially be employed for high-resolution micro-NMR analysis of biological samples.

### BP 7.30 Mon 18:00 P1

Altered local chromatin dynamics in stressed cells - • REBECCA BENELLI and MATTHIAS WEISS — Experimental Physics I, University of Bayreuth, Germany The dynamic re-organization of chromatin is of crucial importance for cell viability and replication. During interphase, chromatin is mostly decondensed to allow for the transcription of genes, i.e. individual chromatin elements can be supposed to move like monomers of a polymer. Yet, recent reports have suggested chromatin to behave like a solid body on mesoscopic scales, questioning any free motion of chromatin elements. To explore the motion of integral chromatin markers, we have performed extensive single-particle tracking on telomeres under varying conditions. In agreement with previous findings, we observed a strongly subdiffusive and anti-persistent motion of telomeres in untreated culture cells, akin to the motion of monomers in a Rouse polymer. Reducing the ambient temperature or challenging cells by hyper- or hypo-osmotic stress resulted in a significant reduction of telomere mobility. In addition, significant jumps of telomeres between dynamically caged loci, observed in untreated cells, subsided or even vanished in response to these challenges. Altogether, our data indicate that local chromatin dynamics with long-range jumps between different loci are possible in untreated cells whereas a more compact/solid configuration of chromatin might explain the strongly reduced mobility of telomeres in stressed cells.

### BP 7.31 Mon 18:00 P1

Image segmentation of irradiated tumour spheroids by Fully Convolutional Networks — •MATTHIAS STRELLER¹, SONA MICHLIKOVA², LEONI A. KUNZ-SCHUGHART², STEFFEN LANGE¹, and ANJA VOSS-BOEHME¹ — ¹University of Applied Sciences Dresden — ²OncoRay, National Center for Radiation Research in Oncology

Multicellular tumour spheroids are an established in-vitro model to quantify the effectiveness of cancer therapies. Spheroids are treated with radiotherapy and their therapeutic response over time is most frequently monitored via microscopic imaging. For analysis, it is necessary to segment the spheroids in these images, to extract their characteristics like the average diameter or circularity. While several image analysis algorithms have been developed for the automatic segmentation of spheroid images, they focus on more or less compact and circular spheroids with clearly distinguishable outer rim throughout growth. In contrast, treated spheroids are usually obscured by debris of dead cells and might be partly detached and destroyed. We train and optimize two Fully Convolutional Networks, in particular UNet and HRNet, to create an automatic segmentation which covers both cases, spheroids with and without therapy. While we successfully demonstrate the automatic segmentation for one spheroid type, we plan to extent the segmentation to other spheroid models.

### BP 7.32 Mon 18:00 P1

**Investigating Nanoparticle Dynamics in a High-Finesse Optical Microcavity** — LARISSA KOHLER, •SHALOM PALKHIVALA, and DAVID HUNGER — Karlsruhe Institute of Technology – Institute of Physics, Karlsruhe, Germany

We explore the dynamics of nanoparticles using a novel fibre-based high-finesse Fabry-Perot microcavity with integrated microfluidic channels. Silica nanospheres with radii down to 25 nm and gold nanorods with lengths of 20 nm have thus been investigated.

The three-dimensional Brownian motion of a single nanosphere in the cavity has been tracked by the simultaneous measurement of the fundamental and higher-order transverse modes. The particle's position was derived with spatial and temporal resolutions of down to 8 nm and 0.3 ms respectively.

To resolve the faster motion of even smaller nanoparticles, a cavity-locking system has been implemented. This achieved an rms stability of 4% of the resonance linewidth in a water-filled cavity having a finesse of  $5 \times 10^4$ . Hence, the dynamics of 20 nm gold nanorods could be detected with high measurement bandwidth. We shall report progress towards a quantitative evaluation of

nanorod diffusion, and the measurement of nanoparticle rotation using a cavity-locked polarisation-splitting scheme.

Based on this, we aim to explore the dynamic and optical behaviour of single biomolecules, such as DNA.

### BP 7.33 Mon 18:00 P1

Fixed 4-channel detection in 2D polarization fluorescence imaging (2DPOLIM) and compensation of depolarization caused by dichroic mirrors – •YUTONG WANG^{1,2}, ASAD HAFEEZ^{1,2}, DIJO MOONNUKANDATHIL JOSEPH^{1,2}, MOHAMMAD SOLTANINEZHAD^{1,2}, RAINER HEINTZMANN^{1,2}, and DANIELA TÄUBER^{1,2} – ¹Leibniz Institute of Photonic Technology – ²Friedrich-Schiller-University Jena, Germany

Polarization resolved fluorescence imaging (POLIM) can reveal macromolecular structure in the range of 2-10 nm via Förster resonance energy transfer between similar fluorophores (homo-FRET, emFRET). 2D POLIM is superior to conventional fluorescence anisotropy methods for studies of anisotropic samples[1,2]. Implementing a variable electrooptic polarization control in the excitation together with a fixed 4-channel detection[3] speeds up the acquisition giving access to polarization resolved snapshots of dynamic samples. A major issue in POLIM setups is depolarization caused by the multilayer coating of dichroic mirrors, which introduces phase shifts between s- and p-polarized components. We implemented two pairs of dichroics with orientations crossed to each other. By this, incident s- and p-polarization is exchanged within each pair. The design proved to be an effective and reliable approach to significantly improve the quality of polarization by compensating the depolarization introduced by a single dichroic. Funding: DFG-Ta1049/2 - [1] R. Camacho et al. Adv. Mater. 2019, 1805671. [2] R. Camacho et al. Commun. Biol. 2018, 1, 157. [3] F. Zimmermann et al. in Optically Induced Nanostructures, 2015.

Scanning small angle x-ray scattering of hydrated, keratin-rich cells — •Boram Yu¹, Chiara Cassini¹, Sophie-Charlotte August¹, Manfred Burghammer², and Sarah Köster¹ — ¹Institute for X-Ray Physics, Universität Göttingen, Germany — ²ESRF, Grenoble, France

Intermediate filaments (IFs), one of the three main components of the cytoskeleton, form a network that contributes to cell mechanic. Thus, collecting structural information about IFs in their physiological setting, i.e., in whole cells, is crucial. We use scanning small angle x-ray scattering(SAXS) to obtain this information, as it offers both real space overview images with moderate resolution and reciprocal space information with high resolution. X-ray imaging of cells in aqueous state is challenging as their electron density contrast is low. Additionally, the aqueous environment contributes to extremely rapidly spreading radiation damage. For this reason, a fast-scanning mode is employed by moving the sample continuously through the beam rather than step by step, resulting in a significant reduction in exposure time, thus diminishing the radiation damage. As a benchmark for ordered intracellular structures, we investigate mammalian cells expressing the IF protein keratin. A purpose-built chamber maintains the cells hydrated while minimizing the volume of the liquid in the optical path. Despite weak contrast and short exposure times, we are able to retrieve the local main orientation of subcellular structures, thus demonstrating how scanning SAXS offers valuable information from hydrated cells.

### BP 7.35 Mon 18:00 P1

Microfluidics-based analysis of the mobility and migration pattern of Trypanosoma brucei — •HANNES WUNDERLICH¹, LUCAS BREHM², JANA JENTZSCH², SEBASTIAN KRAUSS¹, KLAUS ERSFELD², and MATTHIAS WEISS¹ — ¹Experimental Physics I, University of Bayreuth, Germany — ²Molecular Parasitology, University of Bayreuth, Germany

Trypanosoma brucei is a unicellular parasite that causes the African sleeping sickness after entering the human bloodstream. An active movement of trypanosomes, mediated by the beating of a microtubule-powered flagellum that spirals along the elastic cell body, is crucial for escaping the host's immune response. A highly ordered, subpellicular array of aligned microtubules beneath the cell membrane determines the effective elasticity of parasite and hence its propulsion during flagellar beating. Using soft lithography to create well-definded two-dimensional chambers, we have studied the mobility and migration pattern of trypanosomes without and with genetically induced changes of posttranslational microtubule modifications. Using a set of informative measures that have been developed for (persistent) random walks, we have analyzed trypanosome trajectories that exhibit clear run-and-tumble patterns. Our data reveal that posttranslational modifications of microtubules significantly alter trypanosome mobility and migration.

### BP 7.36 Mon 18:00 P1

**Topological artifacts in mid-IR photo-induced force microscopy (PiF-IR)** — •SAJIB BARUA^{1,2}, HARDIK GADHER^{1,3}, UWE HÜBNER¹, and DANIELA TÄUBER^{1,2} — ¹Leibniz Institute of Photonic Technology, Jena — ²Institute of Physical Chemistry & Abbe Center of Photonics, Friedrich-Schiller-University Jena, Germany — ³Leibniz University Hannover, Germany The use of tapping mode atomic force microscopy (AFM) for detecting mid IR absorption can provide nanoscale chemical information. Several studies report on successful applications for qualitative characterization of biomaterials [1]. Implementing such methods for quantitative evaluation of chemical sample compositions requires further understanding of underlying physical processes [2]. In general, the surface of biological cells and tissue is rough on a sub-micron scale. This may cause artifacts in signal detection due to non-planar interactions with the AFM tip. We use structured polymer layers to investigate implications of sample topography on the signal intensity in mid-IR photo-induced force microscopy (PiF-IR). – [1] Wang et al. Super-Resolution Mid-Infrared Spectro-Microscopy of Biological Applications through Tapping Mode and Peak Force Tapping Mode Atomic Force Microscope. Adv. Drug Deliv. Rev. 2022, 180. [2] Täuber et al. Interference Effects in Nanoscale Infrared Spectroscopy Methods, submitted.

### BP 7.37 Mon 18:00 P1

Investigation of biofilm formation on metal surfaces — •BERNHARD KALTSCHMIDT¹, ANNIKA KIEL², EHSAN ASGHARI², JULIAN CREMER³, DARIO ANSELMETTI³, BARBARA KALTSCHMIDT², CHRISTIAN KALTSCHMIDT², and ANDREAS HÜTTEN¹ — ¹Thin Films & Physics of Nanostructures, University of Bielefeld — ²Department of Cell Biology, University of Bielefeld — ³Biophysics & Nanosciences - "Physics of Life", University of Bielefeld

Biofilms can cause major problems in many different areas, such as corrosion and contamination of medical products. The aim of this work was to investigate biofilm formation on stainless steels and on sputtered transition metals. Steel disks of the chromium steels 1.4016, 1.4301 and 1.4510 were inoculated with bacteria in LB medium for 7 and 14 days. As bacteria we used Pseudomonas aeruginosa, which we use as our in vitro model for strong biofilm formation. After 14 days the first signs of bio-corrosion were detected by scanning electron microscopy (SEM) and atomic force microscopy. In another series of investigations, glass slides were coated with the transition metals Gold, Ruthenium and Tantal by magnetron sputtering and incubated with Pseudomonas aeruginosa for 24 hours. An uncoated glass surface served as a reference. Comparative studies of biofilm growth on the reference and on the different transition metals were carried out using SEM, confocal laser scanning microscopy and the colony forming unit assay. The analysis revealed that biofilm growth on transition metals is severely hindered compared to our non coated glass slide reference.

### BP 7.38 Mon 18:00 P1

Observation of two-step aggregation kinetics of amyloid-β42 peptide from fractal analysis — •SOHAM ΜυκΗΟΡΑDΗΥΑΥ — Chair of Mathematics in Life Sciences, Friedrich-Alexander Universität Erlangen-Nürnberg, Cauerstr. 11, 91058 Erlangen, Germany — Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany

Proteins are responsible for controlling and catalyzing the reactions and processes that make life possible. Proper folding of protein molecules into their native states is critical for them to function correctly; conversely, misfolded proteins often cause damaging effects on the biological processes they are involved in. Misfolded proteins often undergo self-aggregation, a process that has been the subject of intense research due to its importance in biological contexts. Of particular interest is the formation of stable filamentous aggregates termed amyloids — implicated in the pathology of several diseases such as Alzheimer's, Parkinson's, type-II diabetes, etc. Several models propose a two-step aggregation mechanism, with linearly growing fibrils and branch formation through secondary growth.

In this work, we employ tools from fractal geometry to develop an analysis technique for images of protein aggregation obtained from TIRF microscopy. Fractal geometry provides an instinctive framework for analyzing 1- and 2-dimensional growth. We use this framework to study the aggregation of the amyloid- $\beta$ 42 peptide and find the initial aggregation to proceed in a one-dimensional fashion, with later branching events leading to two-dimensional growth. This provides direct evidence for the two-step aggregation model.

#### BP 7.39 Mon 18:00 P1

Influence of varying pH on individual and collective behavior of filamentous cyanobacteria — •FRANZISKA PAPENFUSS, MAXIMILIAN KURJAHN, ANTARAN DEKA, and STEFAN KARPITSCHKA — MPI for Dynamics and Self-Organization, Göttingen, Germany

Photoautotrophic cyanobacteria are responsible for about 10 % of global primary production of reduced carbon and represent a sustainable source of carbon dioxide neutral bio-fuel. Adaptation to environmental changes is a key factor of their evolutionary success, but the emergent phenomena that couple the individual to their collective behavior remain elusive. Here, we investigate three species of filamentous cyanobacteria cultivated in pH-buffered and non-buffered medium over three weeks of cultivation. During cultivation, colony-scale properties like external pH and aggregate morphology were measured as well as properties of individual filaments like gliding velocity and absorption spectra. In the non-buffered cultures, pH varies in dependence on light-driven photosynthesis. Different species seem to adapt colony morphology from compact aggregates to reticulate layers at different pH values in the low alcalic range. Yet, the external pH has no influence on the gliding velocities, but influences the abundance of the dominant photo-pigments Chlorophyll-a, beta-carotene and phycocyanin in some species. Our investigations show that the pH is not only governed by the photosynthetic activity, but also influences the fate of the cyanobacterial colony in a regulating feedback mechanism.

BP 7.40 Mon 18:00 P1

Identifying malignant tissue using Laser Induced Breakdown Spectroscopy (LIBS) and Neural Networks — •ELENA RAMELA CIOBOTEA¹, CHRISTOPH BURGHARD MORSCHER¹, CRISTIAN SARPE¹, BASTIAN ZIELINSKI¹, HENDRIKE BRAUN¹, ARNE SENFTLEBEN¹, JOSEF RÜSCHOFF², and THOMAS BAUMERT¹ — ¹Kassel Universität, Kassel, Germany — ²Institut für Pathologie Nortdhessen, Kassel, Germany

The problem of differentiating cancerous tissue from a healthy one is currently solved in the diagnostic process through microscopic imaging of stained biopsy sections by pathologists. During surgical removal of cancerous tissue, oncological safety margins must be established to ensure the complete removal of the tumor without affecting much of the neighboring healthy tissue. For this purpose, on-site pathological analysis is done on freshly frozen, stained cuts, which is time consuming. We investigate a new approach to minimize the time of discrimination between malign and benign tissue by an in situ, non-contact spectroscopic analysis. In a proof of principle experiment, a plasma is generated by focusing an 800 nm femtosecond laser on the pathologic postoperative sample. The spectrum of plasma radiation contains information on the element composition of the ablated tissue. Since the recorded spectra are complex and full of information, neural networks are employed to find differences between malign and benign tissue with a high speed and accuracy. This contribution presents the experimental parameters that allow for the best possible differentiation of some biological tissues through fs-LIBS by minimizing deviations between the measurements.

### BP 7.41 Mon 18:00 P1

**Deep learning for single particle tracking in noisy data** — •MATTIAS LUBER, MOHAMMAD AMIN ESKANDARI, and TIMO BETZ — University of Goettingen, Goettingen, Germany

The quantitative analysis of particle motion critically depends on the quality of particle trajectory detection. Especially the position detection of particles in fluorescence microscopy images is an important task faced in biophysics. Trajectories are used to study processes like intra-cellular transport protein diffusion within and through membranes and the reconstruction of force fields driving the particle motion. In such settings, high spatial and temporal resolution are be desired. However, in practice those factors have contradictory measurement requirements. High temporal resolution requires short exposure times, which limit the photon budget and thus lead to low signal to noise ratios. We developed an approach to reconstruct the particle position from noisy images, by applying U-NET based deep learning models to fluorescence microscopy images. Using this we can successfully track particles with shorter exposure times, compared to traditional denoising techniques.

BP 7.42 Mon 18:00 P1

Analyses of the outer membrane of vital mitochondria — •ERIC LIEBERWIRTH¹, CHRISTIAN VÖLKNER¹, REGINA LANGE¹, ANJA SCHAEPER², MAGDALENA OTTE², ARMIN SPRINGER³, MARKUS FRANK³, INGO BARKE¹, SI-MONE BALTRUSCH², and SYLVIA SPELLER¹ — ¹University of Rostock, Institute of Physics, 18059 Rostock, Germany — ²Rostock University Medical Center, Institute for Medical Biochemistry and Molecular Biology, 18057 Rostock, Germany — ³Rostock University Medical Center, Medical Biology and Electron Microscopy Center, 18057 Rostock, Germany

A network of mitochondria enables a cell to perform oxidative metabolism. These organelles have a double membrane that is subject to constant remodeling during the regular fusion and fission processes. This study aims to gain more knowledge about the outer membrane containing translocase, porin and ion channels. Via Scanning Ion Conductance Microscopy (SICM) is it possible to measure the outer membrane of vital mitochondria at lateral spatial resolution of approx. 50 nm and at height resolution of a few nanometer. We immobilize the organelle in phosphate buffered saline (PBS) on collagen-coated substrates and scan the outer membrane with nanopipettes. Though the nanoprobe was, on each pixel, approached from top, the observed shapes exhibit forward-backward hysteresis and flat plateaus. The corrugation amplitude amounts to a few 10 nm and soft steps are present. Labeling translocase of the outer membrane (TOM) with nanoscopic gold particles may help learning about their spatial distribution and help to identify signatures in SICM and SEM.

### BP 7.43 Mon 18:00 P1

Multiple thermophoretic particle trapping at single molecule resolution — •BENJAMIN FANSELOW, TOBIAS THALHEIM, and FRANK CICHOS — Peter-Debye Institute for Soft Matter Physics, Leipzig University, Germany

Achieving single molecule resolution for microscopy enabled to gain valuable insight into processes, that otherwise would be hidden in the ensemble, such as

amyloid fibril fragmentation, volume exclusion of DNA molecules, or localization of proteins within a cell. One technique is the combination of fluorescence microscopy with thermophoretic trapping. It utilizes thermophoresis for confining freely diffusing single molecules within a liquid into a region of interest and allows observing these molecules without surface immobilization, over a time period of several minutes. The required temperature fields are generated via optical heating using a focused laser beam steered on a thin chromium layer. So far, only one trap at a time could be used, entailing multiple time-consuming measurements to achieve a reasonable statistics. We present the realization and characterization of up to four thermophoretic traps, which can be controlled simultaneously while preserving the single molecule resolution. This mode is characterized by a model system of 200-nm polystyrene particles in water, trapped with a feedback assisted mode. Analyzing the molecule displacement framewise, the trap stiffness and temperature induced velocities can be calculated. While it could be shown, that the stiffness is scalable with the laser power and the number of used traps, it also revealed an upper limit caused by the feedback loop frequency.

### BP 7.44 Mon 18:00 P1

adaptive interferometric light-sheets for resolution enhanced imaging -•MEELAD LALENEJAD and ALEXANDER ROHRBACH — Laboratory for Bio- and Nano-Photonics, Department of Microsystems Engineering (IMTEK), University of Freiburg, Georges-Koehler-Allee 102, 79110 Freiburg, Germany

The success of light-sheet microscopy bases on the idea that only the parts of the object being are illuminated with laser beams from the side, which are in focus of the objective lens. This concept leads to increased image contrast and reduces photo-bleaching / -toxicity. In addition, larger volumes are scanned plane-wise or line-wise, such that LSM is significantly faster than point-wise scanning methods. However, compromises in spatial resolution have had to be made because of objective lenses with limited numerical aperture and aberrations from light scattering. On the detection side, such phase aberrations could often be corrected with adaptive optics. However, spatial light modulation and phase adaptation of the illumination side still leave plenty of room for improvements. In our research we want to combine the principles of holographically shaped illumination beams with interferometric arrangements of the illumination beams. Since the modulation contrast can be deteriorated by refractive index inhomogeneities of the sample, future phase adaptation for each of the counter propagating beams shall be used as an effective aberration compensation. Using the principles of structured illumination microscopy, we show 3D images in scattering media such as cancer cell clusters obtained from two laterally scanned, counter-propagating Bessel beams.

### BP 7.45 Mon 18:00 P1

Absorption-based specificity in ROCS microscopy - •VICTOR CHUMAN and ALEXANDER ROHRBACH — University of Freiburg, Department of Microsystems Engineering - IMTEK, Laboratory for Bio- and Nano-Photonics, Georges-Köhler-Allee 102, 79110 Freiburg, Germany

Fluorescence techniques dominate the field of live-cell microscopy, but bleaching and motion blur from too long integration times limit dynamic investigations of small objects. High contrast, label-free life-cell imaging of thousands of acquisitions at 150nm and 200 Hz is possible by Rotating Coherent Scattering (ROCS) microscopy, where intensity speckle patterns from all azimuthal illumination directions are added up within a few milliseconds. However, ROCS lacks the important imaging feature of specificity. We address this deficiency by using different absorption markers, characterized by their different complex valued refractive indices to achieve a difference in image contrast in the observed structures. We demonstrate how different gray values in the image are obtained from interferences between scattered and unscattered light, resulting from material dependent phase shifts of the scattered light. Absorption-based specificity in ROCS imaging may open new fields of applications, adding on top of its high spatio-temporal resolution.

### BP 7.46 Mon 18:00 P1

Novel concepts in scanned light-sheet microscopy to improve speed, contrast and resolution —  $\cdot$ YATISH YATISH^{1,2,3} and ALEXANDER ROHRBACH^{1,2} - ¹Laboratory for Bio- and Nano-Photonics, Department of Microsystems Engineering-IMTEK, University of Freiburg, 79110 Freiburg, Germany -²CIBSS - Centre for Integrative Biological Signalling Studies, Freiburg, Germany - ³Spemann Graduate School of Biology and Medicine (SGBM), University of Freiburg, Freiburg, Germany

Light-sheet microscopy (LSM) enables fast 3D, high contrast imaging offering effective sectioning and low photo-toxicity. LSM allows to investigate the issue of light scattering in both the illumination and detections, and to better understand the complex image formation. Switchable computer holograms can generate special Bessel beams that are scanned through the object offering increased penetration depths due to their self-reconstruction capability. These beams generate images with better contrast and resolution, when combined with confocal line detection. A future challenge will be to automatically adapt the illumination beam dimensions to the specific structure of object to enhance the 3D image quality. We have investigated the propagation of different beams through classes of spheres. All experiments were performed in combination with advanced computer simulations to better understand the effects of scattering. This includes the loss in quality of bead images along the optical illumination and detection axes through bead clusters, but also the position dependent scattering and absorbing of illumination and fluorescence light in cancer cell clusters.

### **BP 8: Focus Session: Phase Separation in Biochemical Systems**

organized by Christoph Weber (University of Augsburg) and David Zwicker (MPIDS Göttingen)

Time: Tuesday 9:30-13:00

### **Invited Talk**

BP 8.1 Tue 9:30 H15 Phase separation in cells: gene localization and noise buffering - •SAMUEL

SAFRAN — Weizmann Institute of Science, Rehovot, Israel Biomolecular condensates formed by phase separation allow the cell to organize itself in space and can promote or inhibit biochemical reactions. I will focus upon recent observations of phase separation of chromatin (chains of DNA and proteins) in the nucleus that suggests a new paradigm in which the genetic material is separated into domains, which in some cases, have a complex, marshland, mesoscale structure. How this mesoscale structure affects gene expression noise is a topic of current research. While many of the equilibrium properties of biomolecular condensates can be understood by extensions of statistical physics, biological molecules often do not maintain constant overall compositions, in contrast to equilibrium phase separation; over time, the cell stochastically produces and degrades many proteins, resulting in a noise-induced concentration distribution. Our theory shows how in the limit of slow production/degradation relative to molecular diffusion, one can incorporate the effects of such noise into the equilibrium phase diagram to predict the extent of noise reduction (buffering) by the phase separation in multicomponent systems.

### BP 8.2 Tue 10:00 H15

**RNA** polymerase II clusters form in line with surface condensation on reg-ulatory chromatin — •TIM KLINGBERG^{1,2}, AGNIESZKA PANCHOLI³, WEICHUN Zhang³, Roshan Prizak³, Irina Mamontova³, Marcel Sobucki³, Andrei Yu Kobitski³, Gerd Ulrich Nienhaus³, Vasily Zaburdaev^{1,2}, and Lennart  $\begin{array}{l} {\rm Hilbert}^3-{}^1{\rm Friedrich-Alexander-Universit\"at Erlangen-Nürnberg-{}^2{\rm Max-Planck-Zentrum f\"ur Physik und Medizin-{}^3{\rm Karlsruhe Institute of Technology} \end{array}$ Transcription of eukaryotic genes by the RNA polymerase II (Pol II) has two Location: H15

major control points: recruitment to the regulatory region of a specific gene, and subsequent release into the elongation of RNA transcripts. We find that recruited Pol II forms macromolecular clusters with a large variety of shapes in the embryos of zebrafish, which we investigated by live and super-resolution microscopy. To delineate the essential physical mechanisms underlying Pol II cluster formation, we use coarse-grained lattice kinetic Monte Carlo simulations containing monomeric particles (recruited Pol II) that can interact with polymer chains (regulatory regions). We propose that the regulatory chromatin regions act as surfaces for the condensation of recruited Pol II into a liquid-phase. The numerical simulations of our model qualitatively reproduce the different forms of RNA Pol II clusters that we detected with microscopy. Taken together, our results suggest that recruited Pol II contributes to the surface-associated condensates, whereas elongating Pol II is excluded from these condensates and thereby drives unfolding of the condensates.

### BP 8.3 Tue 10:15 H15

Lattice based model and continuum theory of active microemulsion -•RAKESH CHATTERJEE^{1,2}, HUI-SHUN KUAN^{1,2}, and VASILY ZABURDAEV^{1,2} ¹Friedrich-Alexander University, Erlangen-Nuremberg, Erlangen, Germany — ²Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany

During transcription, RNA polymerase II (Pol II) attaches and moves along the DNA strand to produce messenger-RNA (mRNA) transcript. It has been recently shown that in the nucleus, DNA and RNA are spatially organised in agreement with a microphase separation process [1], where the full phase separation of the RNA-rich phase from DNA is prevented by the transcribing Pol II playing the role of an amphiphile. To gain the comprehensive understanding of physical mechanisms behind this process we propose a phenomenological lattice model where DNA, mRNA and Pol II serve as the three basic components similar to the equilibrium oil-water-amphiphile system, which exhibits two and three phase coexistence. Here however, Pol II undergoes chemical transitions reflecting different stages of the transcription process. In the model, it is realised by assuming transient dynamics of the amphiphiles which switches between active and inactive states. Numerical simulations of the lattice model show that amphiphile activity significantly modifies phase behaviour of the system compared to the equilibrium scenario. Furthermore, by rigorous coarse-graining of the lattice model we could derive the continuum theory and predict the relaxation dynamics of the dynamic structure factor of active microemulsion.

BP 8.4 Tue 10:30 H15 Molecular assembly lines regulate the size of active droplets — •Tyler Har-MON — Leibniz Institute for Polymer Research, Dresden, Germany

Large protein complexes are assembled from protein subunits to form a specific structure. In our previous work, we used theory to propose that assembly into the correct structure could be reliably achieved through an assembly line with a specific sequence of assembly steps. We illustrated that the assembly line can be self-organized through utilizing existing membraneless organelles. In this way, the droplet directly regulates the formation of the assembly line.

In this work we explore how the assembly line can directly regulate the droplet. It has been observed that the core element can act as an important structural factor for the droplet formation. By introducing this feature into the model, we see that the assembly line also regulates the size of the droplet in a productive way.

### BP 8.5 Tue 10:45 H15

**Droplet differentiation induced by chemical reactions** — •XI CHEN¹, FRANK JÜLICHER², JENS-UWE SOMMER¹, and TYLER HARMON¹ — ¹Leibniz-Institut für Polymerforschung Dresden, Institut Theory der Polymere, 01069 Dresden — ²Max Planck Institute for the Physics of Complex Systems, 01187 Dresden

Membraneless compartments are formed in cells by liquid-liquid phase separation. The compartments enrich many components including enzymes which resemble chemically active droplets. A major paradigm for studying these droplets is to consider two types of species, scaffolds, which thermodynamically hold the droplets together, and clients, such as enzymes which utilize the droplets that are formed. We investigate through theory a model system where two competing enzymes which can modify the scaffold, for example a kinase and a phosphatase, are clients to the droplets. Interestingly, by introducing a preferential affinity between enzymes and their product scaffold, the system becomes unstable and differentiates into two types of droplets concentrated in either modified scaffold. Additionally, these features can lead to unexpected behaviors such as droplets which repel each other. This may correspond to an unexplored mechanism of the spatial control of biochemical reactions in biological cells.

Non-specific adhesive forces reorganize the cytoskeleton around membraneless organelles — •THOMAS J. BÖDDEKER, KATHRYN A. ROSOWSKI, ROBERT W. STYLE, and ERIC R. DUFRESNE — Department of Materials, ETH Zurich, Switzerland

Phase-separation of biomolecules in cells takes place in a complex environment crossed by multiple filaments of the cytoskeleton or chromatin. To understand the potential coupling between emerging droplets and the surrounding network, we study the interactions of stress granules, a phase-separated protein-RNA droplet in the cytosol, with the microtubule network. Statistical tools similar to the radial distribution function enable us to quantify long-ranged enhancement in microtubule density in the vicinity of stress granules. When microtubules are depolymerized, the molecular subunits partition to the surface of the droplet. We interpret the data using a thermodynamic model, revealing a weak non-specific affinity of the subunits to the surface of about 0.1  $k_b T$ . As filaments polymerize, the affinity is amplified leading to significant adhesion of filaments to the granule surface. This adhesion leads to reorganization of filaments around the granule and makes microtubule rich regions of the cell energetically favorable for stress granules. We find that the liquid nature of membraneless organelles leads to nonspecific adhesion of larger particles to their surface due to the surface tension of these protein droplets, reminiscent of Pickering emulsions.

**Catalysis-Induced Phase Separation and Autoregulation of Enzymatic Activity** — MATTHEW W. COTTON^{1,2}, RAMIN GOLESTANIAN^{2,3}, and •JAIME AGUDO-CANALEJO^{2,4} — ¹Mathematical Institute, University of Oxford, Oxford, United Kingdom — ²Department of Living Matter Physics, Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — ³Rudolf Peierls Centre for Theoretical Physics, University of Oxford, Oxford, United Kingdom — ⁴Institute for Theoretical Physics, University of Heidelberg, Heidelberg, Germany

Studying the effect of non-equilibrium activity on intracellular phase separation is a very active research area, but all previous studies have still relied on equilibrium interactions as the driver for phase separation. Here, we present a thermodynamically consistent model describing the dynamics of a multi-component mixture where one enzyme component catalyzes a reaction between other components. We find that the catalytic activity alone can induce phase separation for sufficiently active systems and large enzymes, without any equilibrium interactions between components [1]. In the limit of fast reaction rates, binodal lines can be calculated using a mapping to an effective free energy. We also explain how this catalysis-induced phase separation (CIPS) can act to autoregulate the enzymatic activity, which points at the biological relevance of this phenomenon.

Structure and dynamics of water molecules in FUS protein molecular condensates — •DANIEL CHAVEZ ROJAS, MARTIN GIRARD, and JOSEPH RUDZINSKI — Max Planck Institute for Polymer Research, Mainz, Germany

There is evidence that molecular condensates of the FUS protein play a role in the development of some neurodegenerative diseases like ALS. For this reason, understanding the molecular mechanism by which these condensates form at an atomistic level is of therapeutic interest. The molecular structure and waterprotein interactions of these condensates is poorly understood. In order to study these interactions, we make use of multi-scale molecular dynamics simulations. Through the analysis of these simulations we report on the water-protein hydrogen bonding interactions of the individual amino acids of FUS proteins in the condensate versus in solution.

### BP 8.9 Tue 12:00 H15

Regulation of chromatin microphase separation by adsorbed protein complexes — •Omar Adame-Arana, Gaurav Bajpai, Dana Lorber, Talila VOLK, and SAMUEL A. SAFRAN — Weizmann Institute of Science, Rehovot, Israel The spatial arrangement of chromatin in the nucleus serves as a template for DNA transcription. Regions of chromatin that are loosely packed (active regions) are accessible to the transcription machinery and can be readily transcribed; in contrast, regions that are tightly packed are usually not transcribed (inactive regions). These two types of chromatin regions separate from the nucleoplasm and further form distinct compartments reminiscent of microphase separation. Chromatin phase separation due to self-attraction has been experimentally described in the past. But what controls the further, observed microphase separation into active and inactive chromatin regions? Here, we present a minimal theory in which the inactive regions experience poor solvent conditions (due to self-attraction,) but where the solvent quality for the active chromatin regions can be regulated by the adsorption of protein complexes. Using the theory of polymer brushes as well as Brownian dynamics simulations, we find that such adsorption leads to swelling of the active regions which in turn, decreases the thickness (in a flat geometry) or radius of curvature (in a spherical geometry) of the inactive chromatin microphase. We compare the theory with experiments to suggest that the solvent quality modulated by adsorption of protein complexes may be a key contributing factor in establishing and regulating the physical organization of the genome.

(De)hydration far away from equilibrium can speed up chemical processes —  $\cdot$ Ivar Svalheim Haugerud, Pranay Jaiswal, and Christoph Weber — Institute of Physics, Universität Augsburg, Augsburg, Germany

Under early earth conditions, wet-dry cycles and phase-separated droplets are believed to facilitate chemical processes. Recent experimental studies suggest that chemical reactions can accelerate when subject to non-equilibrium conditions of hydration or dehydration. We develop a theoretical model studying the interplay between wet-dry cycles, phase separation, and chemical processes. We find that both hydration and dehydration can significantly increase chemical reaction rates. Interestingly, we show that the conditions that enhance reaction rates coincide with the conditions necessary for the mixture to phase separate. The findings show under what conditions the physics of wet-dry cycles can play a role similar to enzymes in living cells, speeding up slow reactions in prebiotic soups.

### BP 8.11 Tue 12:30 H15

**Chemically Active Wetting** — •SUSANNE LIESE¹, XUEPING ZHAO², FRANK JÜLICHER², and CHRISTOPH WEBER¹ — ¹University of Augsburg, Germany — ²MPI Physics of Complex Systems, Dresden, Germany

In living cells, the wetting of condensed phases at membrane surfaces provides a mechanism for positioning biomolecules. Biomolecules can also bind to such membrane surfaces. In living cells, this binding is often chemically active since it is maintained away from equilibrium by supplying energy and matter. Here, we investigate how active binding on membranes affects the wetting of condensates. To this, we derive the non-equilibrium thermodynamic theory of active wetting. We find that active binding significantly alters the wetting behavior leading to non-equilibrium steady states with condensate shapes reminiscent of a fried egg or a mushroom. We further show that such condensate shapes are determined by the strength of active binding in the dense and dilute phases, respectively. Strikingly, such condensate shapes can be explained by an electrostatic analogy where binding sinks and sources correspond to electrostatic dipoles along the triple line. Through this analogy, we can understand how fluxes at the triple line control the three-dimensional shape of condensates.

### BP 8.12 Tue 12:45 H15

Interface resistance can govern transport of molecules across phase boundaries — •LARS HUBATSCH^{1,2}, ANATOL FRITSCH^{1,2}, TYLER HARMON³, FRANK JÜLICHER^{2,4}, CHRISTOPH WEBER⁵, and ANTHONY HYMAN^{1,2} — ¹Max Planck Institute of Molecular Cell Biology and Genetics — ²Center for Systems Biology Dresden — ³Leibniz Institute for Polymer Research — ⁴Max Planck Institute for the Physics of Complex Systems — ⁵University of Augsburg

Cells can achieve compartmentalization of biochemical processes via organelles

Location: H16

by the selective admission of biomolecules. Organelles are enclosed by a membrane or, in the case of biomolecular condensates, by the condensate-bulk interface. While transport across membranes has been studied for decades, it is less clear how biomolecular condensates regulate transport across their interface. Using a combination of live-imaging and theory, we show that the flux of molecules across the condensate-bulk interface exhibits transients that cannot be explained by local equilibrium between the coexisting phases, a phenomenon also referred to as interface resistance. It is unclear whether this interface resistance stems from molecules adsorbing to the interface or from a kinetic barrier reflecting molecules at the interface. Using single-particle imaging of PGL-3 droplets, we observe no accumulation of molecules at the interface. This observation suggests that molecules are reflected rather than adsorbed at the interface. We quantify the strength of interface resistance by accounting for molecule dynamics outside, inside, and at the droplet interface and thus provide a framework to characterize molecular fluxes across condensate-bulk interfaces.

BP 9.1 Tue 9:30 H16

Nano-infrared spectroscopic imaging (NanIRim): Promises and Challenges for Application in Biophotonics — •DANIELA TÄUBER — Leibniz Institute of Photonic Technology, Jena, Germany — Friedrich-Schiller University Jena, Germany

A number of nano IR spectroscopic methods have been developed, which provide chemical information at subcellular and single molecule level. High spatial resolution leads to a reduction of the number of chemical bonds contributing to the signal. Thus, variations have to be identified above a heterogeneous background. Since 2019, I have investigated advantages and limitations of mid IR photo-induced force microscopy (PIF-IR) together with my team and collaborators. We applied PIF-IR to materials ranging from organic monolayers on various substrates, and biopolymer compositions to single bacteria and human retina. Recently, we studied interference effects in layered systems comparing experimental and calculated FTIR spectra of polymer films on different substrates to PIF-IR spectra. PIF-IR enables hyperspectral imaging at a fascinating spatial resolution of ~5 nm. A drawback are the small data sets. We applied PIF-IR to well-known interactions of antibiotics with Bacillus subtilis. To meet the challenge of finding the local interactions in hyperspectral images of single bacteria, we developed an advanced cluster analysis together with colleagues in the Heintzmann Lab. Our findings are very promising for successful applications of PIF-IR to the investigation of local variations in the surface areas of cells and tissues. Such visualization at the single cell level will boost our understanding of interactions in the Life Sciences

BP 9.2 Tue 9:45 H16

Phase reconstruction of low-energy electron holograms of individual proteins — •HANNAH OCHNER¹, SVEN SZILAGYI¹, MORITZ EDTE¹, STEPHAN RAUSCHENBACH^{1,2}, LUIGI MALAVOLTI¹, and KLAUS KERN^{1,3} — ¹Max Planck Institute for Solid State Research, Stuttgart — ²Department of Chemistry, University of Oxford — ³Institut de Physique, École Polytechnique Fédérale de Lausanne

Low-energy electron holography (LEEH) can image proteins and their conformational variability on the single-molecule level [1,2]. However, the technique does not yield a real-space image, but rather a hologram from which the information about the molecule needs to be recovered via a reconstruction process. While a one-step reconstruction process can reproduce molecular size and shape via amplitude imaging, it cannot directly recover the phase information encoded in the hologram. Here, we apply an iterative phase retrieval algorithm to experimentally acquired low-energy electron holograms of proteins. This allows us to reconstruct the phase shift induced by the protein along with its amplitude distribution. We provide evidence that phase imaging is sensitive to changes in local potential, as indicated by the strong correlation between reconstructed phase shift and the number of scatterers in the electron path, and the strong phase signatures induced by localised charges. LEEH phase imaging thus yields insights into structural features beyond size and shape and could, at high spatial resolution, open up the possibility of chemically sensitive single-molecule imaging.

Investigation of human platelet volume changes with scanning ion conductance microscopy (SICM) — •KONSTANTIN KRUTZKE, JAN SEIFERT, JOHANNES RHEINLAENDER, and TILMAN E. SCHÄFFER — Institute of Applied Physics, Eberhard-Karls-Universität Tübingen, Germany

Human blood platelets (thrombocytes) are anucleate cells that play an important role in wound closure in the case of vessel injury. Changes in morphology and activation of platelets are linked to blood vessel diseases such as atherosclerosis or can cause thrombosis. Water-induced swelling promotes procoagulant activity and possibly initiates thrombosis. Volume changes of platelets can be measured by light transmittance or light scattering techniques. However, these studies have only qualitatively shown that platelets regulate their volume as a response to different osmotic conditions and usually have not been performed on a single-cell level. To elucidate the volume regulatory mechanisms of platelets, we used scanning ion conductance microscopy (SICM) to quantitatively measure dynamic volume changes of single adhered platelets under different osmotic conditions with down to sub-minute time-resolution. SICM is a nanopipettebased, contact-free imaging technique ideally suited for sensitive live cells such as platelets. Our data show that rapid volume regulation of non-activated adherent platelets occurs in direct response to different osmotic conditions. Activated platelets, however, seem not to be able to regulate their volume when the osmolarity changes. We thereby highlight the usability of SICM for high-speed volume measurements.

### BP 9.4 Tue 10:15 H16

**Pool formation of synaptic vesicles by synapsin investigated by X-ray diffraction and cryo-EM** — •JETTE ALFKEN¹, CHARLOTTE NEUHAUS¹, MORITZ STAMMER¹, MARCELO GANZELLA³, ARSEN PETROVIC⁴, RUBÉN FERNÁNDEZ-BUSNADIEGO⁴, REINHARD JAHN³, DRAGOMIR MILOVANOVIC², and TIM SALDITT¹ — ¹Georg-August-Universität, Institute for X-ray Physics, 37077 Göttingen — ²Laboratory of Molecular Neuroscience, German Center for Neurodegenerative Diseases (DZNE), 10117 Berlin — ³Laboratory of Neurobiology, Max Planck Institute for Multidisciplinary Sciences, 37077 Göttingen, Germany — ⁴Institute of Neuropathology, University Medical Center Göttingen, 37099 Göttingen

Synaptic vesicles (SVs) are organized in dense pools close to the synaptic membrane. A key protein for this structural arrangement within the synapse is synapsin, which forms droplets containing SVs, due to liquid-liquid phase separation. To study the structure and interactions underlying pool formation in a controlled in vitro model, we have investigated phases made of SVs purified from rat brain and varied synapsin concentration. We have studied the pools by two complementary techniques: cryo-EM yielding the 3D structural arrangement of the adhering vesicles in pools at resolution of a few nanometers in the vitrified state, and solution SAXS under varied buffer conditions and concentrations. In addition, the pools were studied for comparison in a controlled system consisting of artificially prepared lipid vesicles and synapsin. We report these experiments and preliminary results (data analysis still ongoing).

Understanding calcareous biomineralization on the nanoscale through invivo growth imaging by x-ray nanodiffraction — •TILMAN GRÜNEWALD¹, JEREMIE VIDAL-DUPIOL², JULIEN DUBOISSET¹, BRUNO PETTON³, JACQUELINE LEGRAND³, MICHAEL SZTUCKI⁴, MANFRED BURGHAMMER⁴, and VIRGINIE CHAMARD¹ — ¹Institut Fresnel, Marseille, France — ²Ifremer, Montpellier, France — ³Ifremer, Plouzané, France — ⁴ESRF, Grenoble, France

Biomineralized tissues combine properties such as low weight with highstrength and are formed from abundant atoms via low-energy processes. However, the nanostructural formation process of biominerals is not well understood, relying on post-mortem investigations of the bivalve growth edge [1]. Insights by in-vivo experiments requires studying a live organism in its environment at the crystalline level with sub-um spatial resolution. The associated problems have been overcome by 4th generation synchrotrons, enabling faster measurements. We show that crystallization occurs without the presence of the animal mantle, over several hours and follows a layer-by-layer deposition scheme with slightly misaligned grains. These results imply a cyclic crystallization, driven by a physico-chemical mechanism. This provides the animal with an efficient way of building its shell.

### BP 9.6 Tue 11:00 H16

An open-top scanned oblique lightsheet microscope for neuronal network imaging — •ACHIM THEO BRINKOP¹, STEFAN STÖBERL¹, FLORIAN SCHORRE¹, and FRIEDHELM SERWANE^{1,2,3} — ¹Faculty of Physics, LMU Munich, Germany — ²Munich Cluster for Systems Neurology (SyNergy), Germany — ³Graduate School of Systemic Neuroscience (GSN), Munich, Germany

Understanding signal processing in neuronal networks such as brain organoids on a single-neuron level has remained a challenge. Imaging network activity requires a millisecond temporal resolution with single-neuron spatial resolution, all in an observation volume containing the 3D network. Advances in lightsheet microscopy have brought this goal closer to experimental reach, but at the cost of complex optical set-ups which (i) impose geometrical constraints to sample mounting or (ii) require multiple imaging objectives with custom optical components.

We report on the development of an open-top single-objective oblique lightsheet microscope which reduces the complexity compared to existing set-ups. We implement the open-top geometry by using only two primary objectives. The lightsheet is digital scanned by a fast galvo mirror to maintain high image quality. Our first prototype with excitation wavelengths of 561 (488, 638) nm is expected to allow for a  $1/e^2$ -resolution of 1.84 (1.47, 1.95)  $\mu$ m axially and 0.27 (0.23, 0.30)  $\mu$ m laterally. It offers a volumetric temporal resolution of 8 (2) Hz for a volume of 400 x 90 (360) x 100  $\mu$ m³.

With this set-up, we aim to gain insights into large neuronal networks of retina organoids, both in wildtype and disease condition.

### BP 9.7 Tue 11:15 H16

Extraction of Calcium Traces from Volumetric Lightsheet Images of 3D Neuron Ensembles — •FILIPPO KIESSLER¹, PAULINA WYSMOLEK⁴, KATJA SALBAUM^{1,2}, ELIJAH SHELTON¹, SELINA SONNTAG¹, and FRIEDHELM SERWANE^{1,2,3} — ¹Faculty of Physics and Center for NanoScience, Ludwig-Maximilians-Universität München, Munich — ²Graduate School of Systemic Neuroscience (GSN), Munich, Germany — ³Munich Cluster for Systems Neurology (SyNergy), Germany — ⁴Max Planck Institute for Medical Research, Heidelberg, Germany

In vitro systems resembling brain regions, such as brain organoids, are slowly changing the field of neuroscience. However, characterization of their electrical activity has remained a challenge as this requires electrophysiological readout in 3D at single-neuron resolution. We use a custom-built single-photon light-sheet microscope to record calcium activity in 3D neuron ensembles which we grow from mouse embryonic stem cells. To extract calcium intensities from the volumetric light-sheet data, we developed a custom software pipeline that augments the CaImAn software. Our pipeline includes a median filter to remove sample bleaching effects. In addition, typical artifacts arising from the illumination of or u light-sheet microscope are removed with a custom Fourier filter. With this setup we obtained connectivity graphs based on correlation of the extracted calcium traces. We envision this platform as a non-invasive toy-model to understand neuronal information generation and processing.

### BP 9.8 Tue 11:30 H16

Thermal fluctuations of the trapped bead as the complementary tool to the microscopy for investigation of a phagocytosis. — •TETIANA UDOD and ALEXANDER ROHRBACH — Lab for Bio- and Nano-Photonics, Department of Microsystems Engineering (IMTEK), University of Freiburg, Georges-Koehler-Allee 102, 79110 Freiburg, Germany

Phagocytosis, the uptake of particle by cells, is typically investigated in vivo by different microscopy technics, such as Brightfield, DIC, or Fluorescence microscopy. But even with highest possible resolution we can*t observe receptor binding or derive binding strengths to the cell membrane during binding and uptake. In addition to continuously recording 3D stacks of J774 macrophages cells by DIC microscopy, we record the thermal fluctuations of beads during the engulfment process. We measure the bead*s position in 3D with nanometer precision at MHz rates with back focal plane interferometry. Running both methods in parallel we can correlate the bead position relative to the cell to record changes in binding parameters like stiffnesses or, viscous drags derived from position fluctuations. Furthermore, remaining measurement ambiguities are resolved by Brownian Dynamic simulations.

To better understand such processes we use a combination of experiments with Photonic Force Microscopy, Brownian Dynamic simulation and analytical theory.

BP 9.9 Tue 11:45 H16

Assessing the cochlear morphology from the whole organ down to cellular resolution with multi-scale phase-contrast x-ray tomography — •JANNIS JUSTUS SCHAEPER¹, CHRISTOPH KAMPSHOFF², BETTINA WOLF², DANIEL KEPPELER², TOBIAS MOSER², and TIM SALDITT¹ — ¹Institut für Röntgenphysik, Georg-August-Universität Göttingen — ²InnerEarLab, Universitätsmedizin Göttingen

The cochlea is the receptor organ of the inner ear which transduces sound into neuronal activity. Both fundamental aspects of signal transduction and neurophysiology as well as biomedical research (implant technology, hearing loss and disorders) require 3D imaging techniques capable to quantify the micro-anatomy (1).

We present multi-scale 3D imaging of small-animal cochleae by phasecontrast x-ray tomography (PC-CT) using both synchrotron radiation (SR) and lab  $\mu$ -CT to assess the morphology of the cochlea, orientation of cochlear implants (CIs), and the number and density of spiral ganglion neurons (SGNs). Due to optimization in sample preparation, image acquisition and phase retrieval we achieve high contrast for unstained soft tissue. Without extensive sample preparation, shape and volume of every SGN in the entire organ can be identified. In the high-resolution PC-CT, and in the parallel beam, we reach cellular resolution in the organ of Corti. Lab  $\mu$ -CT is suitable to analyze cochlear morphology and to assess the correct positioning of CIs and resulting (non-)optimal signal transduction.

Studying biomolecular dynamics and structure with high-speed atomic force microscopy — •DIMITAR STAMOV, ANDREAS KRAUS, ANDRÉ KÖRNIG, and НЕІКО НАSCHKE — JPK BioAFM, Bruker Nano GmbH, Am Studio 2D, 12489 Berlin, Germany

Studying the molecular dynamics and structural conformations is important for understanding the function and biological significance of samples ranging from single membrane proteins to complex macromolecular systems. Recent atomic force microscopy (AFM) developments have led to unprecedented imaging rates in fluid, enabling temporal resolution on the sub-20-milisecond scale.

Annexin V (A5) serves as an important regulator of membrane repair in eukaryotic cells, where it shows a strong Ca2+ binding affinity to phosphatidylserine. We have used high-speed AFM to study the 2D crystal formation in a model system containing supported lipid bilayers and A5 molecules. We demonstrate the lateral dynamics and preferred structural orientations of the mobile A5 trimers.

We previously demonstrated that pUC19 plasmids bind to poly-L-ornithine substrate in supercoiled states that are very high in torsional energy, thereby driving dehybridization of the double-helical DNA strands. Here we have quantified the process kinetics with a temporal resolution of 25 ms per frame and identified stages that include formation of metastable dehybridization bubbles, thermodynamic single strand fluctuations, and ultimately rehybridization to an intact double-stranded state.

Super-resolution STED and MINFLUX Nanoscopes by Abberior Instruments — •GERALD DONNERT — Abberior Instruments GmbH, Göttingen, Germany — Laureate of the Technology-Transfer-Prize 2022

Abberior Instruments GmbH was founded 10 years ago from the laboratory of Nobel Laureate Stefan Hell at the Max Planck Institute in Göttingen. In 2022, Abberior Instruments was awarded the Technology Transfer Prize of the German Physical Society (DPG).

Abberior Instruments develops and markets super-resolution light microscopes, namely confocal plus STED microscopes and MINFLUX microscopes. The latter are the latest generation of super-resolution instruments with resolutions down to the molecular level, i.e. 1 nm resolution; unrivaled in resolution today. Understanding life at the molecular level - both in terms of structure and dynamics - is a human dream and is becoming feasible with the latest generation of super-resolution instruments with multicolor capabilities. We expect to soon gain new insights into the dynamic structural changes of e.g. protein machines in living cells.

In this talk, I will present the latest imaging and tracking results with our super-resolution STED and MINFLUX nanoscopes, such as single-particle tracking of lipids in lipid membranes, the structure of nuclear pore complex (NPC) subunits, and the nanoscale assembly of proteins in neuronal synapses.

Physics of gut motility governs digestion and bacterial growth — •AGNESE CODUTTI^{1,2}, JONAS CREMER³, and KAREN ALIM^{1,2} — ¹Physics Department and CPA, Technische Universität München — ²Max-Planck-Institut für Dyanmik und Selbstorgansiation, Göttingen — ³Stanford University

Malfunctioning of the small intestine contractility and the ensuing bacterial population therein are linked to a plethora of diseases. We, here, study how the small intestine's variety of contractility patterns impacts nutrient uptake and bacterial population. Our analytical derivations in agreement with simulations identify flow velocity as the key control parameter of the nutrients uptake efficiency and bacterial growth, independently of the specifics of contractility patterns. Selfregulating flow velocity in response to the number of nutrients and bacteria in the gut allows achieving 100% efficiency in nutrient uptake. Instead of the specifics of intestine contractility, our work points to the flow velocity and its variation in time within the intestine to prevent malfunctioning.

#### BP 10.2 Tue 10:15 H13

Blue-light photoreceptors regulating light-switchable adhesion in *Chlamy-domonas reinhardtii* — •RODRIGO CATALAN^{1,2}, ANTOINE GIROT^{1,2}, ALEXANDROS FRAGKOPOULOS^{1,2}, SIMON KELTERBORN³, DARIUS RAUCH³, PETER HEGEMANN³, and OLIVER BÄUMCHEN^{1,2} — ¹Max Planck Institute for Dynamics and Self-Organization (MPIDS), 37077 Göttingen , Germany — ²University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany — ³Humboldt University Berlin, Institute of Biology, 10115 Berlin, Germany

Photoactive organisms have evolved a variety of light-sensitive molecules, called photoreceptors, which regulate phenotypes such as phototaxis, circadian life cycle and sexual reproduction. Recently it was discovered that the unicellular, eukaryotic microalga *Chlamydomonas reinhardtii* exhibits light-switchable flagellar adhesion to surfaces [Kreis *et al.*, Nature Physics, 2018]; a phenotype triggered by a blue-light photoreceptor. Using single-cell micropipette force measurements, we show that the action spectrum of flagellar adhesion forces in wildtype (WT) cells resembles the adsorption spectrum of photoreceptors called cryptochromes. Furthermore, adsorption experiments show that the number of WT cells adsorbing to surfaces under blue light increases after the start of the cells' day-phase, which coincides with the light degradation of plant cryptochrome (pCRY). Adhesion force and adsorption experiments of WT and photoreceptor deletion mutants illuminate the role of photoreceptors in this adhesion phenotype.

#### BP 10.3 Tue 10:30 H13

Motility and collective behavior of gliding *Chlamydomonas* populations — •ALEXANDROS FRAGKOPOULOS^{1,2}, SEBASTIAN TILL¹, FLORIAN EBMEIER¹, MARCO G. MAZZA^{1,3}, and OLIVER BÄUMCHEN^{1,2} — ¹Max Planck Institute for Dynamics and Self-Organization (MPIDS), 37077 Göttingen, Germany — ²University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany — ³Department of Mathematical Sciences, Loughborough University, Loughborough, Leicestershire LE11 3TU, UK

The model microbe *Chlamydomonas reinhardtii*, a unicellular biflagellated microalga, can adhere and colonize almost any surface under particular light conditions. Once the cells attach to a surface, an intraflagellar transport machinery translocates the cell body along the flagella, which are oriented in a 180° configuration. This motion is known as gliding motility. We find that gliding enables surface-associated *Chlamydomonas* cells to cluster and form compact, interconnected microbial communities [1]. We detect and analyze the movement of single cells and characterize the spatio-temporal evolution of the morphology of the colony. The motion of single cells exhibits rapid movements, followed by prolonged immobility. By analyzing the cell clustering, we observe the colony transitioning from local clusters to a single global network with increasing cell density. Simulations based on a purely mechanistic approach cannot capture the non-random cell positions. However, by including flagellar mechanosensing through a cognitive model, we quantitavely reproduce the experimental observations.

Spatiotemporally resolved single-cell growth in bacterial biofilms — •ERIC JELLI^{1,2,3}, TAKUYA OHMURA^{2,4}, NIKLAS NETTER^{2,3,4}, MARTIN ABT^{2,3}, EVA JIMÉNEZ-SIEBERT^{2,3,4}, KONSTANTIN NEUHAUS^{2,3,4}, DANIEL KARL-HEINZ RODE^{2,3,4}, and KNUT DRESCHER^{2,3,4} — ¹Max Planck Institute for Neurobiology of Behavior - caesar, Bonn, Germany — ²Max Planck Institute for Terrestrial Microbiology, Marburg, Germany — ³Department of Physics, Philipps-Universität Marburg, Marburg, Germany — ⁴Biozentrum - University of Basel, Basel, Switzerland

Bacterial biofilms are dense multicellular communities that are embedded in a self-produced matrix. The high density of cells gives rise to nutrient, oxyLocation: H13

gen, and metabolite gradients in space and time. To understand the underlying spatio-temporal growth principles in biofilms, single-cell segmentation algorithms are required. Current Deep Learning algorithms provide the required accuracy for tracking-dependent investigations, yet depend on suitable large training datasets.

We used an iterative training pipeline to densely annotate complete biofilms with thousands of cells in 3D. The pipeline reduced the required manual labeling steps which would otherwise be prohibitive for a dataset of a similar size. The collected data enabled us to compare the single-cell segmentation accuracy of recent Deep Learning algorithms with the results of classical biofilm segmentation approaches. We used the trained algorithms for single-cell tracking in 3D time-lapse confocal microscopy data and identified regions with different division rates inside the microbial communities.

**The advantage of network topology in avoidance reaction** – •SIYU CHEN¹, JEAN-DANIEL JULIEN¹, and KAREN ALIM^{1,2} – ¹Max-Planck-Institut für Dyanmik und Selbstorgansiation, Göttingen – ²Physics Department and CPA, Technische Universität München, München

The unicellular slime mould Physarum polycephalum stands out among other unicellular organisms for having a network-shaped body. Which advantage does a network structure provide when facing a challenging environment with adverse conditions? We, here, follow how network topology impacts P. polycephalum's avoidance response to adverse blue light. We stimulate either an elongated amoeboid or a simple Y-shaped networked specimen and quantify the retraction velocity of the light-exposed body part. The result shows that Y-shaped specimen can complete the avoidance retraction without increasing the migration velocity, while an elongated amoeboid requires bursts of higher velocities - an energetically costly expense. Our theoretical predictions suggest that a light-triggered change in cytoplasm viscosity may account for the difference in response, as the more complex topology of a network allows P. polycephalum to maintain large flows that enable quick retraction out of the blue light. The difference in the retraction behaviour suggest the complexity of network topology provides a key advantage in dealing with adverse environments. Our findings could lead to the better understanding of the evolutionary transition from unicellular to multicellularity.

BP 10.6 Tue 11:30 H13 Model-Based Prediction of an Effective Adhesion Parameter Guiding Multi-

**Type Cell Segregation** — •PHILIPP ROSSBACH, HANS-JOACHIM BÖHME, STEF-FEN LANGE, and ANJA VOSS-BÖHME — DataMedAssist, HTW - University of Applied Sciences, 01062 Dresden, Germany

The process of cell-sorting is essential for development and maintenance of tissues. With the Differential Adhesion Hypothesis, Steinberg proposed that cellsorting is determined by quantitative differences in cell-type-specific intercellular adhesion strengths. An implementation of the Differential Adhesion Hypothesis is the Differential Migration Model by Voss-Böhme and Deutsch. There, an effective adhesion parameter was derived analytically for systems with two cell types, which predicts the asymptotic sorting pattern. However, the existence and form of such a parameter for more than two cell types is unclear. Here, we generalize analytically the concept of an effective adhesion parameter to three and more cell types and demonstrate its existence numerically for three cell types based on in silico time-series data that is produced by a cellular-automaton implementation of the Differential Migration Model. Additionally, we classify the segregation behavior using statistical learning methods and show that the estimated effective adhesion parameter for three cell types matches our analytical prediction. Finally, we demonstrate that the effective adhesion parameter can resolve a recent dispute about the impact of interfacial adhesion, cortical tension and heterotypic repulsion on cell segregation.

### BP 10.7 Tue 11:45 H13

Is cell segregation like oil and water: asymptotic versus transitory regime — •FLORIAN FRANKE^{1,2}, SEBASTIAN ALAND^{2,3}, HANS-JOACHIM BOEHME^{1,2}, ANJA VOSS-BOEHME^{1,2}, and STEFFEN LANGE^{1,2} — ¹DataMedAssist, HTW Dresden — ²Faculty of Informatics/Mathematics, HTW Dresden - University of Applied Sciences — ³Faculty of Mathematics and Computer Science, TU Freiberg

Segregation of different cell types is a crucial process for the pattern formation in tissues. Since the involved cell interactions are complex and difficult to measure individually in experiments, mathematical modelling plays an increasingly important role to unravel the mechanisms governing segregation. The analysis of these theoretical models focuses mainly on the asymptotic behavior at large times, in a steady regime and for large numbers of cells. Most famously, cell-segregation models based on the minimization of the total surface energy,

Tuesday

a mechanism also driving the demixing of immiscible fluids, are known to exhibit asymptotically a particular algebraic scaling behavior. However, it is not clear, whether the asymptotic regime of the numerical models is relevant at the spatio-temporal scales of actual biological processes and in-vitro experiments. By developing a mapping between cell-based models and experimental settings, we are able to directly compare previous experimental data to numerical simulations of cell segregation quantitatively. We demonstrate that the experiments are reproduced by the transitory regime of the models rather than the asymptotic one. Our work puts a new perspective on previous model-driven conclusions on cell segregation mechanisms.

### BP 10.8 Tue 12:00 H13

Self-Buckling of filamentous cyanobacteria reveals gliding forces — •MAXIMILIAN KURJAHN¹, ANTARAN DEKA¹, ANTOINE GIROT^{1,2}, LEILA ABBASPOUR^{3,4}, STEFAN KLUMPP^{3,4}, MAIKE LORENZ⁵, OLIVER BÄUMCHEN^{1,2}, and STEFAN KARPITSCHKA¹ — ¹Max Planck Institute for Dynamics and Self-Organization (MPI-DS), Göttingen — ²Experimental Physics V, University of Bayreuth — ³Max Planck School Matter to Life, University of Göttingen — ⁴Institute for Dynamics of Complex Systems, University of Göttingen — ⁵Department of Experimental Phycology and SAG Culture Collection of Algae, University of Göttingen

Filamentous cyanobacteria are one of the oldest and today still most abundant lifeforms on earth, with manifold implications in ecology and economics. These phototrophic organisms form long and flexible filaments that do not actively swim in bulk liquid but exhibit gliding motility in contact with solid surfaces. The underlying force generating mechanism of their gliding apparatus is not yet understood. We measure their bending modulus with micropipette force sensors, and investigate how filaments buckle after gliding onto an obstacle. Comparing Kirchhoff theory to the experiments, we derive the active forces and the friction coefficients associated with gliding from the observed critical filament length for buckling. Remarkably, we find that these two quantities are strongly coupled, while dependencies on other observables are largely absent. The critical length also aligns with the peak of their natural length distribution, indicating the importance of buckling for their collective.

BP 10.9 Tue 12:15 H13

Structural and mechanical properties of filamentous cyanobacteria — •MIXON FALUWEK1^{1,2} and LUCAS GOEHRING¹ — ¹Nottingham Trent University, Nottingham, UK. — ²Malawi University of Science and Technology, Limbe, Malawi.

Filamentous cyanobacteria, long strands of connected cells, are one of Earth's earliest forms of life. They are found in multiple environments playing different roles and forming large-scale patterns in structures like biomats and stromatolites. The mechanical properties of these structures contribute to cyanobacteria's success in inhabiting their environments and are useful in applications such as algae-based biofuel production. One of the most important mechanical properties of these active polymers is the bending modulus or flexural rigidity. Here, we quantify the flexural rigidity of three cyanobacteria species, of order *Oscilla-toriales*, via bending tests in a microfluidic flow device, where single cyanobacteria flow. Our measurements are confirmed separately by measuring the Young's modulus and cell wall thickness using atomic force microscopy and transmission electron microscopy, respectively. These measurements can be used to model interactions between cyanobacteria, or with their environment, and how their collective behaviour emerges from such interactions.

Holographic vibration spectroscopy: Probe- and contact-free viscoelastic analysis of adherent cells — •BOB FREGIN^{1,2}, STEFANIE SPIEGLER^{1,2}, and OLIVER OTTO^{1,2} — ¹ZIK HIKE, University of Greifswald, Greifswald, Germany — ²DZHK, University Medicine Greifswald, Greifswald, Germany

Cell mechanical properties can be used as an inherent biomarker for cell state, fate and function. Several high-throughput methods are available to characterize suspension cells, e.g., peripheral blood cells, without any labeling. However, fast and robust methods are lacking for adherent cells, although the majority of cells, e.g., in our human body, is aggregated into tissues.

Here, we introduce a new probe- and contact-free method for label-free mechanical phenotyping of adherent cells at high spatiotemporal resolution. While cells are excited mechanically by a vibration in the range of 100 kHz, their response is determined optically from cell height oscillations utilizing holographic laser Doppler interferometry. In proof-of-concept experiments on a monolayer of induced pluripotent stem cells (iPSCs), we present a cell amplitude response as a function of varying excitation amplitudes. This amplitude response is proportional to the elastic properties of a cell.

In future work, we plan to perform a spectroscopic evaluation, where experiments are carried out at multiple frequencies. Further, we aim to extend our analysis to a complete viscoelastic description.

### BP 12.2 Tue 17:30 P4

Heterogenous cell structures in AFM and shear flow simulations — •SEBASTIAN WOHLRAB, SEBASTIAN MÜLLER, and STEPHAN GEKLE — Theoretical Physics VI, University of Bayreuth

In biophysical cell mechanics simulations, the complex inner structure of cells is often simplified as homogeneous material. However, this approach neglects individual properties of the cell's components, e.g., the significantly stiffer nucleus.

By introducing a stiff inhomogeneity inside our hyperelastic cell, we investigate it during AFM compression and inside shear flow in finite-element and Lattice Boltzmann calculations.

We show that a heterogenous cell exhibits almost identical deformation behavior under load and in flow as compared to a homogeneous cell with equal averaged stiffness, supporting the validity of the homogeneity assumed in both mechanical characterization as well as numerical computations. Location: H18

Location: P4

### BP 12.3 Tue 17:30 P4

Cell migration dynamics and nuclear deformation in three-dimensional micro-dumbbells — •STEFAN STÖBERL¹, JOHANNES FLOMMERSFELD², MAXIMILIAN M. KREFT¹, CHASE P. BROEDERSZ², and JOACHIM O. RÄDLER¹ — ¹Faculty of Physics and Center for NanoScience, Ludwig-Maximilians-University, Munich, Germany — ²Department of Physics and Astronomy, Vrije Universiteit Amsterdam, 1081 HV Amsterdam, The Netherlands

Cell migration plays a key role in physiological processes such as wound healing, cancer metastasis and immune response. In previous work we have studied the non-linear dynamics of single cells migrating between two surface-patterned adhesion sites guided by a bridging line.

Here we study the dynamics of MDA-MB-231 cells captured in threedimensional (3D)-dumbbell-like microcavities. The structures formed by photolithography of PEG-norbonene hydrogels provide a soft and hence deformable frame, while cells attach and migrate on a fibronectin coated bottom. In our experiments we find that the dwell-time of cells before transitioning is retarded when the width of the dumbbell-constriction is narrowed below 8 m. We are hypothesizing that the observed deformation of the nucleus, which is the biggest organelle in the cell, determines the time course of the repeated stochastic transitions. To study the external and internal forces involved we measure the displacement field of beads embedded in the vicinity of the 3D constriction.

### BP 12.4 Tue 17:30 P4

The Weakness of Senescent Dermal Fibroblast — •LYDIA REBEHN¹, SAMIRA KHALAJI¹, FENNEKE KLEINJAN¹, ANJA KLEEMANN¹, PATRICK PAUL¹, CONSTANTIN HUSTER³, ULLA NOLTE¹, KARMVEER SINGH², TANER PULA⁴, PAMELA FISCHER-POSOVSZKY⁴, KARIN SCHARFFETTER-KOCKANEK², and KAY-E GOTTSCHALK¹ — ¹Institute for Experimental Physics, Ulm University, Ulm, Germany — ²Department of Dermatology and Allergology, Ulm University, Ulm, Germany — ³Institut für Theoretische Physik, Universität Leipzig, Leipzig, Germany — ⁴Department of Pediatrics and Adolescent Medicine, Ulm University, Ulm, Germany

As human tissues age, there is chronological accumulation of biophysical changes from internal and environmental factors. Skin aging leads to loss of dermal matrix integrity via degradation and decreased elasticity. The mechanical properties of the dermal matrix are maintained by fibroblasts, whose properties change during replicative aging. Here, we compare biophysical proper-

92

ties of young versus proliferatively aged primary fibroblasts via fluorescence and traction force microscopy, single-cell AFM, and microrheology of the cytoskeleton. Results show senescent fibroblasts have decreased cytoskeletal tension and myosin II regulatory light chain phosphorylation, in addition to significant loss of traction force. The alteration of cellular forces is harmful to the process of building and maintaining extracellular matrix, while decreased cytoskeletal tension can amplify epigenetic changes involved in senescence. Exploration of these mechanical phenomena provide possibilities for unexplored pharmaceutical targets against aging.

### BP 12.5 Tue 17:30 P4

Unravelling the collective behaviour of protrusions for directed migration — •LUCAS TRÖGER¹ and KAREN ALIM^{1,2} — ¹Physics Department and CPA, Technische Universität München — ²Max Planck Institute for Dynamics and Self-Organization, Göttingen

Living systems are often challenged to coordinate collective behaviour of individual entities across large spatial scales. The morphology of amoeboid cells, for example, arises due to the coordination of randomly forming protrusions that facilitates the cell's directed migration. The slime mold Physarum polycephalum grows as a single giant cell of network-like shape, spanning orders of magnitude in size ranging from 500 micrometers to tens of centimeters. Due to the large extent, chemotaxis and morphogenesis of the entire cell require a mechanism for coordination among competing protrusions. P. polycephalum is renowned for its organism-wide cytoplasmic fluid flows spanning the fluid-filled tubular network in a peristaltic wave. These strong and large-scale flows make this organism an ideal model to investigate the role of fluid flows in coordinating the collective behaviour of competing protrusions during the morphological changes in chemotaxis. We perform experiments of chemotacting P. polycephalum specimen of varying sizes and quantify the dynamics of individual protrusions in addition to the chemotactic performance of the entire specimen. We correlate growing and retracting protrusions over time to identify the mechanism of communication. The project will teach us how fluid flows control the collective behaviour of protrusions during directed migration.

BP 12.6 Tue 17:30 P4

**Neutrophil mechanotransduction during durotaxis** — •FATEMEH ABBASI¹, MATTHIAS BRANDT², and TIMO BETZ¹ — ¹Third Institute of Physics-Biophysics, Georg August University Göttingen — ²Institute of Cell Biology, ZMBE, University of Münster

In Vivo, cells experience complex tissue environments with various chemical and physical features. 3D confinement is one of the major physical obstacles for cells in their natural environment. Neutrophils are among the most abundant immune cells in our body, which have to cope with various physical constrictions on their way from production to the infection site. In addition to confinement, the stiffness of the microenvironment is another mechanical feature these rapidly moving cells are exposed to. Neutrophils experience various tissue stiffness, from 1 kPa (bone marrow) to 20 MPa (bone). Previous studies have demonstrated that these cells are responsive to their microenvironment stiffness by adjusting their adhesion and spreading. Based on this knowledge we decided to combine confinement and stiffness change and investigate the impact of 3D stiffness gradient on cell behaviour and migration, a fact called durotaxis. We hypothesized that stiffness gradient might be a triggering factor of neutrophil migration toward the infection site. We confine neutrophils in between 2 layers of polyacrylamide hydrogels with 2 different stiffness and keep this distance stable for the desired period of time to investigate cell mechanotransduction during durotaxis from different points of view. Our preliminary results regarding the neutrophil durotaxis show a surprising and transient force peak on the soft substrate during cell shifting.

BP 12.7 Tue 17:30 P4 Cytoskeletal Networks in Cells Under Strain — •RUTH MEYER, ANNA V. SCHEPERS, PETER LULEY, and SARAH KÖSTER — Institute for X-Ray Physics, University of Göttingen

The cytoskeleton of eukaryotic cells mainly consists of three types of filamentous proteins: F-actin, microtubules and intermediate filaments (IFs). In contrast to microtubules and actin filaments, IFs are expressed in a cell-type specific manner, and keratins are found in epithelial cells. In certain cell types, the IF keratin forms a layer close to the membrane, referred to as an "IF-cortex". It has been observed that this IF-cortex arranges in a "rim-and-spokes" structure in epithelia. Based on this hypothesis, IFs and actin filaments might add complementary mechanical properties to the cellular cortex. When stretching single IFs, it was previously shown that IFs remain undamaged even at high forces. We now ask the question of whether this unique force-extension behavior of single IFs is also relevant in the filament network within a cell. The experiment is conducted by seeding cells on an elastic substrate and then stretching the substrate uniaxially or equibiaxially to high strains. In combination with fluorescence and atomic force microscopy, this setup allows us to study the structure and the mechanical properties of actin and IF networks close to the cell membrane.

### BP 12.8 Tue 17:30 P4

Cell mechanics and cytoskeletal structures under unifor, equibiaxial strain — •ANNA V. SCHEPERS, RUTH MEYER, PETER LULEY, and SARAH KÖSTER — Universität Göttingen

The cytoskeleton, which largely determines the mechanical properties of cells, has to withstand various mechanical stresses throughout the lifetime of a cell. In mechanically stressed cells, structural and mechanical changes often go hand-inhand. Understanding how cytoskeletal remodelling accompanies the mechanical changes will give insight into the mechanism by which cells adjust to mechanical load and how this reaction might be altered in diseases. Remodelling of the cytoskeleton has been observed under uniaxial and equibiaxial stretching. However, combined structural and force measurements under well-defined mechanical conditions are sparse. We therefore present a uniform, equibiaxial cell stretching device that is compatible with fluorescence microscopy as well as single cell force spectroscopy. The device allows for the study of living single cells or cell monolayers throughout equibiaxial stretching. Changes in the mechanical properties of cells can thus be linked to the remodelling of the cytoskeleton.

### BP 12.9 Tue 17:30 P4

**Force generation in human blood platelets mediated by actin structures** — •ANNA ZELENA¹, JOHANNES BLUMBERG², ULRICH S. SCHWARZ², and SARAH KÖSTER¹ — ¹Institute for X-Ray Physics, University of Göttingen, Germany — ²Institute for Theoretical Physics, University Heidelberg, Germany

Blood platelets are known for their importance in blood clotting: Their correct function significantly affects the early steps of wound closing and thus restoration of blood circulation. The hemostatic function of platelets is directly connected to their mechanics and cytoskeletal morphology, however, the exact mechanism and connection between them remain elusive. As was previously investigated, the reorganization of the platelet cytoskeleton upon spreading is a very fast process, which occurs within minutes, and it leads to pronounced stress fiber morphologies. In this study, we investigate single platelets by combining traction force measurements with fluorescence imaging of the actin structures in a time-resolved manner. Thus, we can spatially and temporally correlate the force generation with the emerging acting structures. Interestingly, the spots of highest force remain very stable in time and spatially align very closely with the visualized end points of fibrous actin structures. Additionally, our data show that the force generation is a very robust mechanism independent of changes in the amount of added thrombin in solution or fibrinogen coverage on the substrate, which may be physiologically important so as to ensure reliable blood clotting independent of environmental parameters.

## BP 12.10 Tue 17:30 P4

**Mechanical fingerprint of the intra-cellular space** — •TILL M MUENKER and TIMO BETZ — University of Goettingen, Goettingen, Germany

Many important cellular functions such as organelle positioning and internal cargo transport are dependent on the viscoelastic intracellular mechanical properties of cells. A range of different mechanical models has been proposed to describe these properties. Whilst simple models such as Maxwell or Kelvin-Voigt models don't seem sufficient to capture the full complexity of cells, more elaborate models like generalized Kelvin-Voigt models require a huge number of parameters. This hinders the comparison and interpretation of experimental findings. Further, from a physics perspective, cells are systems out of thermodynamic equilibrium, permanently consuming metabolic energy to carry out mechanical work. The level of "non-equilibrium" can be proposed as an indicator for cell type, cell state or even diseases. To determine both, the viscoelastic properties and the cellular activity, we use optical tweezers based active and passive microrheology in a diverse group of 9 different cell-types. Surprisingly, despite differences in origin and function, the complex moduli of all cell types can be described using a 4 parameter based fractional Kelvin-Voigt model. Additionally, the frequency dependent activity can be described with a simple power law. This approach allows to reduce those complex and frequency dependent properties down to a fingerprint of 6 parameter. Further principal component analysis shows that only 2 of them may be sufficient to characterize the mechanical intracellular state.

### BP 12.11 Tue 17:30 P4

Measuring the stiffness of neuronal growth cones with scanning ion conductance microscopy — •AYLIN BALMES¹, HANNES SCHMIDT², and TILMAN E. SCHÄFFER¹ — ¹Institute of Applied Physics, University Tübingen, Germany — ²Interfaculty Institute of Biochemistry (IFIB), University Tübingen, Germany It was recently demonstrated that nanoscale dynamic structural changes in live neurons can be visualized using scanning ion conductance microscopy (SICM). In SICM imaging the sample is scanned with an electrolyte-filled nanopipette to which a voltage and a pressure are applied and the ion current through the nanopipette is measured. The sample topography and stiffness (Young's modulus) can thereby be derived with high spatial and temporal resolution. There is no direct mechanical contact between the probe and the sample during SICM imaging, making it a very suitable technique to study fragile samples such as neurons. In this study we use SICM to investigate the stiffness of growth cones of dorsal

root ganglion (DRG) neurons, which have previously been used to study axonal branching, an important process in neuronal development. Studies showed that a signaling cascade involving the second messenger cyclic guanosine monophosphate (cGMP) which is generated upon binding of C-type natriuretic peptide (CNP) to the receptor guanylyl cyclase B regulates the bifurcation of DRG axons. Our measurements show that the presence of cGMP and CNP reduces growth cone stiffness. This alteration in stiffness could be linked to changes in the actin cytoskeleton and might play a role in the regulation of axon bifurcation.

### BP 12.12 Tue 17:30 P4

**Optimization of patterned polyacrylamide gels for traction force microscopy** — •INA BRAUN, MOHAMMAD ARMIN ESKANDARI, FATEMEH ABASSI, and TIMO BETZ — Third Institute, Biophysics, Georg August Universität, Göttingen, Germany

Combining micropatterned adhesion with soft polyacrylamide gels is widely described in literature, however the practical experience shows a series of possible artifacts. The problems are typically a variation of fluorescent bead localization in response to the ECM proteins applied. In detail we find changes in the bead distribution that we aim to understand and avoid. Micropatterns of various ECM proteins are initially created on glass coverslips using a photomask. Subsequently, they are transferred on the polyacrylamide gels containing fluorescent beads during the polymerization process. In an additional step we compare the classical protocol of pattern tranfer during polymerization with a more specific approach by including NHS-acrylamide in the hydrogel premix. After pattern transfer we quantify the bead localization, homogeneity and potential clustering at the pattern sites with the non-patterned regions. We optimize the bead distribution by systematic variation of pH value and ion composition of the premix. The potential of cell adhesion and traction force microscopy is assed in the final step.

### BP 12.13 Tue 17:30 P4

**Dystrophin as a tension regulator in human skeletal muscles** — •MARIAM RISTAU¹, ARNE HOFEMEIER^{1,2}, and TIMO BETZ¹ — ¹Third Institute of Physics - Biophysics, Georg-August-University Göttingen, Germany — ²ZMBE - Institute of Cell Biology, University of Münster, Germany

Skeletal muscles are associated with contraction, movement and force generation. They are important for maintaining posture and maintaining bone and joint stability. Muscular dystrophies such as Duchenne muscular dystrophy (DMD) result in progressive weakening of skeletal muscles. DMD is caused by the loss of the protein dystrophin which is thought to stabilize and protect muscle fibers from injury. In the progression of the disease, damaged muscle fibers degrade, muscle mass is lost and greater functional impairments develop. We have studied the contractile potential of myoblasts and reconstituted tissue derived from healthy and DMD patients, and found that they were mechanically different in muscle tension and contractility. DMD derived myoblast exhibited an overall weaker contractility compared to healthy derived myoblast. In contrast, DMD derived myoblast showed an overall higher muscle tension, suggesting that dystrophin may function as a tension regulator in skeletal muscles. In order to rule out the possibility that these findings are due to patient variability we intend to establish a genetic model in which we knockout dystrophin with the CRISPR/Cas9 system in healthy myoblasts and rescue dystrophin in DMD myoblasts by integrating micro-dystrophins (µDys).

### BP 12.14 Tue 17:30 P4

**Modelling internal cell structure for bioprinting processes** — •RICHARD KELLNBERGER, FABIAN HÄUSL, MORITZ LEHMANN, and STEPHAN GEKLE — Universität Bayreuth, Bayreuth, Deutschland

The deformation cells experience during bioprinting processes depends on the structure of the cell and the stresses exerted by the surrounding fluid. We extended a Lattice-Boltzmann solver with a cell model using the immersed boundary method to model the cell membrane as well as discretizing the cell as elastic tetrahedrons in order to model the cytoskeleton. Furthermore, we extended the fluid model to take viscoelastic effects into account. With these extended models we improve our qualitative investigations of the deformation of cells during the printing process.

### BP 12.15 Tue 17:30 P4

Neutrophil cell behavior as a response to mechanical confinement and substrate stiffness — •KATHARINA RIECK^{1,2,3}, FATEMEH ABBASI^{2,3}, MATTHIAS BRANDT², and TIMO BETZ^{2,3} — ¹Department of Physics, University of Münster, Germany — ²Institute of Cell Biology, ZMBE, University of Münster, Germany — ³Third Institute of Physics, Biophysics, University of Göttingen, Germany Neutrophils are among the first immune cells attacking invading microorganisms in our body. To reach the site of infection they must undergo extreme cellular deformations while experiencing high shear stress during their migration through highly confined microenvironments. In order to investigate the mechanisms driving their confined migration and cell shape adjustment, we probe cell behavior and traction force generation in different levels of confinement with variable stiffnesses of the confining boundaries. We seed Neutrophils between two polyacrylamide (PAA) gels of the same stiffness and vary substrate Young*s modulus (3kPa, 15kPa, 30kPa) as well as the distance between the gels. This allows to examine the impact of microenvironment stiffness and confinement level on cell migration and forces. Using the substrate elastic modulus and cell induced gel deformation we are able to measure their traction stress. Our preliminary results demonstrate that cells exert higher traction forces on stiffer substrates. In confinement cells show higher traction forces than on 2D substrates. Furthermore, cells are more motile in confinement and show more motility on gels of higher stiffnesses. However, no significant difference of traction forces in different levels of confinement was observed.

#### BP 12.16 Tue 17:30 P4

**Development of a platform for accessing the membrane tension of cells in microchannels** — •ERIC SÜNDERMANN, BOB FREGIN, DOREEN BIEDENWEG, STE-FANIE SPIEGLER, and OLIVER OTTO — ZIK HIKE, University of Greifswald, Greifswald, Germany

Real-time deformability cytometry (RT-DC) is a biomechanical method which is able to characterise the physical properties of cells. To do so, the cells travel through a microfluidic chip assembled on an inverted microscope. Every cell is imaged by a high-speed camera, and its shape is fitted to calculate the deformation. While the acting stress and cell tension can be derived from hydrodynamic simulations we can not disentangle different tension contributors.

Here, we introduce a new method of directly accessing the membrane tension of a cell, passing a microfluidic constriction. Measurements are carried out in a microfluidic channel, and the cells are illuminated with a pulsed laser. The cells were stained with the Flipper-TR probe, which has a fluorescent lifetime depending on the membrane tension. The signal is acquired with a fluorescence lifetime imaging (FLIM) point detector.

In preliminary experiments, we measure the membrane tension and simultaneously image the cells to perform RT-DC leading to the cell mechanical properties. Having access to the ensemble mechanical properties of a cell as well as its membrane tension, the method allows for studying the interaction between the latter and the derived cortex tension. In future studies, we also want to investigate the tension distribution on the cell membrane.

### BP 12.17 Tue 17:30 P4

Nuclear mechanics probed by optical tweezers-based active microrheology — •BART VOS¹, IVAN AVILOV², TILL MÜNCKER¹, PETER LENART², and TIMO BETZ¹ — ¹Third Institute of Physics, University of Göttingen, Göttingen, Germany — ²Max Planck Institute for Biophysical Chemistry, Göttingen, Germany

Mechanics play a crucial role in a wide range of cellular processes, from differentiation to division and metastatic invasion. Consequently, the mechanical properties of the cytoskeleton, providing shape, motility and mechanical stability to the cell, have been extensively studied. However, remarkably little is known about the mechanical environment within the nucleus of a cell, and fundamental questions remain unanswered, such as the role of nuclear actin or the sudden "freezing" of the cell during cellular division that prevents diffusion or active mixing of the nucleus and the cytoplasm.

To address these questions, we perform optical tweezers-based microrheology in the nucleus. Microrheology has proven to be a suitable tool for intracellular mechanical measurements, as it enables local, non-invasive measurements. However, although the cytoskeleton has been extensively studied this way, the cell nucleus has not been investigated, mainly due to difficulties with inserting appropriate probe particles. By using starfish oocytes that have larger dimensions than most other cell types, we are able to perform microinjection of micrometersized particles. We observe, similar to the cytoskeleton, viscoelastic behavior of the nucleoplasm. In addition, we mechanically follow the oocyte during its development after fertilization.

### BP 12.18 Tue 17:30 P4

Predicting the distribution of mechanical stresses in the S. aureus cell wall during the cell cycle — •SHEILA HOSHYARIPOUR¹, MARCO MAURI¹, JAMIE K. HOBBS², SIMON J. FOSTER², and ROSALIND J. ALLEN¹ — ¹Friedrich-Schiller-Universität Jena, Jena, Germany — ²University of Sheffield, Sheffield, United Kingdom

Staphylococcus aureus is a Gram-positive bacterium which is clinically important due to its ability to act as an opportunistic pathogen and to generate antibioticresistant strains. During the cell cycle, the cell synthesizes a flat septum that divides the spherical cell into two hemispheres. Division then happens in few milliseconds, suggesting an important role for mechanics in the separation process. In this work, we used concepts from mechanical engineering to create an elastic model of the cell wall, in order to predict the spatial distribution of stress in the cell wall, and the induced deformations, during the cell cycle. Our modelling shows that the presence of the growing septum decreases the cell wall stress in its vicinity and leads to an invagination. The amount of this invagination and reduction in stress depends on the mechanical and geometrical properties of the cell wall and the septum. For a smaller cell with thicker wall, the stress is less during the whole cell cycle, and a stiffer septum leads to more invagination. Comparing these predictions with experimental data for various mutants in the presence and absence of cell-wall targeting antibiotics should provide a useful tool for understanding the role of mechanical stress in the S. aureus cell cycle.

### BP 12.19 Tue 17:30 P4

**Optical Stretcher for Adherent Cells** — •ALEXANDER JANIK, TOBIAS NECKER-NUSS, and OTHMAR MARTI — Institute of Experimental Physics, Ulm University We have demonstrated a method to stretch adherent cells with a parallel laser beam, that is capable of distinguishing between stiff and softened cells. Recently, a new method for the detection of the membrane displacement was developed. It relies on off-axis interferometry, which allows for high precision as well as arbitrary positioning of the probed spot and makes the method completely contactfree.

### BP 12.20 Tue 17:30 P4

**Cell volume changes in confined environments on short timescales** — •FELIX GRAF, BOB FREGIN, DOREEN BIEDENWEG, YESASWINI KOMARAGIRI, STEFANIE SPIEGLER, and OLIVER OTTO — ZIK HIKE, University of Greifswald, Greifswald, Germany

Dynamic real-time deformability cytometry (dRT-DC) is a high-throughput method for extracting the viscoelastic material properties of cells. Cells are dynamically tracked while they translocate through a microfluidic channel and deform in response to the hydrodynamic stress. We extend the time-dependent analysis of dRT-DC towards cellular volume and perform experiments on vesicles and different cell lines in a channel of  $30 \times 30 \mu m^2$  cross-section with buffers as well as cell velocities resembling physiological conditions. Our measurements reveal a volume change of  $\approx 5 - 10\%$  on a millisecond timescale over the entire length of the microchannel, which is  $300\mu m$ . We propose an explanation of our observation by water transport through transmembrane channel proteins. In preliminary experiments, we examined the relationship between the presence and amount of channel proteins, as well as the applied stress and the volume change observed in vesicles and cells. We expect our results to provide insights into the processes involved in physiological volume changes of cells in flow.

### BP 12.21 Tue 17:30 P4

New directions in traction force microscopy — •JOHANNES W. BLUMBERG^{1,2}, Тімотну J. Herbst³, Ullrich Koethe⁴, and Ulrich Schwarz^{1,2} —  1 Institute for Theoretical Physics, Heidelberg University, Germany – ²BioQuant, Heidelberg University, Germany — ³German Cancer Research Center (DKFZ), Heidelberg, Germany —  4 Visual Learning Lab, IWR, Heidelberg University, Germany In traction force microscopy (TFM), the mechanical forces of cells adhering to an elastic substrate are estimated from the substrate displacements as measured by the movement of embedded marker beads. While it is straightforward to calculate the deformation field resulting from a given traction pattern (direct problem), it is challenging to estimate the traction pattern from the deformation field (ill-posed inverse problem). Usually, an estimate is obtained by minimizing the mean squared distance between experimentally observed and predicted displacements (inverse TFM). Here we explore two alternative approaches in TFM. First, we compare inverse TFM to the direct method, in which the stress tensor is calculated directly from the displacement data, thus avoiding the use of a loss function. Second, we explore the potential of machine learning and convolutional neuronal networks. By applying recently developed conditional invertible neuronal networks (cINN), we can address questions regarding the stability and uniqueness of the obtained traction field estimates.

### BP 12.22 Tue 17:30 P4

Quantifying the relation between cell membrane and nucleus through Shape**based Voronoi tessellation** — •Madhura Ramani¹, Maxime Hubert¹, Sara Kaliman¹, Simone Gehrer¹, Florian Rehfeldt², and Ana-Sunčana SMITH^{1,3} — ¹PULS group, FAU Erlangen-Nürnberg, Erlangen, Germany — ²Experimental Physics 1, Universität Bayreuth, Bayreuth, Germany — ³Group for Computational Life Sciences, Ruđer Bošković Institute, Zagreb, Croatia Numerous disorders caused by genetic alterations empathize the im portance of nuclear shape and position within the cell. It is crucial to understand how the cell and nuclei relate mechanically to each other in various conditions. We investigate this relation using confluent MDCK-II monolayers grown unconstrained on substrates of various elasticities. The synergy between the cell mem brane and nucleus is measured through the quality of the Shape-based Voronoi Tessellation (SVT), which is then compared to the tessella tion of space provided by the cell membranes in the tissue. To address the precision, we compare SVT-extracted morphological information to the corresponding membrane-segmented ones and show that the method outclasses classical Voronoi Tessellation. As the SVT relies on the nuclei position to approximate the cell membrane, we present a systematic measure of the distance between the cell and nucleus center of mass. Our method offers insights regarding the mechanical feedback between the cell membrane shape and nuclei positioning, and is central in the creation of theoretical and numerical models of tissues.

### BP 12.23 Tue 17:30 P4

Reactive oxygen species induce cell stiffening through lysosomal disruption and subsequent intracellular acidosis in HL60 cells — •YESASWINI KOMARAGIRI^{1,2}, RICARDO HUGO PIRES^{1,2}, STEFANIE SPIEGLER^{1,2}, HUY TUNG DAU¹, DOREEN BIEDENWEG¹, CLARA ORTEGON SALAS³, MD FARUQ HOSSAIN¹, BOB FREGIN^{1,2}, STEFAN GROSS^{2,3}, MANUELA GELLERT³, UWE LENDECKEL³, CHRISTOPHER LILLIG³, and OLIVER OTTO^{1,2} - ¹ZIK HIKE, University of Greifswald, Greifswald, Germany - ²DZHK, University Medicine Greifswald, Greifswald, Germany - ³University Medicine Greifswald, Germany

Reactive oxygen species (ROS) are important players of redox homeostasis and associated with cellular alterations in both, physiological and pathological conditions. Effects of different ROS on the cytoskeleton have been reported earlier; however, the exact mechanism by which they alter cell mechanics remains to be understood. Here, we used varying concentrations of hydrogen peroxide to induce intracellular ROS in human myeloid precursor cells (HL60). Using real-time fluorescence and deformability cytometry, we combined the mechanical characterization of cells with simultaneous fluorometric assessment of intracellular superoxide levels. Our work reveals a direct correlation of cell stiffening with increasing levels of superoxide. While no global changes of F-actin or microtubule networks could be observed, we show increased elastic properties as a consequence of lysosomal damage followed by intracellular acidification.

### BP 12.24 Tue 17:30 P4

Nuclear Volume, Density and Dry Mass are Controled by Chromatin and Nucleocytoplasmic Transport — •OMAR MUÑOZ^{1,2}, ABIN BISWAS^{1,3,4}, KYOOHYUN KIM^{1,3}, SIMONE REBER⁴, VASILY ZABURDAEV^{1,2}, and JOCHEN GUCK^{1,3} — ¹Max Planck Zentrum für Physik und Medizin — ²Department of Biology, Friedrich-Alexander-Universität Erlangen-Nürnberg — ³Max Planck Institute for the Science of Light — ⁴IRI Life Sciences, Humboldt-Universität zu Berlin

The cell nucleus is an organelle responsible for hosting essential processes such as DNA replication and transcription. Many important biophysical properties of the nucleus are not well understood, for example, its density is lower than the density of the cytoplasm despite the nucleus hosting the highly compressed genome. Motivated by this observation, we combined optical diffraction tomography and confocal fluorescence microscopy and measured, in real time, the material properties of nuclei reconstituted in *Xenopus* egg extract. We found that nuclear growth has two phases: the first one driven by chromatin decondensation and the second one, by nucleocytoplasmic transport and replication. We also developed a simple theoretical model, where nuclear volume is determined by an entropic polymer pressure exerted by chromatin and an osmotic pressure caused by the protein concentration gradient across the nuclear envelope. The good agreement between the model predictions and experimental results supports a view, where chromatin and nucleocytoplasmic transport are essential contributors to the biophysical properties of the nucleus.

#### BP 12.25 Tue 17:30 P4

Mechanical Characterization of Pharmaceutical Nanoparticles — •HENRIK SIBONI^{1,2}, LEONHARD GRILL¹, and ANDREAS ZIMMER² — ¹Single Molecule Chemistry, Institute of Chemistry, University of Graz — ²Pharmaceutical Technology & Biopharmacy, Institute of Pharmaceutical Sciences, University of Graz Nanoscale Drug Delivery Systems are becoming an essential part of modern medicine, but lack of understanding of the underlying physical mechanisms hinders its progress. Focusing on self-assembled nanoparticles called proticles, we employ Atomic Force Microscopy to gain new insights. We find that we are able to characterize particle shape and its dependence on formulation. We further show that proticles can be imaged on biological cells and that the mechanical changes in cells can be measured using nanoindentation experiments. Our methods can be used in the future to accelerate early-stage development of pharmaceutical nanoparticles.

#### BP 12.26 Tue 17:30 P4

The role of vimentin phosphorylation in mechanotransduction — •JULIA KRAXNER^{1,2} and HOLGER GERHARDT^{1,2} — ¹Max Delbrück Center for Molecular Medicine in the Helmholtz Association (MDC), Berlin — ²German Centre for Cardiovascular Research (DZHK)

Vascular endothelial cells (VECs) need to be able to constantly sense, withstand and adapt to varying mechanical stresses. One way cells adapt their mechanics to these varying requirements is through differential expression of cytoskeletal proteins. Here, we focus on the intermediate filament vimentin and introduce post-translational modifications (PTMs). Interestingly, PTMs provide a mechanism for mechanical modulation on short time scales. We study the impact of one such PTM, phosphorylation and one effect of phosphorylation is, for example, the disassembly of intermediate filaments. Experiments on VECs under flow reveal an increase of specific phosphorylation sites in vimentin. We investigate the role of these phosphorylation sites on the mechanotransduction. Therefore, we want to combine traction force microscopy under flow with mutations in vimentin which inhibit phosphorylation of specific sites. Additionally, we plan on tuning the substrate stiffness to study the effect of tissue mechanics observed in aging of the vascular system and possible effects on mechanotransduction. These insights have the potential to improve our understanding of the complex mechanism of mechanotransduction in vascular endothelial cells.

### BP 12.27 Tue 17:30 P4

Towards observing entry of Particulate Matter into lung cells using Photonic Force Microscopy — •JEREMIAS GUTEKUNST and ALEXANDER ROHRBACH — Lab for Bio- and Nano-Photonics, Department of Microsystems Engineering (IMTEK), University of Freiburg, Georges-Koehler-Allee 102, 79110 Freiburg, Germany,

The uptake of Particulate Matter (PM) into lung cells increases the risk of stroke and coronary heart disease. Following an in vitro approach, we expose single particulates to lung epithelial cells on a coverslip and examine their fluctuation based binding and entry paths with a photonic force microscope (PFM). The PFM consists of a highly focused laser beam, which is used to optically trap and interferometrically track a PM particle at 1 MHz frequency and with nm precision.

The central part of this work is to investigate the influence of additional scatterers below and above the nano particle of a PFM. The understanding of their optical influence is crucial, as in particle entry experiments the cell scatters light and alters the interference signal used to track the probe. We address the problem by simplifying and controlling the situation: In addition to the particle used as a probe, we introduce a further particles positioned in the same beam path, but trapped with a second laser. By decorrelating the combined scattering signals on different frequencies, we want to recover the precise position of the trapped PM probe on a broad temporal bandwidth to reliably study cell particle interactions.

### BP 12.28 Tue 17:30 P4

Motion-correlated particle transport along filopodia and lamellipodia — •MARIO BREHM and ALEXANDER ROHRBACH — Laboratory for Bio- and Nanophotonics, Department of Microsystems Engineering - IMTEK, Georges-Köhler-Allee 102, 79110 Freiburg, Germany

Macrophages play an important role in cleaning up the body from cell debris, bacteria and viruses. As a prior step to phagocytosis, extracellular particles can attach to cell protrusions like filopodia and be pulled towards the cell body. Our data points to the idea that particles such as bacteria or viruses get mechanically coupled to the actin fibers within the cell, similarly to focal adhesions. The aim of this study is to improve mechanistic models that describe the mechanical coupling of extracellular particles to proteins connected to the retrograde flow of actin fibers. In addition, we investigate whether and how the transport along filopodia and lamellipodia differ from each other.

The high image contrast combined with the high temporal and spatial resolution of ROCS microscopy enables us to observe directed motion and fluctuations along filopodia at 100 Hz and without fluorescence. By recording, tracking and analyzing the nanoparticle's fluctuations it is possible to derive changes of the particle's viscoelastic properties and their relation to molecular bonds during their transport along the cell's protrusions.

### BP 12.29 Tue 17:30 P4

Local organization of F-actin studied via Förster resonance energy transfer using 2D polarization fluorescence imaging (2DPOLIM) — •MOHAMMAD SOLTANINZEHAD^{1,2}, RAINER HEINTZMANN^{1,2}, ADRIAN T. PRESS^{3,4}, and DANIELA TÄUBER^{1,2} — ¹Leibniz Institute of Photonic Technology, Jena — ²Institute of Physical Chemistry & Abbe Center of Photonics, Friedrich-Schiller-University Jena, Germany — ³Department of Anesthesiology and Intensive Care Medicine, Jena University Hospital — ⁴Faculty of Medicine, Friedrich Schiller University Jena, Germany

2D polarization fluorescence imaging (2DPOLIM) provides complete in-plane evaluation of the polarization state of the sample[1,2], giving access to macromolecular arrangement in the range of 2-10 nm via Förster resonance energy transfer between similar fluorophores (homo-FRET, emFRET). Phalloidindye complexes map the structure of F-Actin, by binding specifically. We applied 2DPOLIM to phalloidin-DY490 stained liver tissue of mice from different treatment groups in the context of polymicrobial sepsis[1,3]. Qualitative analysis showed significant differences in the molecular arrangement of F-actin in agreement with the survival of the animals. Further information will be obtained from comparing the experimental data to a series of simulations[2]. – Funding by DAAD-GSSP, DFG-Ta1049/2, Interdisziplinäre Zentrum für Klinische Forschung Jena (AMSP-05). – [1] D. Täuber et al. ELMI 2021, https://doi.org/10.22443/RMS.ELMI2021.6. [2] R. Camacho et al. Commun. Biol. 2018, 1, 157. [3] A.T. Press et al. EMBO Mol. Med. 2021, 13 (10), e14436.

### BP 12.30 Tue 17:30 P4

Interactions between cytoskeletal filaments — •MAGDALENA HAAF, ANNA SCHEPERS, and SARAH KÖSTER — Institute of X-Ray Physics, Göttingen, Germany

The cytoskeletal filaments –F-actin, microtubules and intermediate filaments (IFs)– constitute an interpenetrating network that performs essential cellular functions. Next to the mechanical properties of the single filaments, the interactions between the filamentous proteins play an important role in cytoskeletal network mechanics. To gain a deeper understanding of the composite network it is useful to quantify such interactions in a controlled setting. Cell experiments have revealed a functional and structural interplay between F-actin and vimentin IFs. However, in reconstituted systems studies of mixed networks come to conflicting conclusions. To clearly solve this conflict, it is crucial to simplify the system even further to the single filament level. We use a quadruple optical trap in combination with microfluidics and confocal microscopy to directly quantify the interaction strength and dynamics between F-actin and vimentin IFs. Our approach allows us to characterize the interactions independent of the network morphology. This setup further enables us to probe the influence of electrostatic and hydrophobic effects on the interactions between single filaments.

#### BP 12.31 Tue 17:30 P4

Comparative investigation of F-actin using Nano IR spectroscopic and polarization resolved fluorescence microscopy imaging — •DIJO MOON-NUKANDATHIL JOSEPH^{1,2}, LUKAS SPANTZEL^{2,3}, KATHARINA REGLINSKI^{1,2}, ASAD HAFEZZ^{1,2}, YUTONG WANG^{1,2}, MOHAMMAD SOLTANINEZHAD^{1,2}, CHRISTIAN EGGELING^{1,2}, RAINER HEINTZMANN^{1,2}, MICHAEL BÖRSCH^{2,3}, and DANIELA TÄUBER^{1,2} — ¹Leibniz Institute of Photonic Technology, Jena — ²Friedrich-Schiller University Jena — ³University Hospital Jena, Germany

Fibrillar actin is one of the major structural components in cells. Thus, its organization has been studied extensively. Nevertheless there are still open questions, in particular, related to pathogenic infections. We examine the potential contributions of two complementary recently developed imaging methods for increasing our understanding on local F-actin: IR spectroscopic photo-induced force microscopy (PiF-IR) and 2D polarization resolved fluorescence microscopy imaging (2DPOLIM). PiF-IR provides local chemical information at high spatial resolution below 10 nm. 2DPOLIM allows to study the local aggregation of fluorescence labeled F-actin via Förster resonance energy transfer (FRET) in the range of 2-10 nm [1]. – Funding by DAAD-GSSP, DFG-Ta1049/2 – [1] R. Camacho et al. Commun. Biol. 2018, 1, 157.

### BP 12.32 Tue 17:30 P4

How do muscles self-assemble? — •FRANCINE KOLLEY¹, IAN D. ESTABROOK¹, CLEMENT RODIER², FRANK SCHNORRER², and BENJAMIN M. FRIEDRICH^{1,3} — ¹cfaed, TU Dresden — ²IBDM, Aix Marseille University — ³Physics of Life, TU Dresden.

For voluntary movements, all animal life relies myofibrils in striated muscle, which are highly organised crystal-like cytoskeletal structures comprising chains of micrometer-sized sarcomeres. The size of sarcomeres is supposedly set by giant proteins such as titin. Titin elastically links myosin molecular motors in the middle of a sarcomere to a structure called Z-disc rich in actin crosslinkers at the sarcomere boundary. To investigate putative mechanisms for the self-assembly of myofibrils, we develop minimal mathematical models. We show that minimal models accounting for non-local interactions between three key proteins is sufficient to account for the spontaneous emergence of periodic sarcomeric patterns. We employ mean-field models, as well as agent-based simulations, which reveal the influence of small-number fluctuations on emergent patterns. Additionally, analysing images of the *Drosophila* flight muscle during early development provided by the Schnorrer lab (IBDM, Marseilles), we were able to identify titin as the first protein forming periodic patterns, with myosin and later actin following subsequently, which constrains possible models.

### BP 12.33 Tue 17:30 P4

Simulation and machine-learning-based analysis of active Brownian magnetic microswimmers — •ANAS HUSSIN, SASCHA LAMBERT, and STEFAN KLUMPP — Institute for the Dynamics of Complex Systems, University of Göttingen, Göttingen

Magnetic microswimmers, whether these are biological organisms or designed nanomachines, show promise in biomedical microrobotics, as they can be steered remotely with a magnetic field. Often, these swimmers encounter complex environments characterized by obstacles and confinement. To understand their navigation in such complex environment, we simulate their swimming as active Brownian particles with an intrinsic magnetic moment and interactions with obstacles and walls that can be of hydrodynamic and/or steric nature. In addition, we use the resulting trajectories to train a neural network with an optimized architecture in order to explore the ability of machine learning algorithms to infer parameters of the motion from trajectories.

### BP 12.34 Tue 17:30 P4

**Function of Morphodynamics in Foraging** *Physarum polycephalum* — •LISA SCHICK^{1,2} and KAREN ALIM^{1,2} — ¹Physics Department and CPA, Technische Universität München — ²Max-Planck-Institut für Dyanmik und Selbstorgansiation, Göttingen

Foraging for nutrients and shelter in an heterogeneous environment is key for the survival of living organisms. Foraging behaviour of animals is generally viewed as optimised for maximal energy uptake per search time by balancing time spent for environmental exploration and food exploitation. Yet, it is unclear which foraging behaviour can be adopted by spatially extended organisms like the unicellular slime mould *Physarum polycephalum*. What foraging strategy does the large and adaptive network-like morphology allow for? Here, we follow the plasmodial network of *P. polycephalum* as it adapts its morphology, gradually moving its body mass as it is foraging for food. We evaluate the morphodynamics of the foraging plasmodia by calculating morphology and velocity of the specimen. We

identify three different morphological states by network compactness and the density of moving fronts. In order to understand the purpose of the continuous morphological changes, we investigate the energy distribution within the different morphologies. In particular we discuss how the morphological variability allows the organism to adjust its energetic costs during foraging.

### BP 12.35 Tue 17:30 P4

Lattice based model to study wound healing in biofilms — •YUSONG YE¹, MNAR GHRAYEB², LIRAZ CHAI², and VASILY ZABURDAEV¹ — ¹Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU) & Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany — ²Institute of Chemistry, The Hebrew University of Jerusalem, Jerusalem, Israel

Biofilms are multicellular heterogeneous bacterial communities excelling in social-like cooperation, division of labor, and resource capture. Bacteria in biofilms are embedded in the self-produced extracellular matrix (ECM). Increasingly more often an analogy between biofilms and higher multicellular organisms is drawn. One illustrative example is the process of wound healing. While it is extensively studied in eukaryotic tissues, the mechanisms of wound healing in biofilms are barely understood. The wound healing in biofilm is a regulated growth by which bacteria alter their physiological state in response to a damage. Motivated by experiments in a model biofilm forming bacteria Bacillus subtilis, we developed a lattice based model of a biofilm growth. It explicitly considers cells and ECM produced by cells, as well as nutrient fluxes and helps to elucidate the role of biofilm components (matrix, cells), aging, and nutrient availability in damage repair. Division of labor (growth vs. ECM production) and nutrient consumption play key roles in heterogeneous wound closure. Even under most general assumptions, the model qualitatively reproduces the wound healing phenotypes observed in our experiments and can be further generalised to include signalling and regulatory mechanisms.

### BP 12.36 Tue 17:30 P4

Fluid Flow and Microvascular Remodeling — •FATEMEH MIRZAPOUR-SHAFIYI¹ and KAREN ALIM^{1,2} — ¹Physics Department and CPA, Technische Universität München — ²Max Planck Institute for Dynamics and Self-Organization, Göttingen

As a transport network optimised through evolution, vessel morphology is adapted to minimise energetic costs of dissipation and homogenize flow transport in the network. Resource-deprived tissues produce chemotactic agents to induce vessel formation during development and in tissue homeostasis. The primitive, mesh-like vascular network formed through neovascularisation is highly ramified. Later, vascular network is normalised into a hemodynamically preferred tree-like structure. The normalisation process, termed vessel remodeling, leads to an organ-specific network architecture which better meets the metabolic needs of its surrounding tissue. As vessel growth and remodeling is found impaired in various disease states, several factors regulating vessel formation and branching morphology were identified over the past decades. However, while some of these factors have been undergoing clinical trials, their effects on transport properties of the altered vessel morphology are not fully elucidated yet. Establishing a perfusable human capillary-on-a-chip (hCOC) model system, here we aim to investigate how vascular morphology correlates with fluid flows. Our hCOC model allows extensive quantitative analyses of network morphology and adaptive remodeling under fluid flow applied by a low-pressure syringe pump. Results of our analyses will contribute to the next generation therapeutics targeting vessel development.

### BP 12.37 Tue 17:30 P4

**Cancer tissue dynamics as active liquids** — •MAHBOUBEH FARAJIAN¹, SWETHA RAGHURAMAN², ALEJANDRO JURADO JIMENEZ¹, FATEMEH ABBASI¹, and TIMO BETZ¹ — ¹Third Institute of Physics - Biophysics Georg August University Göttingen — ²Institute for Cell biology ZMBE - University of Münster

Collective cell migration can be found in some key biological processes such as Metastasis, wound healing and tissue rearrangement. While the molecular mechanisms of collective migration already represent a strong research focus, the mechanical processes driving it are currently less studied. Here we propose to answer this question: "Can statistical mechanics explain the local and global characteristics of cell migration in the tumors?" Someone can imagine 3 kinds of phenotypes regarding the collective cell migration: "Sub-diffusive", "Diffusive" and "Super-diffusive" motion. We aim to change the physical parameters of the environment such as Volume (by letting the tumor models grow) and Pressure (by addition of Dextran to the environment), and then look at the statistical mechanics of the cells' collective motion, different phenotypes and the transition between different phenotypes. and we use 3D individual cell tracks for this aim.

### BP 12.38 Tue 17:30 P4

Assessing statistical properties of resident tissue macrophages — •MIRIAM SCHNITZERLEIN^{1,2}, ANJA WEGNER³, STEFAN UDERHARDT³, and VASILY ZABURDAEV^{1,2} — ¹Department of Biology, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — ²Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany — ³Department of Internal Medicine 3 - Rheumatol-

ogy and Immunology, Friedrich-Alexander-Universität Erlangen-Nürnberg und Universitätsklinikum Erlangen, Germany

Resident tissue macrophages (RTMs) are present in essentially all tissues in the human body. While macrophages in general are mostly known as part of the immune response, RTMs are additionally crucial for ensuring tissue homeostasis. This includes removing dead cells, providing growth factors and protecting the tissue from inflammatory damage. To monitor their surroundings, RTMs show continuous sampling behaviour by extensions and retractions of protrusions as well as endocytosis behaviour. Quantifying the growth and shrinkage of protrusions under different conditions is thereby essential to understand the overall dynamics of RTMs together with their approach of ensuring tissue homeostasis. In this project, we have employed a high-resolution intravital imaging protocol to generate movies of RTMs *in vivo*. Subsequently we have built an image processing pipeline to assess cell properties - such as area and perimeter of whole RTMs or the diffusion coefficient and thereby the dynamics of their protrusions. Such measurements will help to build a mathematical model for protrusion dynamics as well as to establish a biophysical model of RTMs.

#### BP 12.39 Tue 17:30 P4

**3D** Force Model of early zebrafish development via NeuralODEs — •LEON LETTERMANN, SEBASTIAN HERZOG, ALEJANDRO JURADO, FLORENTIN WÖRGÖTTER, and TIMO BETZ — 3rd Institute of Physics - Biophysics, University of Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen

The astonishing process of embryo development still poses a great variety of unanswered questions today. Motivated by the importance of understanding cell migration and organization patterns, we want to study the movements in the early development of zebrafish embryos on a mesoscopic scale. A coarsegrained tissue flow obtained from light sheet microscopy data is analyzed based on a hydrodynamic model. This model is enhanced by active stresses and forces, redirecting the flow away from a dead liquid's description. Using a Neural Ordinary Differential Equation, the active contributions can be reconstructed from observations, shedding light on the distribution of active forces and stresses in the embryo. This allows for quantifying symmetry breaking due to active effects and early recognition of the forming body axes.

### BP 12.40 Tue 17:30 P4

Tissue tension during zebrafish development — •MING HONG LUI^{1,2}, ALE-JANDRO JURADO¹, LEON LETTERMANN¹, and TIMO BETZ^{1,2} — ¹3rd Institute of Physics - Biophysics, University of Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen — ²Max Planck School Matter to Life

Understanding the morphogenesis during development is one of the emerging fields where the interaction between developmental and tissue biology with biophysics has provided a series of deep new insights into natures physical working principles. In particular, during embryonic development of zebrafish, cells in the blastoderm exhibit collective migration towards the yolk in a process known as epiboly, as well as the subsequent gastrulation that involves symmetry breaking. These elegantly robust processes are facilitated by both biochemical and mechanical interactions. To determine how tissue stresses contribute mechanically we use photoablation to create mechanical defects in the tissue and record the subsequent tension relaxation using light sheet microscopy of the whole embryonic volume. We analyze and contrast the nuclei trajectories, density, velocity and force maps with and without the ablative perturbation. From the changes in these quantities, we can infer the adaptive response of the embryo, the source of force generation, and the role played by tissue tension in guiding the coordinated movement.

### BP 12.41 Tue 17:30 P4

Single Cell Force Spectroscopy: The Impact of Cell Contact Area – •SOPHIE GEIGER¹, MARIA VILLIOU^{1,2,3}, and CHRISTINE SELHUBER-UNKEL^{1,2,3} – ¹Institute for Molecular Systems Engineering, University of Heidelberg, DE – ²Max Planck Schools: Matter to Life, University of Heidelberg, DE – ³Cluster of Excellence 3DMM2O KIT & Heidelberg University, DE

Single cell force spectroscopy is a versatile method for characterising cellsubstrate interactions. It has already been applied in several studies to investigate the effect of photomechanical stimulation and the influence of structuring molecules on cell detachment forces.

A critical aspect is the contact area between cell and substrate, as a larger contact area usually leads to higher cell detachment forces. However, the contact area between cell and substrate varies with cell size and with the deformation of the cell pressed onto the surface.

We aim to avoid the distortion that these variations exert on the cell detachment forces by limiting the adhesion area. This is achieved using micropatterned substrates. We use light-induced molecular adsorption of proteins (LIMAP) to generate circular fibronectin micropatterns on an inert background. In a systematic study, we investigate the dependence of cell detachment forces on the cell-substrate interaction surface.

### BP 12.42 Tue 17:30 P4

Investigation of the binding behaviour of proteins in various patterns — •JONAS WALTHER¹ and ANA-SUNČANA SMITH^{1,2} — ¹PULS Group, Department of Physics, Interdisciplinary Center for Nanostructured Films, Friedrich-Alexander-Universität Erlangen-Nürnberg, Cauerstraße 3, 91058 Erlangen, Germany — ²Group for Computational Life Sciences, Ruðer Bošković Institute, Zagreb, Croatia

The coupling of two or more cellular membranes is an important part of cell interactions and therefore affects many biological mechanisms. Cells may restrict the movement of proteins in certain areas of their membrane creating functionally specialized regions, or membrane domains. Here we analyse whether the arrangement of proteins in different patterns changes the binding kinetics of the proteins. In our investigation we combine kinetic Monte Carlo simulations and explicit calculations of the binding rates of the patterns. Results show that there is indeed a difference in binding of the different patterns. An important factor seems to be the amount of proteins within a pattern due to the correlations between the proteins. The exact difference of the binding rates depends on the mechanical properties of the membrane and the proteins. We furthermore analyse the dynamics of bond formation and compare the results to experimental data on the activation of natural-killer cells binding to analogous patterns (experiment by the group of Mark Schvartzman at the Ben-Gurion Univeristy of the Negev).

### BP 12.43 Tue 17:30 P4

Electrostimulation of osteoblasts on coated planar resistive electrodes — •FRANZISKA DORN¹, CHRISTIAN VÖLKNER¹, MEIKE GENZOW², MARTINA GRÜNING², SVEN NEUBER³, REGINA LANGE¹, INGO BARKE¹, CHRISTIANE A. HELM³, BARBARA NEBE², and SYLVIA SPELLER¹ — ¹Institute of Physics, University of Rostock — ²University Medical Center Rostock, University of Rostock — ³Institute of Physics, University of Greifswald

The development of electrically active implants may profit from knowledge and understanding of how osteoblasts respond to electrostimulation. Besides the aim to find routes to accelerate adhesion of osteoblasts, the cellular response in terms of migration and deformation is interesting. For our experiments we use a planar resistive electrode configuration with DC electrostimulation. The glass substrate is covered with a few bilayers of polyelectrolyte (PDADMA/PEI) with carbon nanotubes incorporated to enhance electrical conductivity. In physiologic medium the sheet resistance increases from few k $\Omega$  to more than 10 k $\Omega$ . Human osteoblast-like cells (MG-63) were seeded on the electrode and, after 24 h cell growth, stimulated by a couple of cycles at voltages between 1V and 2V. The observed cellular shape changes and mobility are only subtle and the dependence on the orientation of the electric field axes is not obvious. Experiments at an earlier phase in the adhesion process i.e., in a shorter time frame of cell adhesion, are considered. [1] C. Voelkner, et al, Beilstein J. Nanotechnol. 12, 242 (2021) [2] M. Gruening, et al, Front. Bioeng. Biotechnol. 8,1016 (2020) [3] H. Rebl, et al, Adv. Engin. Mater. 12, B356 (2010)

### BP 12.44 Tue 17:30 P4

The zeta potential as parameter in electric field landscapes for guiding cell adhesion — •Wanda Witte¹, Christian Völkner¹, Regina Lange¹, Susanne Seemann², Barbara Nebe², Ingo Barke¹, and Sylvia Speller¹ — ¹Institute of Physics, University of Rostock, Rostock, Germany — ²Department of Cell Biology, Rostock University Medical Center, Rostock, Germany

In osseointegration of implants, chemical and physical material properties influence inital cell adhesion. The relevant surface potential for cells is the zeta potential at the shear plane or hydrodynamic distance. We investigate how the zeta potential of glass can be modified by an aggregated molecular monolayer, with the aim of using the zeta potential to create electric field landscapes. To achieve the aggregation of a molecule monolayer, amine-terminated dendrimers and albumin were deposited on the glass by micro-contact printing or immersion. An electrokinetic analyzer was used to determine the zeta potential of the coated and uncoated samples. The successful physisorption of molecules was verified by fluorescence microscopy and force microscopy (AFM). It could be shown that the application of albumin or amine-terminated dendrimers increases the zeta potential by approx. 25 eV and 40 eV. The choices and shape responses of osteoblasts (MG-65) in molecule stripe landscapes are discussed.

#### BP 12.45 Tue 17:30 P4

**Quantification of the dynamics of confluent endothelial cells** — •ANSELM HOHLSTAMM, ANDREAS DEUSSEN, and PETER DIETERICH — Institut für Physiologie, Medizinische Fakultät, TU Dresden

Cooperative cell dynamics resulting from a complex interplay of single cell migration and cell-to-cell interactions plays a fundamental role in maintaining a confluent cell layer despite continuous changes in cell numbers and environmental conditions. It is the aim of this work to extract the essential components of this dynamics. Therefore, we seeded human umbilical vein endothelial cells and stained their nuclei with a fluorescent dye. Cells were observed within 48 hours (dt = 10 minutes). We obtained up to 50.000 cell trajectories within an area of 6 x 7 millimeters for 10 different experiments. All analyses were performed under nearly confluent conditions. Cells continued to show lively proliferations and a non-stationary behavior indicated by a two-phase decay of the mean squared velocity. This behavior is accompanied by a decay of the velocity correlation. In addition, we found an exponential repulsion between cells that could transiently rise cell velocities due to cell proliferations. We put these observations into a mathematical model coupling cell proliferation and mean squared velocities over time. Bayesian analysis was applied to determine the best model and its parameters. In summary, we are able to perform a characterization of the complex cell dynamics. This approach can be used for simulations and application to different experimental conditions.

Adaptive microfluidics using hydrogels with irreversible response -•ONURCAN BEKTAS^{1,2,3,4}, CHARLOTT LEU³, JOACHIM RÄDLER^{1,3}, and KARE , and KAREN ALIM^{1,2,5} - ¹Max Planck School Matter to Life, Germany - ²Physics Department and CPA, Technische Universität München — ³Faculty of Physics and and Center for NanoScience (CeNS), Ludwig-Maximilians-Universität München, München, Germany — ⁴Physics Department, University of Göttingen, Göttingen — ⁵Max Planck Institute for Dynamics and Self-Organization, Göttingen Microfluidic devices have triggered technological revolutions in biology and separation technology. Their increased surface-to-volume ratio shortens reaction times, and make reactions more accurate and effective in an automated fashion, thus reducing error rates and allowing for highthroughput assays. However, fabricating multifunctional devices with integrated modules requires complicated control systems and is by far from being trivial. Here we present a novel bioinspired approach to design adaptable microfluidic devices that can adapt the sizes of its channels using local feedback mechanisms for uniform flow. We fabricate a random porous media using an hydrogel made of Poly(ethylene glycol)norbornene backbone and MMP-degradable cross-linker. When perfused with MMP-1 enzyme, the boundaries of the channels are cleaved such that the size of the channels and the flow are coupled. We investigate how the feedback mechanism between the flow and the channel size allows the network to optimise the flow rate distribution. Our methodology will lay the foundation for designing microfluidic devices that are adaptive to biological activity.

### BP 12.47 Tue 17:30 P4

Adaptive microfluidics using irreversibly responsive hydrogels — •ONURCAN BEKTAS^{1,2,3,4}, CHARLOTT LEU³, JOACHIM RÄDLER^{1,3}, and KAREN ALIM^{1,2,5} — ¹Max Planck School Matter to Life, Germany — ²Physics Department and CPA, Technische Universität München — ³Faculty of Physics and and Center for NanoScience (CeNS), Ludwig-Maximilians-Universität München, Germany — ⁴Physics Department, University of Göttingen, Göttingen — ⁵Max Planck Institute for Dynamics and Self-Organization, Göttingen

Microfluidic devices have triggered a technological revolution in the pharmaceutical industry and biotechnology. Integrated modular microfluidic devices allow for high throughput assays while making them more precise by eliminating human-induced errors. The fabrication process, however, introduces inhomogeneities which limit the efficiency and the precision of the produced devices. Here, we present a novel bio-inspired approach to designing adaptable microfluidic devices that can adapt the sizes of their channels using local feedback mechanisms for uniform flow. We test our approach by fabricating a random porous media using Matrix-Metalloproteinase(MMP)-degradable poly(ethylene glycol)-norbornene hydrogel and measure how the flow rate distribution changes by using Particle Image Velocimetry technique. As the device is perfused with an MMP-enzyme, the degradation of the hydrogel is coupled to the flow. We investigate how this coupling could result in a uniform flow. Our method could be used to eliminate inhomogeneities introduced during the fabricating processes to produce spatially homogeneous microfluidic devices.

### BP 12.48 Tue 17:30 P4

Self-organization of microtubule filaments in energy dissipativeevaporating droplet — •VAHID NASIRIMAREKANI, OLINKA RAMIREZ-SOTO, STEFAN KARPITSCHKA, and ISABELLA GUIDO — Max Planck Institute for Dynamics and Self-Organization, 37077 Göttingen, Germany

Cytoskeletal assemblies such as microtubule networks and motor proteins of the kinesin family drive vital cellular processes that, together with cargo delivery and cell division, also include providing mechanical stability when cells are exposed to external stresses. How these self-organising structures can orchestrate such response is not yet well understood. In this study, we develop a bioinspired system resembling intracellular cytoskeletal networks and characterise its activity under the influence of external stress. For this purpose, we confine an active network of microtubules and kinesin motors in an evaporating aqueous droplet. This setup serves as a bioreactor that enables to apply forces to the active system. Namely, the flow field generated by the Marangoni and capillary flow couples with the active stress of the microtubule-motor protein network. We observe that this coupling influences the spatio-temporal distribution of the driving forces and the emergent behaviour of the system, which shows contracting and relaxing behaviour. By analysing such non-equilibrium systems, our study can contribute to understand the response of biological structures to cues from the external environment.

### BP 12.49 Tue 17:30 P4

Establishment of a microfluidic UV-Vis analysis of single cell E. coli — •TIM R. BAUMANN¹, ALEXANDER GRÜNBERGER², DARIO ANSELMETTI¹, HARALD GRÖGER³, and MARTINA VIEFHUES¹ — ¹Experimental Biophysics & Applied Nanosciences, Department of Physics, Bielefeld University — ²Multiscale Bioengineering, Department of Technology, Bielefeld University — ³Industrial organic chemistry and biotechnology, Department of Chemistry, Bielefeld University

Whole-cell biocatalysts like, E. coli DH5-α are widely used in industrial organic chemistry and biotechnology. For efficient production an appropriate cultivation media composition is of high importance. Harmful organic solvents, like ethanol are needed to solve insoluble substrates, those often lead to a permeabilisation of the bacterial membranes. In this study, we established a microfluidic method to analyse the impact of ethanol on leaching of certain intracellular cofactors e.g., NAD(P)H and exploited the contribution of NAD(P)H to the cells autofluorescence. In order to detect the losses in intensity due to leaching, a UV-LiF analysis of single cells was conducted, using a Nd:YAG Laser ( $\lambda = 266$  nm). We evaluated the impact of incubation in 5% ethanol for either 5 or 10 minutes on single cells in a PDMS microfluidic chip with a UV transparent fused silica base layer, including a carbon black PDMS spot at the detection point to reduce the PDMS's autofluorescence. The intensity data was assessed and plotted in histograms. Those exhibited a reduction of the FWHM and a displacement of the distribution maxima to smaller intensities depending on the incubation time and proved the cofactor leaching due to ethanol exposition.

### BP 12.50 Tue 17:30 P4

Study of the temporal stability of evaporated SLBs for technological applications — •Nancy Gomez-Vierling¹, Marcelo A. Cisternas², María José Retamal¹, Nicolás Moraga¹, Marco A. Soto-Arriaza³, Tomás P. CORRALES⁴, FELIX KLEEMANN⁵, and ULRICH G. VOLKMANN¹ - ¹Instituto de Física and CIEN-UC, P. Univ. Católica de Chile - ²Escuela de Ingeniería Industrial, Univ. de Valparaíso, Chile-  3 Facultad de Química y Farmacia and CIEN-UC, P. Univ. Católica de Chile-  4 Departamento de Física, UTFSM, Valparaíso, Chile — ⁵Departamento de Física, Technische Universität Clausthal, Germany. Artificial membranes are models for biological systems. We introduce a dry two-step self-assembly method, first performing a high-vacuum evaporation of phospholipid molecules over silicon, followed by an annealing step in air. Our evaporated membranes show long-term stability and no restructuring after storage in air during at least fifteen months. This extreme stability of the Supported Lipid Bilayer (SLB) structures make this system interesting for technical applications in the field of functional biointerfaces, e.g., for fabrication of biosensors and membrane protein platforms, including cleanroom-compatible fabrication technology. It is expected that SLBs can help to gain insight into the lifetime of viral structures protected by a surrounding phospholipid bilayer adsorbed on static solid surfaces or on inhalable particulate material (PM), which contributes to the spread of the SARS-CoV-2 virus. Acknowledgment: FONDECYT grant numbers 1180939 (UGV), 1171047 (MS-A) and 1211901 (TPC).

### BP 12.51 Tue 17:30 P4

Measurements of topologies and Young moduli of DPPC films deposited from the gas phase onto silicon substrates at different temperatures — •NICOLÁS MORAGA¹, GABRIEL ALFARO¹, NANCY GOMEZ-VIERLING¹, DANIEL SAAVEDRA¹, MARCELO A. CISTERNAS², MARÍA JOSÉ RETAMAL¹, MARCO A. SOTO-ARRIAZA³, TOMÁS P. CORRALES⁴, FELIX KLEEMANN⁵, and ULRICH G. VOLKMANN¹ — ¹Instituto de Física and CIEN-UC, P. Univ. Católica de Chile — ²Escuela de Ingeniería Industrial, Univ. de Valparaíso, Chile — ³Facultad de Química y de Farmacia and CIEN-UC, P. Univ. Católica de Chile — ⁴Departamento de Física, UTFSM, Valparaíso, Chile — ⁵Departamento de Física, Technische Universität Clausthal, Clausthal, Germany.

Supported lipid bilayers (SLBs) are suited to gain insight into the physical behavior of cell membranes. In this work, DPPC deposition by Physical Vapor Deposition (PVD) is performed on silicon (100) substrates at different substrate temperatures and deposition rates. Our goal is finding growth parameters, to optimize coverage and homogeneity of the DPPC SLBs. We observe a modification of topologies and Young moduli and an optimization of the homogeneity for substrate temperatures between 310 and 315 K and deposition rates in the range of 0,78 to 0,93 Å/min. Homogeneous, planar biomimic phospholipid membranes avail protein insertion and an easier detection of ionic channels which will form in case of Gramicidin [Kelkar et. al, BBA 1768 (2007) 2011-25]. Acknowledgment: FONDECYT grant numbers 1180939 (UGV), 1171047 (MS-A) and 1211901 (TPC).

### BP 12.52 Tue 17:30 P4

The effect of additives on the lamellar-to-cubic transition dynamics of monoolein at excess water conditions — •JAQUELINE SAVELKOULS, MICHELLE DARGASZ, GÖRAN SURMEIER, and MICHAEL PAULUS — Fakultät Physik/DELTA, Technische Universität Dortmund, 44221 Dortmund, Germany

Monoolein is an amphiphilic lipid, which is of particular interest in the pharmaceutical industry. Monoolein swells in excess water and forms several lyotropic liquid crystalline structures. In the cubic Pn3m phase, monoolein can release a previously added drug by slow diffusion in the human body [1]. Measurements are performed at the beamline BL2 of the synchrotron radiation source DELTA (Dortmund, Germany) using the small angle X-ray scattering (SAXS) set-up to study the pressure-induced transition from the lamellar crystalline phase to the cubic Pn3m phase. 20 wt% monoolein was mixed in water with salts or drugs. Diffraction patterns are recorded, from which the lattice constants for each phase can be determined. The results show that a much larger lattice constant of the Pn3m phase is formed after the pressure jump compared to the equilibrium state before the pressure increase. Given some time, the system relaxes, causing the lattice constant to approach the equilibrium lattice constant. The rate of relax-ation depends on the added additives. In summary, the formation of the liquid crystalline phases of monoolein allows drugs to be released over a long period of time. The speed of diffusion can be optimized by the addition of salts.

#### BP 12.53 Tue 17:30 P4

Simulation of Double-Walled Vesicles Surrounded by Mixed Membranes — •PAUL LOUIS SONEK and FRIEDERIKE SCHMID — Johannes Gutenberg-Universität, Mainz, Germany

The simulation of membranes from cells and organelles has been a subject of research for quite some time. Some organelles, like the mitochondria, are surrounded by two membranes, where the area of the inner one is much larger than that of the outer one. Such organelles are characterized by numerous invaginations in the inner membrane. The goal of our work is to investigate to which extent simple membrane models can reproduce such structures.

We use the triangulated surface model of Noguchi and Gompper [1] to model double-walled vesicles and combine it with a field model on the model's surface to simulate a membrane with different lipid compositions on different parts of the membrane. Depending on the volume and surface of the inner membrane, we obtain different stable and metastable shapes for the resulting invagination, including flat invaginations, which have a shape similar to the ones observed in mitochondria. Furthermore, configurations with more than one of such folds are found to be metastable.

Our results may shed light on the mechanisms responsible for the peculiar membrane shapes observed in organelles.

### BP 12.54 Tue 17:30 P4

Single-particle Diffractive Imaging at the European XFEL: Instrumentation, Data Acquisition and Hit-finding — •MORITZ STAMMER¹, CHARLOTTE NEUHAUS¹, JETTE ALFKEN¹, MARKUS OSTERHOFF¹, RICHARD BEAN², JOHAN BIELECKI², JUNCHENG E², SAFI RAFIE-ZINEDINE², RAPHAEL DE WIJN², ROMAIN LETRUN², ADRIAN MANCUSO², REINHART JAHN³, and TIM SALDITT¹ — ¹Georg-August-Universität, Institute for X-ray Physics, 37077 Göttingen — ²Scientific Instrument SPB/SFX, European XFEL GmbH, Holzkoppel 4, 22869 Schenefeld Germany — ³Laboratory of Neurobiology, Max Planck Institute for Multidisciplinary Sciences, 37077 Göttingen, Germany

The European XFEL provides state-of-the-art instrumentation for absolving single-pulse, single-particle coherent diffractive imaging, which we have used to investigate synaptic vesicles, harvested from rat brain, with high spatial resolution. The method involves serial bio-sample delivery by aerosol jet such that droplets incorporating single particles are probed by femto-second pulses. In this way two prevalent challenges of SAXS (polydispersity and radiation damage for high brilliance beams) can be met. Stochastic distribution of sample and a nano-focused beam means only a fraction of the recorded data was of interest (1.2 PB in total, roughly  $3 \cdot 10^8$  images). We present technical details behind the data acquisition used for this proof-of-concept experiment at the SPB instrument of the European FEL as well as our strategy in "hit-finding". Further, first steps towards electron density reconstruction will be presented as well as comparison to preceding SAXS work.

### BP 12.55 Tue 17:30 P4

Live imaging on single cell arrays (LISCA) as platform to study mRNA codon optimization based on ribosome modelling — •JUDITH MÜLLER¹, GERLINDE SCHWAKE¹, ANITA REISER¹, DANIEL WOSCHÉE¹, ZAHARA ALIREZAEIZANJANI³, JOACHIM RÄDLER¹, and SOPHIA RUDORF² — ¹Ludwig-Maximilians-Universität, München — ²Leibniz Universität, Hannover — ³Max Planck Institute of Colloids and Interfaces, Potsdam

mRNA based therapies have the potential to evolve as one of the most powerful therapeutic technologies of our future. Massive efforts have been made to deeply study the underlying mechanisms of mRNA delivery and translation. Synony-mous re-coding of the mRNA's open reading frame is one approach to investigate and optimize the physics of mRNA translation. In this project, we evaluate the potential of bias in codon usage on influencing the mRNA's translation and degradation kinetics. Live imaging on single cell arrays (LISCA) enables the quantification of translation of hundreds of single cells in parallel on microstructured surfaces. By describing the translation in biochemical rate equations, we analyse mRNA expression and degradation rates with high accuracy. Ribosome

movement on the open reading frame (ORF) is simulated to generate mRNA constructs coding for reporter genes with varying ribosome speeds and densities. We observe distinct differences in expression and degradation rates for GFP mRNAs with various optimized ORFs in agreement with simulation. Secondly, we study how specifically provoked ribosome jams on the ORF influence mRNA stability.

### BP 12.56 Tue 17:30 P4

The pH dependent phase transition in lipid nanoparticle cores leads to changes of protein expression in single cells — •JULIAN PHILIPP¹, LENNART LINDFORS², and JOACHIM RÄDLER¹ — ¹LMU, Munich, Germany — ²AstraZeneca, Mölndal, Sweden

Lipid nanoparticles developed into the most powerful delivery platform for mRNA based vaccination and therapies. In general LNPs are core/shell particles exhibiting PEG-lipid and DSPC at the surface and ionizable lipid, cholesterol and mRNA in the core. However, the pH dependent changes induced by ionizable lipids in the context of endosomal release are little understood. Here we study the ionizable lipids MC3, KC2, DLin-DMA as model systems as they exhibit different efficacy despite similar pK values. Using synchrotron X-ray scattering we study the structure of bulk phases containing ionizable lipid/cholesterol with and without polyA as mRNA surrogate. The bulk phases exhibit ordered mesophases at low pH and a transition into isotropic swollen phases at higher pH. We find inverse hexagonal  $H_{II}$  lipid phases in case of MC3 and KC2 and cubic Pn3m and  $H_{II}$  phases in case of DLin. Bulk phases with polyA show coexistence of pure lipid phases and condensed nucleic acid lipid phases. We show that the observed bulk structures are consistent with the SAXS scattering profile of mRNA containing LNPs. The difference in structural features is also consistant with the delayed onset and reduced level of GFP expression observed in single cell time courses after transfection with DLin LNPs compared to MC3 and KC2. We conclude that pH dependent bulk phase transitions trigger endosomal release.

### BP 12.57 Tue 17:30 P4

Spatial-Stochastic Model of Cell Fate Decisions in Early Mouse Development — •MICHAEL ALEXANDER RAMIREZ SIERRA¹, TIM LIEBISCH^{1,2}, SABINE C. FISCHER³, FRANZISKA MATTHÄUS^{1,2}, and THOMAS R. SOKOLOWSKI¹ — ¹Frankfurt Institute for Advanced Studies (FIAS), Frankfurt am Main, Germany — ²Goethe Universität Frankfurt am Main, Germany — ³Julius-Maximilians-Universität Würzburg, Germany

The delicate balance necessary for ensuring reliable specification of cell lineages is an intriguing problem in developmental biology. As an important paradigm in tissue development, the early mouse embryo cell fate decisions have been extensively researched, but the underlying mechanisms remain poorly understood. Current approaches to this problem still primarily rely on deterministic modeling techniques, although stochasticity is an inherent feature of this biological process. We are developing a multi-scale event-driven spatial-stochastic simulator for emerging-tissue development. We build up new simulation schemes for incorporating suitable tissue-scale phenomena, and we fix important parameters by using experimental values or numerical optimization to infer biophysicallyfeasible regimes. We first explore the characteristics of this system in a single-cell setting. We then extend the study to a multi-cellular setting in order to understand how positional information is robustly achieved and preserved. Our latest results indicate a potential signaling mechanism for reliable patterning emergence, despite strong constraints imposed by cell cycles. We are closely exploring how these signals redefine cell fates.

### BP 12.58 Tue 17:30 P4

Protein Dynamics in the Complex Physical Environment of the Synapse — •SIMON DANNENBERG, SARAH MOHAMMADINEJAD, and STEFAN KLUMPP — Institut für Dynamik komplexer Systeme Georg-August-Universität Göttingen, Göttingen, Germany

The synapse is a complex environment that is densely packed with proteins and has an internal geometry structured by membranes. This affects the mobility of proteins involved in signal transmission and hence, their availability at corresponding reaction sides.

In our work we use dynamic Monte Carlo simulations to investigate the individual influences of different physical features of the synapse on protein mobility. The simulations are parameterized by mobility measurements via FRAP experiments. By simulating protein mobility in synapses with different geometric features such as synapse volume and vesicle number, we study the influence of these features on concentration profiles in the synapse and other key aspects of signal transmission.

### BP 12.59 Tue 17:30 P4

Single Cell Prime Editing Kinetics — •NATHALIE SCHÄFFLER¹, JULIAN GEILENKEUSER², DONG-JIUNN JEFFERY TRUONG², GIL WESTMEYER², and JOACHIM RÄDLER¹ — ¹LMU München, Deutschland — ²Institute for Synthetic Biomedicine, Helmholtz-Zentrum München, Deutschland

CRISPR-Cas technology opens up new ways of approaching biological computing, taking advantage of the native language of biology and the inherent possibilities of DNA which could enable easier parallelism and higher storage capacities. However, to effectively leverage this technology a solid understanding of the kinetics and efficiency of gene editing is essential.

A key advancement in CRISPR-Cas is Prime Editing (PE), which enables precise "search-and-replace" of specific DNA sections without templates. However, PE requires delivery of both the PE specific Cas-9 protein and a guide RNA (pegRNA) into living cells. Two common strategies of non-viral in vivo delivery are via mRNA or pDNA constructs encoding both PE components. We compare these two methods and study their efficiency and timing using Live Imaging on Single Cell Arrays (LISCA).

Our experiments use a HEK293T cell line with stable expressing blue shifted mGreenLantern (mGL) as reporter system, taking advantage of the fact that only a short DNA sequence edit is needed to reverse the blue shift back to the green mGL. By recording the single cell kinetics and statistics of PE converting bs-mGL into mGL starting from the time point of transfection, we can assess editing times and efficiencies.

### BP 12.60 Tue 17:30 P4

Self-generated oxygen gradients control the collective aggregation of photosynthetic microbes — •ALEXANDROS FRAGKOPOULOS^{1,2}, JEREMY VACHIER¹, JOHANNES FREY¹, FLORA-MAUD LE MENN¹, MARCO G. MAZZA^{1,3}, MICHAEL WILCZEK^{1,4}, DAVID ZWICKER¹, and OLIVER BÄUMCHEN^{1,2} — ¹Max Planck Institute for Dynamics and Self-Organization, 37077 Göttingen, Germany — ²University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany — ³Interdisciplinary Centre for Mathematical Modelling and Department of Mathematical Sciences, Loughborough University, Loughborough, Leicestershire LE11 3TU, UK — ⁴University of Bayreuth, Theoretical Physics I, 95447 Bayreuth, Germany

In the absence of light, photosynthetic microbes can still sustain essential metabolic functionalities and motility by switching their energy production from photosynthesis to oxygen respiration. For suspensions of motile *C. reinhardtii* cells above a critical density, we demonstrate that this switch reversibly controls collective microbial aggregation [1]. Aerobic respiration dominates over photosynthesis in conditions of low light, which causes the microbial motility to sensitively depend on the local availability of oxygen. For dense microbial populations in self-generated oxygen gradients, microfluidic experiments and continuum theory based on a reaction-diffusion mechanism show that oxygen-regulated motility enables the collective emergence of highly localized regions of high and low cell densities.

### BP 12.61 Tue 17:30 P4

**Physical heterogeneities in bacterial mixtures under flow** — •GIACOMO DI DIO, VICTOR SOURJIK, and REMY COLIN — Max Planck Institute for Terrestrial Microbiology, Marburg, Germany

Bacteria are often found in heterogeneous communities organized thorough physical interaction with their surrounding environment. Although external physical constraints like shear flow are frequent in natural situations, little is still known about their effect on the distribution of bacteria within complex communities. Under no flow condition, previous experiments have shown the emergence of large density fluctuations of passive bacterial cells driven by the activity of motile bacteria with which they are mixed. Through microfluidic experiments, we investigate how the spatiotemporal organization and the density distribution of a binary mixture of active and passive E. coli bacteria react under different configurations of shear flow. Our initial focus is on the effect of Poiseuille flow (linear shear profile) on the mixture, but we also plan to study the behavior under Couette flow. We notably focus on possible transport effects emerging from the combined action of external shear and active swimming on the non-motile species of the mixture. Our experiments aim at understanding the physical roles of flow and shear in the spatiotemporal organization of multispecies bacterial communities

### BP 12.62 Tue 17:30 P4

**Fast sorting of microfluidic droplets by content type with combined bright field and fluorescence detection** – •JONAS PFEIL, PATRICIA SCHWILLING, and OTHMAR MARTI – Universität Ulm, Ulm, Germany

Droplet-based microfluidics in context of fluorescent imaging can be used for a multitude of applications in biophysics, medicine, and lab-on-a-chip. One remaining issue in the encapsulation process of particle-like objects is that the number of encapsulated objects is Poisson or Poission-like distributed. A sorting step immediately after the encapsulation reduces the number of falsely-laden droplets.

Here we present results of sorting of beads with similar diameters and different fluorescent signals. Therefore, we encapsulate similar sized beads with different fluorescent signature and sort them using a time multiplexed imaging approach to simultaneously detect the population for each bead type. Thereby, we show that it is possible to achieve a user-defined, homogeneous configuration of fluorescent and non fluorescent particles in droplets.

**Physics of optimal odor detection** — •SWATI SEN and DAVID ZWICKER — Max Planck Institute for Dynamics and Self-organization, Göttingen, Germany Animals need to detect and discriminate odors for survival. In contrast to other

senses, olfaction is shaped by physical processes, including odorant transport by the airflow and adsorption in the nasal mucus layer. These processes crucially affect what the brain can learn about the chemical composition of the environment. We study how the olfactory system relays information by using a simplified theoretical description of the airflow and the adsorption in the mucus. We predict the length scales over which odorants absorb along the olfactory epithelium. This length scale depends significantly on the odorant's solubility but is only weakly affected by odorant diffusivity and adsorption strength of mucus wall. We use these predictions to obtain the optimal arrangement of odorant receptor neurons that maximizes the information relay to the brain. We notice that the receptors sensitive to odorants with shorter adsorption length scale always reside closer to the cavity inlet side and cover the cavity in an increasing fraction of total cavity length with adsorption length scale. Taken together, we study design principles of optimal odor information encoding using a simple fluid dynamical model and information theory. Our approach could help to understand the natural olfaction process and develop artificial noses.

### BP 12.64 Tue 17:30 P4

Assembly of plant-pollinator networks with rare and common plants — •LUCA SCHÄFER, LARA BECKER, and BARBARA DROSSEL — TU Darmstadt, Darmstadt, Germany

Species interaction networks are subject to natural and anthropogenic disturbances that lead to their disassembly, while natural regeneration or restoration efforts facilitate their reassembly. Since over 90% of all angiosperms are pollinated by animals, understanding the stability and assembly of plant-pollinator networks is crucial for ecosystem conservation.

We introduce and investigate a model for the assembly of plant-pollinator networks from an infinite species pool, based on trait-matching between plants and animals. Population dynamics equations include different intraspecific competition strengths and niche width, to allow for the occurrence of rare (high intraspecific competition and small niche width) and common plants. We show that computer simulations of the model lead to the emergence of plant-pollinator networks where rare plants can persist despite the effect of pollen dilution. Over time, pollinators become more specialized, but this trend is stopped if stochasticity in the form of demographic noise is taken into account.

### BP 12.65 Tue 17:30 P4

Statistical modelling of cerebral blood flow and transport in microvascular networks — •FLORIAN GOIRAND¹, TANGUY LE BORGNE², and LORTHOIS SYLVIE³ — ¹Center for Protein Assemblies, Physics Department, Technische Universität München, Garching bei München, Germany — ²University of Rennes, CNRS, Géosciences Rennes, UMR 6118, Rennes, France — ³Institut de Mécanique des Fluides de Toulouse, UMR 5502, CNRS, University of Toulouse, Toulouse, France

Despite of the high dependency of brain cells function on the efficiency of blood transport throughout the micro-vasculature, only little is known about the physical processes that drive neural cell supply. Here, based on the statistical analysis of realistic blood flow computations in mouse brain micro-vascular networks, we develop a statistical framework relating the structure of micro-vascular networks to the observed blood flow and transport heterogeneities. In particular, this framework enables to investigate the detrimental consequences of the cerebral blood flow decrease, a key phenomenon at early stage of Alzheimer's disease. We notably predict, in agreement with simulations, that the anomalous nature of the transport induces a non-linear evolution of the size of the regions exhibiting a critical concentration in oxygen or in neuro-toxic metabolic wastes with the decrease of the cerebral blood flow, unraveling an additionnal mechanism contributing to Alzheimer's disease progress.

### BP 12.66 Tue 17:30 P4

Investigation of nonlinear effects on polarizable  $\mu$ beads in AC/DC-Dielectrophoresis — •TIM R. BAUMANN, DARIO ANSELMETTI, and MARTINA VIEFHUES — Experimental Biophysics & Applied Nanosciences, Department of Physics, Bielefeld University

Dielectrophoresis (DEP) is a common selective force used for separation applications in microfluidics. Due to a non-uniform electric field, polarizable particles migrate through a fluid. Depending on the applied electric field, intrinsic parameters like surface charge, polarizability or ion mobility and extrinsic parameters like pH-value objects lead to acceleration, deceleration or trapping in dielectrophoretic potentials. Thus, analysis of the migration in electric fields yields access to characteristic electric parameter of particles. The direction of movement is given by the value of charge and the direction of the electric field. Here a constant direct current (DC) is set in range 0 - 40V and incrementally raised by 5V to drive the beads through a microfluidic device. An alternating current (AC) (f = 1 kHz) ranging from 100 – 450 V in amplitude (increment size: 50 V) was superimposed to generate dielectrophoretic trapping forces that should decelerate the beads. An increase of migration velocity was observed though, which is assumed to be due to higher order terms of the electric field as recently presented by the group of Perez-Gonzales for DC electric fields [1]. In this work, we investigate if this effect also applies in AC electric fields. [1]Anal. Chem. 2020, 92, 12871-12879

### Invited Talk BP 13.1 Wed 9:30 H15 Cortex mechanics - how subtle modifications matter — •ANDREAS JANSHOFF

— Institute of Physical Chemistry, Tammannstr. 6, University of Goettingen, 37077 Goettingen

Cell cortices are responsible for the resilience and morphological dynamics of cells. Measuring their mechanical properties is impeded by contributions from other filament types, organelles, and the crowded cytoplasm. Therefore, we established two routes to examine its essential features using i) a bottom-up approach to create artificial minimal actin cortices (MACs) and b) by extracting cortices from living cells. Apical cell membranes of confluent MDCK II cells as well as MACs were deposited or formed on porous substrates and either locally deformed using an atomic force microscope setup or explored by microrheology techniques. Force cycles could be described with a time-dependent area compressibility modulus obeying the same power law as employed for whole cells. We found that subtle modifications such as the composition of the plasma membrane and origin of actin, i.e., the chosen isoform or its posttranslational modification are important for the dynamics and mechanics of the cortex. We found that the presence of phosphatidylserine in the inner leaflet of the plasma membranes is crucial for cortex contractility and efficient binding of F-actin to the membrane.

### BP 13.2 Wed 10:00 H15

Dynamic bridging explains sub-diffusive movement of chromosomal loci — •SRIKANTH SUBRAMANIAN and SEÁN MURRAY — Max Planck Institute for Terrestrial Microbiology, Marburg, Germany

Chromosomal loci in bacterial cells show a robust sub-diffusive scaling of the mean square displacement (MSD) ~  $\tau^{\alpha}$ , with  $\alpha < 0.5$  under various growth conditions and antibiotic treatments. Recent experiments have also shown that

DNA-bridging Nucleoid Associated Proteins (NAPs) play an important role in chromosome organisation and compaction. Here, using polymer simulations we investigate the role of DNA bridging in determining the dynamics of chromosomal loci. We find that bridging compacts the polymer and reproduces the sub-diffusive dynamics of monomers at timescales shorter than the bridge lifetime. Furthermore, the measured scaling exponent defines a relationship between chromosome compaction and bridge lifetime. Importantly, measuring the MSD of tagged chromosomal loci in WT and NAP mutant ( $\Delta$ H-NS) we find that the decompacted mutant has a higher scaling exponent as expected. Based on the observed mobility of chromosomal loci and our simulations, we predict a lower bound on the average bridge lifetime of NAPs to be around 5 seconds.

Image analysis and modelling of nascent sarcomeres during myofibrillogenesis — •IAN D. ESTABROOK¹, FRANCINE KOLLEY¹, CLÉMENT RODIER², FRANK SCHNORRER², and BENJAMIN M. FRIEDRICH^{1,3} — ¹cfaed, TU Dresden — ²IBDM, Aix Marseille University — ³Physics of Life, TU Dresden.

All animals possess striated muscle, which enable their voluntary movements. Inside muscle cells, actin and myosin molecular motors together with actin crosslinkers and the giant protein titin are arranged in long chains of sarcomeres in so-called myofibrils of almost crystalline regularity. Despite their physiological importance, it remains poorly understood how myofibrils spontaneously self-assemble during myofibrillogenesis. To investigate this molecular pattern formation process, our group combines image analysis and mathematical modelling, in close collaboration with the experimental Schnorrer lab.

We automatically analysed thousands of sarcomeres using a custom Matlabbased feature detection algorithm to analyse three-dimensional multi-channel fluorescence images of the Drosophila flight muscle. This allows us to compute averaged spatial intensity profiles of key proteins at different stages of myofibrillogenesis, providing a pseudo-time course of sarcomere assembly. Additionally, we observe rare abnormal sarcomeres, which reveals a a new mechanism by which a 'mother sarcomere' splits into two 'daughter sarcomeres'. This data drives mathematical modelling: minimal models demonstrate that non-local interactions between spatially extended myosin and titin molecules, as well as actin crosslinkers are sufficient to replicate sarcomeric pattern formation.

Torques within microtubule bundles generate the curved shape of the mitotic spindle — •ARIAN IVEC¹, MAJA NOVAK¹, MONIKA TRUPINIĆ², IVANA PONJAVIĆ², IVA TOLIĆ², and NENAD PAVIN¹ — ¹Department of Physics, Faculty of Science, University of Zagreb, Bijenička cesta 32, 10000 Zagreb, Croatia — ²Division of Molecular Biology, Ruder Bošković Institute, Bijenička cesta 54, 10000 Zagreb, Croatia

The mitotic spindle is a complex micro-machine made up of microtubules and associated proteins, which are highly ordered in space and time to ensure its proper biological functioning. A functional spindle has a characteristic shape, which includes curved bundles of microtubules that are twisted around the poleto-pole axis. An understanding of both how the linear and rotational forces define the overall shape of the mitotic spindle and how the twisted shapes arise as a result of interactions between microtubules and motor proteins is still missing. To answer this, we model the entire spindle by using a mean-field approach, in which we describe the forces and torques along microtubule bundles throughout the spindle. We compare our theoretical modeling with experimentally observed shapes of bundles in the mitotic spindle, including both unperturbed spindles and those compressed by an external force. We conclude that the observed shape of the spindle is predominately determined by rotational forces. Additionally, we find that a difference in bending forces explains the disparity in the shapes of inner and outer bundles, and that the chirality of the spindle is the result of a constant twisting moment.

Length-dependent poleward flux of sister kinetochore fibres promotes chromosome alignment — •DOMAGOJ BOŽAN — Department of Physics, Faculty of Science, University of Zagreb, Bijenička cesta 32, 10000 Zagreb, Croatia

Chromosome alignment at the spindle equator promotes proper chromosome segregation and depends on pulling forces exerted at kinetochore fiber tips together with polar ejection forces. However, kinetochore fibers are also subjected to forces exerted by motor proteins that drive their poleward flux. Here we introduce a flux-driven centering model that relies on flux generated by forces within the overlaps of bridging and kinetochore fibers. This centering mechanism works so that the longer kinetochore fiber fluxes faster than the shorter one, moving the kinetochores towards the center. Our collaborators developed speckle microscopy in human spindles and confirmed the key prediction that kinetochore fiber flux is length-dependent. The experiments also confirmed that kinetochores are better centered when overlaps are shorter and the kinetochore fiber flux markedly slower than the bridging fiber flux. Furthermore, we extend the model to describe congression of chromosomes by considering dynamics of microtubule-kinetochore attachments and motor proteins at kinetochores and find that the length-dependent forces exerted by microtubules from farther pole can overcome the forces exerted by the greater number of microtubules from nearer pole. Thus, length-dependent sliding forces exerted by the bridging fiber onto kinetochore fibers promote chromosome congression and alignment.

Mechanical properties of keratin and vimentin intermediate filaments — •CHARLOTTA LORENZ¹, JOHANNA FORSTING¹, STEFAN KLUMPP², and SARAH KÖSTER¹ — ¹Institute for X-Ray Physics, University of Göttingen, Göttingen, Göttingen, Göttingen, Göttingen, Göttingen, Göttingen, Göttingen, Germany

Different cell types require different mechanical properties. Prominent examples include cell contracting muscle cells, or migrating versus non-migrating cells. Cells change from a migrating to a non-migrating phenotype during cancer metastasis, wound-healing and embryogenesis (epithelial-to-mesenchymal transition). Interestingly, the expression of different intermediate filament (IF) proteins correlates with this transition: epithelial-like cells express mostly keratin, whereas mesenchymal cells primiarily express vimentin. We compare the mechanical response of keratin and vimentin on the single filament level using optical tweezers. We find that both filament types dissipate a large amount of mechanical input energy, which predestines them to act as a cellular shock absorbers, yet by very different mechanisms, internal friction of sliding filament subunits, or nonequilibrium unfolding of alpha helices for keratin and vimentin filaments, respectively. We conclude that cells can tune their mechanics by differential expression of keratin versus vimentin.

### BP 13.7 Wed 11:30 H15

Influence of vimentin intermediate filaments on microtubules in cells – •ANNA  $BLOB^1$ , ROMAN DAVID VENTZKE^{1,2}, CAROLIN SCHLEIN¹, LAURA SCHAEDEL³, AXEL MUNK², and SARAH KÖSTER¹ – ¹Institute for X-Ray Physics, University of Göttingen – ²Institute for Mathematical Stochastics, University of Göttingen – ³Center for Biophysics, Saarland University

The cytoskeleton in eucaryotic cells is an intricate network of three different filamentous proteins: microtubules, actin filaments and intermediate filaments. Together, they are essential for the mechanical properties as well as important functions of the cell, such as intracellular transport and division. Each protein has it own unique properties and there is evidence for important interactions between them. It has been shown that vimentin intermediate filaments stabilize microtubules in vitro and can template the microtubule network in migrating cells. Following up on this idea, we are interested in the influence of vimentin networks on microtubule mechanics. Cellular microtubules show characteristic buckling and bending behavior that is still not fully understood. Investigating the role of vimentin for the bending of microtubules will improve our understanding of the mechanical consequences and importance of the interactions between these filament systems. We compare microtubule networks in vimentin-knockout and wildtype mouse fibroblasts on micropatterns. Microscopy images are processed and analyzed with respect to the curvature of microtubules. We find that the local curvature of microtubules depends on the cellular region and increases with increasing vimentin density.

**Microscopic modelling of forces and torques in the mitotic spindles** – •MAJA NOVAK¹, ARIAN IVEC¹, IVA M. TOLIĆ², and NENAD PAVIN¹ – ¹University of Zagreb, Faculty of Science, Bijenička c. 32, 10 000 Zagreb – ²Rudjer Bosković Institute, Biophysics of Cell Division, Bijenička c. 54, 10000 Zagreb

The mitotic spindle is a complex micro-machine built from microtubules and associated proteins, with a purpose to properly separate genetic material into two nascent cells. In our previous work we found that microtubule bundles in human spindles follow a left-handed helical path [1], from which we concluded that torques, in addition to forces, exist in the mitotic spindle. However, theoretical description of molecular origin of forces and torques in the mitotic spindle is still missing. Here we show that single-molecule rotational forces regulate the volume of mitotic spindle, where larger twisting moment increases the spindle width. Our model describes microtubules as flexible rods, which are cross-linked by the motor proteins and passive linkers. The model predicts angular distribution of microtubules at the pole, based on experimentally observed shapes of microtubule bundles in the spindle midzone. Finally we found that the bending and twisting moment at the pole change between the inner and outer bundles in a manner qualitatively similar to curvature and twist obtained from the experimental data. In conclusion, our microscopic description opens up the possibility to quantify and understand both function and details of the twisting moment in the mitotic spindle. [1] Novak et al., Nat. Commun.(2018)9:3571

**Correlative Super-Resolution Microscopy and Structural Analysis of Cells and Tissues** — •DIMITAR STAMOV, TANJA NEUMANN, ANDRÉ KÖRNIG, TORSTEN MÜLLER, and HEIKO HASCHKE — JPK BioAFM, Bruker Nano GmbH, Am Studio 2D, 12489 Berlin, Germany

Active forces in biological systems define the interactions between single molecules, growing cells and developing tissues. Cells adapt their shape and react to the surrounding environment by a dynamic reorganization of the F-actin cytoskeleton. We will demonstrate how cell spreading and migration in living KPG-7 fibroblasts and CHO cells, can be studied with high-speed AFM and associated with spatially resolved cytoskeletal reorganization events. We will further extend this with high-speed mechanical mapping of confluent cell layers, which in combination with optical tiling can be applied to automated analysis of large sample areas. We will show how AFM imaging and super-resolution 2color easy3D STED measurements can be combined and will show results of colocalized imaging and sample manipulation with a precision below the diffraction limit. We will discuss how to calculate the viscoelastic properties, characterized by the dynamic storage and loss modulus distribution in such samples.

**Processive molecular motors stimulate microtubule turnover** — WILLIAM LECOMPTE¹, SARAH TRICLIN², LAURENT BLANCHOIN^{2,3}, MANUEL THÉRY^{2,3}, and •KARIN JOHN¹ — ¹Univ. Grenoble-Alpes, CNRS, Laboratoire Interdisciplinaire de Physique, 38000 Grenoble, France. — ²Univ. Grenoble-Alpes, CEA, CNRS, INRA, Institute de Recherche Interdisciplinaire de Grenoble, Laboratoire de Physiologie Cellulaire & Végétale, CytoMorpho Lab, 38054 Grenoble, France. — ³Univ. Paris Diderot, INSERM, CEA, Hôpital Saint Louis, Institut Universitaire d'Hematologie, UMRS1160, CytoMorpho Lab, 75010 Paris, France

Microtubules (MTs) and molecular motors are ubiquitous in eukaryotic cells and are vital for many key cellular functions (eg. chromosome segregation, intracellular protein transport). Recent experiments have shown that processive molecular motors may damage the underlying microtubule lattice yet a mechanistic model has remained elusive. Here we investigate theoretically how molecular motors collectively remodel the shaft lattice, as opposed to a vision, where a single motor damages the microtubule as a rare event. Our leading concept is, that the walk of molecular motors locally and transiently destabilizes the lattice and may facilitate the removal of tubulin dimers. This mechanism (i) accelerates fracture of MTs in the absence of free tubulin and (ii) stimulates localized free tubulin dimer incorporation. The model reveals that a small transient perturbation (a few kT with a lifetime of 0.1 s) induced by the motor's walk is sufficient to modify significantly the lattice dynamics.

**Collective foraging of microrobots trained by reinforcement learning** — •ROBERT C. LÖFFLER¹, EMANUELE PANIZON², and CLEMENS BECHINGER¹ — ¹Fachbereich Physik, Universität Konstanz, Konstanz, Germany — ²Department of Quantitative Life Science, International Centre for Theoretical Physics, Trieste, Italy

From bacteria to mammals, collective behavior can be observed on all scales in nature. It is generally driven by the benefit to individuals when cooperating with others. However, the exact motivation of individuals to participate is challenging to investigate, as biological creatures are complex systems theirself. At the same time engineers seek to create collective groups of autonomous systems to perform dedicated tasks by cooperation.

Here we present an experimental model system of feedback-controlled microswimmers which are trained with multi agent reinforcement learning in an actor-critic scheme. A group of active particles is situated in a 2D environment containing a virtual food source which is changing position over time. Despite being rewarded individually for being inside the food source, particles show cohesive collective motion forming flocks and swirls. This is driven by the benefit of social information and collision avoidance, resulting in faster migration to a relocated food source. Understanding those mechanisms behind the emergence of collective behavior is of biological interest as well as to understand human crowd behavior and to design future robotic systems.

### BP 14.2 Wed 9:45 H16

**Collective response of microrobotic swarms to external threats** — •CHUN-JEN CHEN¹ and CLEMENS BECHINGER^{1,2} — ¹Fachbereich Physik, Universität Konstanz, 78464 Konstanz, Germany — ²Centre for the Advanced Study of Collective Behaviour, Universität Konstanz, 78464 Konstanz, Germany

Many animal species organize within groups to achieve advantages compared to being isolated. Such advantages can be found e.g. in collective responses which are less prone to individual failures or noise and thus provide better group performance. Inspired by social animals, here we demonstrate with a swarm of microrobots made from programmable active colloidal particles (APs) that their escape from a hazardous area can originate from a cooperative group formation. As a consequence, the escape efficiency remains almost unchanged even when half of the APs are not responding to the threat. Our results not only confirm that incomplete or missing individual information in robotic swarms can be compensated by other group members but also suggest strategies to increase the responsiveness and fault-tolerance of robotic swarms when performing tasks in complex environments.

Soft robots powered by magnetically driven active particles —  $\bullet$  Hongri Gu and Clemens Bechinger — Fachbereich Physik, University of Konstanz, Germany

Active matter describes systems of a large number of self-driving particles that convert surrounding energy into active motion. Many of the emergent behaviors resemble life-like behaviors in nature. However, it is still unclear how one can utilize such active collective motions for engineering and robotic applications. In this talk, we would like to bridge the research fields of active matter and soft robots by designing soft machines powered by active matter. The main objective is to investigate the general interactions between swarm active particles and soft structures and use this knowledge to design a new type of soft robots that are driven by swarm active particles. To facilitate the investigation, we built a highly customizable fabrication process for magnetic composite soft structures at mesoscales based on two-step micromolding. We also built a modular magRotating coherent scattering (ROCS) microscopy is a label-free super-resolution microscopy technique enabling 150 nm spatial and 10 ms temporal resolution, which is highly beneficial for live-cell imaging. We have applied ROCS in total internal reflection (TIR) mode to acquire high-quality images from tunneling nanotubes (TNTs). TNTs or membrane nanotubes, are more than 10 micrometers in length and about 100 nm thin and directly connect distant cells. It seems that after heart injuries, such as myocardial infarction, mechanical and biochemical communication between heart fibroblasts (FB) and cardio myocytes (CM) is established by TNTs, which helped to generate an extracellular matrix (ECM). TNTs could be involved in the exchange of small molecules and ions between neighbor cells, injury-signal recognition, and directed collagen deposition. We measured the interaction between CMs and FBs, i.e. the dynamics of TNT fluctuations by 100 Hz ROCS movies. With a post-processing activity analysis with frequency decomposition, we detected TNT stiffening over minutes. Computer simulations of stimulated TNT motions or thermal particle motions help to confirm or reject the underlying assumptions forming a mechanistic picture.

netic actuation system based on rotating permanent magnets. This new experimental platform has an enormous design space for magnetic soft matters with the capability to tune individual system parameters. By carefully designing these parameters, it is possible to precisely tune the local magnetic, elastic, and hydrodynamic interactions between active particles and soft structures. This new type of soft machine can potentially take advantage of the robust dynamic states of the active matter, which can recover their functions from extreme mechanical deformations.

 $\begin{array}{rl} BP \ 14.4 & Wed \ 10:15 & H16 \\ \textbf{Microswimmers in viscosity gradients} & - \bullet SEBASTIAN \ ZIEGLER^1, \ MAXIME \\ HUBERT^1, \ and \ ANA-SUNČANA \ SMITH^{1,2} & - \ ^1PULS \ Group, \ Friedrich-Alexander-Universität \ Erlangen-Nürnberg, \ Germany & - \ ^2Division \ of \ Physical \ Chemistry, \\ Ruder \ Bošković \ Institute \ Zagreb, \ Croatia \\ \end{array}$ 

Regions of variant viscosity are ubiquitous in both inanimate systems as well as in living systems. It is therefore of great interest to understand the effect of viscosity gradients on the mobility of both passive particles as well as on active systems. We firstly study a system of passive spheres and provide a general expression for the asymptotic mobility matrix in small viscosity gradients. We apply this result to linear viscosity gradients, where we unveil the existence of radially constant flows and elaborate on the effect of asymmetry of the particle position within the finite-size gradient, which hitherto has not been considered.

These results are subsequently applied to bead-spring microswimmers as model systems for self-propelling active matter. In contrast to the common approach of prescribing the stroke of the swimmer, we here employ a force-based swimmer model, allowing for an adaption of the swimming stroke to the environment, and reveal the rich viscotactic properties of such a microswimmer. We also construct a simple swimmer inspired by the Chlamydomonas algae and compare the viscotactic behavior of the biological swimmer to ours.

Noisy pursuit of active Brownian particles — •SEGUN GOH, ROLAND G. WINKER, and GERHARD GOMPPER — IBI-5, Forschungszentrum Jülich, 52425 Jülich, Germany

Many biological and artificial agents are not only motile, but also capable of adjusting their motion based upon information gathered from their environment. This study considers sensing of a target and as a consequence reorientation of the direction of self-propulsion, which enables active pursuit. Specifically, an active Brownian particle is employed as a model agent to investigate pursuit dynamics in two dimensions, for both stationary as well as moving targets. We discuss how the interplay between intrinsic persistent self-propulsion and active reorientation by sensing gives rise to unexpected complex behaviors. In particular, the noise plays a pivotal role with both positive and negative influences on the success of pursuit. Numerical simulations and analytical calculations reveal that strong motility results in overshooting of the target, while pursuers cannot approach the target effectively at low Péclet numbers. Moreover, we propose a strategy to sort active pursuers according to their motility and reorientation capability by employing particular target trajectories.

BP 14.6 Wed 11:00 H16 Rheotaxis of the ciliate — •TAKUYA OHMURA¹, YUKINORI NISHIGAMI², and MASATOSHI ICHIKAWA³ — ¹Biozentrum, University of Basel, Switzerland — ²Research Institute for Electronic Science, Hokkaido University, Japan — ³Department of Physics, Kyoto University, Japan Rheotaxis, a property of organisms to move against an external flow, has a crucial role to stay in living environment. For instance, freshwater fishes in rivers swim upstream to avoid being swept away to the sea. Interestingly, recent studies reported that not only fish but also swimming cells show rheotaxis. We elucidated the rheotaxis of the ciliate, Tetrahymena, a well-known single-celled freshwater microorganism swimming by cilia [1]. While that microorganism doesn*t have a sensor to detect flow direction and micrometer-sized particles are swept away downstream in a viscous flow, what dynamics underlie the rheotaxis of the ciliate? Our experiments revealed that the ciliate slid upstream along a wall, which indicates that the cells receive rotational torque from shear flow to align swimming orientation. To evaluate the shear torque, we performed a numerical simulation with a hydrodynamic model swimmer adopting cilia dynamics in a shear flow. The result suggests that the ciliate automatically slides upstream by using cilia-stalling mechanics.

BP 14.7 Wed 11:15 H16 Analytical study of active semiflexible ring polymer — •CHRISTIAN A. PHILIPPS, GERHARD GOMPPER, and ROLAND G. WINKLER — Forschungszentrum Jülich, Jülich, Germany

Nature provides a variety of active matter systems, with self-propelled agents consuming internal energy or extracting it from their vicinity for locomotion [1]. Examples on the cellular level are self-propelled semiflexible actomyosin ring-like filaments driven by myosin motors in the cytoskeleton. We present a theoretical study of an active ring polymer [2] with tangential propulsion applying the continuous Gaussian semiflexible polymer model [3]. By a normal-mode expansion, the ring polymer conformational and dynamical properties, emerging by the homogeneous active force, and its interplay with rigidity are determined. Remarkably, the ring conformations are unaffected by activity for any rigidity. In contrast to linear filaments, the center-of-mass motion is independent of propulsion. However, activity strongly influences the internal dynamics with an activity enhanced diffusive for the flexible and a ballistic regime for the semiflexible ring polymer. Furthermore, a dominant rotational mode over several orders of magnitude in time emerges for high activities, which implies a rotational motion of the entire ring polymer. [1] R. G. Winkler, G. Gompper, J. Chem. Phys. 153, 040901 (2020); [2] M. Mousavi, R. G. Winkler, G. Gompper, J. Chem. Phys. 150, 064913 (2019); [3] T. Eisenstecken, G. Gompper, R. G. Winkler, Polymers 8, 304 (2016).

Dynamical Renormalization Group approach to the collective behavior of natural swarms — ANDREA CAVAGNA¹, LUCA DI CARLO¹, IRENE GIARDINA¹, TOMAS GRIGERA^{1,3}, •GIULIA PISEGNA^{1,2}, and MATTIA SCANDOLO¹ — ¹Sapienza Università di Roma, Roma IT — ²Max Planck Institute for Dynamics and Self-Organization, Goettingen DE — ³IFLYSIB, La Plata, Argentina

Recent data on strongly correlated biological systems showed the validity of scaling laws as one of the fundamental traits of collective behaviour. Experiments on natural swarms of insects unveiled traces of critical dynamics, with inertial features and a dynamical critical exponent z=1.2. To rationalize this evidence, we develop an inertial active field theory in which the velocity is coupled to its generator of internal rotations, namely the spin, through a mode-coupling interaction. We study its near-critical regime with a one-loop Renormalization Group approach under the assumption of incompressibility. The presence of friction in the dynamics of the spin rules a paramount crossover between two fixed points: the unstable underdamped fixed point with z=1.3 and the stable overdamped fixed point with z=1.7, where dissipation takes over. We show how finite-size systems with weak dissipation, such as swarms, can actually exhibit the critical dynamics of the unstable fixed point thus providing a theoretical result which is in fair agreement with experimental data.

**Dynamics and rheology of active suspensions in viscoelastic media** — •AKASH CHOUDHARY¹, SANKALP NAMBIAR², and HOLGER STARK¹ — ¹Institute of Theoretical Physics, Technische Universität Berlin, 10623 Berlin, Germany — ²Nordita, KTH Royal Institute of Technology and Stockholm University, Stockholm 10691, Sweden

Active suspensions are systems of motile organisms or active motors that are driven out of equilibrium through self-propulsion. This localized energy-work conversion imparts rich phenomenology and anomalous macroscale properties that are in stark contrast to passive suspensions and polymeric fluids. Motivated by the ubiquitous microbial systems in biological fluids, we analyse the impact of non-Newtonian fluids on the rheological response of active suspensions to steady shear flows.

We first study the suspension at an individual scale and show that elongated pushers (representative of *E. coli*) and pullers (*C. reinhardtii*) exhibit diverse orbital dynamics in a viscoelastic fluid. We find that the active stresses not only modify the Jeffery orbits, well-known for viscous fluids, but microswimmers can even resist flow-induced rotation and align themselves at an angle with the flow. To analyze the impact of such behavior on the bulk rheological response, we study an ensemble of a dilute suspension of such swimmers in the presence of stochastic noise from bacterial tumbling and rotary diffusion. In comparison to Newtonian media, the polymeric elastic stresses substantially and non-monotonically amplify the swimmer-induced viscosity, in particular, the superfluid transition of pusher solutions.

 $\begin{array}{ccc} & BP \ 14.10 & Wed \ 12:15 & H16 \\ \textbf{Intercellular transport in Chara corallina} & \bullet \text{FLORIAN VON R}\"{Uling}^1, \ \text{Anna} \\ \text{Alova}^2, \ \text{Alexander Bulychev}^2, \ \text{and } \ \text{Alexey Eremin}^1 & - \ ^1 \text{Otto von Guericke} \\ \text{University Magdeburg, Germany} & - \ ^2 \text{Moscow, Russia} \end{array}$ 

We explore the kinetics of the intercellular transport between the giant cells of characean algae. The transport involves advection via cytoplasmic streaming and diffusion through the plasmodesmata, pores that penetrate the cell walls. Using fluorescent dye as a tracer, we measure the permeation through the node of tandem cells. The permeability is extracted from the experimental data using an advection-diffusion model. The current work is focused on the roles of cytoplasmic streaming and the nodal cells in the transport mechanism. To separate the diffusive permeation from the advective contribution, cyclosis was temporarily inhibited using action potentials. Streaming cessation results in dye accumulation in the vicinity of the node. The shape of regions with high dye concentration indicates that action potentials may induce closure of the plasmodesmata in central nodal cells.

Angle-dependent strength of a single chemical bond by stereographic force spectroscopy — WANHAO CAI¹, •JAKOB TÓMAS BULLERJAHN², MAX LALLEMANG^{1,3}, KLAUS KROY⁴, BIZAN BALZER^{1,3,5}, and THORSTEN HUGEL^{1,3} — ¹Institute of Physical Chemistry, University of Freiburg, Germany — ²Department of Theoretical Biophysics, Max Planck Institute of Biophysics, Frankfurt am Main, Germany — ³Cluster of Excellence livMatS@FIT - Freiburg Center for Interactive Materials and Bioinspired Technologies, University of Freiburg, Germany — ⁴Institute for Theoretical Physics, Leipzig University, Germany — ⁵Freiburg Materials Research Center, University of Freiburg, Germany — ⁴Institute for Second Physics, Leipzig University, Germany — ⁵Freiburg Materials Research Center, University of Freiburg, Germany

A wealth of chemical bonds and polymers have been studied with singlemolecule force spectroscopy, usually by applying a force perpendicular to the anchoring surface. However, the direction-dependence of the bond strength lacks fundamental understanding. Here we establish stereographic force spectroscopy to study the single-bond strength for various pulling angles. Surprisingly, we find that the apparent bond strength increases with increasing pulling angle relative to the anchoring surface normal, indicating a sturdy mechanical anisotropy of a chemical bond. This finding can be rationalized by a fixed pathway for the rupture of the bond, resulting in an effective projection of the applied pulling force onto a nearly fixed rupture direction. Our study is fundamental for the molecular understanding of the role of the direction of force application in molecular adhesion and friction.

BP 15.3 Wed 10:30 H13

**Rebinding kinetics from single-molecule force spectroscopy experiments close to equilibrium** — •JAKOB TÓMAS BULLERJAHN¹ and GERHARD HUMMER^{1,2} — ¹Department of Theoretical Biophysics, Max Planck Institute of Biophysics, 60438 Frankfurt am Main, Germany — ²Institute of Biophysics, Goethe University Frankfurt, 60438 Frankfurt am Main, Germany

Analysis of bond rupture data from single-molecule force spectroscopy experiments commonly relies on the strong assumption that the bond dissociation process is irreversible. However, with increased spatiotemporal resolution of instruments it is now possible to observe multiple unbinding-rebinding events in a single pulling experiment. Here, we augment the theory of force-induced unbinding by explicitly taking into account rebinding kinetics, and provide approximate analytic solutions of the resulting rate equations. Furthermore, we use a short-time expansion of the exact kinetics to construct numerically efficient maximum likelihood estimators for the parameters of the force-dependent unbinding and rebinding rates, which pair well with and complement established methods, such as the analysis of rate maps. We provide an open-source implementation of the theory, evaluated for Bell-like rates, which we apply to synthetic data generated by a Gillespie stochastic simulation algorithm for time-dependent rates.

BP 15.5 Wed 11:30 H13 Exploring the molecular details of the role of methylation and ATP in chemotaxis signaling — •HIMANSHU JOSHI¹ and MEHER PRAKASH² — ¹Jawaharlal Nehru Centre for Advanced Scientific Research (JNCASR), Bengaluru, 560064 — ²EPFL EssentialTech Center, Switzerland

Chemotaxis is the movement of bacteria in response to the surrounding chemical concentration gradients. Bacteria perform runs and tumbles due to the anti-clockwise and clockwise rotation of their flagella depending on the type and gradient of chemical concentration. The molecular concentration sensed by the binding of nutrients is transmitted across the membrane and over 200 Angstroms for a kinase domain actuation. The question then arises as to what is the molecular basis of this signal propagation? Performing long all atom molecular dynamics (MD) simulations on the CryoEM structures that have become recently available, we study the plausible interactions between the methylation and the ATP hydrolysis. Our study, the MD first one which includes methylation and ATP, finds several correlations with the experimental data such as the matching contacts among the dynamic domains, the intermediate state, higher gamma-phosphate coordination by the methylated protein. The results on this very important signaling mechanism are encouraging, a validation which is nontrivial when performing MD on an extended spatial or time scale or with a new class of proteins (fibrillar in this case), to perform further MD studies on this large protein complex.

Identifying the Functional Dynamics in Proteins - Divide and Conquer the Feature Space — •DANIEL NAGEL, GEORG DIEZ, and GERHARD STOCK — Biomolecular Dynamics, Institute of Physics, Albert-Ludwigs-Universität, 79104 Freiburg, Germany

The function of proteins is closely linked to their conformational changes. To support experiments, molecular dynamics simulations allow high spatiotemporal resolution while generating large amounts of data. To model and interpret them, it is essential to identify suitable features, such as backbone dihedral angles or interresidual distances. However, in this high-dimensional feature space—in addition to the motion of interest—one finds uncorrelated motions described by small subsets of features, which poses a difficult challenge for the subsequent dimensionality reduction and understanding of the underlying biological process.

In the following we present an effective and scalable correlation-based feature selection method (MoSAIC) that identifies functional dynamics in the feature space and separates it from noise in order to facilitate the further analysis. To demonstrate the different application purposes, we adopt the unsupervised method to systems of various complexity.

G. Diez, D. Nagel, and G. Stock, Correlation-based feature selection to identify functional dynamics in proteins, arxiv:2204.02770, 2022

**Understanding friction in ligand protein systems** — •MIRIAM JÄGER¹, WAN-HAO CAI², JAKOB T. BULLERJAHN³, THORSTEN HUGEL², STEFFEN WOLF¹, and BIZAN N. BALZER² — ¹Biomolecular Dynamics, Institute of Physics, University of Freiburg, Hermann-Herder-Str. 3, 79104 Freiburg, Germany — ²Institute of Physical Chemistry, University of Freiburg, Albertstr. 21, 79104 Freiburg, Germany — ³Department of Theoretical Biophysics, Max Planck Institute of Biophysics, 60438 Frankfurt am Main, Germany

Both experiments and simulations have shown the importance of friction in biomolecular system dynamics. To gain a deeper understanding of the connection between directional forces and friction, we study the streptavidin-biotin complex in a combination of stereographic force spectroscopy experiments and biased molecular dynamics simulations. While experiments show an increasing mean rupture force and rupture force variance with steeper pulling angles, the simulations display similar internal friction, but an anisotropy in the free energy barriers. Based on the simulation results, we propose that this anisotropy in barriers manifests itself in experiments as the increase in friction. This effect can be viewed as anisotropic friction.

See SOE 12 for details of this session.

### **BP 17: Membranes and Vesicles**

Time: Wednesday 15:00-17:00

BP 17.1 Wed 15:00 H13 Lipid domain diffusion in confined geometry — •Claudia Steinem, Niko-Las K. Teiwes, and Ole M. Schütte — Georg-August Universität, Göttingen, Germany

Pore-spanning membranes (PSMs) are well-suited to investigate lipid domain diffusion. Recent findings have highlighted the dynamic nature of such lipid domains in the plasma membrane of mammalian cells and the key role of the underlying cytoskeleton network in confining their diffusion. We established PSMs

composed of DOPC, sphingomyelin, and cholesterol with co-existing liquid ordered (lo)/liquid disordered (ld) domains on silicon substrates with micrometersized pores to investigate the diffusion of lo-domains confined in the freestanding parts of the PSMs. We compared the lo-domains in the artificial PSMs with PSMs derived from spreading giant plasma membrane vesicles (GPMVs) obtained from HEK-293 cells. In both cases, mobile ordered domains are visualized by fluorescence microscopy. From the trajectories of the individual mobile domains, the MSD is determined, which provides the diffusion constants as a function of domain size. The analysis reveals that the domains' diffusion constants are slowed down by orders of magnitude due to the confinement in the PSM, where the drag force is governed by both the friction in the bilayer and the coupling to the aqueous phase compared to the unrestricted case. From the analysis, the membrane surface viscosity can be extracted, which is by a factor of four smaller in case of the naturally derived membranes compared to the artificial ones, which can be explained in terms of the large protein content in the GPMV-derived membranes.

### BP 17.2 Wed 15:15 H13

SAXS measurements of photoswitching in azobenzene lipid vesicles - MAR-TINA OBER¹, ADRIAN MÜLLER-DEKU², OLIVER THORN-SESHOLD², and •BERT NICKEL¹ — ¹Faculty of Physics and CeNS, Ludwig-Maximilians-Universiät München, Geschwister-Scholl-Platz 1, Munich 80539, Germany — ²Department of Pharmacy, Ludwig-Maximilians-Universität München, Butenandtstraße 5-13, Munich 81377, Germany,

We study the switching of photoresponsive lipids that allow for precise and reversible manipulation of membrane shape, permeability, and fluidity. Though these macroscopic responses are clear, it is unclear how large the changes of trans/cis ratio are, and whether they can be improved. Here, we use small-angle X-ray scattering to measure the thickness of photoswitchable lipid membranes, and we correlate lipid bilayer thickness to trans/cis ratios [1]. This reveals an unexpected dependency of photoswitching ratio upon aqueous phase composition. In buffer with ionic strength, we observe thickness variations twice as large as previously observed. Furthermore, soft X-rays can quantitatively isomerise photolipid membranes to the all-trans state; enabling X-ray-based membrane control. High energy X-rays do not influence the state of the photoswitches, presumably because they deposit less dose in the sample.

BP 17.3 Wed 15:30 H13

Buoyant adhered vesicles in finite-range membrane-substrate interactions -•LUCIA WESENBERG and MARCUS MÜLLER — Georg-August University, Göttingen, Germany

Constructing switchable interlayers between soft, biological objects and hard solids is a major challenge to dynamically regulate interface interactions. Here, we focus on the adhesion of lipid vesicles on bio-inspired polymer substrates. Experiments on the adhesion of liquid droplets or vesicles on switchable surfaces often facilitate contact with the substrate by a density difference. But when compared to theoretical expectations, this key experimental characteristic as well as the finite range of the membrane-substrate interaction have mostly been neglected. Thus, we systematically studied the adhesion of axially symmetric vesicles for finite-range membrane-substrate interaction and buoyancy through simulations. We investigated the adhesion transition of vesicles in the absence of thermal fluctuations. For downward buoyancy, vesicles sediment onto the substrate and there is no mean-field adhesion transition. Whereas for upward buoyancy, adhered vesicles are metastable at best. A proper adhesion transition can only occur at zero buoyancy. Moreover, length scales such as the capillary length, extrapolation length, and curvature-decay scale exhibit a pronounced dependence on interaction range and buoyancy and should not be used uninformed. Whereas these characteristics significantly modified the adhesion diagram, the local transversality condition - relating contact curvature to adhesion strength and vesicle's bending rigidity - remains accurate in the presence of moderate buoyancy.

### BP 17.4 Wed 15:45 H13

Seaweed and dendritic domains of erucic acid monolayers - •FLORIAN GELLERT, HEIKO AHRENS, HARM WULFF, and CHRISTIANE A. HELM - Institute of Physics, University of Greifswald, Germany

Nucleation and growth of domains in the liquid expanded/liquid condensed phase transition in monolayers of erucic acid at the air/water interface is studied with a Brewster Angle Microscope. With increase of the compression speed of the monolayer, the growth mode of the domains changes from seaweed to dendritic. Seaweed domains have broad tips, and wide, variable side branch spacing. Dendritic domains have narrower tips, and small, well-defined side branch spacing and a larger fractal dimension. The domains have different growth mechanisms: seaweed domains grow by surface diffusion while dendrite domains grow

by diffusion in the subphase (Marangoni effect). The hydrodynamic models of domain growth will be discussed.

### BP 17.5 Wed 16:15 H13

Asymmetric membranes, chemical potentials and homeostasis - •MARTIN GIRARD — Max-Planck-Institut für Polymerforschung

The properties of membranes in cells are tightly regulated. For instance, Sineski clearly established that E. Coli cells maintain a viscosity of around 2 poise, which is achieved by modulating the chemical composition of the membrane. How cells choose to alter this composition is not obvious, and has been associated with various controversies over the years.

I have recently introduced usage of chemical potential in computer simulations as a proxy for membrane homeostasis in cells. In coarse-grained simulations, this results in surprisingly good agreement between trends measured in cells and simulation results. I have also shown that this model can be used as a proxy for flippase proteins, and thus enables simulations of asymmetric membranes. Using this model, I will show that imposing asymmetries in membranes can result in surprising behavior. For example, that cholesterol concentration can become correlated with the presence of unsaturated lipids, in accord with experimental measurements. I will discuss the biological implications of these results.

### BP 17.6 Wed 16:30 H13

Coherent Diffractive Imaging of Synaptic Vesicles by Femtosecond FEL pulses – •Charlotte Neuhaus¹, Jette Alfken¹, Moritz Stammer¹, SPB TEAM², MARCELO GANZELLA³, REINHARD JAHN³, and TIM SALDITT¹ — ¹Georg-August-Universität, Institute for X-ray Physics, Friedrich-Hund-Platz 1, 37077 Göttingen — ²European XFEL, Holzkoppel 4, 22869, Schenefeld, Germany — ³Department of Neurobiology, Max-Planck-Institut for Multidisciplinary Sciences, Am Faßberg 11, 37077, Göttingen, Germany

Synaptic Vesicles (SVs) are secretory organelles which store neurotransmitters in presynaptic nerve endings. Due to the small size of vesicles ( $R \approx 20 \text{ nm}$ ), a high spatial resolution is needed to gain more insights into the structure and structural dynamics of SVs, including functional lipid and protein components. To this end, solution SAXS experiments were previously used, yielding information about the average electron density of SVs. However, many of the relevant structural properties and parameters are screened by ensemble averaging, given the substantial polydispersity of SVs and unavoidable contaminations in the preparations. To overcome these limitations, we have carried out serial diffraction experiments on single vesicles (including lipid vesicles, proteoliposomes and SVs) delivered by an aerosol jet into a nano-focused X-ray Free Electron Laser (XFEL) beam. By the 'diffraction before destroy' principle, the individual vesicles can be probed without radiation damage. Thousands of diffraction patterns can now be analyzed and reconstructed. We report these experiments and preliminary results (data analysis still ongoing).

BP 17.7 Wed 16:45 H13

Location: H15

Dynamics of active vesicles - PRIYANKA IYER, MASOUD HOORE, THORSTEN AUTH, GERHARD GOMPPER, and •DMITRY FEDOSOV - Institute of Biological Information Processing and Institute for Advanced Simulation, Forschungszentrum Juelich, Juelich 52425, Germany

Biological cells are able to generate intricate structures and respond to external stimuli, sculpting their membrane from inside. Simplified biomimetic systems can aid in understanding the principles which govern these shape changes and elucidate the response of the cell membrane under strong deformations. We employ simulations of vesicles enclosing active self-propelled particles to investigate different non-equilibrium shapes with tether-like protrusions and highly branched, dendritic structures. Furthermore, adhesive interactions between active particles and the membrane result in highly branched tethers at low particle activity, where the system exhibits 'pseudo-equilibrium' shapes. The resulting membrane fluctuations present anomalous behaviour at high adhesive strengths, as they show an initial decrease with increasing activity. The active particles show ordering at the membrane surface which initially increases with activity and then decreases. The obtained state diagram characterizes shapes of active vesicles for various conditions applied.

### **BP 18: Biomaterials (joint session BP/CPP)**

Time: Wednesday 15:00-17:30

### Invited Talk

BP 18.1 Wed 15:00 H15 Bottom-up molecular control of biomimetic hydrogels — •KERSTIN G. BLANK - Johannes Kepler University, Institute of Experimental Physics, Altenberger Str. 69, 4040 Linz, Austria

The development of biomimetic hydrogels has greatly facilitated fundamental studies aimed at understanding cellular mechanosensing and mechanotransduction processes. It is now widely accepted that cells sense the elastic and viscoelastic properties of their surroundings and respond to these properties via a

range of different mechanisms. It is still unknown, however, how cells determine these material properties. Hydrogels are usually characterized as bulk samples while cells interact with these materials in a highly localized manner via specific receptor-ligand interactions. It is thus essential to adopt the cellular point of view and establish a link between microscopic and macroscopic material properties. Towards this goal, we utilize biomimetic hydrogels consisting of mechanically characterized synthetic polymers and extracellular matrix-inspired peptides that serve as physical crosslinks. Using selected examples, we show how crosslink thermodynamics, kinetics and mechanics as well as network topology affect the linear and non-linear viscoelastic properties of molecularly programmed hydrogels. In particular, we highlight that both individual crosslink properties and network topology affect network stress relaxation and show how molecular bond rupture correlates with bulk material failure. Our modular hydrogel system allows for tuning different parameters independently and thus serves as an excellent platform for disentangling the roles of different material properties on cellular responses.

### BP 18.2 Wed 15:30 H15

The role of protein constriction in the fission of membrane tubes — •RUSSELL SPENCER and MARCUS MÜLLER — Georg-August Universität Göttingen, Institute for Theoretical Physics, 37077 Göttingen, Germany

Membrane remodelling, such as fusion and fission, is involved in a variety of basic, cellular processes. When unaided, the free energy barriers for such remodelling can be prohibitively high, so biological systems employ proteins as catalysts. This work investigates the influence of proteins, such as dynamin, which constrict membrane tubes in order to lower the barrier to fission. We are particularly interested in their role in double-membrane fission as it occurs in mitochondrial division. This work employs self-consistent field theory and utilizes the string method to find the Minimum Free Energy Path (MFEP) in order to determine the most likely pathway for the transition. In addition to lowering the free energy barrier, constriction of the tubes also affects the dominant transition pathway. This work explores the interplay between membrane tension and constriction and the effects that these influences have on fission mechanisms of single and double membrane tubes.

### BP 18.3 Wed 15:45 H15

Rate-Independent Hysteretic Energy Dissipation in Collagen Fibrils — ROBERT MAGERLE, •PAUL ZECH, MARTIN DEHNERT, ALEXANDRA BENDIXEN, and ANDREAS OTTO — Fakultät für Naturwissenschaften, Technische Universität Chemnitz, 09107 Chemnitz, Germany

Nanoindentation data measured with an atomic force microscope on hydrated collagen fibrils above the glass transition, display a rate-independent hysteresis with return point memory. It is caused by the interplay of elastoplastic deformation during tip indentation followed by elastocapillary recovery of the indent during tip retraction. This previously unknown energy dissipation mechanism dominates at slow indentation rates, where viscous friction is negligible. A generic hysteresis model, based on force-distance data measured during one approach-retract cycle, predicts the force (output) for arbitrary indentation trajectories (input). This model describes collagen fibrils' elastic as well as their dissipative nanomechanical properties with high fidelity for a large range of tip velocities and indentation amplitudes.

**Partition complex structure arises from sliding and bridging** — •LARA CON-NOLLEY and SEAN MURRAY — Max Planck Institute for Terrestrial Microbiology, Marburg, Germany

Chromosome segregation is vital for cell replication and in many bacteria is controlled by the ParABS system. A key part of this machinery is the association of ParB proteins to the parS-containing centromeric region to form the partition complex. Despite much work, the formation and structure of this nucleoprotein complex has remained unclear. However, it was recently discovered that CTP binding allows ParB dimers to entrap and slide along the DNA, as well as leading to more efficient condensation through ParB-ParB-mediated DNA bridging. Here, we use stiff polymer simulations to show how these properties of sliding and bridging can explain partition complex formation. We find that dynamic ParB bridges condense the DNA through the formation of two structures, hairpins and helices. In separate stochastic simulations, we show that ParB sliding accurately predicts the experimentally measured multi-peaked binding profile of Caulobacter crescentus, indicating that bridging and other potential roadblocks are sufficiently short-lived that they do not hinder ParB spreading. Indeed, upon coupling the two simulation frameworks into a unified sliding and bridging polymer model, we find that short lived ParB bridges do not hinder ParB sliding from the parS sites, and can reproduce the binding profile of ParB as well as the overall condensation of the nucleoprotein complex. Overall, our model clarifies the mechanism of partition complex formation and predicts its fine structure.

### BP 18.5 Wed 16:30 H15

Single-chain and condensed-state behavior of hnRNPA1 from molecular simulations — •D. Janka Bauer¹, Lukas Stelzl^{1,2}, and Arash Nikoubashman¹

¹Institute of Physics, Johannes Gutenberg University Mainz, Germany —
²Biocenter, Institute of Molecular Physiology, Johannes Gutenberg University Mainz, Germany

Intrinsically disordered proteins (IDPs) are essential components for the formation of membraneless organelles, which play key functional and regulatory roles within biological systems. These complex assemblies form and dissolve spontaneously over time via liquid-liquid phase separation of IDPs. Mutations in their amino acid sequence can alter their phase behavior, which has been linked to the emergence of cancer and neurodegenerative diseases. In this work, we study the conformations and phase behavior of a low-complexity domain of heterogeneous nuclear ribonucleoprotein A1 (hnRNPA1), using coarse-grained molecular simulations. We systematically analyze how the single-chain and condensed-state behavior are affected by the number of aromatic residues within the examined sequences. We find a significant compaction of the chains and an increase in the critical temperature with increasing number of aromatic residues within the IDPs. Both observations strongly support the hypothesis that aromatic residues play a dominant role for driving condensation, which is further corroborated by a detailed analysis of the intermolecular contacts. By establishing quantitative comparisons to the experimental phase behavior, we start to critically assess the reliability of coarse-grained IDP models.

### BP 18.6 Wed 16:45 H15

Water flow elastography for minimal invasive surgery —  $\bullet$ PAUL KALWA and TILMAN SCHÄFFER — University of Tübingen, Germany

Mechanical properties of tissue are of great interest for physicians to differentiate healthy from malign tissue, to determine the status or extent of a disease, and to investigate tissue ageing. The measurement of these properties is therefore a helpful tool for diagnosis. Many elastography techniques have been established and are used in medicine today. However, most of these techniques are not applicable in minimal invasive surgery (MIS), because there the size of probes is limited to a few millimeters and the handling is restricted. We introduce water flow elastography, a novel technique that benefits from a small and inexpensive probe. This technique uses a specialized probe to flow pressurized water against the sample surface, thereby inducing a local indentation. The volume of the indentation, which is measured with a flow meter, is used to quantify the Young's modulus with the help of finite element simulations. We measure the Young's modulus of silicone samples and porcine organs and validate the results with a commercial testing machine, finding agreement within 15 %. We also discuss the suitability of this technique for the determination of viscoelastic tissue properties and for the application in endoscopes for MIS in the future.

### BP 18.7 Wed 17:00 H15

Turning the Corner on the Image Method in Linear Elasticity and Low-Reynolds-Number Hydrodynamics — •Tyler Lutz, Lukas Fischer, Sonja Richter, and Andreas Menzel — Institut für Physik, Otto-von-Guericke-Universität Magdeburg, Universitätsplatz 2, 39106 Magdeburg

In both linear elasticity and low-Reynolds-number hydrodynamics, extensions of the image method—familiar from elementary electrostatics—have been developed to deduce the displacement (resp. velocity) fields arising from point forces applied in the vicinity of a single, flat, infinitely extended boundary. In this work, we assess the applicability of these methods to domains described by multiple, mutually orthogonal boundaries in 2 and 3 dimensions. Already in the case of a single flat boundary, the necessary image forces depend on the specific boundary conditions considered; the images become progressively more complex as one goes from free-slip to no-slip and stress-free surfaces. By iterating the image method fails to generate a self-consistent image if any more than one boundary is anything other than a free-slip surface. For the situations in which the image method may be successfully applied, we explicitly construct and survey the qualitative features of the point-force Green's function near corners.

### BP 18.8 Wed 17:15 H15

Adsorption of laminin and cellular response of neurons and glial cells on ion implanted titania nanotube scaffolds — •JAN FRENZEL^{1,2,3}, ASTRID KUPFERER^{1,2}, MAREIKE ZINK³, and STEFAN G. MAYR^{1,2} — ¹Leibniz Institute of Surface Engineering (IOM), Permoserstraße 15, 04318 Leipzig, Germany — ²Division of Surface Physics, Department of Physics and Earth Sciences, Linnéstraße 5, 04103 Leipzig, Germany — ³Research Group Biotechnology and Biomedicine, Department of Physics and Earth Sciences, Linnéstraße 5, 04103 Leipzig, Germany

Brain-machine interfaces are used in a wide spectrum of neuroscience, as for time-resolved sensing of neural activities and for tackling neurodegenerative diseases. Currently established cultivation platforms, including cellulose filters, often result in loss of long-term adhesion, rejection reaction and glial scarring or do not allow for electrical contact due to their insulating properties. As we demonstrate, ion implanted titania nanotube scaffolds (TNS) are a promising candidate to overcome these issues, since they combine a high biocompatibility with a sufficient large electrical conductivity. In our experiments, we explain how ion implantation induced changes of surface characteristics affect the adsorption of laminin and the viability and adhesion of neurons and glial cells. We link the hindered laminin adsorption due to implantation to the shrinkage of tube diameter and rise of zeta potential. The stable and high neuron viability on all TNS but suppressed glial cell formation of implanted TNS gives rise for a potential interface material. Funding by SMWK (100331694) is gratefully acknowledged.

### **BP 19: Cell Mechanics 2**

Time: Wednesday 15:00-17:15

### BP 19.1 Wed 15:00 H16

Light, proteins, and shape: exploiting protein pattern formation for lightcontrolled oocyte deformations — JINGHUI LIU², •TOM BURKART¹, ALEXAN-DER ZIEPKE¹, ERWIN FREY¹, and NIKTA FAKHRI² — ¹Arnold Sommerfeld Center for Theoretical Physics (ASC) and Center for NanoScience (CeNS), Department of Physics, Ludwig-Maximilians-Universität München, Munich, Germany — ²Department of Physics, Massachusetts Institute of Technology, Cambridge, MA 02139

To coordinate shape deformations, in particular cell division, cells rely on chemical reaction networks that process spatial and temporal cues, such as cell cycle signals, and control the mechanical activity that generates the required deformation. In starfish oocytes, a Rho-GTP protein pattern on the cell membrane regulates actomyosin contractility which induces large-scale cell deformations during meiotic anaphase. By engineering optogenetic activators of Rho-GTP, the native control mechanism can be hijacked to manually trigger the actomyosin contractility and thereby deform the oocyte even before entering meiotic anaphase. We study how such an artificial guiding cue is processed by the mechanochemical machinery in starfish oocytes. We combine simulations of the protein reactiondiffusion dynamics with the dynamic shape deformation of the oocyte to predict spatio-temporal light activation patterns that produce custom cell deformations. Our results contribute to the development of an overarching theoretical framework that allows to study and design minimal artificial cells capable of selfregulated and externally controlled shape changes.

### BP 19.2 Wed 15:15 H16

Modeling Cell Shape and Forces on Structured Environments in Three Dimensions — •RABEA LINK and ULRICH SEBASTIAN SCHWARZ — Institute for Theoretical Physics, University Heidelberg, Germany

Micropatterns are a widely used tool to standardize the mechanical environment single cells or cell collectives experience in experiments. In recent years, microstructures manufactured with direct laser writing have tremendously increased the design possibilities of structured environments for cells. We model the shape, spreading dynamics and forces of a single cell with external adhesive cues using a three-dimensional compartmentalized Cellular Potts Model on 2D micropatterns and in 3D structured environments. This allows us to investigate the influence of the nucleus on the cell shape and spreading dynamics. In addition, we compare the cell shapes obtained by the Cellular Potts Model with the minimal energy shape of a surface under tension in the same mechanical environment and with experimental results.

### BP 19.3 Wed 15:30 H16

**Exploiting nonlinear elasticity for robust mechanosensation in disordered fiber networks** — ESTELLE BERTHIER¹, •PIERRE RONCERAY², and CHASE BROEDERSZ^{1,3} — ¹Arnold-Sommerfeld-Center for Theoretical Physics and Center for NanoScience, Ludwig-Maximilians-Universität München, Germany — ²Centre Turing and Centre de Physique Théorique, Université Aix-Marseille, France — ³Department of Physics and Astronomy, Vrije Universiteit Amsterdam, Netherlands

Cell behavior is steered by guiding cues from their surrounding extracellular environment. Cells anchor to the extracellular matrix (ECM) and perform mechanosensation: they probe their surrounding's mechanical response and regulate their behavior according to the stiffness they sense. Yet, the robustness of cellular mechanosensing is physically limited by the ECM intrinsic disorder and complex mechanical response of both the network and its constituents. Thus, it remains what strategies cells employ to accurately interpret mechanical guiding cues of such a heterogeneous environment.

Using a theoretical framework for disordered fiber networks, we evaluate the mechanical information cell can obtain by performing local measurements. We show that the signal-to-noise ratio of stiffness measurements increases dramatically in the nonlinear regime: the measurements become insensitive to local structural fluctuations of the network. We provide a scaling argument supporting that the local measurement effectively behaves as a sensory device of larger size.

### BP 19.4 Wed 15:45 H16

Competition between cell deformation and depletion force: Quantified by 3D image analysis of red blood cell doublets — •MEHRNAZ BABAKI^{1,2}, MINNE PAUL LETTINGA^{1,2}, and DMITRY FEDOSOV³ — ¹Biomacromolecular Systems and Processes (IBI-4), Forschungszentrum Jülich GmbH, Jülich, Germany —

²Laboratory for Soft Matter and Biophysics, KU Leuven, Leuven, Belgium — ³Theoretical Physics of Living Matter (IBI-5/IAS-2), Forschungszentrum Jülich GmbH, Jülich, Germany

Understanding cell deformation associated with an external force is the key to a full comprehension of the behaviour of cells under mechanical loading. Red Blood Cells (RBCs) are an extreme example of deformable cells. The high deformability of RBCs influences the blood flow and blood circulation in both physiological and pathophysiological conditions as well as RBC aggregation

We investigated the deformation of RBCs using analysis of the 3D reconstructed confocal images of the RBCs in aggregated doublets. Here we use nonabsorbing rod-like particles, causing depletion attraction. Our analysis yields the change in the bending energy of RBCs in a doublet, as well as the change in the depletion energy.

We identified a sequence of configurational transitions of RBC doublets upon increasing rod-like particles concentration, thus maximizing the free volume available for the depletants at the cost of deformation energy. We compared the experimental results with simulations, where we explored the different energy contributions to deformation, as well as the stability of RBC doublets at low depletion force.

Butterfly scale morphogenesis: Wrinkling on the micron scale — •JAN TOTZ¹, ANTHONY MCDOUGAL², and MATHIAS KOLLE² — ¹Departments of Mathematics and Mechanical Engineering, Massachusetts Institute of Technology, Cambridge MA 02139, USA — ²Department of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge MA 02139, USA

Micron-scale surface modulations such as wrinkles or folds underly a number of modern engineering applications, such as photonic structures in photovoltaics and flexible metasurfaces. Controlled and precise fabrication of these modulations is a challenge for human manufacturing techniques. In stark contrast, biological systems robustly utilize morphological changes in their developmental program to create multi-germ bodies, hairs and scales on spatial scales which would be costly to replicate with human manufacturing. In this talk I will present recent measurements of in-vivo butterfly scale development exhibiting wrinkling. The observations are rationalized with a numerical finite element simulation and a parsimonious continuum mechanics model.

BP 19.6 Wed 16:30 H16 Active morphogenesis of patterned epithelial shells — •DIANA KHOROMSKAIA¹ and GUILLAUME SALBREUX^{1,2} — ¹The Francis Crick Institute, 1 Midland Road, NW1 1AT, United Kingdom — ²University of Geneva, Quai Ernest Ansermet 30, 1205 Genève, Switzerland

Shape transformations of epithelial tissues in three dimensions, which are crucial for embryonic development or in vitro organoid growth, can result from active forces generated within the cytoskeleton of the epithelial cells. How the interplay of local differential tensions with tissue geometry and with external forces results in tissue-scale morphogenesis remains an open question. Here, we describe epithelial sheets as active viscoelastic surfaces and study their deformation under patterned internal tensions and bending moments. In addition to isotropic effects, we take into account nematic alignment in the plane of the tissue, which gives rise to shape-dependent, anisotropic active tensions and bending moments. We present phase diagrams of the mechanical equilibrium shapes of pre-patterned closed shells and explore their dynamical deformations. Our results show that a combination of nematic alignment and gradients in internal tensions and bending moments is sufficient to reproduce basic building blocks of epithelial morphogenesis, including fold formation, budding, neck formation, flattening, and tubulation.

So far, topological defects with plus/minus 1/2 charges have been considered to be characteristic features of homogeneous active nematics. Phase-separated systems, in turn, have been known for the formation of dense nematic bands. Here, we use the agent-based model for weakly-aligning self-propelled filaments and, for the first time, demonstrate that phase-separated active nematics form -1/2

### Location: H16

defects of a new kind. In contrast to the homogeneous case, these new defects correspond to high-density regions and coexist with bending bands. We also observe filamentous arc ejections - formations of lateral arcuate structures that separate from the band's bulk and move in a transverse direction. We show that the key control parameters defining the transition from the topologically charged structures to stable bands are the initial density of particles and their path persistence length. Finally, we develop hydrodynamic theory recapitulating observed phenomena.

BP 22.1 Thu 9:30 H15 Cell and tissue mechano-plasticity in development — •VERENA RUPRECHT — Centre for Genomic Regulation (CRG), Barcelona, Spain

The development of a single fertilised cell into an embryo is a highly dynamic process that establishes the structural and functional architecture of the organism. The building of complex multicellular structures fundamentally emerges from the spatio-temporal coordination of dynamic behaviours at the single cell level. How this multi-scale process occurs with high fidelity and robustness is still a major open question. Here I will discuss how embryonic stem cells are able to sense and adapt to mechanical shape deformations in their 3D tissue environment. I will explore the function of the cell nucleus as an intracellular mechano-sensor and how it can act as a non-genetic controller of cell mechanics and migration plasticity. I will further discuss how cellular error correction is established in the earliest stages of embryo development by mechanical cell cooperation that promotes the efficient phagocytic clearance of aberrant apoptotic cells. Theoretical modelling of mechanical force fluctuations at the cell cortex and protrusive force generation in cell collectives will be presented to mechanistically describe the emergence of mechano-plasticity at the single cell and tissue level mediating robust embryo development.

Active T1 transitions in cellular networks — •CHARLIE DUCLUT^{1,2}, JORIS PAIJMANS¹, MANDAR M. INAMDAR³, CARL D. MODES^{4,5,6}, and FRANK JÜLICHER^{1,5,6} – ¹Max Planck Institute for the Physics of Complex Systems, Nöthnitzer Str. 8, 01187 Dresden, Germany – ²Université Paris Cité, Laboratoire Matière et Systèmes Complexes, Paris, France — ³Department of Civil Engineering, Indian Institute of Technology Bombay, Powai, Mumbai 400076, India – ⁴Max Planck Institute for Molecular Cell Biology and Genetics (MPI-CBG), Dresden 01307, Germany — ⁵enter for Systems Biology Dresden, Pfotenhauerstrasse 108, 01307 Dresden, Germany — ⁶Cluster of Excellence, Physics of Life, TU Dresden, Dresden 01307, Germany

In amorphous solids as in tissues, neighbour exchanges can relax local stresses and allow the material to flow. In this talk, I will use an anisotropic vertex model to study T1 rearrangements in polygonal cellular networks. We consider two different physical realization of the active anisotropic stresses: (i) anisotropic bond tension and (ii) anisotropic cell stress. Interestingly, the two types of active stress lead to patterns of oriented T1 transitions that are different. I will describe and explain these observations through the lens of a continuum description of the tissue as an anisotropic active material. I will furthermore discuss the energetics of the tissue and express the energy balance in terms of internal elastic energy, mechanical work, chemical work and heat. This allows us to define active T1 transitions that can perform mechanical work while consuming chemical energy.

Force quantification at this scale has been drastically improved with the emer-

gence of in vivo sensors such as oil droplets or hydrogel beads which open up

the possibility of non-invasive studies. Many approaches in recent literature rely

on numerical processes to iteratively reconstruct the surface of measured beads,

which can be computationally expensive and rendering results that are difficult

to interpret. In this work we present the analysis of arbitrarily deformed beads

based on the expansion in Spherical Harmonics in a Python custom software. We exploit the fast converging algorithms offered by SHTools [1] to reduce the

great complexity of three-dimensional radial deformations to an affordable har-

monic coefficient table which is directly fed into an analytical solution of the

Navier-Cauchy equation. As a first proof-of-concept we show the performance

of the software with polyacrylamide beads injected into zebrafish embryo at early developmental stages, in which the stress field could help understanding the pro-

Bistability between sessile and motile solutions in a nonlinear active gel model for cell migration - •OLIVER M. DROZDOWSKI, FALKO ZIEBERT, and ULRICH S. SCHWARZ - Institute for Theoretical Physics and BioQuant, Heidelberg University, 69120 Heidelberg, Germany

Cell motility is one of the hallmarks of life and often is based on flow in the actin cytoskeleton that is driven by myosin II motors. The standard model to describe such flows is active gel theory, in which myosin II contractility enters as active stress. Recently, we have shown how to include optogenetic control in a minimal active gel model [1]. Here we ask how active gel descriptions of motility need to be modified to explain the experimental observation that a cell's state can be switched between sessile and motile. We show that such bistability emerges in active gel theory if the myosin II motors are modeled as a supercritical van der Waals fluid, including volume exclusion and short-range attraction. We present phase diagrams in cell adhesion and contractility that include sessile, bistable and motile regimes in experimentally relevant parameter ranges. Including optogenetic perturbations of contraction, as done before for a simpler model [1], we find that such external activation can be used to control cell locomotion, in agreement with recent experiments [2].

BP 22.4 Thu 10:30 H15

Rotation of an aspherical organoid within its matrix - a continuum model - •Anne Materne¹, Charlie Duclut^{1,2}, and Frank Jülicher^{1,3,4} — ¹Max Planck Institute for the Physics of Complex Systems, Dresden, Germany -²Université Paris Cité, Laboratoire Matière et Systèmes Complexes, Paris, France –  3 Center for Systems Biology Dresden, Dresden, Germany —  4 Cluster of Excellence Physics of Life, TU Dresden, Germany

Organoids and other 3D in vitro multicellular systems have frequently been observed to display rotational motion within their matrix. Collective rotational motion can also be witnessed in vivo, for example in the Drosophila egg chamber. We propose that this motion results from cell-matrix interactions. Cells are thought to move similarly to 2D migration - however, a (near-)spherical geometry of cell clusters can lead to the observed rotation in 3D. Here, we present a

Location: H15

Location: H15

Location: H18

continuum mechanics descripion of an organoid rotating within its embedding matrix. We discuss the extreme cases of the matrix being either purely elastic or purely viscous. The organoid is considered to be a non-deformable solid with a surface polarity field, exerting traction forces on the matrix. Importantly, our study is not limited to perfectly spherical organoids but takes small shape deformations into account. This permits to distinguish between purely rotational and deformation-induced cell-matrix interactions. Our work clarifies how matrix material properties and cellular traction forces enable collective organoid rotation. Reciprocally, the rotating organoid can serve as an active rheology probe, revealing key information about the matrix properties.

**Exploiting Onsager regression in passive measurements to reveal active mechanics of living systems** — TILL MÜNKER, GABRIEL KNOTZ, MATTHIAS KRÜGER, and •TIMO BETZ — Faculty of Physics, Georg-August-University Göttingen

Understanding life is arguably among the most complex scientific problems faced in modern research. From a physics perspective, living systems are complex dynamic entities that operate far from thermodynamic equilibrium. This active, non-equilibrium behaviour, with its constant hunger for energy, allows life to overcome the dispersing forces of entropy, and hence drives cellular organisation and dynamics at the micrometer scale. Unfortunately, most analysis methods provided by the powerful toolbox of statistical mechanics cannot be used in such non-equilibrium situations, forcing researchers to use sophisticated and often invasive approaches to study the mechanistic processes inside living organisms. Inspired by Onsager's regression hypothesis, we introduce here a Mean Back Relaxation (MBR) observable, which detects active motion in purely passive measurements of particle fluctuations. The MBR, which is based on three point probabilities, is theoretically and experimentally shown to exhibit markers of non-equilibrium, i.e., of detailed balance breaking dynamics. We furthermore observe an astonishing relation between the MBR and the effective nonequilibrium energy in living cellular systems. This is used to successfully predict the viscoelastic response function and the complex shear modulus from a purely passive approach, hence opening the door for rapid and simple passive mechanics measurements even in active systems.

## BP 22.6 Thu 11:15 H15

Redirecting early embryogenesis of the model organism *Caenorhabditis ele*gans via altered mechanical cues — •VINCENT BORNE and MATTHIAS WEISS — Experimental Physics I, University of Bayreuth, Universitätsstr. 30, D-95447 Bayreuth, Germany

During early development, somatic and germline precursor cells of the model organism Caenorhabditis elegans undergo an apparently predetermined and robust division scheme, suggesting early embryogenesis to run on autopilot. While the role of biochemical signaling in this process has long been recognized, the influence of mechanical forces for proper cell arrangement until gastrulation has only recently been revealed. Aiming to further explore, how mechanical cues contribute to proper embryogenesis, we have challenged the natural development at early stages via laser microsurgery and physical compression. As a result, we were able to significantly perturb the embryonic division scheme with both approaches, leading to catastrophic failures of cell divisions. While defects introduced by laser ablation remained mostly restricted to cells that had been challenged, compression frequently resulted in a global perturbation: Cytokinesis was compromised, leading to multinucleated cells or even a syncytium state in which nuclei kept on dividing up to stages of 60 nuclei or more with similar timing characteristics as observed in unperturbed embryos. Our data therefore underline the crucial role of properly adjusted mechanical cues during the early embryogenesis of C. elegans.

#### BP 22.7 Thu 11:30 H15

Active cell mechanisms reveal rich tissue-wide structures and dynamics in simulations — •MAXIME HUBERT¹, LOVRO NUIĆ², KEVIN HÖLLRING¹, and ANA-SUNČANA SMITH^{1,2} — ¹PULS group, FAU Erlangen-Nürnberg, Erlangen, Germany — ²Group for Computational Life Sciences, Ruđer Bošković Institute, Zagreb, Croatia

Dissipative Particle Dynamics simulations provide a robust numerical platform of investigation to understand the dynamics of epithelial tissues. The technique allows to implement various properties at the cell level that can be related to tissue-wide structures and dynamics on various time scales, from hours to days in experiments. In this talk, we present our recent progresses in the field of epithelium numerical simulations by implementing different active ingredients that relate to the immediate neighbourhood of the cell within a tissue monolayer. We show, through comparisons with experiments performed with MDCK-II cells, that we are able to capture the formation of macroscopic compartments of the tissue, the complex relation between average cell velocity and cell density, and the rate of expansion of the tissue. These results highlight the importance of "nuclei"-based approaches along with "membrane"-based approaches in order to provide a complete numerical and mechanical perspective of epithelial tissues across various time- and length-scales.

#### BP 22.8 Thu 11:45 H15

'Forcing' changes in health and disease: New access into bioengineered skeletal muscle mechanics — •Arne Hofmeier^{1,2}, Till Muenker², Fabian Herkenrath¹, and Timo Betz^{1,2} — ¹University of Muenster, Muenster, Germany — ²University of Goettingen, Goettingen, Germany

Mechanical properties of skeletal muscles are tightly related to proper functionality, which makes experimental access to the biomechanics of skeletal muscle tissue a key requirement to advance our understanding of muscle function, development and disease. Recently devised in vitro culture chambers allow for raising 3D skeletal muscle tissues under controlled conditions and to measure global tissue force generation. However, these PDMS-based systems are inherently incompatible with high resolution microscopy. Here, we present a new chamber design that allows real-time high resolution 3D microscopy and simultaneous non-invasive quantification of global contractile forces and local tension during muscle formation for the first time. With this in hand, we observed an early mechanical homeostasis within mouse myoblast derived skeletal muscle tissues after one week of development, despite progressing myotube maturation. Additionally, we raised human in vitro skeletal muscles derived from patients suffering from Duchenne muscular dystrophy caused by loss of a functional membrane linker protein, called dystrophin. Interestingly, bioengineered Duchenne skeletal muscles displayed a disturbed mechanical homeostasis that correlates with functional impairment, suggesting a novel function of dystrophin being a molecular tension sensor and regulator.

On multistability and constitutive relations of cell motion on Fibronectin lanes — BEHNAM AMIRI¹, •JOHANNES CLEMENS JULIUS HEYN², JOACHIM OS-KAR RÄDLER², and MARTIN FALCKE^{1,3} — ¹Max Delbrück Center for Molecular Medicine in the Helmholtz Association, Robert Rössle Str. 10, 13125 Berlin, Germany — ²Ludwig-Maximilians-Universität München (LMU), Fakultät für Physik, Geschwister-Scholl-Platz 1, 80539 München, Germany — ³Dept. of Physics, Humboldt University, Newtonstr. 15, 12489 Berlin, Germany

Migration of eukaryotic cells is a fundamental process for embryonic development, wound healing, immune responses, and tumour metastasis. Many cell types exhibit coexisting steady and oscillatory morphodynamics on flat substrates. There is, however, little quantitative understanding of how adhesion controls these dynamic states.

We study the motion of MDA-MB-231 cells on microlanes of a broad range of Fibronectin densities to address this topic and derive a biophysical model.

The experiments exhibit cells with steady or oscillatory morphodynamics and either spread or moving with spontaneous transitions between the dynamic states. Our biophysical model is based on the force balance at the protrusion edge, the noisy clutch of retrograde flow and a response function of friction and membrane drag to integrin signaling. The theory reproduces the experimentally observed cell states, characteristics of oscillations and state probabilities.

New phenotypes appear in an evolving population in non-Poissonian bursts – •Nora S. Martin¹, Steffen Schaper¹, Chico Q. Camargo^{1,2}, and Ard A. Louis¹ – ¹Department of Physics, University of Oxford, Oxford, UK – ²Department of Computer Science, University of Exeter, Exeter, UK

For adaptive evolution, a central question is when and how frequently random mutations produce the specific rare adaptive phenotypes that have a selective advantage. A widely studied scenario is the following: a population starts with a given initial phenotype and accumulates neutral mutations, and new phenotypes are also introduced at a certain rate. Many theories implicitly assume that

new phenotypes appear through simple stochastic processes which lead to Poissonian statistics. In this contribution, we use simulations on the biophysically motivated computational genotype-phenotype map from RNA sequences to secondary structures and show that new structures appear in highly non-Poissonian "bursts". In other words, if a new structure appears once, it is highly likely to appear multiple times in a relatively small number of generations. We show that there are several sources for this non-Poissonian behaviour, for example correlations in the mappings from genotypes to phenotypes, which may be a generic property of realistic genotype to phenotype maps. We find that these bursts can affect probabilities of fixation, especially when there are multiple competing adaptive phenotypes.

## BP 23.2 Thu 10:15 H13

**Proliferative advantage of specific an euploid cells drives evolution of tumor karyotypes** — •LUCIJA TOMAŠIĆ¹, IVANA BAN¹, MARIANNA TRAKALA², IVA TOLIĆ³, and NENAD PAVIN¹ — ¹Department of Physics, Faculty of Science, University of Zagreb, Croatia — ²David H. Koch Institute for Integrative Cancer Research, Howard Hughes Medical Institute, Massachusetts Institute of Technology, Cambridge, Massachusetts 02142, USA — ³Division of Molecular Biology, Ruder Bošković Institute, Croatia

Most tumors have abnormal karyotypes, which arise from mistakes during mitotic division of healthy euploid cells and evolve through numerous complex mechanisms. In a recent mouse model with high levels of chromosome missegregation, chromosome gains dominate over losses both in pretumor and tumor tissues, whereas tumors are characterized by gains of chromosomes 14 and 15. However, the mechanisms driving clonal selection leading to tumor karyotype evolution remain unclear. Here we show, by introducing a mathematical model based on a concept of a macro-karyotype, that tumor karyotypes can be explained by proliferation-driven evolution of aneuploid cells. In pretumor cells, increased apoptosis and slower proliferation of cells with monosomies lead to predominant chromosome gains over losses. Tumor karyotypes with gain of one chromosome can be explained by karyotype-dependent proliferation, while for those with two chromosomes an interplay with karyotype-dependent apoptosis is an additional possible pathway. Thus, evolution of tumor-specific karyotypes requires proliferative advantage of specific aneuploid karyotypes.

## BP 23.3 Thu 10:30 H13

**Data-driven modeling of social interactions in bats across time scales** – •FRANK SCHWEITZER¹, PAVLIN MAVRODIEV¹, and GERALD KERTH² – ¹Chair of Systems Design, ETH Zürich, Switzerland – ²Applied Zoology and Nature Conservation, University of Greifswald, Germany

The study of bat's social and foraging behavior is of great relevance to forecast the outbreak and distribution of virus induced deseases. To analyze this behavior we use a large-scale data set from two colonies of Bechstein's bats over five years. From this data, we reconstruct the social interactions of bats at three different time scales: (a) At the scale of minutes: social influence and information transfer. This leads to the formation of leader-follower pairs, where an informed individual leads an uninformed one to a roost box. (b) At the time scale of days: fission-fusion dynamics. This leads to the formation and dissolution of roosting groups of different size, composed of different individuals. (c) At the time scale of months: Emergence of social structures. This leads to the formation of communities within a colony. While the analysis of (a) requires statistical data analysis and hypothesis testing, for (b) we employ agent-based models, and for (c) social network analysis. The combination of these approaches allows us to bridge time scales in social behavior, which cannot be observed together. With our models we are able to develop the bigger picture of how social interactions feed back to long-term social structures.

## BP 24.1 Thu 10:30 H16

Actin waves as building blocks of cellular function — •CARSTEN BETA — Institute of Physics and Astronomy, University of Potsdam, Potsdam, Germany Many cellular functions, such was motility, phagocytosis, and cell division, are driven by coherent patterns of activity in the actin cytoskeleton. Among them, actin waves are a recurrent motive that is commonly observed across different cell types. Here, we present experimental results demonstrating the rich variety of wave patterns in the actin cortex of motile amoeboid cells. We show that ringshaped actin waves, commonly acting as precursors of macropinocytic cups, can mediate switches between different modes of motility, a pseudopod-based amoeboid mode, and a more persistent, wave-driven migratory mode, reminiscent of keratocyte motility. In multinucleate, oversized amoeboid cells, the same waves may also trigger spontaneous, cell cycle-independent cytofission events, resulting in mononucleated daughter cells of a well-defined size. We also demonstrate that a second wave pattern can coexist with the ring-shaped macropinocytic waves. It emerges in a cell-size dependent manner and consists of rapidly moving planar pulses that show typical signatures of an excitable system. Our experimental findings demonstrate the functional versatility of cortical waves patterns. They can be rationalized based on minimal reaction-diffusion models that mimic the evolution of cortical wave patterns and are coupled to a dynamic phase field to take the cell shape evolution into account. In addition, bifurcation analysis provides a more detailed understanding of how regimes of pattern coexistence may emerge.

## BP 24.2 Thu 11:00 H16 Quantifying Dynamic Information Transfer in Stochastic Biochemical Networks — •ANNE-LENA MOOR^{1,2} and CHRISTOPH ZECHNER^{1,2} — ¹Max-Planck Institute of Molecular Cell Biology and Genetics, Dresden Germany — ²Center for Systems Biology, Dresden, Germany

Transmission and encoding of information are fundamental processes for the functioning of biochemical systems. Information theoretical concepts, such as the mutual information, provide a rigorous mathematical framework to study intracellular signal transmission. In many biological systems, information is encoded in the time-trajectory of signalling components as opposed to instantaneous levels. However, performing information theoretical analysis on the trajectory-level is computationally demanding. In this work, we present an effective approach to calculate mutual information between complete trajectories of biochemical components. The resulting measure provides useful insights into the dynamic information transfer through networks of chemical reactions.

#### BP 24.3 Thu 11:15 H16

**Optimal ligand discrimination by asymmetric dimerization of interferon receptors** — •PATRICK BINDER^{1,2,3}, NIKOLAS D. SCHNELLBÄCHER^{1,2}, THOMAS HÖFER^{2,3}, NILS B. BECKER^{2,3}, and ULRICH S. SCHWARZ^{1,2} — ¹Institute for Theoretical Physics, Heidelberg University, 69120 Heidelberg, Germany — ²BioQuant Center for Quantitative Biology, Heidelberg University, 69120 Heidelberg, Germany — ³Theoretical Systems Biology, German Cancer Research Center, 69120 Heidelberg, Germany

In multicellular organisms, antiviral defense is mediated by ligands. These signaling molecules are usually characterized by highly inhomogeneous distributions due to scarcity of producer cells, diffusion and localized degradation. And yet, a molecular hub of the antiviral response, the interferon I receptor (IF-NAR), discriminates between ligand types by their affinity regardless of concentration. In my talk, I address the long-standing question of how a single receptor can decode robustly ligand type. I frame ligand discrimination as an information-theoretic problem and systematically compare the major classes of receptor architectures: allosteric, homodimerizing, and heterodimerizing. As a result, asymmetric heterodimers achieve the best discrimination power over the entire physiological range of local ligand concentrations, enabling sensing of ligand presence and type. IFNAR exhibits this optimal architecture, suggesting that it has evolved the optimal design to detect and separate the presence of different ligand types in a noisy environment.

## BP 24.4 Thu 11:45 H16

**Rationalizing the optimality of the Drosophila gap gene system by ab-initio derivation of optimal solutions for morphogenetic patterns** — •THOMAS R. SOKOLOWSKI^{1,2}, THOMAS GREGOR^{3,4}, WILLIAM BIALEK³, and GAŠPER TKAČIK¹ — ¹IST Austria, Am Campus 1, A-4300 Klosterneuburg, Austria — ²Present Address: Frankfurt Institute for Advanced Studies, Ruth-Moufang-Str. 1, D-60438 Frankfurt, Germany — ³Department of Physics, Princeton University, Princeton, NJ 08540, U.S.A. — ⁴Insitut Pasteur, Department of Developmental and Stem Cell Biology, 25 Rue du Dr. Roux, F-75015, Paris, France

Early fruit fly development is outstandingly precise in spite of the high level of stochasticity in the underlying biochemical processes. While the gap gene system driving fly embryo patterning has been shown to encode positional information optimally, the precise mechanisms that enable this remain elusive. We show that optimal solutions for the gap gene regulatory network can be obtained by optimizing a biophysically realistic spatial-stochastic embryo model, without inferring from data. Firstly, our predictions mechanistically explain how the observed developmental precision can be attained. Secondly, by exploring rich sets of optimal solutions, we elucidate the role of key components controlling early

BP 24.6 Thu 12:15 H16

fly patterning. To our knowledge our work provides the first successful ab-initio derivation of a nontrivial biological network in a biophysically realistic setting. Our results suggest that even though real biological networks are hard to intuit, they may represent optimal solutions to optimization problems which evolution can find.

BP 24.5 Thu 12:00 H16

Stability of gene expression patterns in developmental systems with dynamic morphogen sources — •MACIEJ MAJKA — Jagiellonian University, Krakow, Poland

In developmental systems cells determine their fate by decoding chemical signals, called morphogens. In this presentation I will address the problem of gene expression patterns stability in the systems where two diffusible morphogens affect each other production and control the growth of their own source regions. Such systems are encountered in e.g. spinal cord development, limb formation and many others. The reaction-diffusion equation with bi-stable production term is employed as a generic model for this problem. The phase transition is found, between the phase of indeterminate patterning, where region of mixed gene expression is ever growing, and the phase of travelling gene expression patterns, where two expression domains form and preserve a well-defined contact zone. A sub-class of genuinely stationary patterns is then identified, alongside the exact conditions ensuring this stability. This allows me to classify the pattern stability for all possible two-gene regulatory motifs.

Bottom-up assembly of synthetic cell-based tumor immune microenvironments in pancreatic cancer organoids — •OSKAR STAUFER — University of Oxford, Kennedy Institute of Rheumatology, Oxford, United Kingdom

Understanding the communication and interactions between tumour and immune cells is pivotal for holistic understanding of tumour biology and therapy. I present strategies to recreate immune cells, the defining elements of the tumor immune microenvironment (TIME), as synthetic cells by bottom-up assembly from their single molecular building blocks. The programmable synthetic cells are introduced into tumor organoids to function as lifelike leukocyte mimics presenting immune effector functions. By this, a molecularly defined artificial TIME (ART-TIME) is created inside tumor models. The central objective of this approach is to reduce the complexity of the intricate TIME composition to a comprehensible and systematic level by applying a novel bioinspired systems approach. This strategy links TIME architectures to cancer adaptation and immune evasion for quantitative description of therapy resistance. ART-TIME strive to de-convolute the dynamic complexity of the tumor immune microenvironment towards a rational dissection. Strategies for stable incorporation of synthetic cells into organoids, chemical, biophysical and ultrastructural characterizations of the synthetic immune cells as well as their molecular interactions with cancer cells inside the organoids are presented.

## BP 25.2 Thu 11:15 H13

**Frustrated frustules: geometrical frustration in** *Coscinodiscus* diatom frustules — •MARIA FEOFILOVA and ERIC DUFRESNE — Vladimir-Prelog-Weg 5, 8093 Zürich, Switzerland

Diatoms are single-celled organisms with a cell wall made of silica, called the frustule. Their elaborate patterns have fascinated scientists for years, however little is known about the biological and physical mechanisms involved in their organizations.

In this work, we take a top-down approach and examine the micron-scale organization of diatoms from the *Coscinodiscus* family. We find two competing tendencies of organization, which appear to be controlled by distinct biological pathways. On one hand, micron-scale pores organize locally on a triangular lattice. On the other, lattice vectors tend to point globally toward a center of symmetry. This competition results in a frustrated triangular lattice, populated with geometrically necessary defects whose density increases near the center.

## BP 25.3 Thu 11:30 H13

Structured keratin films as artificial nail plate model — •KIM THOMANN, AN-DREAS SPÄTH, and RAINER H. FINK — Lehrstuhl für Physikalische Chemie II, Friedrich-Alexander Universität Erlangen-Nürnberg, Egerlandstr. 3, D-91058, Erlangen, Germany Human fingernails can be studied ex vivo only in form of clippings which offer limited insight as they do not necessarily reflect the behavior of the whole nail. Keratin films (KFs) may potentially serve as human fingernail substitute, which is especially relevant for the medical and cosmetics sector. In order to model the nail's adhesive characteristics, structured and unstructured films from keratin extracted from human hair and nails were produced. The fingernail being the reference, the KFs were characterized with a number of complementary techniques, including SEM, confocal microscopy, contact angle (CA) measurements, XPS, ATR-FTIR and SAXS. In terms of composition, the prepared films show good resemblance, regardless of keratin origin. The nail's microstructured topography is well matched by the structured KFs. CA measurements revealed that the surface free energy is in the same range for both KF types. However, the structured KFs fit the nail's component composition better. Thus, the structured KFs represent a good approach to achieve a satisfying model in terms of wetting while combining both composition and topography aspects. The research is funded by the BMBF within project 05K19WE2.

Memory effect of red blood cells in a 3D microfluidic chip — •AMIRREZA GHOLIVAND^{1,2} and MINNE PAUL LETTINGA^{1,2} — ¹Forschungszentrum Jülich, IBI-4, Jülich, Germany — ²KU Leuven, Laboratory of Soft Matter and Biophysics, Leuven, Belgium

The significance of healthy blood vessels and blood flow for proper brain functioning is becoming more recognized, for example due to its involvement in the development of human neurodegenerative disorders, notably Alzheimer's disease. Therefore, it is of interest to develop a platform to investigate blood flow and blood cell behavior through the brain vasculature.

Here we present model 3-D microfluidic channels to study the RBCs flow through different vessels geometry and their flow dynamics. RBCs in microcirculation and at bifurcation may attain different memory effect, which we studied systematically varying the interaction strength between the red blood cells and the complexity of flow geometries. To this end, we make use of a novel technique, Selective Laser-induced Etching (SLE), which can produce 3D structures in glass with any desirable shape. To study the shape memory of the vessels the second generation of the bifurcation has been implemented with a parallel and perpendicular orientation relative to the first bifurcation. Using ultra-fast microscopy in combination with velocimetric analysis, we identify a new memory effect, where there is a shift in the maximum velocity, depending on the orientation of the downstream bifurcation.

#### BP 26.1 Thu 15:00 H15 Molecular robots working cooperatively in swarm - •AKIRA KAKUGO -Hokkaido University, Sapporo, Japan

Cooperation is a strategy that has been adopted by groups of organisms to execute complex tasks more efficiently than single entities. Cooperation increases the robustness and flexibility of the working groups and permits sharing of the workload among individuals. Here, we demonstrate molecular transportation through the cooperative action of a large number of artificial molecular machines, photoresponsive DNA-conjugated microtubules driven by kinesin motor proteins. Mechanical communication via conjugated photoresponsive DNA enables these microtubules to organize into groups upon photoirradiation. The groups of transporters load and transport cargo, and cargo unloading is achieved by dissociating the groups into single microtubules. The group formation permits the loading and transport of cargoes with larger sizes and in larger numbers over long distances compared with single transporters. We also demonstrate that cargo can be collected at user-determined locations defined by ultraviolet light exposure.

## BP 26.2 Thu 15:30 H15

Self-organization of microtubule filaments in energy dissipative evaporating droplet — •Vahid Nasirimarekani, Olinka Ramirez-soto, Stefan KARPITSCHKA, and ISABELLA GUIDO — Max Planck Institute for Dynamics and Self-Organization, 37077 Göttingen, Germany

Cytoskeletal assemblies such as microtubule networks and motor proteins of the kinesin family drive vital cellular processes that, together with cargo delivery and cell division, also include providing mechanical stability when cells are exposed to external stresses. How these self-organising structures can orchestrate such response is not yet well understood. In this study, we develop a bioinspired system resembling intracellular cytoskeletal networks and characterise its activity under the influence of external stress. For this purpose, we confine an active network of microtubules and kinesin motors in an evaporating aqueous droplet. This setup serves as a bioreactor that enables to apply forces to the active system. Namely, the flow field generated by the Marangoni and capillary flow couples with the active stress of the microtubule-motor protein network. We observe that this coupling influences the spatio-temporal distribution of the driving forces and the emergent behaviour of the system, which shows contracting and relaxing behaviour. By analysing such non-equilibrium systems, our study can contribute to understand the response of biological structures to cues from the external environment.

BP 26.3 Thu 15:45 H15

Amphiphile-stabilized microemulsions formed from synthetic DNA- ${\bf nanomotifs}$ — Xenia Tschurikow¹, Mai Tran², Rakesh Chatterjee^{3,4}, Vasily Zaburdaev^{3,4}, Kerstin Göpfrich², and •Lennart Hilbert¹ — ¹Karlsruhe Institute of Technology – ²Max Planck Institute for Medical Research — ³Friedrich-Alexander-Universität Erlangen — ⁴Max-Planck-Zentrum für Physik und Medizin

DNA in the nuclei of pluripotent cells exhibits a unique, finely dispersed microdomain pattern. This pattern is formed from DNA and RNA, which behave as two separating phases, and is stabilized in a microemulsified configuration by amphiphiles forming at sites where DNA is transcribed into RNA. Here, we synthetically reproduce such an amphiphile-stabilised microemulsion using DNA oligo-based nanomotifs. Specifically, we implemented a droplet phase in the form of DNA-nanomotifs with three self-affine "sticky ends", to which we add amphiphile particles that additionally harbour negative charges that are repelled from DNA-dense droplets. We confirmed behaviors expected upon amphiphile addition in titration experiments, time-lapse microscopy, and by mapping the amphiphile distribution within droplets. We are currently carrying out lattice simulations with multi-ended particles, which explicitly capture the interaction rules that are encoded via the different DNA-nanomotif ends. Our work provides an avenue towards the model-guided design of more complex multi-phase systems, to reproduce, for instance, the multitude of nuclear bodies observed in biological cells.

Bottom-up assembly of synthetic cells with bio-inspired DNA-based cytoskeletons — •Kevin Jahnke¹, Pengfei Zhan², Maja Illig¹, Na Liu², and Kerstin Göpfrich¹ — ¹Max Planck Institute for Medical Research — ²Stuttgart University

The bottom-up assembly of synthetic cells with a functional cytoskeleton sets a major milestone to understand cell mechanics and to develop man-made cellular machines. However, the combination of multiple elements and functions remained elusive, which stimulates endeavors to explore entirely synthetic bioinspired and rationally designed solutions towards engineering life. To this end, DNA nanotechnology represents one of the most promising routes. Here, we demonstrate functional DNA-based cytoskeletons operating in microfluidic cellsized compartments and lipid vesicles. The synthetic cytoskeletons consist of DNA tiles self-assembled into filament networks (Zhan*, Jahnke* et al., in press at Nat. Chem. 2022; Jahnke et al., ACS Nano 2022). These synthetic cytoskeletons can be rationally designed and controlled to imitate features of natural cytoskeletons, including ATP-triggered polymerization, morphology control and vesicle transport in cell-sized confinement. Also, they possess engineerable characteristics, including assembly and disassembly powered by DNA hybridization, light or aptamer-target interactions. Moreover, we incorporate membranespanning DNA origami signalling units to allow for mechanochemical signal transduction across the GUV membrane (Jahnke, Illig et al., biorxiv 2022). This work underpins DNA nanotechnology as a key player in building synthetic cells from the bottom up.

Synchronization, enhanced catalysis of mechanically coupled enzymes and how to design them — •MICHALIS CHATZITTOFI¹, JAIME AGUDO-CANALEJO¹, Tunrayo Adeleke-Larodo², Pierre Illien³, and Ramin Golestanian^{1,2} ¹Department of Living Matter Physics, MPI -DS, D-37077 Göttingen, Germany

- ²Rudolf Peierls Centre for Theoretical Physics, University of Oxford, OX1 3PU, UK - ³Sorbonne Universite, CNRS, Laboratoire Physicochimie des Electrolytes et Nanosystemes Interfaciaux, 75005, France

Enzymes are the catalysts of the chemical processes that take place in living organisms. These processes, during which chemical energy is converted to mechanical energy and heat, occur stochastically as a result of a noise-activated barrier-crossing event. Despite this stochasticity, it has been shown recently that two mechanically coupled enzymes can synchronize their catalytic reaction [1]. Even more interestingly, the coupling enhances the catalysis of the two enzymes. This effect can be understood as arising from a bifurcation in the deterministic dynamics of the system. In this work, we use a similar approach to describe the dynamics of an enzyme by assuming that the enzyme is attached to a passive molecule. The goal is to design the properties of the enzyme so that its motion favours a chemical reaction, for example dissociation or a shape switch of the molecule. A bifurcation in the deterministic dynamics can cause a change in the molecules state after one enzymatic reaction. The stochastic simulations, also show that the enzyme's activity affects the state of the molecule.

Dynamic formation and size control of cell-like compartments - •SEBASTIAN W. KRAUSS, PIERRE-YVES GIRES, MITHUN THAMPI, and MATTHIAS WEISS - Experimental Physics I, University of Bayreuth, Germany

A fundamental feature of living matter is its spatial organization into individual units, with the replication of template-like entities during cell division supposedly being the most familiar process linked to this feature. Yet, spatially ordered arrays of cell-like compartments ('protocells') also emerge spontaneously in homogeneous, isotropic Xenopus egg extracts in the absence of template structures and genetic material. We show that the geometry of these patterns has properties of a random-packing problem, i.e. randomly placed seeds grow at a uniform rate until competition for material becomes limiting. We also show that the pattern undergoes a coarse-graining over time while maintaining its overall organization. Moreover, fluorescence imaging reveals the cytoskeleton to be the driving force behind the compartmentalization. In line with this notion, a perturbed dynamics of microtubules is observed to result in strongly reduced protocell areas. Altogether, our experimental observations suggest that space compartmentalization in living matter relies on few but robust generic physico-chemical principles.

#### BP 26.7 Thu 17:00 H15

New insights into the DNA origami silicification reaction mechanism by in situ small angle X-ray scattering — •Amelie Heuer-Jungemann^{1,3}, Martina Ober², Lea Wassermann¹, Anna Baptist¹, and Bert Nickel^{2,3} — ¹Max Planck Institut für Biochemie, Am Klopferspitz 18, 82152 Martinsried — ²Ludwig-Maximilians-Universität, Geschwister-Scholl-Platz 1, 80539 München — ³Center for Nanoscience, LMU München, Geschwister-Scholl-Platz 1, 80539 München

DNA origami allows for the formation of arbitrarily shaped nanostructures with nm precision control. Yet, many potential real-life applications have been hampered due to the biologicL instability of DNA origami: Silicification provides an excellent way of increasing DNA origami stability. However, so far, it remains unclear how silicification affects the internal structure of the DNA origami and whether the whole DNA framework is embedded or if silica just forms an outer shell. By using in situ small angle x-ray scattering (SAXS), we were able to show that silica growth is not restricted to the outer origami surface, but also occurs on the inner surface, penetrating the whole structure and induces substantial condensation of the structure at early reaction times. Remarkably, we found that thermal stabilization of the origami up to 60°C as well as resistance towards degradation by nucleases could already be observed for sub-nm silica deposition in the highly condensed state. In this state DNA origami addressability could also be retained, resulting in the first fully site-specifically addressable silica nanostructure.

BP 26.8 Thu 17:15 H15 Energy transfer between coupled colloidal clusters — •ANDREAS EHRMANN and CARL GOODRICH — Institute of Science and Technology Austria, Am Campus 1, 3400 Klosterneuburg, Austria

Can biology-inspired complexity be obtained without biochemical components? Can we replicate ubiquitous biological processes using only model physical building blocks like DNA-coated colloids that have simple but programmable interactions? The last decades have seen tremendous progress in understanding the self-assembly mechanisms that enable the formation of complex, sub-micron scale structures, but embedding these structures with bio-inspired functional behaviors remains a considerable challenge. Here, we demonstrate a scheme for transferring energy between two colloidal clusters, in analogy to ATP hydrolysis. By coupling the two clusters, we show how the one acting as a receiver catalyzes a structural transition in the one acting as a fuel source, releasing energy that drives the receiver into a higher energy structural state. The coupled system shows a significantly reduced mean-first passage time. This work demonstrates that a fundamental and enabling biological process can be replicated without complex biochemical reactions. In contrast, theories of active matter often focus on the effect of energy consumption, not on the mechanism itself. However, the mechanism is intimately connected to the type of physical phenomena that can result. In a next step, we extend the scheme to convert energy into work by driving a net flux in the receiver, which is not possible in equilibrium and requires a fuel source.

# BP 27: Statistical Physics of Biological Systems 2 (joint session BP/DY)

Time: Thursday 15:00-16:30

## BP 27.1 Thu 15:00 H16

Sensing and making sense of fluctuating cellular states — •Felix J. Meigel¹, LINA HELLWIG², PHILIPP MERGENTHALER², and STEFFEN RULANDS^{1,3} — ¹Max Planck Institute for Physics of Complex Systems, Dresden — ²Neurology Department, Charité University Medicine Berlin — ³Center for Systems Biology Dresden

The self-organisation of cells into complex tissue relies on the tight regulation of cellular responses to fluctuating cues. Typically, the regulation of cell decisions is attributed to pathways controlling the concentration of molecular species in response to intrinsic or extrinsic signal. Here, by contrast, we show in the paradigmatic example of cell death that cells manipulate how fluctuations propagate across spatial scales to regulate cellular behavior. Specifically, we find that the feedback between molecular and mesoscopic organelle fluctuations gives rise to a quasi-particle degree of freedom whose intriguing kinetic properties construct a kinetic low-pass filter of time-dependent concentrations of signaling molecules. We show that the collective dynamics of the quasi-particle degree of freedom exhibits different kinetics on different temporal scales. This allows cells to distinguish between fast fluctuations and slow, biologically relevant changes in environmental signals. We demonstrate an order of magnitude effect of this phenomenon on the quality of the cell death decision and validate our predictions experimentally by dynamically perturbing the intrinsic apoptosis pathway. Our work reveals a new mechanism of cell fate decision making.

## BP 27.2 Thu 15:15 H16

Guidance and optimization in branching morphogenesis — •MEHMET CAN UCAR and EDOUARD HANNEZO — Institute of Science and Technology Austria, Am Campus 1, 3400 Klosterneuburg, Austria

The development of branched, tree-like biological structures such as lung, kidney, or the neurovascular system has been a pivotal question in biology, physics and mathematics. Recently, many studies based on combinatorial, mechanical, or stochastic models explored local, selforganizing rules leading to branched morphologies in specific systems. However, in addition to local interactions, the growth of branched structures is also regulated globally by external chemical or mechanical guidance cues. In this talk, we present our recent theoretical framework that integrates local and global regulatory mechanisms of branching morphogenesis. Combining analytical theory and numerical simulations, we show that branch orientations follow a generic scaling law that depends on the strength of global guidance. Local interactions such as self-avoidance of branches, on the other hand, lead to denser, efficiently space-filling networks, with a minimal influence on the overall shape and territory. These quantitative predictions of the model are corroborated by experimental data on sensory neurons in the zebrafish caudal fin. Finally, we discuss effects of local interactions on optimal tiling of space in branched distribution networks such as in lymphatic vasculature.

#### BP 27.3 Thu 15:30 H16

**Random force yielding transition in spherical epithelia** — ABOUTALEB AMIRI¹, CHARLIE DUCLUT², FRANK JÜLICHER¹, and •MARKO POPOVIĆ¹ — ¹Max Planck Institute for Physics of Complex Systems, Dresden — ²Université Paris Diderot, Paris

Developing biological tissues are often described as active viscoelastic fluids on long time-scales, due to fluidization by cell division and apoptosis. However, on shorter time-scales they can behave as amorphous solids with a finite yield stress

[Mongera et al., Nature, 2018]. Under shear stress beyond the yield stress value amorphous solids begin to flow. This yielding transition is a dynamical phase transition characterized by a diverging correlation length and a set of critical exponents. Developing tissues are active matter systems whose constitutive cells can propel themselves by exerting traction forces. Recently, a remarkable correspondence has been proposed between uniformly sheared amorphous solids and dense self-propelled particle systems [Morse et al., PNAS, 2021] based on the identical scaling of non-linear properties of their energy landscapes. Here, we use a vertex model of epithelial tissues to study how randomly oriented traction forces fluidize a spherical epithelial tissue. In particular, we identify a sharp transition between quiescent and randomly flowing states separated by the critical value of the traction force magnitude, analogous to the yield stress. Moreover, we show that this transition is characterized by the same set of exponents as the classical yielding transition, and the corresponding scaling relations provide a non-trivial relation between cell geometry, cell rearrangement dynamics and tissue flow.

## BP 27.4 Thu 15:45 H16

Location: H16

**Biological tissues as living amorphous solids** — •ALI TAHAEI and MARKO POPOVIĆ — Max Planck Institute for Physics of Complex Systems, Dresden Biological tissues are often described as viscoelastic fluids on long time-scales. However, on shorter times-scales, tissues can behave as amorphous solids, such as clay, changing shape only when exposed to a shear stress above the material yield stress  $\Sigma_c$ . Amorphous solids near  $\Sigma_c$  display critical behaviour with a diverging correlation length-scale characterising dynamics of plastic activity. Here, we ask how would this critical behaviour be affected by active processes present in biological tissues, such as cell divisions.

In order to model yielding of biological tissues we employ the mesoscopic elasto-plastic model, commonly used to describe yielding of amorphous solids. Here, we extend the classical elasto-plastic model by introducing cell divisions as an additional source of plastic activity. We find that cell divisions strongly fluidise the solid phase of the system at stresses lower than  $\Sigma_c$ , consistent with literature. Furthermore, we find that critical behaviour is strongly suppressed, leading to localised dynamics of plastic activity nucleated by cell divisions. Finally, in our model we can describe how well is the cell division orientation aligned with local shear stress. We find that low alignment strength leads to less mechanically stable tissues where, consequently, most of the plastic flow arises from cell rearrangements, and vice versa.

BP 27.5 Thu 16:00 H16

**Order-disorder transition in epithelial tissues** — •KARTIK CHHAJED, MARKO POPOVIĆ, and FRANK JÜLICHER — Max Planck Institute for Physics of Complex Systems, Dresden

Two dimensional packings of cells in developing epithelial tissues are commonly found to be disordered. However, highly organised packings can emerge during development, such as hexagonal pattern of ommatidia in the eye epithelium of the fruit fly. Here, we observe a disorder to order transition in the packing of the fruit fly pupal wing epithelium. In particular, we find a sudden increase in the hexatic order parameter  $\psi_6$ , which suggests a presence of hexatic and crystalline phases in two dimensional systems, as described by the classical KTHNY theory. The melting transition scenario with the intermediate hexatic phase has been reproduced in a model of epithelial tissues [Pashupalak et al. Soft Mat-

ter, 2020] where the stochastic active forces generated by the cells play the role of an effective temperature. However, both KTHNY theory and recent literature on packings of epithelial tissues assume uniform properties of particles and cells, respectively. In a proliferating tissue cells grow and divide, which inevitably leads to a heterogeneity of cell sizes. Here, we use the vertex model of epithelial tissues to study how the disorder to order transition is affected by the heterogeneity of cell sizes. We find that reducing cell heterogeneity as a control parameter drives the system through an ordering transition. We compare our results with the experimental data of the fruit fly wing to identify the role of cell size heterogeneity in the observed disorder to order transition.

## BP 27.6 Thu 16:15 H16

The Influence of Contact Maps on RNA Structure Prediction — •CHRISTIAN FABER¹ and Alexander Schug^{1,2} — ¹Jülich Supercomputing Centre, FZ Jülich — ²Steinbuch Centre for Computing, KIT

The 3d structure of Proteins and non coding RNA are essential for their function, but hard to determine via NMR or x-ray crystallography. Therefore an effective

way of simulation with the knowledge of the sequence only would be a huge improvement. Impressive progress has been made in recent years, most notably AlphaFold2 for protein structure prediction using Machine Learning techniques. Such a break through is still missing for RNA.

For RNA, there are folding programs such as SimRNA, that simulate the structure with a physical force field [1]. The outcome can be improved by incorporating evolutionary data from homologous sequences. From the evolutionary data, we can make predictions about possible contacts in the form of contact maps [2].

We investigate how contact maps can influence prediction quality and what are particularly valuable contacts. From these insights we develop new measures for machine learning algorithms.

**Ternary blend approach for boosting performance and stability of organic solar cells** — •TAYEBEH AMERI — University of Edinburgh, School of Engineering, Edinburgh, UK

Organic solar cells (OSCs) have now reached power conversion efficiencies over 18% on laboratory-scale devices, an important milestone towards their commercialization. The evolution in organic photovoltaic technology along with introducing non-fullerene acceptor materials and ternary blend approach caused this significant boost in the performance of solar cells.

However, for longer than a decade, when researchers were focused on boosting the power conversion efficiency of solar cells, the importance of lifetime and stability issues was overlooked by the organic photovoltaic community. Recently, more studies have been conducted and reported on the lifetime and stability of OSCs, employing different strategies to either understand the degradation mechanisms or enhance the lifetime of solar cells.

In this presentation, we overview how the ternary blend approach was developed to boost the power conversion efficiency. Moreover, we discuss how this approach can also address the stability issues related to the mostly used electron transport layer of zinc oxide and significantly increase the photostability of organic solar cells. And finally, we explain how zinc oxide must be manufactured and pretreated to avoid UV light activation, and in parallel, increase the thermal stability of the devices.

# CPP 1.2 Mon 10:00 H38

Structure control during in situ printing of donor-acceptor blend films — KERSTIN S. WIENHOLD¹, MANUEL A. REUS¹, DAN YANG¹, BAOJUN LIN², HENG ZHAO², WEI MA², and •PETER MÜLLER-BUSCHBAUM^{1,3} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²State Key Laboratory for Mechanical Behavior of Materials, Xi'an Jiaotong University, Xi'an, 710049 China — ³Heinz Maier-Leibnitz Zentrum (MLZ), TU München, 85748 Garching, Germany

Among the next generation solar cells, in particular organic photovoltaics are gaining impact as a promising alternative to conventional silicon-based solar cells. However, despite big achievements in the last years, it remains an unresolved challenge to fabricate large-area organic solar cells without sacrificing efficiencies. The reason behind is that basic understanding is still very limited due to the complexity of the systems. Moreover, presently a substantial number of researchers use spin-coating for film fabrication, which is not compatible with the needs of a large scale production. Thus, using up-scalable fabrication methods such as printing are of immanent interest. In the present work, we use GISAXS and GIWAXS in situ during printing of donor:acceptor blends to gain fundamental understanding about the underlying film formation processes. Different examples of polymer donors and small molecule acceptors are presented and the resulting morphologies are correlated with solar cell device performance.

#### CPP 1.3 Mon 10:15 H38

**Revealing the Thermally Induced Degradation of PM6:Y6 based Bulk Heterojunction Organic Solar Cell** — •SHAHIDUL ALAM, HUA TANG, MARYAM ALQURASHI, WEJDAN ALTHOBAITI, SI CHEN, HAYA ALDOSARI, JAFAR I. KHAN, and FRÉDÉRIC LAQUAI — King Abdullah University of Science and Technology (KAUST), KAUST Solar Center (KSC), Physical Sciences and Engineering Division (PSE), Material Science and Engineering Program (MSE), Thuwal 23955-6900, Kingdom of Saudi Arabia

Thermally-induced degradation in bulk-heterojunction OSCs is an obvious barrier to the fabrication of stable devices. Thus, practical approaches and strategies need to be identified their inherent thermal instability. In this work, the thermally induced degradation of the most commonly used system PM6:Y6 is investigated by varying temperatures and different exposure conditions. The degradation pathways have been identified by applying several opto-electrical and spectroscopic characterizations methods. Due to the reduced charge carrier mobility and extraction probability, the thermally degraded device exhibits significant losses in the VOC and FF. Furthermore, the field dependence of charge generation, charge extraction, photo-generated charge density, and charge recombination dynamics in solar cells were studied by the TDCF optical-pump electronic-probe technique. By using all the analyses, we can explain the significant recombination process that dominates device performance and thermal stability. Finally, device simulation by SETFOS of the JV characteristics was used to confirm experimentally determined thermally induced degradation. Location: H38

CPP 1.4 Mon 10:30 H38

Developing the next generation of photovoltaics with high efficiencies — •ELISABETH ERBES^{1,2}, MATTHIAS SCHWARTZKOPF¹, CONSTANTIN HARDER^{1,3}, SUSANN FRENZKE¹, BENEDIKT SOCHOR¹, NAIREETA BISWAS^{1,2}, STEPHAN V. ROTH^{1,4}, and SIMONE TECHERT^{1,2} — ¹Deutsches Elektronen-Synchrotron (DESY), Hamburg, Germany — ²Institute for X-ray Physics, Goettingen University, Goettingen, Germany — ³Technical University of Munich, Munich, Germany — ⁴Department of Fibre and Polymer Technology, KTH Royal Institute of Technology, Stockholm, Sweden

A crucial challenge in bio-inspired energy research is to develop a rationale for the synthesis and use of sustainable, bio-based materials. Cellulose fibers have excellent mechanical strength, are thermally stable, are very lightweight and have a very low surface roughness in thin films. On the other hand, the use of small molecules in OSC is well known to increase the power conversion efficiency. The idea is to combine the use of cellulose and small molecules to create a sustainable organic solar cell with high efficiencies. The current study aims to investigate systematically the OSC matrix PM6:Y6 doped with optical-light absorbing, electron transfer (ET) dyes. The structural and morphological integrity of the dyes were studied with grazing incidence small angle and wide angle X-ray scattering techniques (in situ GISAXS and static GIWAXS) and photo-sensitization experiments. This analysis showed us the intercalation dynamics, distribution and function of pyrene-based photo-dopants within the PM6:Y6 matrix and whether these dopants alter the overall polymer structures.

## CPP 1.5 Mon 10:45 H38

**Ultrafast charge carriers separation at organic donor-acceptor interfaces - Influence of molecular vibrations** — •MAXIMILIAN F. X. DORFNER¹, SEBASTIAN HUTSCH¹, RAFFAELE BORRELLI², MAXIM F. GELIN³, and FRANK ORTMANN¹ — ¹Department of Chemistry, Technische Universität München, 85748 Garching b. München (Germany) — ²DISAFA, University of Torino, Largo Paolo Braccini 2, I-10095 Grugliasco (TO), Italy — ³School of Sciences, Hangzhou Dianzi University, Hangzhou 310018, China

In this work the charge transfer dynamics of photogenerated excitons at a donoracceptor interface of an organic solar cell blend is examined. This is done by means of a fully quantum mechanical treatment of an effective Holstein model including the relevant electronic orbitals coupled to over one hundred vibrational modes, parametrized by density functional theory calculations. To solve this coupled electron-phonon system we make use of the numerically quasi-exact matrix-product-state ansatz. We find that, depending on the driving energy, different mechanisms are predominantly responsible for the charge separation at the interface. For near zero driving the ultrafast electron transfer is prevalently due to kinetic processes, while at larger driving the separation of carriers can be traced back to dissipative phonon emission connected with the dominant molecular vibrations. This charge transfer picture is consistent with a novel semi-classical hopping approach, with which we compare. These results show that dissipation of energy to the phonon is essential for charge separation for systems with a moderate driving force.

## CPP 1.6 Mon 11:00 H38

Revealing the formation kinetics of the active layer for non-fullerene organic solar cells — •XINYU JIANG¹, SUO TU¹, MANUEL A. REUS¹, JULIJA Reitenbach¹, Christian L. Weindl¹, Matthias Schwartzkopf², Stephan V. ROTH², and PETER MÜLLER-BUSCHBAUM¹ — ¹Lehrstuhl für Funktionelle Materialien, Physik Department, Technische Universität München, James-Franck-Str. 1, 85748 Garching, Germany — ²DESY, Notkestraße 85, 22607 Hamburg Bulk heterojunction (BHJ) organic solar cells have gained significant improvements in the past few years, however, traditional laboratory deposition methods like spin coating are limited to small-scale production. In addition, it is difficult to observe the structure formation process of the active layer during deposition, which is crucial for gaining a fundamental understanding. Encouragingly, the emergence of printing techniques and the development of in-situ observation technology open new windows for lager-area device manufacturing and inspection of the formation process of the printed active layer, respectively. In this work, we fabricate an active layer, which contains a donor polymer (PDTBT2T-FTBDT) and a non-fullerene acceptor (BTP-4F) with a slot-die coating. The structure formation of the polymer domains kinetics is followed in-situ during the printing process with GIWAXS and UV-Vis spectroscopy measurements, respectively. Thus, structure evolution is coupled with optical properties during the printing process, thereby providing an understanding of the drying of non-fullerene organic BHJ thin films.

## 15 min. break

CPP 1.7 Mon 11:30 H38

Re-evaluation of Published Figures of Merit and Introduction of Novel figure of merit for Transparent Conducting Electrodes used in Photovoltaics — •AMAN ANAND^{1,2}, MD MOIDUL ISLAM^{1,2}, RICO MEITZNER^{1,2}, ULRICH S. SCHUBERT^{1,2}, and HARALD HOPPE^{1,2} — ¹Laboratory of Organic and Macromolecular Chemistry (IOMC), Friedrich Schiller University Jena, Humboldtstraße 10, 07743 Jena, Germany — ²Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich Schiller University Jena, Philosophenweg 7a, 07743 Jena, Germany

Transparent conductive electrodes (TCEs) are one of the important components of photovoltaic technologies. Since they are transparent and conductive, they allow light to enter the device and the photocurrent generated to be drawn into the outer electric circuit. In theory, TCEs should have the highest light transmission and conductivity. Both traits, however, must be balanced. The selection of the best TCE depends on the photovoltaic material system and is evaluated using so-called figures-of-merit (FOM). A novel and exact FOM is presented here that explicitly analyzes the impact on photovoltaic performance. This novel and exact FOM has several important properties, including i) proportionality to the solar device's potential power output, ii) normalization to the theoretically ultimately attainable photovoltaic performance, and, thus, iii) significant direction for the development of advanced TCEs. This work reassesses and compares a variety of realized state-of-the-art semitransparent electrodes.

CPP 1.8 Mon 11:45 H38

**Cycling stability of cellulose-based electronics** — •STEPHAN V. ROTH^{1,2}, CALVIN J. BRETT^{1,2}, OLA K. FORSLUND¹, ELISABETTA NOCERINO¹, LUCAS P. KREUZER³, LIONEL PORCAR⁴, NORIFUMI L. YAMADA⁵, MARTIN MANSSON¹, PE-TER MÜLLER-BUSCHBAUM³, and L. DANIEL SÖDERBERG¹ — ¹KTH Royal Institute of Technology, SE-10044 Stockholm — ²DESY, D-22607 Hamburg — ³TU München, Physik-Department, Lehrst. f. Funktionelle Materialien, D-85748 Garching — ⁴ILL, F-38042 Grenoble — ⁵KEK, Tokai (JPN)

In organic electronics, hybrid materials combining high-strength biomaterials and conducting organic polymers allow for disentangling mechanical flexibility and functionality. Yet, degradation in such complex organic electronics applications is still less addressed. We thus combine sprayed cellulose nanofibrils (CNF) templates due to their hierarchical, nanoporous morphology and a conductive polymer blend poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate) (PE-DOT:PSS) to correlate the impact of cyclic relative humidity changes with device performance and nanostructure evolution. The conductivity of the CNF/PEDOT:PSS hybrid shows reversible changes: The PEDOT:PSS blend undergoes cyclic wetting/dewetting on the CNF backbone accompanied by swelling and deswelling of PEDOT:PSS moieties in the pores. The cycling stability of the device performance is ensured by reversible rearrangement of the CNF backbone. With CNF acting as structural reinforcing template, interestingly, no macroscopic swelling is observed, proving the applicability in e.g. supercapacitors.

## CPP 1.9 Mon 12:00 H38

**Dual-Gate Organic Electrochemical Transistors and Circuits** — •HSIN TSENG, ANTON WEISSBACH, KARL LEO, and HANS KLEEMANN — Dresden Integrated Center for Applied Physics and Photonic Materials, TU Dresden, Dresden, Germany

Organic mixed ionic-electronic conductors (OMIECs) are currently in the spotlight of research for diverse applications. Among all, organic electrochemical transistors (OECTs) stand out as organic synaptic devices for integrated bioelectronics leading to neuromorphic computing applications, thanks to their low operating voltage, biocompatibility, and the ionic and electronic interactions in OMIECs. Modifying OMIECs by molecular design enables accumulation-mode OECTs, resulting in broad IC applications. However, the side chain molecular design of the polymer is unfavorable for IC design and manufacturing processes. Here, we show an OECT with photo-patternable solid electrolyte advancing towards integrated circuits. We discuss how alterable device parameters can be employed to adjust the OECT performance. In particular, we demonstrate how the biasing conditions govern the time constant of OECTs. In addition, we discuss how a dual-gate OECT architecture can be employed to tune the threshold voltage of OECTs and control the ionic and electronic charge transport in the electrolyte and OMIECs without any complicated molecular design. The electrical analysis of solid-state electrolyte OECTs provides new insights stimulating higher investigations on ionic and electronic interactions and coupled transport properties in OMIECs and paves the foundation for the integration of OECTs for advanced applications.

#### CPP 1.10 Mon 12:15 H38

**Design of Monolithic All-Organic Oxygen Sensors** — •TONI BÄRSCHNEIDER and SEBASTIAN REINEKE — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP), Technische Universität Dresden

Organic electronic devices, such as light-emitting diodes (OLEDs) and photodetectors (OPDs), are ideal for sensor application because of their versatility and flexibility. Additionally, they can be easily fabricated on any substrate, making monolithic sensor application possible. This allows for an easy miniaturization and a cheap fabrication. Organic room temperature phosphorescence (RTP) materials are well suited for optical oxygen sensors because of their strong oxygen dependency.

In this work, we developed a monolithic all-organic oxygen sensor which is composed a RTP sensing layer, an ultraviolet OLED as excitation source, and a novel narrow bandwidth OPD for detection. The RTP sensing layer shows fluorescence and phosphorescence at room temperature at the same time which enables self-referencing to avoid photodegradation-caused distortion. Due to the long phosphorescence lifetime, sensing withing the ultra-trace range is possible.

The presented sensors overcome drawbacks of common optical oxygen sensors such as complexity, expensive read-out electronics, and a lack of possible miniaturization.

CPP 1.11 Mon 12:30 H38

Towards all solution-processed OFETs using microcontact printed electrodes — •KIRILL GUBANOV¹, MANUEL JOHNSON¹, MELDA AKAY¹, KIM THOMANN¹, DAN SHEN^{1,2}, XING CHENG², and RAINER H. FINK¹ — ¹Physikalische Chemie II, Friedrich-Alexander Universität Erlangen-Nürnberg, Germany — ²South University of Science and Technology, Shenzhen, China

Printed electronics is expected to facilitate low-cost solvent prepared devices for potential applications in RFID, flexible displays, OLEDs and transistors. Furthermore, microcontact printing may be used in a large-scale production using roll-to-roll printing with direct access to structures on the micrometer level. The preparation of the microstructured conductive electrodes using PEDOT:PSS ink for applications in OFETs was successful in various aspects: the electrodes were fabricated with very good structural definition and high reproducibility on solvent-prepared 2D-extended single-crystalline C8-BTBT films. A defined mechanical load of the PDMS stamps pre-treated with O2 plasma yielded good structural quality and competitive electrical performance. In particular, the implementation of the MWCNTs in the PEDOT:PSS ink has a direct impact on the charge carriers transport efficiency, leading to the contact resistance decrease. In addition to electrical characterization made with KPFM and IV-curves, the morphology and structure analysis was performed using VLM, AFM and 3D Microscopy, providing with an insight into the structural quality of the contacts and relate their structures to the overall device performances. The research is funded by the BMBF (contract 05K19WE2).

CPP 1.12 Mon 12:45 H38 Effect of trap states on the performance of organic photodetectors — •JAKOB WOLANSKY¹, SEBASTIAN HUTSCH², FELIX TALNACK¹, MICHEL PANHANS², JONAS KUBLITSKI¹, STEFAN MANNSFELD¹, FRANK ORTMANN², JOHANNES BENDUHN¹, and KARL LEO¹ — ¹Technische Universität Dresden, Dresden, Germany — ²Technische Universität München, Garching b. München, Germany Due to the broad range of modern applications, the demand for photodetectors is drastically increasing, and in particular, organic photodetectors (OPDs) can meet the diverse requirements. However, the specific detectivity of OPDs is significantly below the thermal limit and is currently restricted by the high noise spectral density. Kublitski *et al.*[1] recently showed that the shot noise and hence the dark current (J_D) dominates the noise spectral density at negative bias. Further, the authors suspect that mid-gap trap states cause the high J_D.

Here, we study devices with a well-performing absorber layer without an electron acceptor and, therefore, we do not expect any charge-transfer states to form. Nevertheless, we can observe sub-bandgap absorption in ultra-sensitive external quantum efficiency measurements. By utilizing different device processing parameters and employing different interface layers, we identify the origin of these sub-bandgap excitations. Interestingly, we observe a clear correlation between the device performance and the presence and quantity of trap states. The relation between molecular structure and device performance gives a new direction for reducing J_D further in OPDs and improving their specific detectivity. [1] Kublitski, J. *et al.* Nat Commun 12, 551 (2021)

# CPP 2: Polymer Networks and Elastomers

Time: Monday 9:30-10:30

CPP 2.1 Mon 9:30 H39

The non-ideal preparation state of polymer (model) networks — •MICHAEL LANG¹ and TONI MÜLLER^{1,2} — ¹Institut Theorie der Polymere, Leibniz Institut für Polymerforschung Dresden, Hohe Straße 6, 01069 Dresden, Germany — ²Institut für Theoretische Physik, Technische Universität Dresden, Zellescher Weg 17, 01069 Dresden, Germany

We demonstrate that the phantom modulus can be split into two major contributions: the cycle rank of the active network structure and a correction resulting predominantly from non-ideal chain conformations at the instance of cross-linking. The correction contains several contributions related to loop formation, an effective repulsion between network junctions, and an excess strain of chains that develops towards the end of the reactions, if reaction partners become sparse. This challenges the text-book assumption that network strands are incorporated into the network with the same conformations as a free chain inside the reaction container. Our results are relevant for developing a better understanding of rubber elasticity and its dependence on the network formation process.

## CPP 2.2 Mon 9:45 H39

Nonlinear elasticity under constraints and predeformations: a group theoretical approach — •SEGUN GOH^{1,2}, HARTMUT LÖWEN², and ANDREAS M. MENZEL³ — ¹Forschungszentrum Jülich, 52425 Jülich, Germany — ²Heinrich-Heine Universität Düsseldorf, 40225 Düsseldorf, Germany — ³Otto-von-Guericke-Universität Magdeburg, 39106 Magdeburg, Germany

The mechanical response of elastic materials frequently involves predeformations. Moreover, if an active or driven material is exposed to an external condition, a mismatch between the activity/driving and external condition may lead to a hidden predeformation in the system in its mechanical equilibrium state. Then the assumption of linear response breaks down, making descriptions of nonlinear elasticity compulsory even if the applied deformation is infinitesimally small. In this talk, we discuss how to develop a theoretical framework to meet this challenge and thereby, to address elasticity consistently for both small and large deformations. Specifically, employing concepts from group theory and Lie algebra, we suggest an idea to construct finite deformation gradients from infinitesimal group generators. Generalized nonlinear shear deformations and elastic moduli are defined subsequently. Possible applications will also be discussed.

## Location: H39

CPP 2.3 Mon 10:00 H39

Surface structure and rheology of amphiphilic co-polymer networks on different length scales — •KEVIN HAGMANN¹, NORA FRIBICZER², SEBASTIAN SEIFFERT², CAROLIN BUNK³, FRANK BÖHME³, and REGINE VON KLITZING¹ — ¹Institute for Condensed Matter Physics, Technische Universität Darmstadt, D-64289 Darmstadt — ²Department of Chemistry, Johannes Gutenberg University Mainz, D-55128 Mainz — ³Leibniz-Institut für Polymerforschung Dresden e.V., D-01069 Dresden

This study focuses on the relation between structure, swelling abilities and mechanical/rheological properties of films of amphiphilic co-polymer networks (ACNs). First, the correlation between different synthesis strategies for gel films and their resulting properties will be described. Secondly, the effect of solvents of different polarity on the swelling ability will be presented on different length scales. For this purpose, topology and near surface structure are studied with atomic force microscopy (AFM) and grazing incidence small angle x-ray scattering (GISAXS), respectively. We also put special emphasis on the determination of mechanical and rheological properties laterally and orthogonally to the gel surface by carrying out dynamic AFM indentation experiments. In order to evaluate heterogeneities the mechanical and rheological behaviour at the interface of the ACNs will be presented on various length scales (nm -  $\mu$ m). The study shows that the synthesis strategy has a strong effect on the gel structure and on nano/microrheological properties. The structure and rheology of gel films will be compared with results obtained of the respective bulk gel.

#### CPP 2.4 Mon 10:15 H39

Correlations of infrared spectroscopy and DSC measurements to determine the yield of scission under irradiation in biopolyesters — •DAVID KRIEG, MIRKO RENNERT, and MICHAEL NASE — Institut für Biopoylmerforschung der Hochschule für Angewandte Wissenschaften Hof

Under the influence of ionizing irradiation, biopolyesters can either undergo crosslinking or scissioning. It was shown that the yield of corsslinking for polyesters such as polybutylenadipat-terephthalat (PBAT) can be correlated to changes in peaks in the IR spectrum and the onset time of the melting peak while heating during DSC measurements using the Avrami equation [Kijchavengkul 2008]. For biopolyesters such as polyhydroxybutyrate (PHB) and polylactic acid (PLA) sicsioning is the dominant process under irradiation. This talk will go into detail, whether similar correlations as seen in crosslinking PBAT can be found in PLA and PH3B, when scission is the dominate reaction and what structural changes in the polymer make this correlation possible.

# CPP 3: Perovskite and Photovoltaics 1 (joint session HL/CPP/KFM)

# CPP 7: Wetting, Fluidics and Liquids at Interfaces and Surfaces

Time: Monday 10:45-13:00

## CPP 7.1 Mon 10:45 H39

**Coupling of liquid-liquid phase separation and wetting dynamics** — •YOUCHUANG CHAO, OLINKA RAMÍREZ-SOTO, CHRISTIAN BAHR, and STEFAN KARPITSCHKA — Max Planck Institute for Dynamics and Self-Organization, 37077 Göttingen, Germany

The interplay of phase separation and surface wetting is of great interest for various fields, ranging from industrial applications of oil recovery to the formation of membraneless organelles in living cells. Most of previous studies focus on understanding the interaction of phase separation with static wetting, i.e., pinned contact line conditions; nevertheless, how phase separation interacts with dynamical wetting, for instance, advancing contact lines is still unclear. Here, using highly mobile, Marangoni-contracted droplets of evaporating, binary liquid mixtures with a well-defined miscibility gap on fully wetting substrates, we explore the interplay of phase separation and wetting dynamics. Interestingly, we observe an abrupt wetting transition: from a contracted droplet state in the one-phase region to an actively driven spreading motion in the two-phase region; This is caused by the strong coupling of liquid-liquid phase separation and advancing contact lines, together with effects of evaporative enrichment and surface forces. Our finding may enable the development of novel surface processing strategies.

## CPP 7.2 Mon 11:00 H39

Liquid phase separation during soft dynamic wetting — •LUKAS HAUER¹, ZHUOYUN CA1², JONATHAN T. PHAM², and DORIS VOLLMER¹ — ¹Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany — ²Department of Chemical and Materials Engineering, University of Kentucky,Lexington, Kentucky, USA

Droplets sitting on soft substrates deform the material around the three-phase contact line, i.e., the formation of the wetting ridge. While on liquid films the ridge geometry is solely governed by capillarity, on (visco)elastic films elastic contributions add to the ridge geometry. Recently, on (visco)elastic materials a capillary induced phase-separated region of pure liquid was observed. Here, we investigate this phase separation on crosslinked PDMS films with differing amounts of free oligomer chains during dynamic wetting. We let droplets forcefully slide over PDMS films while monitoring the ridge zone with laser scanning confocal microscopy. Different dyes in the crosslinked network and in the free oligomers enable discrimination between the two phases. We find that phase-separation competes with the motion of the droplet: by tuning the droplets' speed, the phase-separated ridge height ranges from > 30  $\mu$ m (at 5  $\mu$ m/s) to no phase separation at all for fast speeds.

#### 15 min. break

## CPP 7.3 Mon 11:30 H39

**Deep learning to analyze sliding drops** — •SAJJAD SHUMALY, FAHIMEH DARVISH, XIAOMEI LI, ALEXANDER SAAL, CHIRAG HINDUJA, WERNER STEF-FEN, OLEKSANDRA KUKHARENKO, RÜDIGER BERGER, and HANS-JÜRGEN BUTT — Max Planck Institute for Polymer Research, Ackermannweg 10, D-55128, Mainz, Germany

Investigation of drop sliding forces requires knowledge of the shape of the drop close to the three-phase contact line. State-of-the-art contact angle measurement methods are designed for analyzing symmetric and high-resolution images of the drop. The analysis of videos of drops sliding down a tilted plane is hampered due to the low-resolution of the cutout area where the drop is visible. The drop is just a part of the whole image. In addition, drops sliding down a tilted plate are unsymmetrical in shape and the three-phase contact line may deform due to the sticky points.

In order to increase the accuracy of the measured contact angle, we trained a deep learning-based super-resolution model with an up-scale ratio of 3, i.e. the trained model is able to enlarge droplet images 9 times. In the second step, we performed an optimized polynomial fitting approach to measure the contact angle even for symmetric, asymmetric, or deformed droplets without the need for liquid parameters. To find the best parameters for polynomial fitting in our special problem, we conducted a systematic experiment using synthetic images.

## CPP 7.4 Mon 11:45 H39

How often a Drops Sticks and Slips at a Wetting Transition — CHIRAG HINDUJA¹, ALEXANDRE LAROCHE^{1,2}, SAJJAD SHUMALX¹, YUJIAO WANG^{3,4}, DORIS VOLLMER¹, HANS-JÜRGEN BUTT¹, and •RÜDIGER BERGER¹ — ¹Max Planck Institute for Polymer Research, 55128 Mainz, Germany — ²University of Zurich, 8057 Zurich, Switzerland — ³Key Laboratory of Interfacial Physics and Technology, Shanghai Institute of Applied Physics, Chinese Academy of Sciences, Shanghai 201800, China — ⁴University of Chinese Academy of Sciences, Beijing 100049, China

We will discuss forces of sliding drops at a sharp wetting transitions featuring no topographic variation. Such surfaces with different wetting properties were made from chemical vapor deposition of trichlorootcylsilane (OTS) and trichloro(perfluoro) octylsilane (PFOCTS). We observed that drops sliding from an area of low to high contact angle hysteresis exhibit two force maxima. The drop motion is characterized by pinning of the advancing and receding contact lines, respectively. Accordingly, the motion of the drop follows two stick-slip processes. Drops sliding from an area of high to low contact angle hysteresis exhibit a single local force maximum, a single stick process, but two slip processes.

Sliding forces of drops were measured by a novel tool named scanning Drop Adhesion Force Instrument (sDAFI) which we use to image, locate and characterize wetting properties of cm-large areas with a resolution down to the micrometer-scale.

## CPP 7.5 Mon 12:00 H39

**Tunable lamellar topography driven by wetting dynamics** — •GISSELA CONSTANTE¹, INDRA APSITE¹, PAUL AUERBACH², SEBASTIAN ALAND², DENNIS SCHÖNFELD³, THORSTEN PRETSCH³, PAVEL MILKIN¹, and LEONID IONOV^{1,4} — ¹University of Bayreuth, Bayreuth, Germany — ²Hochschule für Technik und Wirtschaft Dresden, Dresden, Germany — ³Fraunhofer Institute for Applied Polymer Research IAP, Postdam, Germany — ⁴Bavarian Polymer Institute, Bayreuth, Germany

The fabrication of switchable surfaces has been of interest in several fields such as biotechnology, industry, and others. The selection of materials and methods is crucial to provide proper control on the tunable surface. In this research, an exceptional high aspect ratio lamellar surface topography was fabricated by melt-electrowriting of microfibers of a shape-memory thermo-responsive polyurethane. Two different types of stimuli: temperature and light exposition were applied to modify the mechanical properties of shape memory polymer and thus program deformation and recovery of the surface. Wetting studies showed that the deformation of the high aspect ratio lamellar surface can be tunned not only manually, but as well by a liquid droplet. This behavior is controlled by temperature changes during direct heating/cooling or by exposure to light. The liquid in combination with thermo-responsive topography presents a new type of wetting behavior. This feature opens the possibility to apply such topographies for the design of smart elements for microfluidic devices, for example, smart valves.

## CPP 7.6 Mon 12:15 H39

Gradient dynamics model for sessile drop evaporation in a gap: from simple to applied scenarios — •SIMON HARTMANN¹, UWE THIELE¹, CHRISTIAN DIDDENS², and MAZIYAR JALAAL³ — ¹Institut für Theoretische Physik and Center for Nonlinear Science, Universität Münster — ²Physics of Fluids group, Max Planck Center Twente for Complex Fluid Dynamics, and J. M. Burgers Center for Fluid Dynamics, University of Twente — ³Van der Waals-Zeeman Institute, Institute of Physics, University of Amsterdam

We consider an evaporating drop of volatile partially wetting liquid on a rigid solid substrate. In addition, the setup is covered with a plate, forming a narrow gap with the substrate. First, we develop an efficient mesoscopic description of the liquid and vapor dynamics in a gradient dynamics form. It couples the diffusive dynamics of the vertically averaged vapour density in the narrow gap to an evolution equation for the drop profile. The dynamics is purely driven by a free energy functional that incorporates wetting, bulk and interface energies of the liquid as well as vapour entropy.

Subsequently, we employ numerical simulations to validate the model against both experiments and simulations based on Stokes equation. Finally, we show that the gradient dynamics approach allows for extensions of our model to cover more intricate scenarios, e.g., spreading drops of volatile liquid on polymer brushes or on porous media.

## CPP 7.7 Mon 12:30 H39

Dewetting of thin lubricating films under aqueous drops on high and low surface energy surfaces — •BIDISHA BHATT, SHIVAM GUPTA, VASUDEVAN SUMATHI, SIVASURENDER CHANDRAN, and KRISHNACHARYA KHARE — Indian Institute of Technology Kanpur, Kanpur, India

Understanding the stability of thin liquid films under different environments is important due to their potential applications, such as coatings, paints, and printing, to name a few. In this work, we investigate the stability of thin liquid films of a lubricating fluid under aqueous drops on slippery surfaces. Lubricating films under aqueous drops are found stable when the total excess free energy of the system is positive, which otherwise would dewet into droplets on hydrophilic surfaces. The dewetting dynamics and the apparent contact angle of the aqueous drop depend on the thickness of the lubricating film and the final morphology depends on interfacial boundary conditions between film and the substrate. However, the lubricating films on hydrophobic surfaces are stable under the aqueous drops, yet they can be destabilized using external perturbations like an electric field. Due to the electric field, surface capillary waves are

Location: H39

generated at the film-drop interface, and the amplitude of the waves grows exponentially with time, similar to spinodal dewetting. Experimentally observed wavelength and growth rate of the surface capillary waves show good agreement with the theoretically predicted value using linear stability analysis. The dewetted droplets coalesce and form a uniform film again upon removing the applied voltage, making the dewetting process fully reversible.

 $CPP \ 7.8 \quad Mon \ 12:45 \quad H39 \\ \textbf{Cloaking Transition of Droplets on Lubricated Brushes} & - \$ RODRIQUE BADR^1, \\ FRIEDERIKE \ SCHMID^1, \ DORIS \ VOLLMER^2, \ and \ LUKAS \ HAUER^2 & - \ ^1 Johannes \\ Gutenberg \ University, \ Mainz, \ Germany & - \ ^2 Max \ Plank \ Institute \ for \ Polymer \\ Physics, \ Mainz, \ Germany & - \ ^2 Max \ Plank \ Institute \ for \ Polymer \\ Physics, \ Mainz, \ Germany & - \ ^2 Max \ Plank \ Institute \ for \ Polymer \\ Physics, \ Mainz, \ Germany & - \ ^2 Max \ Plank \ Institute \ for \ Polymer \\ Physics, \ Mainz, \ Germany & - \ ^2 Max \ Plank \ Institute \ for \ Polymer \\ Physics, \ Mainz, \ Germany & - \ ^2 Max \ Plank \ Institute \ for \ Polymer \\ Physics, \ Mainz, \ Germany & - \ ^2 Max \ Plank \ Institute \ For \ Polymer \\ Physics, \ Physics,$ 

a polymer brush, with and without the presence of lubricant. We investigate the behavior of the brush in terms of grafting density and the amount of lubricant present. As for the wetting behavior, we study a sessile droplet on top of the brush. Our model and choice of parameters results in the formation of a wetting ridge and in the cloaking of the droplet by the lubricant, a phenomenon that is observed experimentally and is of integral importance to the dynamics of sliding droplets. We quantify the cloaking in terms of its thickness, which increases with the amount of lubricant present, and provide thermodynamic theory to explain the behavior. In addition, we investigate the dependence of contact angles on the size of the droplet and the possible effect of line tension, as well as the dependence on the cloaking/lubrication of the brush.

We study the equilibrium properties and wetting behavior of a simple liquid on

# CPP 8: Focus Session: Photonic Structures from Polymer and Colloidal Self-Assembly

organized by Ilja Gunkel (University of Fribourg) and Bodo Wilts (University of Salzburg)

Time: Monday 15:00-17:15

Invited TalkCPP 8.1Mon 15:00H38Stimuli-Responsive Opal Films based on Core-Shell Particle Self-Assembly- •MARKUS GALLEI — Lehrstuhl für Polymerchemie, Universität des Saarlandes, Campus C4 2, Saarbrücken

In the last decade stimuli-responsive polymers have proven their feasibility for a wide range of important applications. These polymers are capable of changing their conformation, solubility, or they can even break or form covalent bonds upon a change of temperature or pH, light irradiation or by electrochemical stimuli, or combinations thereof. The presentation will focus on materials, which contain at least one selectively addressable segment, either chemically or physically. Functional porous nanostructures based on inverse opal films obtained after shear-induced particle self-assembly will be highlighted and discussed in more detail. In the case of soft colloidal crystal and their inverted structures, external triggers additionally lead to a remarkably fast and reversible change of their intriguing optical properties. Moreover, such opal structures can be used for the design of smart catch and release systems based on responsive moieties, but also as soft templates for ceramic materials. The talk will give some recent examples for the rational design of functional organic as well as hybrid porous materials with hierarchical architectures. Some of the highlighted polymer or polymer-templated structures can be advantageously used for direct conversion into ordered ceramic or carbonaceous materials. Herein presented preparation strategies will pave the way for a manifold of applications in the field of sensing and robust membrane technologies.

 $\begin{array}{c} \mbox{CPP 8.2} & \mbox{Mon 15:30} & \mbox{H38} \\ \mbox{Strategies for increased colour saturation in colloidal photonic crystals} & - \\ \mbox{-} \mbo$ 

Germany Monodisperse polystyrene nanoparticles are easily synthesized using surfactant free emulsion polymerization, making them ideal accessible building block for photonic crystals via self-assembly.

However, structures made only with polystyrene display a whitish hue of colour as incoherent scattering at defects in the crystal structure overlaps with the photonic stop band from constructive interference. We investigate how the colour saturation in colloidal photonic crystals depends on the local and global ordering of the particles and the absorptive properties of additive materials.

First, we assemble photonic crystals using two methods resulting in structures displaying different defect characteristics. We then correlate the photonic properties as a function of these defects using correlative microscopy connecting optical imaging, reflectance spectra and SEM measurements to establish the structure-property relationship.

Secondly, we introduce absorbing material at defined positions within the colloidal photonic crystal with the goal to optimize not only the amount but the absorber position as well, allowing for an optimized colour saturation.

CPP 8.3 Mon 15:45 H38 tlebrush block copolymers —

Self-assembled photonic pigments from bottlebrush block copolymers — •RICHARD PARKER, TIANHENG ZHAO, ZHEN WANG, CLEMENT CHAN, and SIL-VIA VIGNOLINI — Yusuf Hamied Department of Chemistry, University of Cambridge, United Kingdom

The self-assembly of bottlebrush block copolymers (BBCPs) into photonic materials has drawn significant attention due to the flexibility and diversity of the building blocks that can be synthesised. In this talk we will introduce a robust strategy for the fabrication of hierarchical photonic pigments via the confined self-assembly of BBCPs within emulsified microdroplets. By utilising an amphiphilic BBCP and optimising the emulsification conditions, we will demon-

Location: H38

strate the formation of structurally coloured particles with a correlated disordered structure (i.e. a photonic glass) and compare them to particles with a highly-ordered concentric lamellar structure (i.e. a 1D photonic crystal). The mechanisms behind these two different architectures will be proposed and methods to tune the reflected colour of the respective systems considered. Finally, the strengths and weaknesses of the two approaches will be summarised in terms of the optical properties of the particles, the scalability of the approach and their viability as real-world colorants.

CPP 8.4 Mon 16:15 H38 Elucidating the chiral self-assembly of cellulose nanocrystals for photonic films — •THOMAS PARTON, RICHARD PARKER, GEA VAN DE KERKHOF, AURIMAS NARKEVICIUS, JOHANNES HAATAJA, BRUNO FRKA-PETESIC, and SILVIA VIGNO-LINI — Department of Chemistry, University of Cambridge, United Kingdom Cellulose nanocrystals (CNCs) are naturally-sourced elongated nanoparticles that form a cholesteric colloidal liquid crystal phase in suspension. Interestingly, this helicoidal arrangement can be preserved upon drying to create films with vibrant structural colour. However, while CNCs have drawn significant attention as a way to produce sustainable photonic materials, the underlying mechanism by which chirality arises in the mesophase remains unclear. Although the morphology of individual CNCs is believed to play an important role, most particles are not strongly twisted, and the suspensions exhibit considerable polydispersity in both particle size and shape.

In this study, we performed an in-depth morphological analysis of CNCs observed using transmission electron microscopy (TEM) and atomic force microscopy (AFM). We sequentially tuned the size and shape of the CNCs using ultrasonication and correlated the morphology of individual nanoparticles with their ensemble liquid crystalline behaviour and photonic response. This analysis revealed that a sub-population of CNC "bundles" (i.e. clusters of laterally-bound elementary crystallites) act as chiral dopants, analogous to those used for molecular liquid crystals, and are therefore essential for the formation of the cholesteric phase.

CPP 8.5 Mon 16:45 H38

Hierarchically structured mechanochromic deformation-sensing pigments — •JESSICA CLOUGH¹, CÉDRIC KILCHOER¹, BODO WILTS^{1,2}, and CHRIS WEDER¹ — ¹Adolphe Merkle Institute, University of Fribourg, Chemin des Verdiers 4, Fribourg 1700, Switzerland — ²Chemistry and Physics of Materials, University of Salzburg, Jakob-Haringer-Str. 2a, 5020 Salzburg, Austria.

Mechanochromic materials can change their colour in response to mechanical force and are useful for fundamental studies as well as practical applications. A versatile platform with extended sensing capabilities would be valuable for monitoring complex mechanical behaviours and failure events. Here, we report that this is possible by combining photonic structures, which alter their reflection upon deformation, and covalent mechanophores, whose absorption changes upon mechanically induced bond scission, in hierarchically structured assemblies. This was achieved by synthesising microspheres of an elastic polymer with spiropyran-based cross-links and incorporating non-close-packed silica nanoparticles into this matrix. The shift of the reflection band produced by the silica is noticeable at less than 1% strain, while the conversion of the spiropyran can require strains exceeding 50%. The two responses can be tailored via the silica content and the cross-link density. The mechano-sensing pigments can readily be incorporated into different materials of interest and probe local deformations from within. This was demonstrated by monitoring high-strain deformation of poly(dimethyl siloxane) in compression and local strain field variations caused by the necking of semicrystalline polyethylene.

Time: Monday 15:00-17:45

## CPP 9.1 Mon 15:00 H39

**Machine Learning of consistent thermodynamic models using automatic differentiation** – •DAVID ROSENBERGER¹, KIPTON BARROS², TIMOTHY GERMANN², and NICHOLAS LUBBERS² – ¹Freie Universität Berlin, Berlin, Germany – ²Los Alamos National Laboratory, Los Alamaos, NM, USA

Instead of fitting suitable analytical expressions to thermophysical data, we propose to combine automatic differentiation and artificial neural networks (ANNs) to obtain complex equations of state (EOS) for arbitrary systems. Rather than training directly on the properties of interest, we train an ANN on a model free energy whose partial derivatives match the thermophysical properties measured in experiment. We show that this method is advantageous over direct learning of thermodynamic properties, in terms of both accuracy and the exact preservation of the Maxwell relations. Furthermore, the method can implicitly solve the integration problem of computing the free energy of a system without explicit integration given appropriate data to learn from.

#### CPP 9.2 Mon 15:15 H39

Atomistic Machine Learning for Aqueous Ionic Solutions — •PHILIP LOCHE, KEVIN K. HUGUENIN-DUMITTAN, and MICHELE CERIOTTI — Laboratory of Computational Science and Modeling, IMX, École Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland

Accurate modeling of matter at the atomic scale requires to simultaneously account for the quantum nature of the chemical bond - that usually manifests itself on short time and length scales - and long-range interactions, such as electrostatics and dispersion, that occur on a large scale and often result in phenomena with a long characteristic time. Electronic structure calculations provide an accurate description of both quantum and long-range effects, but are computationally demanding, and scale poorly with system size. Machine learning (ML) approaches have emerged as a very effective strategy to build surrogate models that provide comparable accuracy at a fraction of the cost, but the most widespread techniques base their efficiency and transferability on a local description of atomic structure, which makes them ill-equipped to deal with long-range effects.

Here, we are going to to connect local and long range physics in a data driven ML approach by applying the current ML techniques to, condensed-phase systems, involving the characterization of aqueous ionic solutions. We show that only a combination of a long and a short range approach is able to predict short distanced molecular vibrations as well a long ranged ionic screening lengths.

#### CPP 9.3 Mon 15:30 H39

Identification of glass transition temperature for polymer melts using datadriven methods — •Atreyee Banerjee, HSIAO-PING HSU, OLEKSANDRA KUKHARENKO, and KURT KREMER — Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany

On fast cooling, the dynamics of polymer melts slow down exponentially, leading to solid glassy states without any drastic change in the structural structure. We employ data-driven methods based on purely confomational fluctuations to identify the glass transition temperature for a coarse-grained weakly semiflexible polymer model. More precisely, we used principal component analysis (PCA) to quantify the conformational fluctuations and identify a sharp change in fluctuation around the glass transition temperature. The first eigen value of PCA shows a clear difference below and above glass transition temperatures. The new method of glass transition temperature predicted from PCA considers local structural fluctuations and does not depend on any fitting parameters like the existing methods.

## CPP 9.4 Mon 15:45 H39

Systematic parametrization of non-Markovian dissipative thermostats for coarse-grained molecular simulations with accurate dynamics — •VIKTOR KLIPPENSTEIN and NICO F. A. VAN DER VEGT — Eduard-Zintl-Institut für Anorganische und Physikalische Chemie, Technische Universität Darmstadt, 64287 Darmstadt, Germany

The Mori-Zwanzig theory, in principle, allows to derive an exact equation of motion for coarse-grained degrees of freedom based on the dynamics of an underlying fine-grained reference system.[1] Still, in practice the simultaneous representation of structural and dynamic properties in particle-based models poses a complicated problem, e.g. due to the non-linearity of the exact coarse-grained equation of motion.

A viable approximate approach is to start from a conservative coarse-grained force-field and to extend the standard Newtonian equation of motion used in molecular simulation with a linear generalized Langevin thermostat. We demonstrate how such a thermostat can be parametrized to correctly represent dynamic properties, both in a purely bottom-up approach[2,3] or by applying iterative optimization.[3] We consider the Asakura-Oosawa model as a simple test case.[3] [1] V. CPP 9.5 Mon 16:00 H39

**Stretching biopolymers with fluctuating bending stiffness** — •PANAYOTIS BENETATOS — Kyungpook National University, Daegu, South Korea

In many biopolymers, the local bending stiffness fluctuates. For example, DNAbinding proteins attach to and detach from DNA to regulate cellular functions, thus causing a change in the local bending stiffness of the polymer backbone. This could also happen due to internal conformational transitions, such as the DNA denaturation or the helix-coil transition in polypeptides. What all these cases have in common is that the change in the local flexibility is transient and reversible. In order to analyse the conformational and elastic behaviour of such biopolymers, we propose a minimal but encompassing model of a freely jointed chain with reversible hinges (rFJC). We show that the tensile response of a rFJC is remarkably different from that of the usual freely jointed chain (uFJC). At small stretching forces, the rFJC is more compliant than the uFJC and the size (mean square end-to-end distance) of the former is greater than that of the latter. At strong stretching forces, in contrast, the rFJC is much stiffer than the uFJC. In this talk, we also discuss a strongly stretched wormlike chain with fluctuating local bending stiffness. We show that, under certain conditions, we get significant ensemble inequivalence (Gibbs vs Helmholtz).

## CPP 9.6 Mon 16:15 H39

Modulating internal transition kinetics of responsive macromolecules by collective crowding — •NILS GÖTH, UPAYAN BAUL, MICHAEL BLEY, and JOACHIM DZUBIELLA — Applied Theoretical Physics—Computational Physics, Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, 79104 Freiburg, Germany Packing and crowding are used in biology as mechanisms to (self-) regulate internal molecular or cellular processes based on collective signaling. Here, we study how the transition kinetics of an internal "switch" of responsive macromolecules is modified collectively by their spatial packing. We employ Brownian dynamics simulations of a model of Responsive Colloids, in which an explicit internal degree of freedom-here, the particle size-moving in a bimodal energy landscape self-consistently responds to the density fluctuations of the crowded environment. The bimodal energy landscape is motivated by existing two-state behavior like in protein folding or hydrogels with bimodal volume transitions. We demonstrate that populations and transition times for the two-state switching kinetics can be tuned over one order of magnitude by "self-crowding". An exponential scaling law derived from a combination of Kramers' and liquid state perturbation theory is in very good agreement with the simulations. [1] Upayan Baul, NG, MB, and JD, J. Chem. Phys. 155, 244902 (2021).

**Modelling process-structure-properties of polymer nanocomposites** — •JANETT PREHL, CONSTANTIN HUSTER, and KARL HEINZ HOFFMANN — TU Chemnitz, Chemnitz, Germany

Twin polymerization is a complex chemical reaction process leading to a broad range of organic-inorganic nano composite materials.

Within this presentation we will show our latest results [1] on the theoretical analysis of the structure formation process of twin polymerization via a previously introduced lattice-based Monte Carlo method, the reactive bond fluctuation model [2]. We analyze the effects of various model parameters, such as movability, attraction, or reaction probabilities on structural properties, like the specific surface area, the radial distribution function, the local porosity distribution, or the total fraction of percolating elements.

From these examinations, we may identify structural key factors and thus chemical properties of the underlying components that need to be adapted to fulfill desired requirements for possible applications.

A cosolvent surfactant mechanism affects polymer collapse in miscible good solvents — •Swaminath Bharadwaj¹, Divya Nayar^{1,2}, Cahit Dalgicdir¹, and Nico van der Vegt¹ — ¹Technische Universität Darmstadt, Germany — ²IIT Delhi, India

The coil-globule transitions of aqueous polymers are of profound significance in understanding the structure and function of responsive soft matter. In particu-

lar, the remarkable effect of amphiphilic cosolvents (which preferentially adsorb on the polymer surface) that leads to both swelling and collapse of stimuli responsive polymers is still hotly debated in the literature [1]. The predominant focus has been on the attractive polymer-(co)solvent interactions and the role of solvent-excluded volume interactions has been largely neglected. The solventexcluded volume contribution to the solvation free energy corresponds to the formation of a repulsive polymer-solvent interface.

Using MD simulations, we herein demonstrate that alcohols reduce the free energy cost of creating a repulsive polymer-solvent interface via a surfactant-like mechanism which surprisingly drives polymer collapse at low alcohol concentrations. This hitherto neglected role of interfacial solvation thermodynamics is common to all coil-globule transitions [2], and rationalizes the experimentally observed effects of higher alcohols and polymer molecular weight on the coil-toglobule transition of thermoresponsive polymers [2]. This mechanism is generic and applicable to other solutions containing amphiphilic cosolvents or cosolutes.

Water transport in soft nanoporous materials: Impact of mechanical response on dynamics, slippage and permeance — •ALEXANDER SCHLAICH^{1,2}, MATTHIEU VANDAMME³, MARIE PLAZANET², and BENOIT COASNE² — ¹Stuttgart Center for Simulation Science (SC SimTech), University of Stuttgart, Germany — ²Univ. Grenoble Alpes, CNRS, LIPhy, 38000 Grenoble, France — ³Navier, Ecole des Ponts, Univ. Gustave Eiffel, CNRS, Marne-la-Vallee, France Transport of water in soft porous materials is relevant to applications such as ultrafiltration and reverse osmosis processes, where polymeric membranes are employed in filtration/separation, or energy related processes. While water transport in hard porous materials such as porous silica glasses is well studied, the situation in soft matter is much more puzzling and remains unclear due to the combination of surface heterogeneity, the diffuse boundary location and pore deformations due to mechanical stresses.

CPP 9.10 Mon 17:30 H39

Solvation structure of polymer cathodes for Li/S batteries — •DIPTESH GAYEN¹, YANNIK SCHUETZE², SEBASTIEN GROH¹, and JOACHIM DZUBIELLA¹ — ¹Institute of Physik, University of Freiburg, Freiburg, Germany — ²Helmholtz Zentrum Berlin, Berlin

Lithium-sulfur (Li/S) batteries are regarded as one of the most promising nextgeneration energy storage devices. Meanwhile, some challenges inherent to Li/S batteries remain to be solved, for instance, the polysulfide shuttle effect and the volume expansion of the cathode during discharge. To suppress the abovementioned drawbacks, polymeric cathodes, e.g., based on poly(4-(thiophen-3yl) benzenethiol) (PTBT) are considered sulfur host material (S/PTBT). Here, we use molecular dynamics (MD) computer simulations to study the structure and dynamics of a single PTBT chain at 300 K in different concentrations and compositions of dimethoxyethane (DME) and dioxolane (DOL) solvents. The force-field parameters for this polymer were constructed based on the OPLS database, with missing parameters newly developed by us by benchmarking to density-functional theory calculations. We report results on polymer conformational behavior, solvent-specific adsorption, and thermodynamic properties such as the partial molar volume. Our results show that DOL is more absorbed at the PTBT compare to DME. We find no significant effect of the solvent on the structure factor of the polymer. Our simulation model enables future systematic studies of PTBT in various solvent mixtures, in particular electrolytes, for the optimizations of modern Li/S batteries.

On the electronic pi-system of 2D covalent organic frameworks — • Konrad Merkel, Johannes Greiner, and Frank Ortmann — TU München

We investigate a family of 2D hexagonal covalent organic frameworks (COFs) with different linker monomers regarding their electronic structure and piconjugation. Molecular orbitals can be obtained from maximally localized Wannier functions and turn out to be sigma- and pi-like orbitals forming distinct sigma- and pi-bands, respectively. The Wannier description enables a detailed analysis of the topology, effective coupling and delocalization of the entire pisystem. We identify conjugated states that are delocalized across multiple building blocks of the COF and show their robustness against perturbations like out-of-plane rotations of molecular fragments and different strength of Anderson disorder. Furthermore, we apply the nucleus-independent chemical shift (NICS), which is an established measure of aromaticity. All results are compared for different types of linker units with different degrees of pi-conjugation. Location: H36

Location: H38

CPP 11.2 Mon 17:30 H38

Permeation of gases through molecularly thin carbon nanomembranes — •VLADISLAV STROGANOV¹, DANIEL HÜGER¹, TABATA NÖTHEL¹, CHRISTOF NEUMANN¹, UWE HÜBNER², MICHAEL STEINERT¹, MONIKA KRUK³, PIOTR CYGANIK³, and ANDREY TURCHANIN¹ — ¹Friedrich-Schiller University Jena, Jena, Germany — ²Leibniz Institute of Photonic Technology, Jena, Germany — ³Jagiellonian University, Kraków, Poland

Atomically thin carbon nanomembranes (CNMs) are promising candidates for next generation filtration and gas separation technologies. However, the gas permeation mechanism through CNMs is not fully understood yet. To improve this knowledge, we investigated permeation of helium, deuterium, water vapor and other gases through a series of CNMs under different conditions. The CNMs were synthesized from biphenyl substituted carboxylic acids on silver substrate  $C_6H_5 - C_6H_4 - (CH_2)_n - COO|Ag$ , with different lengths of aliphatic linker n = 2 - 6. A CNM based on terphenyl thiol (TPT) was used as a well-known reference system. We demonstrated that even the smallest variation in the structure of the molecular precursor lead to significant change of the permeation properties.

Janus particles: Challenges in the preparation process and analysis of their thermophoretic self-propulsion — •FRANZISKA JAKOB and REGINE VON KL-ITZING — Institute for Condensed Matter Physics, Technische Universität Darmstadt, D-64289 Darmstadt

Active colloidal particles with different functionalities at their opposite sides are named Janus particles - motivated by the Roman mythological god. One possible propulsion mechanism is thermophoretic self-propulsion. When laser light ( $\lambda = 532$  nm) illuminates a gold-capped particle, a local temperature gradient is generated along the particle surface due to surface plasmon excitation of the gold cap. This gradient perturbs the equilibrium conditions of the surrounding medium and finally leads to particle self-propulsion.

This contribution focuses on various preparation processes of selfthermophoretic gold-polystyrene (Au-PS) microswimmers. The influence of the preparation technique on the gold cap size and the resulting self-thermophoretic behavior of the Janus particle will be presented. For this purpose, Janus particles are prepared either by metal sputtering, thermal evaporation, or by a combination of gel trapping technique and metal sputtering. With scanning electron microscopy (SEM) and energy-dispersive X-ray spectroscopy (EDX), the dimension of the gold cap was investigated. Dark-field microscopy (DFM) combined with a LabView program enables real-time tracking of the Janus particles. The study shows that the preparation method strongly affects the gold cap size of the Janus particles and thus influences their self-thermophoretic velocity.

## CPP 12.2 Mon 18:00 P1 Modeling Chemotaxis and Cross-Diffusion using MD and cDFT — •PHILIPP

CPP 12.3 Mon 18:00 P1

STÄRK – SC Simtech, Uni Stuttgart, Germany

Multiple experimental studies have observed diffusion of certain particle types such as catalysts—along concentration gradients of other species. Using stochastic, coarse grained reaction dynamics in MD simulations, we present simplified models for this behavior. Furthermore, we present a classical Density Functional Theory which provides a simple model for cross-diffusion on a broader class of particle types.

Cellulose-based programmable, robust, and healable actuators for smart packaging devices — •QING CHEN¹, BENEDIKT SOCHOR¹, ANDREI Chumokov¹, Marie Betker^{1,2}, Nils Ulrich^{3,4}, Maria E. **F-Actin photocleavage as an artificial secondary nucleation model** — •STEPHAN SYDOW, TOBIAS THALHEIM, JÖRG SCHNAUSS, and FRANK CICHOS — Peter Debye Institute for Soft Matter Physics, Universität Leipzig, Leipzig, Germany.

The aggregation of soluble proteins into highly ordered, insoluble amyloid fibrils is characteristic for a range of neurodegenerative disorders, like Alzheimer's or Parkinson's disease. The kinetics in the formation of amyloid fibrils are governed by multiple aggregation mechanisms, which are present simultaneously. One of these being the unspecific spontaneous breaking of Amyloid fibrils, whose cause, rate and break size distribution are still unknown, due to them being hidden in ensemble measurements.

We employ an artificial model system with a controllable fragmentation rate to compare it with current amyloid kinetic models, all assuming a homogeneous break size distribution. Fluorescence labelled Actin filaments exhibit photocleavage. By laser illumination of single, homogeneously labelled filaments in solution, we are able to control the breakage rate. The length and position of filaments and fragments are imaged over time by fluorescence microscopy.

We show, that Actin filaments exhibit a homogeneous break size distribution, verifying our artificial model system. Additionally, the fragment size distribution is independent of the intensity dependent, induced cleavage rate, thus it enables the direct comparison to current amyloid models.

## CPP 12.6 Mon 18:00 P1

Mapping nanomechanics and energy dissipation of collagen fibrils in tendon - •Martin Dehnert, Paul Zech, Mario Zerson, and Robert Magerle — Fakultät für Naturwissenschaften, Technische Universität Chemnitz, Germany We study the nanomechanical properties of hydrated collagen fibrils with AFMbased nanoindentation measurements. Force-distance (FD) data measured with tip velocities <  $1 \mu m/s$  display a rate-independent hysteresis with return point memory depending on only one return point. With different indentation protocols, we show that stress relaxation and creep do not influence the time evolution of the FD data. The main cause of hysteresis is the elastoplastic deformation of collagen fibrils above the glass transition. We explore the variations of these nanomechanical properties in sets of unfixed hydrated collagen fibrils isolated from native chicken Achilles tendon and compare them with collagen fibrils embedded in the natural tendon. AFM imaging in the air with controlled humidity preserves the tissue's native water content and allows for high-resolution imaging and nanoindentation measurements. This sheds new light on the role of interfibrillar bonds, the mechanical properties of the interfibrillar matrix, and the biomechanics of native tendon.

#### CPP 12.7 Mon 18:00 P1

Hydrogel-based electrodes for brain wave detection — •Göκav Erbil¹, HSIN-YIN CHIANG², VOLKER KÖRSTGENS¹, and PETER MÜLLER-BUSCHBAUM¹ — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²Cephalgo, 75014 Strasbourg, France

Electroencephalography (EEG) as method for detecting brain waves is gaining importance for medical applications, since it can non-invasively provide information. Currently, both wet electrodes and dry electrodes are in use for clinical and commercial applications. With both concepts, one has to deal with certain challenges. Dry electrodes often show motion artifacts due to changes in contact and pressure applied between skin and electrode altering the signal quality. For wet electrodes on the other hand, a decrease in signal quality is usually observed with long term signal acquisitions. In this work, mussel inspired hydrogels are presented to address these challenges. The hydrogel electrodes containing tannic acid and silver nanoparticles are optimized in terms of high conductivity and adhesive properties. The elevation of brain waves collected with a headset comprised of hydrogel electrodes is demonstrated in an EEG setup for long term analysis.

Spin-Based Quantum Sensing with Endohedral Fullerenes — •MARCO SOMMER¹, DON-SHENG GUO¹, ANDREAS HENNIG¹, JOHANN P. KLARE¹, and WOLFGANG HARNEIT² — ¹Universität Osnabrück, Osnabrück, Deutschland — ²Nankai University, Tianjin, China

The endohedral fullerene N@C₆₀ in an inhomogeneous environment is investigated with the goal to establish the N@C60 with its outstanding spin properties as a spin label for coupling experiments in biological systems at room temperature. To reveal the preservation of these spin features, the N@C₆₀ is transferred into Triton X-100 micelles, a deep cavitand calixarene (SAC4A) as well as the cavity formed by two y-cyclodextrins building a non-covalently bonded guesthost complex. The spectroscopic tools are based primarily on continuous wave (cw) and pulsed electron paramagnetic resonance (EPR) techniques, in addition to absorption measurements in the ultraviolet-visible light (UV/vis) range and molecular modelling with molecular dynamic (MD) simulation of the complexes. The resulting spin properties are examined with cw and pulsed EPR spectroscopy. The computational modelling and MD simulations of the complexes in combination with UV/vis spectroscopy serves for the unravelling of the arrangement. Initial experiments show a successful transfer of the highly hydrophobic N@C₆₀ into the aqueous phase. The resulting spin-spin relaxation time T₂ strongly depends on the the N@C₆₀'s encapsulation system. Inhomogeneous environments (Triton X-100) decrease the transverse relaxation time whereas a symmetric system ( $\gamma$ -cyclodextrin) provides an increase in T₂.

## CPP 12.9 Mon 18:00 P1

Studying the nanomechanical properties of functional organic and biologic macromolecules — ILKA M. HERMES¹, ANDREA CERRATA², VLADIMIR KOROLKOV², and •ALEXANDER KLASEN² — ¹Leibniz-Institut für Polymerforschung Dresden e.V., Dresden, Germany — ²Park Systems Europe GmbH, Mannheim, Germany

As the functionality of organic and biologic macromolecules is often determined by their nanomechanical properties, visualizing the distribution of mechanical properties on the nanoscale provides crucial insights for soft matter research. [1,2] Here, we present a study on structural and nanomechanical properties of functional organic and biologic macromolecules in different environments as well as under external stimuli, such as temperature, ion concentration and pH. Force-distance measurements with atomic force microscopy (AFM) resolve adhesion and elasticity by pressing a nanometer-sized tip on the end of a cantilever onto the surface. However, the correlation of mechanical data from forcedistance measurements to the local sample morphology additionally requires topographic sample information. PinPointTM nanomechanical imaging simultaneously acquires topographic and force-distance data within short amounts of time and is therefore ideally suited to investigate organic and biologic macromolecules.

#### CPP 12.10 Mon 18:00 P1

Huge pKa-Shifts in Weak Polyelectrolyte Brushes Explained by Coarse-Grained Simulations — •DAVID BEYER¹, CHRISTIAN HOLM¹, and PETER KOŠOVAN² — ¹Institute for Computational Physics, University of Stuttgart, D-70569 Stuttgart, Germany — ²Department of Physical and Macromolecular Chemistry, Charles University, Prague, Czechia

Following recent experiments, we study the titration behaviour of weak (pHresponsive) polyelectrolyte brushes at different salt concentrations using coarsegrained computer simulations. To account for charge regulation and the exchange of small ions with the bulk solution, we make use of the Grand-Reaction Monte-Carlo method (G-RxMC). Our simulations yield ionization curves which strongly deviate from the ideal result. Furthermore, we observe a strong dependence of the deviation on the bulk salt concentration, amounting to a shift of approximately one unit of pH as the salt concentration decreases by one order of magnitude. We theoretically explain the observed titration behaviour as a consequence of the Donnan partitioning between the brush and the bulk solution. To confirm our theoretical explanation we measure the pH inside the brush, which eliminates the Donnan contribution. Our results show that the Donnan effect can account for a shift in pH between the bulk and the brush of more than 4 units in extreme cases. We finally plot the degree of ionization as a function of the pH inside the brush, thus eliminating the Donnan contribution. Up to a small shift due to the electrostatic interactions, the resulting curves almost coincide with the ideal result, thus confirming our hypothesis.

## CPP 12.11 Mon 18:00 P1

Narrow Gap Flow Electrolysis Cells: Atomistic Computer Simulation of Electric Field Effects on Water/Organic Mixtures — •ANASTASIOS SOURPIS and FRIEDERIKE SCHMID — Johannes Gutenberg University, Mainz, Germany Electrolyte-free electrolysis fuel cells are central to a sustainable future with clean water. With growing industrial development, for example, toxic heavy metals, radioactive ions, and inorganic compounds are increasingly discharged into the environment and our sources of drinking water. In novel cutting-edge developed electrolysis fuel cells [1] the case of electrolyte-free electrolysis has been observed for mixtures of water and acetonitrile. These high modular flow cells of electro organic synthesis are very promising for the production of fine chemicals and pharmaceutically active agents. The purpose of this study is to qualitatively and quantitatively evaluate the effect of electric fields on electrolysis cells. Especially in the case of acetonitrile and water mixtures, we have focused on understanding by atomistic simulations the existence of the electrical conductance and how this can be described on larger scales.

CPP 12.12 Mon 18:00 P1 Controlling the phase transitions in surfactant-dna complexes – A.V. Radhakrishnan^{1,2}, S. Madhukar¹, A. Choudhari¹, and •V.A. RAGHUNATHAN¹ — ¹Raman Research Institute Bangalore 560080 India ²Experimental Physics I, University of Bayreuth, Bayreuth 95447 Germany Surfactant-DNA complexes are a special class of polyelectrolyte complexes where one of the macroions is formed by self assembly. They have been studied for their interesting electrostatics and potential applications for gene delivery and photonic applications. The gain in counter ion entropy is driving the complex formation and there is an interesting interplay of electrostatics and entropy leading to a rich phase behavior. The self assembled macroion can be formed either by a bilayer forming lipid or a micelle forming surfactant. We have studied the structural transitions in complexes formed by cationic surfactants such as CTAB, CTAT, DTAB with ds-DNA and constructed phase diagrams. Using small angle xray scattering and polarizing optical microscopy and elemental analysis the presence of a various phases, including a square phase(S), hexagonal phase (H) and a hexagonal super lattice phase (Hs) are identified. Detailed modeling of these structures have been carried out based on the electron density maps to propose the packaging of the macroions in the lattices. Striking differences in the phase diagrams and various ways of controlling the structural transitions will be discussed.

## CPP 12.13 Mon 18:00 P1

Poly((trifluoromethane)sulfonimide lithium styrene) as single-ion conducting binder for lithium iron phosphate electrodes in lithium-ion batteries — •FABIAN A.C. APFELBECK¹, JULIAN E. HEGER¹, TIANFU GUAN¹, MATTHIAS SCHWARTZKOPF², STEPHAN V. ROTH^{2,3}, and PETER MÜLLER-BUSCHBAUM^{1,4} — ¹TU München, Physik- Department, LS Funktionelle Materialien, 85748 Garching — ²DESY, 22607 Hamburg — ³Royal Institute of Technology KTH, 100 44 Stockholm — ⁴MLZ, TU München, 85748 Garching

Lithium-ion batteries turned out as an indispensable energy supplier in modern society which however suffers from safety concerns due to the flammability of the liquid electrolyte. Solid polymer electrolytes (SPEs) represent a safe alternative to conventional electrolytes. Especially single-ion conducting polymers (SICPs), which have the anion covalently bonded to the backbone of the polymer and thus a theoretical transference number of unity, attracted strong interest in battery research. For full-cell performance investigation of these battery cells, the ion-conducting polymer electrolyte is often used as binder instead of the neutral polyvinylidenfluorid (PVDF) in order to enhance ion conduction in the electrode and decrease the interfacial contact. Here, lithium iron phosphate (LFP) cathodes with different weight ratios of PVDF and the SICP poly((trifluoromethane)sulfonimide lithium styrene) (PSTFSILi) as binders are prepared and analysed with real (scanning electron microscopy) and reciprocal (grazing-incidence small/wide angle x-ray scattering) space techniques.

#### CPP 12.14 Mon 18:00 P1

Influence of Li Salt concentration in poly(propylene carbonate) based solid polymer electrolytes — •THIEN AN PHAM^{1,2}, RALPH GILLES¹, and PETER MÜLLER-BUSCHBAUM^{1,2} — ¹MLZ, TU München, 85748 Garching — ²TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching Li metal exhibits a high specific capacity as well as a low discharge potential that makes it interesting as an anode material for Li ion batteries. But Li dendrite growth remains a major safety in cells with liquid electrolyte. Solid polymer electrolytes (SPE) show a higher mechanical stability in comparison to their liquid counterparts and thus, can inhibit dendrite growth. In order to achieve even higher energy densities, high-energy cathode materials such as Ni rich layered transition metal oxides should be combined with Li metal anodes. However, the high operation potentials of those cathodes are a challenge for SPE. Poly(propylene carbonate) (PPC) has an intrinsically high oxidation voltage exceeding 4.5 V making it suitable for high voltage operation. Here, SPE with PPC as polymer host and Lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) as Li salt are prepared and the influence of the salt concentration on the SPE properties are studied with electrochemical impedance spectroscopy and differential scanning calorimetry. Results have shown that the ionic conductivity increasing and the glass transition temperature is decreasing with higher amount of LiTFSI.

## CPP 12.15 Mon 18:00 P1

Influence of Solvent and Lithium Salt on the Structure and Performance of NCM111 Cathode for Lithium Ion Batteries — •YUXIN LIANG¹, ZHUIJUN XU¹, KUN SUN¹, TIANFU GUAN¹, FABIAN APFELBECK¹, PAN DING², and PETER MÜLLER-BUSCHBAUM^{1,3} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²TU München, Walter Schottky Institute, Experimental Semiconductor Physics, 85748 Garching — ³MLZ, TU München, 85748 Garching

Lithium ion batteries (LIBs) with a wide range of applications have emerged as the most promising candidate for electrochemical energy storage due to its higher specific energies, volumetricenergy densities and power densities. However, lithium dendrite will growth and the Coulombic efficiency (CE) will decrease with Li plating and stripping. During past decades, more and more stateof-art materials has been developed to alleviate the abovementioned problems. Nevertheless, fundamental research on the component composition and the effect of additive and solvent on LIBs is still lacking. It is of great value to get a deep understanding and therefore optimize the fabrication process for future studies on the electrode/electrolyte interface of LIBs. In this project, we select the LiNi0.33Mn 0.33C00.33O2 as cathode material to find out the effect of different solvents and extra lithium salt (LiTFSI) on the performance of LIBs. The Li/cathode cells were assembled to observe the battery performance and grazing incidence wide-angle X- ray scattering (GIWAXS) technique is used to detect structure change within the cathode before and after cycling.

#### CPP 12.16 Mon 18:00 P1

Scaling mechanical instabilities in drying micellar droplets — •JAYANT KUMAR DEWANGAN¹, NANDITA BASU², and MITHUN CHOWDHURY¹ — ¹Lab of Soft Interfaces, Metallurgical Engineering and Materials science, IIT Bombay, Mumbai 400076, India — ²Department of Chemistry, IIT Bombay, Mumbai 400076, India

We present unique wrinkling patterns produced by evaporating sessile micellar aqueous droplets on rigid and soft substrates kept at temperatures far above ambient. The wrinkling patterns vary dramatically depending on the material's elastic modulus and substrate, the concentration of the micellar solution, and the temperature of the substrate. Coffee-ring-like morphologies are observed at very low concentration regimes (CTAB concentration < 0.0364 wt%), devoid of any wrinkling morphology, regardless of substrate temperature. Droplets deposited at a temperature above 85°C wrinkle formation begins at the droplet peripheral zone, radial on the stiff glass annular on soft cross-linked PDMS substrate, at the high initial concentration regime (CTAB concentration > 0.0364 wt%). Radial wrinkles on the glass substrate and annular wrinkles on the cross-linked PDMS substrate nucleate from the edges connecting to the deposit's central region at CTAB concentration > 2.73 wt%. The ratio of the width of the gel-like deposit to the radius of the droplet scales with surfactant concentration is dependent on the initial equilibrium contact angle of micellar droplets. Our findings support previous literature on mechanical instabilities of dried deposits by interdependent scaling relationships between deposit radius, wavelength of wrinkle, thickness, and elastic modulus.

## CPP 12.17 Mon 18:00 P1

A scaled-down double-pass optical beam deflection setup for the measurement of diffusion and thermodiffusion in liquid mixtures — MAREIKE HAGER, •ROMAN REH, and WERNER KÖHLER — Physikalisches Institut, Universität Bayreuth, Germany

We report about a compact double-pass optical beam deflection (OBD) setup for measurments on diffusion and thermodiffusion in liquid mixtures. A laserbeam transmitted through the sample gets back-reflected behind the OBD-cell and, thus, traverses the sample volume a second time. Applying a vertical temperature gradient to the sample leads to thermodiffusion and the beam gets deflected by the resulting gradient in refractive index due to the gradients in temperature and concentration. A beamsplitter guides the beam towards a camera, where the time dependent laserposition is recorded. The signal then gives information about the diffusion processes. Since the laserbeam propagates on the same path between the beamsplitter and the cell before and after getting deflected in the sample and since the double-transmission geometry allows little distance between cell and camera, the whole setup could be built very compact. Measurements with different binary mixtures are in good agreement with measurements with a single-transmission-OBD. We present a matrix formalism to describe the optical transfer function of the instrument.

## CPP 12.18 Mon 18:00 P1

Particle sorting by Marangoni convection in microfluidic channels — •ROMAN REH, LORENZ KIEL, DANIEL ZAPF, and WERNER KÖHLER — Physikalisches Institut, Universität Bayreuth, Germany

Thermosolutal and thermocapillary Marangoni convection at a liquid-gas interface in a T-shaped microchannel structure of approximately  $100 \times 20 \ \mu m^2$  cross section creates localized vortices that can be used for particle trapping, steering, and sorting. Experiments have been performed with water-ethanol mixtures as carrier liquid and dispersed micrometer-sized polystyrene beads. Due to collisions with the meniscus, particles are displaced from streamlines that approach the interface closer than one particle radius. These streamlines feed liquid volumes that are entirely cleared of particles. Particle accumulations structures form inside the vortex, from where only small particles can escape by diffusion. Since the critical streamline, which separates the depletion from the accumulation region, depends on the particle radius, the mechanism can be used for particle sorting by superposition of a Poiseuille flow and splitting of the flow downstream from the meniscus. In the simplest case, the initially homogeneous flow is split into two arms, one where the particles are enriched and one where all particles are removed from the liquid. The microchannel structures consist of crosslinked PDMS and the dispersed particles are observed by video microscopy. Numerical simulations are performed that almost perfectly match the experimental observations.

CPP 12.19 Mon 18:00 P1

**Dynamic Ellipsometric Light Scattering: A Feasibility Study** — •Reinhard Sigel — Markdorf, Germany

For colloidal particles dispersed in water, ellipsometric light scattering (ELS) has been established as a means for the characterization of the particles' interface layers [1,2]. These layers are important for the colloidal stabilization. We explore theoretically a combination of ELS with photon correlation measurements to access the fluctuation amplitude and dynamics of soft colloidal layers (e.g. in steric stabilization). They are connected to mechanical properties of the layers and are complementary to the structure information of conventional ELS. The investigation builds on preceding work on Mie scattering by soft core-shell particles [3], correlation ellipsometry [4], extraction of the coherent scattering properties in ELS for polydisperse samples [5,6], and the detection of incoherent dynamics in the ellipsometry minimum [7].

CPP 12.20 Mon 18:00 P1

**Improved virtual orbitals for charge transfer excitations in time dependent DFT** — •ROLF WÜRDEMANN¹ and MICHAEL WALTER^{2,3} — ¹Freiburger Materialforschungszentrum, Freiburg, Germany — ²Freiburger Zentrum für interaktive Werkstoffe und bioinspirierte Technologien, Freiburg, Germany — ³Fraunhofer-Institut für Werkstoffmechanik, Freiburg, Germany

Charge transfer excitations (CTE) are of high importance in photovoltaics, organic electronics and molecular and organic magnetism. Range separated funtionals (RSF) can be used to correctly determine the energetics of CTEs within linear response time dependent density functional theory (TDDFT).

TDDFT becomes numerically very demanding on grids if hybrid or RSF are used due to the inclusion of exact exchange derived from Hartree-Fock theory.

We present an implementation of RSF on real space grids and discuss a way to circumvent the problem mentioned above by utilizing Huzinagas improved virtual orbitals (IVOs) that form an improved basis for this type of calculations. The CTE energetics can obtained by means of DFT ground-state calculations using IVOs[1].

#### CPP 12.21 Mon 18:00 P1

Unravelling Superpositions in GI-XPCS by simultaneous GT-GI-XPCS on Spincoated Thin Films — •CHRISTOPHER R. GREVE¹, MEIKE KUHN¹, FABIAN ELLER¹, GUILLAUME FREYCHET³, ALEXANDER HEXEMER², LUTZ WIEGART³, and EVA M. HERZIG¹ — ¹Dynamik und Strukturbildung - Herzig Group, Universität Bayreuth, Universitätsstr. 30, 95447 Bayreuth, Germany — ²CAMERA, Lawrence Berkeley National Lab Berkeley CA, USA — ³NSLSII, Brookhaven National Lab, Upton NY, USA

X-Ray Photon Correlation Spectroscopy (XPCS) is a flexible tool to quantify dynamics on the nanometer scale in bulk samples and is used in grazing incidence (GI) geometry for application to thin films. By measurements in GI geometry distortions to the scattering signal are introduced, related to refraction and reflection events, known from the Distorted Wave Born Approximation (DWBA). These reflection and refraction events lead to superpositions of signal on the detector, resulting in alterations of analyzed quantities. We applied an approach to quantify the influence of events within the DWBA on decorrelation analysis by measuring grazing incidence transmission (GT) XPCS and GI-XPCS simultaneously for various thin films. Combining GI-GT-XPCS results with calculations of Fresnel coefficients within the simplified DWBA the origin of scattering contributions is determined. Calculations of the non-linear effect of refractions are added to identify comparable regions within GI and GT. Thus, elucidating differences for phenomena like altered decorrelation times, allowing a valid analysis of GI-XPCS experiments for certain experimental conditions.

## CPP 12.22 Mon 18:00 P1

**Propagation of learned sequence patterns to larger chain length using TransEncoder neural networks** — •HUZAIFA SHABBIR, MARCO WERNER, and JENS UWE SOMMER — Leibniz Institute for Polymer Research Dresden

In this work, we investigate artificial neural networks that are capable of learning and transferring hidden variables in chemical sequences from a small sequence length to a larger one. Patterns in the relation between the hydrophilic/hydrophobic sequence of a copolymer and its free energy of interaction with a lipid membrane have been learned with the aid of AutoEncoder neural networks, which were employed to translate between these two properties (TransEncoder)[1]. We demonstrate that the latent space parameters learned by the TransEncoder allow for a physical interpretation of the contributions to the free energy. Furthermore, the learned patterns for a smaller sequence length can be transferred towards a higher sequence length of our interest, which not only significantly reduces the number of training examples required but also increases the accuracy in comparison to the training for individual polymer sequence length. We investigate the computational efficiency and the convergence of learned patterns when multiple chain lengths are addressed at once.

## CPP 12.23 Mon 18:00 P1

Crystallization of short polymer chains at hard walls: stochastic approximation Monte Carlo simulation (SAMC) — •EVGENIIA FILIMONOVA, TIMUR SHAKIROV, and VIKTOR IVANOV — Martin- Luther-University Halle-Wittenberg, Institute of Physics, 06099, Halle, Germany

Our research is devoted to crystallization in polymer melts in the presence of hard walls. An interface to a solid material can initiate crystallization in polymer liquids by either heterogeneous nucleation or prefreezing. Our goal is to reveal physical factors which are responsible for one of these two scenarios of surface-induced polymer crystallization. We use coarse-grained model and perform stochastic approximation Monte Carlo (SAMC) simulation. We have developed an approach that allows us to identify the translational and orientational local ordering by means of comparing our system configurations with reference crystalline structures of different symmetries. In addition to calculating the usual order parameters (Steinhardt parameters, common neighbours analysis, nematic order parameter, etc.), we suggested new order parameters based on scalar products of bonds between nearest neighbours. We observe a coexistence of an isotopic structure in the center of the film with ordered structures at the walls at intermediate values of energies (in microcanonical analysis). A change in the crystal structure accompanying a change in density at different energies is also shown. Financial support of the International Graduate School AGRIPOLY supported by the European Social Fund (ESF) and the Federal State Saxony-Anhalt is acknowledged.

## CPP 12.24 Mon 18:00 P1

Simulation of reversible chain association using the reaction ensemble Monte Carlo — •PABLO M. BLANCO and PETER KOŠOVAN — Department of Physical and Macromolecular Chemistry, Faculty of Science, Charles University, Hlavova 8, 128 00 Prague 2, Czech Republic.

Reversible association reactions are the key feature of many self-healing polymeric materials and controlled release systems. Simulations and theory are lagging behind the experimental progress in investigating such systems, partly due to the lack of a suitable implementation of an algorithm that would allow for such reversible reactions. In this work, we present an implementation of such reversible reactions within the Reaction-ensemble Monte Carlo framework (RxMC). To validate the algorithm, we simulated the polycondensation reactions, illustrated in Fig.1 (top). These reactions are common in polymer chemistry, and analytical predictions of the distribution of chain lengths at equilibrium are available, serving as an ideal test case for numerical simulations. Starting from the free monomers, we let the system evolve towards equilibrium, resulting in an ensemble of chains of various chain lengths, depending on the value of the equilibrium constant of the reaction. By comparing our simulation results with the theoretical predictions, we investigate the limitations of the algorithm, possible finite-size effect, and efficiency of its implementation. After initial validation, this reaction algorithm will be implemented in the ESPResSo simulation software (www.espressomd.org) that will enable its application to a broad class of problems involving reversible association reactions.

## CPP 12.25 Mon 18:00 P1

**Modelling electrode interfaces via multi-scale simulations** — •HENRIK KON-STANTIN JÄGER, PHILIPP STÄRK, and ALEXANDER SCHLAICH — Stuttgart Center for Simulation Science (SC SimTech), University of Stuttgart, Germany

We investigate the interactions of ions at a graphene interface via first-principle simulations using ab initio molecular dynamics. In a multi-scale approach we employ first principle calculations to parametrize semi-classical electrode models based on the Tomas-Fermi screening approach, allowing to access dynamics and adsorption at common electrode-electrolyte interfaces.

 $CPP \ 12.26 \quad Mon \ 18:00 \quad P1 \\ \mbox{Combined first-principles statistical mechanics approach to sulfur structure in organic cathode hosts for polymer based lithium-sulfur (Li-S) batteries — •YANNIK SCHÜTZE^{1,2}, RANIELLE OLIVEIRA DE SILVA^{1,3}, JIAOYI NING¹, JÖRG RAPPICH¹, YAN LU^{1,3}, VICTOR G. RUIZ¹, ANNIKA BANDE³, and JOACHIM DZUBIELLA^{1,4} — ¹Helmholtz-Zentrum Berlin für Energie und Materialien GmbH, Germany — ²Freie Universität Berlin, Germany — ³Universität Potsdam, Germany — ⁴Albert-Ludwigs-Universität Freiburg, Germany$ 

Polymer-based batteries that utilize organic electrode materials are considered viable candidates to overcome the common drawbacks of lithium-sulfur (Li-S) batteries. A promising cathode can be developed using a conductive, flexible, and free-standing polymer, poly(4-thiophen-3-yl)benzenethiol) (PTBT), as the sulfur host material. Here, we present a combination of electronic structure theory and statistical mechanics to characterize the structure of the initial state of the charged cathode on an atomic level. We perform a stability analysis of differently sulfurized TBT dimers as the basic polymer unit calculated within density-functional theory (DFT) and combine this with a statistical binding model for the binding probability distributions of the vulcanization process. This multi-scale approach allows us to bridge the gap between the local description of the covalent bonding process and the derivation of the macroscopic properties of the cathode.

CPP 12.27 Mon 18:00 P1

Correcting Coarse-Grained Dynamics of Molecular Liquids and Their Mixtures Using an Efficient Iterative Memory Reconstruction Method — •MADHUSMITA TRIPATHY, VIKTOR KLIPPENSTEIN, and NICO FA VAN DER VEGT — Eduard-Zintl-Institut für Anorganische und Physikalische Chemie, Technische Universität Darmstadt, 64287 Darmstadt, Germany

Generalized Langevin equation (GLE) based coarse-grained (CG) models are considered to be the most reliable models for dynamically consistent coarsegraining [1]. However, their implementation in molecular simulation is not straight-forward owing to their inherent complexity [2]. With an aim to employ computationally tractable GLE based CG models for dynamic coarse graining of complex molecular systems, we coarse-grain two molecular liquids and their mixtures at various compositions following a novel iterative optimization scheme. Using the memory kernel from an isotropic GLE model as a starting point, we use an efficient iterative memory reconstruction method, which can closely reproduce the underlying fine-grained (FG) dynamics, assessed in terms of the velocity auto-correlation function, within a few iterations. We use this iterative method to correct the artificial dynamic speed-up in CG molecular dynamics (MD) simulations of pure molecular liquids and the relative dynamic speed-up in their mixtures. Furthermore, we investigate the transferability of the resulting memory kernels to molecular mixtures with varying composition. [1] Klippenstein et al. J. Phys. Chem. B 125 (19), 4931-4954 [2] Glatzel and

## CPP 12.28 Mon 18:00 P1

Aggregation of flexible-semiflexible multiblock-copolymers in a dilute solution: MD simulation — •VIKTOR IVANOV^{1,2}, ELIZAVETA SIDLER², JULIA MARTEMYANOVA², TIMUR SHAKIROV¹, and WOLFGANG PAUL¹ — ¹Martin-Luther-University Halle-Wittenberg, Institute of Physics, 06099, Halle, Germany — ²Moscow, Russia

We study aggregation of several regular multi-block copolymer chains in a dilute solution. Chains consist of flexible (F) and semi-flexible (S) blocks with equal composition of F- and S-units having different affinity to a solvent, which is poor for both components. We use coarse-grained MD simulation. Our main goal is to find conditions (values of model parameters) for a shape-persistent aggregation of globules with different non-trivial globular morphologies which are formed in poor solvent, including structures with high orientational ordering of S-blocks and with micro-segregation of S- and F-blocks. Stable aggregates of the following highly anisotropic morphologies have been obtained: "core-shell", "bundle", "dumbbell", "disk", worm-like micelles ("tubes"). The driving forces for formation of structured globules and their anisotropic aggregates are usual van-der-Walls interactions, block length and intramolecular stiffness (there are no specific interactions in our model). We acknowledge the financial support from RFBR (grant 19-53-12006-NNIO-a) and DFG (project PA 473/18-1) and thank Moscow State University Supercomputer Center for providing computational resources.

### CPP 12.29 Mon 18:00 P1

A combined experimental-theoretical study of azo-SAM restructuring under light stimulus: New insights — Alexey Kopyshev^{1,2}, Amrita Pal¹, Svetlana Santer², and •Olga Guskova¹ — ¹IPF Dresden, 01069 Dresden, Germany — ²University of Potsdam, 14469 Potsdam, Germany

The topography transformation of the self-assembled (SAM) layers of azobenzene (azo) surfactant [1] on mica is studied using AFM and modeled in all-atom MD simulations. Under blue light, when azo adopts the trans-state, the smooth SAMs are formed. Under UV stimulus due to a shift in equilibrium between trans and cis isomers, a rapid change in the topography of SAMs occurs. Subsequent blue light irradiation leads to the stabilization of SAMs and smoothing of the upper layers. The explanation of the layer restructuring/mass transport is proposed in simulations. First, we observe that the cis isomers diffuse slower within the adsorbed layers. Second, the expulsion of the cis isomers from SAM is detected independently of the layer compositions. Third, the vertical diffusion for trans isomers is negligible, whereas for cis-state it is comparable to diffusion within the layer. Thus, the change in the topography of SAMs under UV light seen in AFM is related to the vertical diffusion of cis azo. The work is supported by DFG (project GU1510/5-1). [1] Titov E. et al. ChemPhotoChem 5 (2021) 926.

Molecular switch based on bithiophene-azobenzene: How to control conductance through the monolayer using light — •VLADYSLAV SAVCHENKO and OLGA GUSKOVA — IPF Dresden, 01069 Dresden, Germany

Molecular switches based on azobenzene (azo) are defined as light-responsive molecules which can change between two configurational states. Responsive azo monolayers can be used to modulate the work function of the electrodes. In this study, we investigate using DFT what happens to the structures, electronic properties, and the charge redistribution within azo-bithiophene (azo-bt) monolayers depending on the light stimulus. Two types of switches differing in the order of azo and bt counting from the anchor group are modeled: azo-bt and bt-azo. Bt-azo switch is known from the literature [1], while the azo-bt is a product of rational design [2]. We study trans- and cis-isomers for each switch being in a contact with a gold cluster (C-AFM tip). A giant ON/OFF conductance ratio upon UV light observed in the experiment [1] results from an improved electronic coupling between the cis-isomers and the gold tip (ON-state) [1]. The trans-isomers of the simulated switches play the role of the insulators (OFF-state). Moreover, we show which molecular properties are enhanced by molecular design. This study opens up new avenues for the development of the rational design of electrode surface modifications. The work is supported by DFG, project GU1510/5-1. [1] Smaali K. et al. ### CPP 12.31 Mon 18:00 P1

Non-invasively induced amphiphilic self-assemblies from orthogonally switchable block copolymers — •PEIRAN ZHANG¹, RENÉ STEINBRECHER², ANDRE LASCHEWSKY^{2,3}, PETER MÜLLER-BUSCHBAUM⁴, and CHRISTINE M. PAPADAKIS¹ — ¹Fachgebiet Physik weicher Materie, Physik-Department, TU München, Garching — ²Institut für Chemie, Universität Potsdam — ³Fraunhofer IAP, Potsdam-Golm — ⁴Lehrstuhl für Funktionelle Materialien, Physik-Department, TU München, Garching

Amphiphilic self-assemblies arising from orthogonally switchable block copolymers are promising candidate in drug delivery, due to their structure and transformation diversity, which is superior to the presently most studied singly responsive copolymers [1]. To induce this process completely non-invasively, light in combination with temperature is utilized as the stimulus. Introduction of suitable photoactive functional groups could modulate the LCST of the copolymer, thereby achieving the stage that all aggregate scenarios could be concluded in a certain temperature range. For characterization of the copolymer structure, measurements are implemented by dynamic light scattering (DLS), small angle X-ray scattering (SAXS) and -neutron scattering (SANS), while the phase behavior as well as phase transition kinetics are investigated by the time-resolved scattering methods.

#### CPP 12.32 Mon 18:00 P1

Effect of architecture in thermoresponsive methacrylate terpolymers based on PEG analogues — •Feifei Zheng¹, Eirini Melampianaki¹, Wenqi Xu¹, Anna P. Constantinou², Theoni K. Georgiou², and Christine M.  $PAPADAKIS^1 - {}^1Physics$  Department, Technical University of Munich, Garching, Germany — ²Department of Materials, Imperial College, London, England The LCST polymers have attracted great interest for the biomedical sectors, as they have the advantage of being water-soluble at room temperature, while they can form a gel at body temperature [1]. Here, we address the effect of polymer architecture of poly(ethylene glycol) based thermoresponsive terpolymers featuring A, B and C blocks. These consist of the hydrophilic oligo(ethylene glycol) methyl ether methacrylate (OEGMA300, A), hydrophobic n-butyl methacrylate (B), and thermoresponsive di(ethylene glycol) methyl ether methacrylate (C). Several architectures have been synthesised via group transfer polymerisation, varying from statistical, to gradient to block structures. The results from dynamic light scattering indicate that the BABC tetrablock terpolymer and ABC gradient polymer form smaller micelles than ABC triblock terpolymer. This difference points to the importance of the exposed OEGMA300 block for micelle stabilization: bending it back in the BABC architecture enhances the effect of the thermoresponsive block on the thermal behavior.

CPP 12.33 Mon 18:00 P1

Unique colorimetric response of polydiacetylene-Na⁺ microcrystals for detection of hydrochloric acid by naked eye — •RUNGARUNE SAYMUNG¹, CHRISTINE M. PAPADAKIS², NISANART TRAIPHOL³, and RAKCHART TRAIPHOL¹ — ¹School of Materials Science and Innovation, Faculty of Science, Mahidol University, Nakhon Pathom, Thailand — ²Physics Department, Technical University of Munich, Garching, Germany — ³Materials Science Department, Faculty of Science, Chulalongkorn University, Bangkok, Thailand

Polydiacetylenes (PDA), a class of conjugated polymers, are very promising as colorimetric sensors because the change of the color can be easily observed. The commercially available PDA with carboxylic head groups changes color from blue at acidic to red in basic condition. To develop this class of materials for pH sensing applications, many research groups synthesize PDA-based materials by structural modification or addition of foreign materials. Studies by our research group illustrate that incorporating ZnO nanoparticles with PDAs lead to colorimetric response to both acids and bases. Herein, we explore a new route by introducing Na⁺ ions into the PDA system. Upon exposure to hydrochloric acid (HCl) solution, the PDA-Na microcrystals exhibit a unique red to blue color-transition, which has never been observed before. To understand the origins of this behavior, various techniques are employed including Fourier-transformed infrared spectroscopy (FT-IR), scanning electron microscope (SEM), and X-ray diffraction (XRD).

## CPP 12.34 Mon 18:00 P1

Anionic surfactant detection using polydiacetylene-based nanocomposites — •WATSAPON YIMKAEW¹, CHRISTINE M. PAPADAKIS², RAKCHART TRAIPHOL³, and NISANART TRAIPHOL¹ — ¹Laboratory of Advanced Chromic Materials, Department of Materials Science, Faculty of Science, Chulalongkorn University, Bangkok, Thailand — ²Physics Department, Technical University of Munich, Garching, Germany — ³Laboratory of Advanced Polymer and Nanomaterials, School of Materials Science and Innovation, Faculty of Science, Mahidol University, Nakhon Pathom, Thailand

Polydiacetylenes (PDAs) are color-responsive polymers to various stimuli. The development of PDAs as anionic surfactant sensors by structural modification involved complicated and costly processes. In this study, we introduce a facile approach for preparing polydiacetylene/zinc (II) ion/zinc oxide (PDA/Zn2+/ZnO) nanocomposites utilized for anionic surfactant detection. Cationic surfactant, cetyltrimethylammonium bromide (CTAB) is incorporated into the nanocomposites via a simple mixing process to adjust their color transition behaviors. Addition of CTAB at 1 mM induces the blue-to-yellow color transition of the nanocomposites. Interestingly, the nanocomposites exhibit yellow-to-red color transition in response to sodium dodecyl sulfate (SDS). This demonstrates the ability of the nanocomposites as anionic surfactant sensors. A key mechanism of the color transition is the interaction between CTAB and SDS, which induces perturbation in the outer layers of the nanocomposites.

#### CPP 12.35 Mon 18:00 P1

Tunable morphologies in charged multiblock terpolymers in thin film geometry: effect of solvent vapor annealing — •BAHAR YAZDANSHENAS¹, FLORIAN A. JUNG¹, MAXIMILIAN SCHART¹, CONSTANTINOS TSITSILIANIS², and CHRISTINE M. PAPADAKIS¹ — ¹Technische Universität München, Physik-Department, Fachgebiet Physik weicher Materie, Garching, Germany — ²University of Patras, Department of Chemical Engineering, Patras, Greece

Thin films of a pentablock terpolymer with a symmetric architecture of two types of pH-responsive midblocks and short hydrophobic end blocks are investigated. As-prepared spin-coated films from different pH-values have previously shown highly tunable and non-monotonous behavior of the lateral structure sizes, based on the charge [1]. However, with the high glass transition temperatures of the middle pH-responsive block and the hydrophobic end blocks, the films were not necessarily in equilibrium. Here, we investigate further accessible morphologies by swelling the films in the vapors of solvents having different selectivity. Results from spectral reflectance and atomic force microscopy suggest that water (exclusively swelling the pH-responsive blocks) leaves the nanostructures intact, while methanol (swelling all blocks) results in a reorganization. Mixtures of these vapors allow to tune the solubilities of the blocks and thus to find the minimum amount of methanol needed for equilibration.

Transport of thin water films: from thermally activated random walks to hydrodynamics — SIMON GRAVELLE¹, CHRISTIAN HOLM¹, and •ALEXANDER SCHLAICH² — ¹Institute for Computational Physics, University of Stuttgart, Germany — ²Stuttgart Center for Simulation Science (SC SimTech), University of Stuttgart, Germany

Under ambient atmospheric conditions, a thin film of water wets many solid surfaces, including insulators, ice, and salt. The film thickness as well as its transport behavior sensitively depend on the surrounding humidity. Understanding this intricate interplay is of highest relevance for water transport through porous media, particularly in the context of soil salinization induced by evaporation. Here, we use molecular simulations to evaluate the transport properties of thin water films on prototypical salt and soil interfaces.

Our results show two distinct regimes for water transport: at low water coverage, the film permeance scales linearly with the adsorbed amount, in agreement with the activated random walk model. Finally, in the context of water transport through porous material, we determine the humidity-dependent crossover between a vapor dominated and a thin film dominated transport regimes depending on the pore size.

## CPP 12.37 Mon 18:00 P1

**Predicting static wetting morphology of aqueous drops on lubricated surface** — •SHIVAM GUPTA, BIDISHA BHATT, MEENAXI SHARMA, and KRISHNACHARYA KHARE — Indian Institute of Technology Kanpur, Kanpur, India

Static wetting behavior of liquid drops on thin liquid-coated solid surfaces is very different compared to dry solid surfaces. Conventionally, the equilibrium wetting behavior on deformable (soft or thin liquid coated) surfaces is characterized by the Neumann's contact angle, which solely depends on the various interfacial energies of the participating phases. However, due to the difficulty in identifying the Neumann's point, it is often convenient to define apparent contact angles on such surfaces. By controlling the various interfacial energies, drops can be either made to directly contact the substrate or float on the thin liquid layer supported by the substrate resulting in different apparent angles and thus different wetting morphology. Although such systems are highly prevalent, however, to our knowledge, there is no study reported to date that can beforehand predict the static wetting behavior and the quasi-static interfacial profiles as a function of various system parameters, e.g., substrate wettability, thickness of the liquid film, and drop volume. We propose a method to beforehand predict the interfacial profiles using numerical computation with Surface Evolver software. Experimental studies are also performed to validate the simulations. A good quantitative agreement is found for the variation of the drop contact angle as a function of various systems parameters.

## CPP 12.38 Mon 18:00 P1

In-situ white light, near infrared spectroscopy on thin films and photonic crystals of nanoporous silicon during liquid imbibition — •GUIDO DITTRICH^{1,2}, RAUL URTEAGA³, and PATRICK HUBER^{1,2} — ¹Hamburg University of Technology, Institute of Materials and X-Ray Physics, 21073 Hamburg, Germany — ²Deutsches Elektronen-Synchrotron DESY, Centre for X-Ray and Nano Science CXNS, Hamburg, Germany — ³IFIS-Litoral (Universidad Nacional del Litoral-CONICET), Guemes 3450, 3000 Santa Fe, Argentina

Nanoporous materials offer a high specific surface area and spatial confinement. Scientists are aiming to abuse these properties for functional materials in a variety of fields, e.g. thermoelectrics, catalysis, Lab-on-a-Chip as well as energy storage and harvesting applications. Understanding the fundamental transport mechanisms on the nanoscale is required and drives the progress. We present a method to measure liquid imbibition in nanoporous silicon (np-Si) with a resolution even resolving spreading of ultra-thin precursor films in nanopore space with a time resolution of microseconds. Therefore, a photonic crystal (PC) is etched in at a chosen height during the fabrication. The PC has a specific resonance wavelength, which can be monitored with white light spectroscopy. Imbibition by fluids, in our case oligostyrenes, into the central defect of the PC changes the effective refractive index and causes a proportional shift of the resonance wavelength. This offers very localized information on the nanopore filling at the position of the PC. Producing only thin np-Si films, one can measure the shift of the thin film interference with a NIR-spectrometer simultaneously.

## CPP 12.39 Mon 18:00 P1

Single-nanochannel X-ray diffraction on the liquid crystal C8BTBT confined in anodic aluminium oxide membranes — •MARK BUSCH^{1,2}, ZHUOQING LI^{1,2}, MILENA LIPPMANN², ANDREAS SCHROPP², JOHANNES HAGEMANN², CHRISTIAN SCHROER^{2,3}, and PATRICK HUBER^{1,2} — ¹TU Hamburg, Institut für Material- und Röntgenphysik — ²Deutsches Elektronen-Synchrotron DESY — ³Universität Hamburg

We investigate the self-assembly of the liquid crystal C8BTBT within anodic aluminium oxide (AAO) nanochannels in dependence of channel wall chemistry and the diameter of the channels from 60 to 180 nm. Conventional X-ray diffraction experiments use a comparatively large beam and therefore deliver a structural information which is averaged over a large number of nanochannels. In contrast here we investigate the structure of liquid crystals within individual nanochannels by employing an X-ray beam with a diameter in the nanometre range.

## CPP 12.40 Mon 18:00 P1

Investigation of the charge transport of ionic liquid post-treated PEDOT:PSS thin films with in-situ surface plane impedance spectroscopy, under the influence of varying temperature and humidity — •TOBIAS SCHÖNER¹, ANNA LENA OECHSLE¹, and PETER MÜLLER-BUSCHBAUM^{1,2} — ¹Lehrstuhl für Funktionelle Materialien, Physik- Department, Technische Universität München, James-Franck-Straße 1, 85748 Garching, Germany — ²Heinz Maier-Leibnitz-

Zentrum (MLZ), Technische Universität München, Lichtenbergstr. 1, 85748 Garching, Germany

Thermoelectric materials based on polymers are attractive due to their largescale and low cost processability, high mechanical flexibility, low or no toxicity, lightness and intrinsically low thermal conductivity. One highly investigated polymer with promising thermoelectric properties is poly(3,4-ethylene dioxythiophene):poly(styrene sulfonate) (PEDOT:PSS). The post-treatment of PEDOT:PSS thin films with ionic liquids (ILs) enhances the thermoelectric properties for the practical application by simultaneously improving the interdomain conductivity and optimizing the charge carrier concentration. Our recent investigation focuses on the influence of the environmental parameters temperature and humidity on the electronic and ionic charge transport properties in the thin films. For this, the thermoelectric films are contacted with a self-built setup in a planar way and inserted into a humidity chamber. By using a potentiostat surface-plane Galvanostatic Electrochemical Impedance Spectroscopy (GEIS) measurements under alternating humidity and temperature can be performed.

CPP 12.41 Mon 18:00 P1

**Optimization Strategies for Purely Organic Room-Temperature Phosphorescence** — •HEIDI THOMAS and SEBASTIAN REINEKE — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute for Applied Physics, TU Dresden

The development of organic materials displaying room-temperature phosphorescence (RTP) with lifetimes in the range of several hundred milliseconds is a research field that has attracted more and more attention in the last years. By using amorphous purely organic systems, we have been able, for example, to develop programmable luminescent tags. Still, the potential of such emitter systems is far from being exploited. We present a new family of organic luminescent derivatives embedded in amorphous matrices with phosphorescence lifetimes up to 2.6 s, extending their applicability. Hydrogen bonds between the emitters and the matrix presumably suppress vibrational dissipation, thus enabling bright long-lived phosphorescence. Further optimization of the host:emitter system is related to the film preparation technique. By varying host polymer, postannealing temperature, and fabrication procedure, we analyze the phosphorescent lifetime, the photoluminescent quantum yield, and the phosphorescenceto-luminescence ratio. The film thickness turns out to affect the performance the most: Going from thin to thick spin-coated films, the phosphorescence lifetime could be increased by a factor of up to 2.5.

## CPP 12.42 Mon 18:00 P1

Investigating the Impact of Surfactants on Perovskite Crystallization during Thin Film Solution Processing Using In Situ Optical Spectroscopy — •TOBIAS SIEGERT, SIMON BIBERGER, KONSTANTIN SCHÖTZ, and FABIAN PANZER — University, Bayreuth, Germany

Recent reports have shown that adding surfactants in the solution processing of halide perovskites, e.g. by blade-coating, can improve their morphology and optoelectronic properties[1]. In general the crystallization processes of halide perovskites that occur during thin film formation largely determine the final film morphology. Thus, here we investigate the change in crystallization dynamics upon addition of surfactants to the solution processing of halide perovskites. We monitor the film formation processes by multimodal optical in situ spectroscopy[2], so that detailed insights about the film formation process of halide perovskites can be gained[3,4]. This finally allows us to elucidate the exact role and the impact of the presence of surfactants during solution processing on the crystallization behavior of the perovskite.

CPP 12.43 Mon 18:00 P1 Fabrication and Characterisation of Two-Step Slot-Die Coated Methylammonium-Formamidinium Lead Iodide Perovskite Solar Cells — •THOMAS BAIER, MANUEL A. REUS, LENNART K. REB, and PETER MÜLLER-BUSCHBAUM — TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching

Perovskite solar cells (PSCs) are very promising in contributing in the renewable energy mix of the future. They have high power conversion efficiencies and are made of low-cost materials. Especially in combination with slot-die coating as promising thin-film deposition technique for organic-inorganic hybrid perovskite materials, they offer the chance for fast and cheap roll-to-roll solar cell production.

In this work two-step slot-die coated lead iodide layers and slot-die coated methylammonium-formamidinium iodide perovskite solar cells have been prepared. Depending on slot-die coating parameters and additives used in the ink that enhance thin-film formation and optoelectronic properties of the final perovskite semiconductor absorber, morphology changes are observed in the final film. The morphology is investigated by reciprocal (X-ray diffraction) and realspace methods (SEM). Furthermore, the two-step slot-die coated solar cells are produced and characterized via their respective performance parameters.

#### CPP 12.44 Mon 18:00 P1

First-principles study of the electronic and optical properties of perovskite solution precursors — •FREERK SCHÜTT¹, ANA M. VALENCIA^{1,2}, and CATERINA COCCH1^{1,2} — ¹Institut für Physik, Carl von Ossietzky Universität Oldenburg — ²Humboldt-Universität zu Berlin und IRIS Adlershof, Berlin

Metal halide perovskites have shown great promise for next-generation optoelectronic applications but the predominant employment of Pb poses a problem in terms of environmental sustainability of these compounds. Replacing Pb with Sn represents a viable solution, however, despite recent efforts in this direction [1], knowledge of Sn-based perovskites and precursors is to date still insufficient. In a first-principles work based on time-dependent density-functional theory coupled to the polarizable continuum model, we systematically investigate electronic and optical properties of SnI2M4 complexes, with M being common solvent molecules. We find that the structural, electronic, and optical properties are strongly affected by the choice of the solvent. By rationalising the behavior of 15 of such compounds even in comparison with lead-halide counterparts [2,3], we provide useful indications to complement experiments in the choice of the solvent molecules for SnI₂-based solution complexes and in their characterization towards the production of thin films. ## CPP 12.45 Mon 18:00 P1

Ionic liquids tailoring crystal orientation for stable and high fill factor perovskite solar cells — •Yuqin Zou¹, Lukas V Spanier¹, Julian E Heger¹, SHANSHAN YIN¹, CHRISTOPHER R EVERETT¹, and PETER MÜLLER-BUSCHBAUM MÜLLER-BUSCHBAUM^{1,2} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²MLZ, TU München, 85748 Garching Ionic liquids with superior electrical conductivity and thermal stability are used as effective and practical dopants to improve the long-term operation stability and the photovoltaic performance of perovskite solar cells (PSCs). We study different ionic liquids in the perovskite component. Using grazing-incidence wideangle X-ray scattering (GIWAXS), we discover that the incorporation of ionic liquids is beneficial for obtaining homogeneous spherical nano-particle films and tuning the film crystal orientation. We select 1-butyl-1-methylpyrrolidinium tetrafluoroborate (Pyr13BF4) as the main additive to investigate the charge carrier dynamic behavior of PSCs underdoped with Pyr13BF4 using TRPL, TPC, TPV and OCVD methods. In addition to enhancing the fill factor and optimizing energy level alignment, this additive promotes charge transfer and extraction, reduces the charge carrier accumulation in the bulk, and retards recombination. Under ambient atmosphere, the un-encapsulated PSCs retain 97% of their initial efficiencies for 4368 h.

## CPP 12.46 Mon 18:00 P1

Improving morphology and efficiency of slot-die coated perovskite solar cells — •Christoph G. Lindenmeir¹, Andrea Vitaloni¹, Lennart K. Reb¹, MANUEL A. REUs¹, and PETER MÜLLER-BUSCHBAUM^{1,2} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²MLZ, TU München, 85748 Garching

During the last years perovskite solar cells (PSCs) received high attention in industry and research for sustainable power production. Especially due to their low material costs, low weight, high power conversion efficiencies, and the possibility to fabricate them via simple solution-based deposition techniques like slot-die coating or spray coating. Because of the possibility of up-scaling and using minimal material, slot-die coating is one of the most promising techniques to produce high efficiency PSCs. In this work, we compare the properties of slot-die coated PSCs with different perovskite compositions. The perovskite layer is printed out of a solution, containing different ratios of lead iodide (PbI2), methylammonium iodide (MAI), formamidinium iodide (FAI), and methylammonium chloride (MACl) in a solvent mixture of 2-methoxyethanol (2-ME) and dimethyl sulfoxide (DMSO). To improve the film quality of the printed perovskite layer, the influence of nitrogen gas quenching is extensively studied and the print process optimized. The resulting high-quality thin films are analyzed with optical and structure characterization methods like spectroscopy and X-ray scattering methods. For further information, current-voltage and external quantum efficiency measurements are carried out.

## CPP 12.47 Mon 18:00 P1

Slot-die coated perovskite quantum dot layers for solar cell application — •Ahmed Krifa¹, Manuel A. Reus¹, Lennart K. Reb¹, and Peter Müller-Buschbaum^{1,2} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²MLZ, TU München, 85748 Garching

Perovskite quantum dots (PQDs) are semiconductor nanocrystals that have received tremendous attention in photovoltaic devices due to their exceptional optical and electronic properties. PQD solar cells (PQDSCs) have shown great potential to overcome many drawbacks of their large-grain perovskite thin-film (often called bulk) counterparts, such as high defect tolerance and better stability due to the controlled surface properties of the quantum dots. Over the past few years, PQDSCs have shown a quick increase in efficiency, already exceeding 16%, and high stability. However, the fabrication of these solar cells is based on the spin-coating technique, which leads to significant waste. In this work, we develop and optimize a printing process for PQDs layers and study them with various techniques such as UV-Vis, scanning electron microscopy and Xray diffraction to achieve an up scalable fabrication of PQDSCs.

## CPP 12.48 Mon 18:00 P1

In situ study of supperlattice self-assembly during printing of perovskite quantum dot films for solar cell applications — •DAVID P. KOSBAHN¹, MANUEL A. REUS¹, and PETER MÜLLER-BUSCHBAUM^{1,2} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²MLZ, TU München, 85748 Garching

Research into quantum dots (QDs) of lead halide perovskites (LHPs) has become increasingly popular due to their stability and tunable optoelectronic properties. Their controllable surface chemistry and simple preparation make them a promising alternative to bulk perovskite solar cells. The power conversion efficiency (PCE) of  $Cs_xFA_{1-x}PbI_3$  QD solar cells (QDSCs) has been steadily rising, up to a recent record efficiency surpassing 16%. However, the orientation and self-assembly of the colloidal precursor into a superstructure is not yet well-understood. In this work, we study the formation of perovskite QD films using in situ grazing-incidence wide-angle X-ray scattering (GIWAXS) in real time, to achieve a better understanding of the kinetics involved in their fabrication.

## CPP 12.49 Mon 18:00 P1

**Operando study of light and moisture induced degradation of perovskite so**lar cell — •KUN SUN¹, JULIAN E. HEGER¹, MANUEL A. REUS¹, XINYU JIANG¹, LUKAS V. SPANIER¹, SIGRID BERNSTORFF², and PETER MÜLLER-BUSCHBAUM^{1,3} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²Elettra-Sincrotrone Trieste, 34149 Basovizza — ³MLZ, TU München, 85748 Garching

Perovskite solar cells (PSCs) are among the most promising photovoltaic technologies and reached a certified 25.5% efficiency owing to their tuneable bandgap, high charge carrier mobility, long diffusion length and so on. The longterm operational stability of PSCs, however, has been not investigated. Herein, we probe the structure change with grazing-incidence small-angle scattering and solar cell performance under 1-sun illumination and high humidity. We find that PSCs fabricated with and without caesium iodide (CsI) show differences in the device degradation and morphology change. The decrease of open-circuit voltage (VOC) can be attributed to the morphology changes and the evolution of crystallize grain size. With the additive of CsI, solar cells show slow decay of VOC, correlated to improved morphology of active layer and passivation of trap states. Our work presents a crucial step towards a fundamental understanding of morphology change combined with solar cell parameters during the device operation.

#### CPP 12.50 Mon 18:00 P1

Non-invasive characterization of degradation in inverted planar perovskite solar cells via reflectance and optical modelling. — •CHIKEZIE WILLIAMS UGOKWE^{1,2}, KEHINDE OGUNMOYE^{1,2}, ULRICH S. SCHUBERT^{1,2}, and HARALD HOPPE^{1,2} — ¹Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich Schiller University Jena, Philosophenweg 7a, 07743 Jena, Germany — ²Institute for Organic and Macromolecular Chemistry (IOMC), Friedrich Schiller University Jena, Humboldtstrasse 10, 07743 Jena, Germany Despite gains in efficiency since their discovery a little more than a decade ago, hybrid perovskite solar cells (PSCs) are still plagued by poor stability. This poor stability also interferes with their characterization to the point where widely used and easily applicable methods of studying in situ degradation, such as scanning electron microscopy, X-ray diffraction, impact the result because they are invasive and introduce some forms of degradation themselves.

We pursued a non-invasive approach for characterizing the evolution of degradation in PSCs using a combination of optical characterization, modelling, and simulation. Using a software package for coherent light propagation in thin film layer stacks, reflectance and transmittance spectra were used to model the complex refractive index of each functional layer. The evolution of degradation was then studied for ageing methylammonium PSC using periodically measured reflectance data. We will discuss if the evolution of lead iodide, the undoubtable by-product of degradation can be detected using optical simulation.

## CPP 12.51 Mon 18:00 P1

Charge Carrier Properties of Cs₂AgBiBr₆ in Thin Films for Perovskite Solar Cells — •Tim P. Schneider, Jonas Horn, and Derck Schlettwein — Justus-Liebig-Universität Gießen, Institut für Angewandte Physik

The double perovskite  $Cs_2AgBiBr_6$  is regarded as a potential candidate to replace the toxic lead perovskites currently used in perovskite solar cells and can potentially be used for photo- and x-ray detection. For any such technical application the electrical properties of the double perovskite play an important role. Therefore, the charge transport in  $Cs_2AgBiBr_6$  was systematically studied in different sample geometries. Thin films were prepared onto micro-structured interdigitated metal electrode arrays as well as sandwiched between different electronconducting or hole-conducting layers that are often used in perovskite solar cells, to achieve single-carrier-devices. Aside from estimates of the conductivity and a discussion of possible trapping of charge carriers, the obtained current-voltage characteristics yielded insights into contact formation, hysteresis and intrinsic ion migration. Further, atomic force microscopy showed a strong influence of the underlying substrate on the morphology of the  $Cs_2AgBiBr_6$  thin films.

#### CPP 12.52 Mon 18:00 P1

Decoding the Self-assembled Plasmonic Nano-structure in Colloidal Quantum Dots for Photodetectors — •TIANFU GUAN, WEI CHEN, CHRISTIAN L. WEINDL, SUZHE LIANG, and PETER MÜLLER-BUSCHBAUM — Technische Universität München, Physik-Department, Lehrstuhl für Funktionelle Materialien, James-Franck-Straße 1, 85748 Garching, Germany

Hybrid plasmonic nanostructures have raised great interest for being used in a variety of optoelectronic devices, due to the surface plasmon resonance (SPR). Charge carriers trapped in colloidal quantum dots (QDs) at localized surface defects is a key issue in photodetectors. Self-assembled hybrid metal/quantum dots can couple plasmonics and quantum properties to photodetectors and modify their functionality. Arranged and localized hybrid nanostructures impact on excitons traps and light harvesting. Here, we demonstrate a coupling hybrid structure using self-assembled gold nanoparticles (Au NPs) doped in PbS QDs solid for mapping the interface structures and the motion of excitons. Grazing incidence small angle X-ray scattering (GISAXS) was used to characterize the order of the Au NPs in the hybrid structure. Furthermore, by correlating the sizes of the Au NPs in the hybrid structure with corresponding differences in photodetector performance, we could obtain the interface carriers trapping influences in the coupling structure.

## CPP 12.53 Mon 18:00 P1 Einfluss von CO2 auf die Zusammensetzung von Produkten bei der Hydrierung von Kohlenstoffoxiden an einem Katalysator mit GdFeO3-Perowskitstruktur — •POLINA AKHMINA — Moscow, Russia

Heute stehen viele Menschen in der Welt vor der Notwendigkeit, den ständig wachsenden Energiebedarf zu decken. Einen wichtigen Platz nimmt die Energie von Kohlenwasserstoffen ein, eine der vielversprechenden Methoden zu deren Synthese ist die Fischer-Tropsch-Synthese. Bakannte Katalysatoren für die Fischer-Tropsch-Synthese sind Verbindungen auf Eisen- und Kobaltbasis, auch komplexe Oxide mit der ABO3-Perowskitstruktur (A-Kation eines Alkali- oder Seltenerdmetalls, B - Übergangsmetallkation) finden ihre Anwendung. Es wurde ein Experiment mit der Feststellung der Wirkung der Einführung von Kohlendioxid in die Zusammensetzung des Synthesegases CO:H2 durchgeführt. Das Reaktionsgemisch wurde auf einem Gaschromatographen mit einer Edelstahlsäule analysiert, die Menge der Produkten wurde aus der Fläche der chromatographischen Peaks bestimmt. Als Ergebnis wurde erfahren, dass, im Fall wenn der Gehalt von CO2 in der Reaktionsmischung 17 % ist (Verhältnis der Reagenzien (CO:CO2): H2 = (1:1:2)), im Vergleich zu der Reaktionsmischung ohne Kohlendioxid, ist eine Erhöhung der Menge der gebildeten leichten Olefinen und eine Erhöhung der Olefin/Paraffin-Verhältnisse bemerkt. Außerdem gab es eine Verringerung der Umwandlung von CO. Einer der möglichen Gründe für die Verringerung der Umwandlung ist das Auftreten eines Boudouard Nebenreaktion: 2CO = C + CO2

## CPP 12.54 Mon 18:00 P1

Semiconducting Carbon Nitride Thin Films — •Hsu THAZIN MYINT¹, LENNART K. REB¹, MANUEL A. REUS¹, NARENDRA CHAULAGAIN², KARTHIK SHANKAR², and PETER MÜLLER-BUSCHBAUM^{1,3} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²University of Alberta, Department of Electrical and Computer Engineering, Edmonton, AB T6G 1H9, Canada — ³MLZ, TU München, 85748 Garching

Researchers endeavoring for a clean energy resource have focused on a semiconducting material called graphitic carbon nitride  $(g-C_3N_4)$ . The unique property of this material is being environmentally benign due to its metal-free nature, and high solubility in water. Moreover, the earth-abundance of carbon and nitrogen enables easy synthesis at low costs. The astonishing optoelectronic properties, high stability, and absorption in UV-visible region with band-gap energy of 2.7eV render g-C3N4 a prime center for the extensive applications such as solar energy utilization. Fabrication of homogeneous g-C3N4 thin films with tailored thickness and morphology is important to develop novel applications. However, the material deposition to achieve homogeneous thin films is still challenging, rendering information about the bulk material properties essential for device application largely unknown to date. In this work, the low waste and scalable slot-die coating method is fine-tuned to get uniform and high-quality films with good adhesion onto the substrates. The final optimized thin-film properties are studied in terms of spectroscopic, morphological and structural characterization methods.

Comparison of exciton diffusion in organic and inorganic semiconductors — •Dominik Muth, Marina Gerhard, Gregor Witte, Daniel Bischof, and Sebastian Anhäuser — Philipps Universität, Marburg, Deutschland

The mechanisms of exciton and charge carrier transport in organic and inorganic semiconductors differs greatly. To characterize transport processes on the picosecond time scale, a streak camera coupled with a megahertz laser system is employed. The spatio-temporal evolution of the excitation profile is studied at temperatures between 77 K and 295 K. Detailed analysis of the spatial broadening allows us to estimate the underlying exciton diffusion coefficients as a function of time and temperature. In single crystalline tetracene we find evidence for highly dispersive exciton transport, which indicates that excitons populate more localized states on a time scale of a few hundred picoseconds. Moreover, the diffusion coefficients show clear temperature dependence, which will be discussed in this contribution.

#### CPP 12.56 Mon 18:00 P1

**Matrix Influence on the Photodynamics of a TADF-Emitting Molecule** – •BJÖRN EWALD¹, ULRICH MUELLER¹, JONAS GEHRIG¹, JONAS BELLMANN¹, and JENS PFLAUM^{1,2} – ¹Experimental Physics VI, University of Würzburg, 97074 Würzburg – ²ZAE Bayern, 97074 Würzburg

The singlet-triplet dynamics of thermally activated delayed fluorescence (TADF) emitters is of high technological relevance for their application in 3rd generation Organic Light Emitting Diodes. In this respect, the molecular and solidstate properties of the matrix material hosting the molecular TADF-dopant, may drastically influence its confirmation, the related energetics and thus, its rate dynamics and the overall OLED efficiency. By virtue of their dark and long-living nature, spectroscopic access to the population dynamics of involved triplet states in such host-guest systems is not trivial. Here we applied a spectroscopic method, based on transient intensity-modulated photoluminescence (TIM-PL). Resting on a generic three level scheme, this technique yields access to the singlet-triplet population dynamics and the corresponding rates in TADF host-guest blends. We studied the photophysics of the TADF-emitter TXO-TPA doped into matrices with different crystalline order (PMMA and mCP). We can confirm that local matrix effects impose a significant impact on the rate dynamics and the singlet-triplet conversion. Particularly the intersystemcrossing rate can be drastically influenced by the local matrix environment. Hence the data obtained by the TIM-PL method, allow for a more rational selection of suited TADF guestmatrix combinations.

#### CPP 12.57 Mon 18:00 P1

Optically Detected Magnetic Resonance (ODMR) studies on Pentacene doped p-Terphenyl microcrystals — •DOMINIK WINTER¹, BJÖRN EWALD¹, and JENS PFLAUM^{1,2} — ¹Experimental Physics VI, University of Würzburg, 97074 Würzburg — ²ZAE Bayern, 97074 Würzburg

The characteristic wavefunctions of the pentacene triplet states offer the possibility to maintain an asymmetric occupation of the various sublevels even at room temperature. Exposing pentacene single molecules embedded in a crystalline environment to microwaves of suited frequency, a controlled variation in population of the resonant triplet states can be achieved and optically detected - a technique termed optically detected magnetic resonance (ODMR). Here we report on our first results on the triplet polarization of pentacene doped p-terphenyl microcrystals prepared by microspacing in-air sublimation (MAS). By means of zero-field ODMR we analyze the microwave-induced transitions between the contributing triplet states. We will demonstrate and evaluate how the fast and easy method of MAS provides microcrystals that show an enhanced nuclear spin polarization. This process of triplet-induced dynamic nuclear polarization (DNP), is considered a potential approach to enhance the nuclear spin polarization of water and, thus, to significantly improve the image contrast of magnetic resonance imaging (MRI) as well as the sensitivity of non-invasive methods for structural characterization [1].

#### CPP 12.58 Mon 18:00 P1

Dye-induced Fluorescence Quenching of Quantum Dots having Different Excited State Lifetimes and Confinement Potentials — •SALEEM AL-MASKARI¹, ABEY ISSAC¹, EKLAS AL-GHATTAMI¹, SR VARANASI¹, R.G. SUMESH SOFIN¹, and OSAMA K. ABOU-ZIED² — ¹Department of Physics, College of Science, Sultan Qaboos University, Muscat, 123, Oman — ²Department of Chemistry, College of Science, Sultan Qaboos University, Muscat, 123, Oman

We study the role of quantum confinement and the excited-state lifetime on the fluorescence quenching of heavy metal free quantum dots (QDs). Two different types of QDs are selected, namely CuInS2/ZnS (CIS) and InP/ZnS (InP). Quantum confinement in CIS QDs is weak (exciton Bohr radius aB = 4.3 nm versus particle size = 3.5 nm) whereas that in InP QDs is strong (aB = 15 nm versus particle size = 3.9 nm). Moreover, the excited-state lifetime of CIS QDs is ca. 298 ns whereas that of InP QDs is ca. 37 ns. Rhodamine 575 (Rh575) dye molecules adsorbed on the surface of QDs are used as the quencher. Stern-Volmer analysis of steady-state and time-resolved optical spectroscopy data reveal that in CIS-

Rh575 and InP-Rh575 assemblies, although static and dynamic quenching are present, dynamic quenching is dominating. Further, quenching is more efficient in CIS-Rh575 assembly. We propose a model based on the quantum mechanical tunneling of the excited QD electron onto the dye induced surface states and subsequent non-radiative relaxation as the quenching mechanism. In addition, the long-lived excited state of CIS QDs support the tunneling mediated quenching in CIS-Rh575 assembly.

#### CPP 12.59 Mon 18:00 P1

sustainable materials for building-integrated photovoltaics  $- \cdot ZIMEI CHEN^1$ , MARIE BETKER^{1,2}, CONSTANTIN HARDER^{1,3}, BENEDIKT SOCHOR¹, MATTHIAS SCHWARZKOPF¹, DANIEL SÖDERBERG², NADJA KÖLPIN¹, ARIK WILLNER¹, and STEPHAN V. ROTH^{1,2} – ¹Deutsches Elektronen-Synchrotron (DESY), 22607 Hamburg, Germany —  2 KTH Royal Institute of Technology, SE-100 44 Stockholm, Sweden — ³Technische Universität München, 85748 Garching, Germany Cellulose nanofibrils (CNF) as a bio-based material are very attractive due to their resource-saving and renewable property. They are biocompatible, flexible, lightweight, transparent and show excellent mechanical strength. With functionalized properties, they can be used as substrate for incorporating photovoltaic or electronic devices. In this project, we are going for building-integrated photovoltaics. Solar cells with PEDOT:PSS as electron blocking layer, P3HT:PCBM as photoactive layer and ZnO as hole blocking layer will be designed both in standard and inverted devices directly deposited on a CNF composite. A CNF / Ag nanowires mixture can be used as electrode material to improve the conductivity of Ag metal as electrode. Spray deposition will be used as a suitable technique to fabricate such functional layers in a large scale with homogeneous surface and a low roughness. in-situ grazing incidence small- and wide-angle X ray scattering (GISAXS/GIWAXS) will be used to observe the nanostructuring of each layer on the CNF composite base material and to optimize the fabrication process.

#### CPP 12.60 Mon 18:00 P1

**P3HT:PCBM Polymer Solar Cells from a Didactive Perspective** — •SHAHIDUL ALAM¹, AMAN ANAND², MD MOIDUL ISLAM², RICO MEITZNER², AURELIEN SOKENG DJOUMESSI², JOSEF SLOWIK², ZEKARIAS TEKLU², PETER FISCHER³, CHRISTIAN KÄSTNER³, JAFAR I. KHAN¹, ULRICH S. SCHUBERT², FRÉDÉRIC LAQUAI¹, and HARALD HOPPE¹ — ¹King Abdullah University of Science and Technology (KAUST), KAUST Solar Center (KSC), Physical Sciences and Engineering Division (PSE), Kingdom of Saudi Arabia — ²Friedrich Schiller University Jena, Germany — ³Ilmenau University of Technology, Germany

In this work, we studied the influence annealing process on the performance of the common polymer:fullerene bulk heterojunction solar cells with conventional architecture, comprising P3HT:PC60BM blend as a photoactive layer. The non-annealed active layer device exhibited a power conversion efficiency of less than 1%, which was significantly lower than the pre and post-annealed device. In order to investigate the impact of pre and post thermal annealing on the natural morphological state of the polymer, regiorandom and regioregular type P3HT were used in photoactive layers. Changes in solar cell performance were associated with different extraction probabilities due to changed annealing conditions. Several spectroscopic techniques like EL, SS-PL, and TR-PL were employed to comprehend the phenomenon of charge photogeneration processes. Finally, to explore the morphological changes upon annealing, AFM and ELI measurements were performed on films and solar cells, respectively.

#### CPP 12.61 Mon 18:00 P1

Simultaneously enhanced performance and stability of NFA solar cells with **PETMP** interfacial process — •ZERUI L1^{1,2}, CHANGQI MA², and PETER MÜLLER-BUSCHBAUM¹ — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²i-Lab &Printed Electronics Research Center, Suzhou Institute of Nano-Tech and Nano-Bionics, Chinese Academy of Sciences (CAS), Suzhou 215123, P. R. China

With the rapid development of novel non-fullerene acceptors (NFA), the PCE of NFA solar cells has reached over 18.6%, while the poor stability is still the limitation for application. For NFA solar cells, the hydroxyl radicals of ZnO forming under illumination would cause the degradation of the acceptor material, which is one key source for performance decrease. They could be effectively suppressed through modifying ZnO with radical trapping agents, such as 2-phenylethylmercaptan (PET). Unfortunately, PET is highly toxic with a bad smell. Here, PETMP with similar end group as PET is used as the alternative and it's found to be able to suppress the formation of hydroxyl radicals as well as to improve the device stability. Moreover, PETMP can improve the Jsc of devices through promoting the vertical phase separation of the active layer. Lastly, other similar derivatives is also tried and the amount of sulfhydryl is found to be highly important to the enhanced performance and stability, since only molecules with more sulfhydryl groups could work well. The interaction between PETMP and ZnO is the key factor promoting such a benefit. This work provides a perfect interfacial modification agent for more stable NFA solar cells.

#### CPP 12.62 Mon 18:00 P1

Improved hole extraction selectivity of polymer solar cells by combining PE-**DOT:PSS with WO3** — •Aurelien Sokeng Djoumessi^{1,2}, Shahidul Alam^{1,2}, Jose Prince Madalaimuthu^{1,2}, Aman Anand^{1,2}, Josef Slowik^{1,2}, Theo PFLug^{3,4}, Rico Meitzner^{1,2}, Roland Roesch^{1,2}, Enrico Gnecco⁵, Alexander Horn³, Ulrich S. Schubert^{1,2}, and Harald Hoppe^{1,2} — ¹Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich Schiller University Jena, Philosophenweg 7a, 07743 Jena, Germany — ²Laboratory of Organic and Macromolecular Chemistry (IOMC), Friedrich Schiller University Jena, Humboldstrasse 10, 07743 Jena, Germany — ³Laserinstitut Hochschule Mittweida, Hochschule Mittweida, Schillerstraße 10, 09648 Mittweida, Germany ⁴Institut f
ür Physik, Technische Universit
ät Chemnitz, Reichenhainer Straße 70, 09126 Chemnitz, Germany — ⁵Otto Schott Institute of Materials Research, Friedrich Schiller University Jena, Löbdergraben 32, 07743 Jena, Germany Since the device performance and stability of polymer solar cells strongly depend on the interfacial charge extraction layers, we investigated the impact of hole transport layer (HTL) in the devices by varying the HTL material and layer stack systematically between PEDOT:PSS and a sol-gel derived tungsten oxide (WO3). Interestingly there was an increase of the work function upon stack-

ing both materials and the triple layer WO3/PEDOT:PSS/WO3 configuration

resulted in the best device performance and an increased reproducibility in the

lifetime compared to the use of pristine WO3 and PEDOT:PSS

## CPP 12.63 Mon 18:00 P1

Compatible solution-processed interface materials for improving efficiency and prolonging the lifetime of polymer solar cells — •ZHUO XU^{1,2}, JOSE PRINCE MADALAIMUTHU^{1,2}, JOSEF BERND SLOWIK^{1,2}, RICO MEITZNER^{1,2}, SHAHIDUL ALAM^{1,2,3}, ULRICH S SCHUBERT^{1,2}, and HARALD HOPPE^{1,2} — ¹Laboratory of Organic and Macromolecular Chemistry (IOMC), Friedrich Schiller University Jena, Humboldtstraße 10, 07743 Jena, Germany. — ²Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich Schiller University Jena, Philosophenweg 7a, 07743 Jena, Germany. — ³King Abdullah University of Science and Technology (KAUST), KAUST Solar Center (KSC), Physical Sciences and Engineering Division (PSE), Material Science and Engineering Program (MSE), Thuwal 23955-6900, Kingdom of Saudi Arabia

The electron transport layer in a solar cell is one of the main components which plays a crucial role in the separation of charges and improving the efficiency of the solar cells. Herein, solution-processed organic solar cells (PBDTTT-CT:PC70BM) were fabricated with PDINO, Titanium Oxide, and PDINO:TiOx as an ETL. The effect of different ETLs on the performance of solar cells was observed. An efficiency of 7.94% was achieved when PDINO:TiOx was used as an ETL which is one of the highest reported efficiencies for halogen-free solvent processed PBDTTT-CT:PC70BM polymer solar cells. Meanwhile, lower recombination and higher exciton dissociation probability were observed in PDINO:TiOx based PSCs, as well as the superior stability at 45 oC in air.

## CPP 12.64 Mon 18:00 P1

Investigation of solvent dependent morphology degradation of PTQ-2F:BTP-4F bulk heterojunctions — •LUKAS V. SPANIER¹, RENJUN GUO¹, JULIAN E. HEGER¹, YUQIN ZOU¹, MATTHIAS NUBER², MATTHIAS SCHWARTZKOPF³, HRISTO IGLEV², REINHARD KIENBERGER², STEPHAN V. ROTH³, and PETER MÜLLER-BUSCHBAUM^{1,4} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²TU München, Physik-Department, LS Laser- und Röntgenphysik, 85748 Garching — ³DESY, 22607 Hamburg — ⁴MLZ, TU München, 85748 Garching

Lately, organic solar cells (OSCs) have gained increasing attention due to their rapidly increasing efficiencies as well as the relatively easy scalability in their manufacture. To make the manufacturing process of the bulk-heterojunction (BHJ) more environmentally friendly, increased efforts have recently been made to use halogen-free solvents, which, however, can lead to reduced efficiencies.

We investigate and compare the changes in morphology and performance stability of PTQ10:BTP-4F OSCs processed from various solvents, utilising operando grazing-incidence small and wide angle X-ray scattering during illumination and solar cell operation. We further show the impact of solvent composition on the charge carrier generation in the respective BHJs using time-resolved transient absorption spectroscopy, analysing the connection between thin-film morphology and device performance in polymer:non-fullerene acceptor OSCs.

## CPP 12.65 Mon 18:00 P1

Polysulfobetaines as electron transport layers in organic solar cells employing a PBDBTCl-DTBT:BTP-4F active layer — •SEBASTIAN COEN¹, APOSTOLOS VAGIAS², JOHANNA EICHHORN³, LUKAS SPANIER¹, ZERUI Ll¹, XINYU JIANG¹, ANDRÉ LASCHEWSKY^{4,5}, and PETER MÜLLER-BUSCHBAUM^{1,2} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²MLZ, TU München, 85748 Garching — ³WSI, TU München, AG Experimentelle Halbleiterphysik, 85748 Garching — ⁴Universität Potsdam, Institut für Chemie, 14476 Potsdam-Golm — ⁵Fraunhofer IAP, 14476 Potsdam-Golm

Zwitterionic polymers (e.g. polysulfobetaines) have so far been systematically explored as antifouling agents due to their total electroneutrality and superhy-

drophilicity. These macromolecules carry a permanent dipole moment because of the simultaneous presence of positive and negative charges on the backbone. However, this dipole moment can affect the optoelectronic properties and charge transport when such polymers are considered as interlayers for organic solar cells. So far, the role of polyzwitterions as interlayers of organic photovoltaics remains unexplored. We investigate the use of one specific polysulfobetaine (PSPE) in this work. We study its optoelectronic and morphological properties under the aspect of usage in an organic solar cell. For this solar cell, we use an active layer of a PBDBTCI-DTBT:BTP-4F blend with an architecture of ITO/PEDOT:PSS/Active Layer/PSPE or PDIN/Ag. PDIN is a reference electron transport layer material showing similar band positions as PSPE.

#### CPP 12.66 Mon 18:00 P1

Possibilities and limitations for the alignment of polymer chains in photovoltaic materials — •ROBIN TEICHGREBER, FABIAN ELLER, and EVA M. HERZIG — Dynamik und Strukturbildung - Herzig Group, Universität Bayreuth, Universitätsstr. 30, 95447 Bayreuth, Germany

The arrangement of the polymer chains on the nanoscale in thin films influences the optical and electrical properties of the material in a decisive way. For efficient charge transport, a sufficient alignment of the polymers is necessary. Due to the sensitive nature of the microstructure to various influencing variables such as concentration, solubility, and temperature, this goal presents an experimental challenge. However, a deliberate alignment will allow to probe optical and electric photovoltaic properties more systematically. Li et al. [1] have shown that thin films with a high degree of alignment can be produced via dip-coating by varying the coating speed and concentration using the polymer PII-2T. The simple nature of the dip-coating process makes it attractive, also for other polymers, should similar results be obtainable. Here, it will be shown which results can be obtained in a dip-coating based process with P3HT and high performance polymers like PM6. For this purpose, different influencing variables such as coating speed, concentration, solvent quality and temperature are evaluated. In addition, the process is extended to include pre-processing and post-processing steps.

#### CPP 12.67 Mon 18:00 P1

PbS quantum dot solar cells with a IZO buffer layer at quantum dot/ZnO interface — •HUAYING ZHONG¹, WEI CHEN^{1,2}, LUKAS V. SPANIER¹, CHRISTOpher R. Everett¹, Manuel A. Reus¹, Xinyu Jiang¹, Shanshan Yin¹, Marlene Sophie Härtel³, Jiahuan Zhang³, Bertwin Bilgrim Otto SEIBERTZ⁴, MATTHIAS SCHWARTZKOPF⁵, STEPHAN V. ROTH⁵, and PETER MÜLLER-BUSCHBAUM^{1,6} — ¹TU München, Physik-Department, 85748 Garching, Germany — ²James-Franck-Straße 1 — ³HZB, Solar Energy, 14109 Berlin ⁴TU Berlin, Department of Technology for Thin-film Components, 10623 Berlin — ⁵DESY, 22607 Hamburg — ⁶MLZ, TU München, 85748 Garching Colloidal quantum dots (CQDs) have generated great interests in various optoelectronic devices due to their size-tunable bandgap, low-temperature solution processability. Lead sulfide (PbS) CQDs with large Bohr radius enable solar cells to harvest infrared photons of the solar spectrum beyond the absorption edge of crystalline silicon and perovskites. Interface engineering, as one of strategies to improve device performance, is designed to form an energy cascade to enable an efficient charge transfer and promote exciton dissociation. Moreover, it can also offer good interfacial contact and improve device air stability by selecting appropriate materials. Here, we sputter the indium zinc oxide (IZO) as the interlayer between PbS QDs absorption layer and ZnO nanoparticle (NP) electron transport layer (ETL), to fabricate PbS QD solar cells and study the trap densities and charge transport process at QDs interfaces.

## CPP 12.68 Mon 18:00 P1

Preparation of Highly Crystalline ZnO Thin Films at Low Temperatures using ZnO Nanoparticles to Enable High-Quality Organic Solar Cells On Flexible Substrates — •EMANUEL ANWANDER, LUKAS V. SPANIER, and PE-TER MÜLLER-BUSCHBAUM — TU München, Physik-Department, Lehrstuhl für Funktionelle Materialien James-Franck-Straße 1, 85748 Garching

The possibility to build flexible light weight OSCs makes them very promising for aviation and aerospace applications. Therefore, inexpensive and scalable materials such as PET or PEN are desirable substrates. Conventional sol-gel preparation of ZnO thin films, which have proven to be the best choice for electron transport layers (ETLs) in inverted OSCs, requires annealing at temperatures up to 200°C. Since PET and PEN have glass transition temperatures of 69°C and 113°C, respectively, and are long term heat resistant at a maximum of 120°C and 155°C, respectively, a way to produce high-quality ZnO thin films at low temperatures is required. One approach to achieve this goal is to use a solution of pre-synthesized ZnO nanoparticles. These nanoparticles exhibit high crystallinity and thus good ZnO thin films that have higher charge carrier mobility and lower recombination rates than the sol-gel ZnO films can be formed at room temperature without annealing. This approach allows the realization of lightweight OSCs on flexible substrates that have the same or even higher efficiencies than conventional OSCs on rigid substrates with ETLs prepared using the sol-gel method.

#### CPP 12.69 Mon 18:00 P1

**Calculation of vibronic progressions for PPE-PPV polymers** — MONTASSAR CHAABANI¹, SAMIR ROMDHANE¹, and •WICHARD BEENKEN² — ¹Laboratoire Matériaux Avancés et Phénomènes Quantiques, Faculté des Sciences de Tunis, Université Tunis El Manar, Campus Universitaire Tunis, 2092, Tunisia — ²Institut für Physik, Technische Universität Ilmenau, Weimarer Str. 32, 98693 Ilmenau, Germany

We have calculated the vibronic progressions for absorption and photoluminescence spectra of conjugated copolymers with alternating PPE and PPV units and various side-chains.

CPP 12.70 Mon 18:00 P1

Investigation of Crystal Structure of Polydiketopyrrolopyrrole Copolymers — •ROBERT KAHL¹, GERT KRAUSS², ANDREAS ERHARDT², OLEKSANDR DOLYNCHUK¹, MUKUNDAN THELAKKAT², and THOMAS THURN-ALBRECHT¹ — ¹Experimental Polymer Physics, Martin Luther University Halle-Wittenberg — ²Applied Functional Polymers, University of Bayreuth

Polydiketopyrrolopyrrole (PDPP) copolymers are promising materials for applications in organic solar cells and transistors. Their chemical structure offers many possibilities for modifications, allowing to adjust their optoelectronic properties according to the desired application. Here, we investigated the molecular ordering and thermal properties in bulk (WAXS, DSC, TGA) and in thin films (GIWAXS, AFM) of three exemplary PDPPs, two donor polymers: PDPP[T]₂{2-HD}₂-T (PDPP_T) with thiophene flanking units and PDPP[T]₂{2- $HD_{2}^{2}$  T{DEG} (PDPP_{T-OEG}) with thiophene flanking units and an additional OEG side chain, and one acceptor polymer: PDPP[Py]₂{2- HD}₂-T (PDPP_{Py}) with pyridine flanking units. In the ordered state, all three PDPPs show regular  $\pi$ - $\pi$ -stacked backbones (d₀₂₀ = 3.7 - 3.9 Å) and a regular layered structure of demixed backbones and side chains ( $d_{100} = 18.7 - 19.1$  Å). While PDPP_T and  $PDPP_{T-OEG}$  only have sanidic liquid crystalline order,  $PDPP_{Py}$  has a complex triclinic structure.  $PDPP_{T-OEG}$  has the lowest melting temperature and  $PDPP_{Py}$ the poorest thermal stability of the three. These results demonstrate the significant influence of seemingly small chemical modifications on crystal structure and thermal properties of PDPPs.

## CPP 12.71 Mon 18:00 P1

Fluorinated thieno-quinoxalines - a systematic study on conformational locking and accompanied electronic characteristics — •M.M.  $ISLAM^{1,2}$ , A.M. ANTON^{1,2}, R. MEITZNER^{1,2}, C.L. CHOCHOS^{3,4}, U.S. SCHUBERT^{1,2}, and H. HOPPE^{1,2} — ¹Laboratory of Organic and Macromolecular Chemistry (IOMC), Friedrich Schiller University Jena, Humboldstrasse 10, 07743 Jena, Germany — ²Center for Energy and Environmental Chemistry Jena (CEEC Jena), Friedrich Schiller University Jena, Philosophenweg 7a, 07743 Jena, Germany — ³Institute of Chemical Biology, National Hellenic Research Foundation, 48 Vassileos Constantinou Avenue, Athens 11635, Greece. — ⁴Advent Technologies SA, Patras Science Park, Stadiou Street, Platani-Rio, 26504, Patra, Greece

Low band-gap thieno-quinoxaline derivatives are promising donor materials in organic solar cells. Fluorination, on the one hand, can lower both the HOMO as well as LUMO energy levels and thus enhance stability. On the other hand, electron exchange between hydrogen or sulfur and fluorine atoms might cause non-covalent interactions and steric hindrance. Six thieno-quinoxaline derivatives with systematically fluorinated sites have been investigated in solution, pristine films, and blends with ITIC as acceptor. UV-Vis absorption spectra reveal the sensitivity of stacking depending on the particular fashion of fluorination, which affects the size of photochromic units. The stacking propensity is corroborated by DFT simulations. Fluorescence spectroscopic indicates different photoluminescence pathways indicated by excitation-independent and excitation-selective PL signals.

#### CPP 12.72 Mon 18:00 P1

**Optically detected magnetic resonance of OLED materials using a confocal microscope** – •PASCAL SCHADY, FABIAN BINDER, MONA LÖTHER, VLADIMIR DYAKONOV, and ANDREAS SPERLICH — Experimental Physics VI, Julius Maximilian University of Würzburg, 97074 Würzburg

Optically detected magnetic resonance (ODMR) is a specialized technique to investigate spin-dependent optical transitions in solids. This method is also applicable for examining photoluminescence characteristics of semiconducting organic materials which are becoming increasingly popular for, e.g. display applications. In typical ODMR setups a laser beam is guided into a microwave-cavity from one side while the emission spectrum of the sample is detected from the other. To improve upon that, we build a confocal microscope around the cavity, such that white light as well as a laser beam are guided through the cavity opening onto the sample, allowing us to locally excite sample spots while monitoring the laser spot and photoluminescence through a camera and photodetector. By implementing these upgrades we aim to enhance sensitivity while also enabling improved control over the investigated sample spot in order to highlight excited state spin physics processes of potential organic light emitting diode materials.

## CPP 12.73 Mon 18:00 P1

Conception and realization of a highly automated physical vapor deposition system for the fabrication of organic light-emitting diodes — •FABIAN BINDER, MONA LÖTHER, VLADIMIR DYAKONOV, and ANDREAS SPERLICH — Experimental Physics VI, Julius Maximilian University of Würzburg, 97074 Würzburg

Organic light emitting diodes (OLEDs) are most commonly produced in ultrahigh vacuum by physical vapor deposition of different organic and metallic layers on a carrier substrate. We designed a production system that should enable an almost completely automated production of the OLED-devices by the use of many sensor solutions and electric stepper motors. The different stepper motors allow a smooth and precise positioning of the OLED-sample above the evaporation crucibles in the vacuum chamber. Being positioned over an evaporation crucible, the sample needs to rotate with a defined speed to achieve an even deposition of the material. In order to vapor-deposit material, a certain, material-specific temperature range is required. This is realized by a software-based temperature controller which manages the evaporation rate according to the specifications of the user. A user interface makes it possible to design the desired OLED layer stack and provides information about the production progress. Finally, the first OLED devices will be produced and an electrical characterization of these devices, such as an investigation on the quantum efficiency will be done.

## CPP 12.74 Mon 18:00 P1

Nanoscale alignment and chemical characterization of self-assembled all polymer donor-acceptor blends — •DIJO MOONNUKANDATHIL JOSEPH^{1,2}, JUANZI SHI³, WANZHU CAI⁴, HARDIK GADHER¹, MOHAMMAD SOLTANINZEHAD^{1,2}, IVAN G. SCHEBLYKIN³, and DANIELA TÄUBER^{1,2} — ¹Leibniz Institute of Photonic Technology, Jena — ²Friedrich-Schiller University Jena, Germany — ³Lund University, Lund, Sweden — ⁴Jinan University, Guangzhou, China

Control of light polarization properties in self-assembled all-polymer donoracceptor blends enables intrinsic polarization-sensitive applications in organic optoelectronics. In general, the polarization properties of thin conjugated polymer films are related to the polymer chain alignment in the film. Macroscopic domains of polymer alignment were demonstrated in thin films of a quinoxalinethiophene copolymer (TQ1), which had been self-assembled via floating film transfer [1]. The nano-chemical characterization of thin polymer films can be achieved by nano-infrared spectroscopy (NanIR) methods [2]. We use 2D polarization imaging for characterizing the polarization properties of several thin polymer blend films fabricated via floating film transfer. In addition we investigate the chemical nanostructure of these films using mid-infrared photoinduced force microscopy. – [1] Täuber et al. ACS Omega 2017, 2 , 32-40. [2] L. Xiao, Z.D. Schultz, Anal. Chem. 2018, 90 (1), 440-458.

#### CPP 12.75 Mon 18:00 P1

**Ground-state charge transfer and influence on charge carrier transport in organic donor-acceptor mixtures** — •HONGWON KIM¹, FLORIAN FENZEL¹, DOMENIK VÖGEL¹, ANDREAS OPITZ², and WOLFGANG BRÜTTING¹ — ¹Experimental Physics IV, Institute of Physics, University of Augsburg, 86135 Augsburg — ²Supramolekulare Systeme, Institut für Physik, Humboldt-Universität zu Berlin, 12489 Berlin

In organic semiconductors, charge transfer (CT) states form at interfaces or in mixtures of electron accepting and donating molecules. Their mutual electronic interaction is accompanied by a partial or full transfer of electric charges. This charge transfer is crucial to generate excess charges in (opto-)electronic devices, i.e. to facilitate electrical doping.

We have investigated donor-acceptor thin films consisting of electron donating molecules (DIP, 6T, DBTTF, and DBP) mixed with strong acceptors (F6TCNNQ and HATCN). It is investigated that the thermal activation energy (Ea) decreases and the electrical conductivity ( $\sigma$ ) increases through doping by strong acceptors. Furthermore, the formation of CT states accelerates this doping effect and a highly improved conductivity can be obtained on DBTTF/F6TCNNQ as well as DIP/F6TCNNQ mixed thin films. This high conductivity is a result of increased concentration of charge carriers by doping effect as well as its improved mobility by CT states formation. However, the formation of CT states also has characteristic spectroscopic signatures and affects the growth behavior of molecular donor-acceptor blends.

## CPP 12.76 Mon 18:00 P1

**Morphology and stability study of organic thin films** — •MEIKE KUHN¹, CHRIS MCNEILL², and EVA M. HERZIG¹ — ¹Dynamik und Strukturbildung - Herzig Group, Universität Bayreuth, Universitätsstr. 30, 95447 Bayreuth, Germany — ²Material Science and Engineering, Monash University, 20 Research Way, Clayton

New, promising materials with high efficiency are constantly being discovered for organic solar cells. Often, these materials are chosen to mainly maximize efficiency. However, stability also plays an important role when selecting promising materials. The stability of organic materials depends on many variables, such as photochemical stability, photostability and morphological stability. In this analysis, we will attempt to gain a better understanding of nanostructural changes and hence morphological stability. [1] Using GIWAXS and absorption measurements, we systematically investigate how the ageing process affects the structure. In particular, we investigate the behaviour of the morphological ageing mechanisms, such as the orientation and aggregation of the material, as a function of temperature and substrate properties. These experiments are carried out on organic polymers such as PM6.

CPP 12.77 Mon 18:00 P1 **Photoluminescence and Quantum Yield of a deep blue TADF emitter** — •Mona Löther, Fabian Binder, Pascal Schady, Jeannine Grüne, Vladimir Dyakonov, and Andreas Sperlich — Experimental Physics VI, Julius Maxi-

milian University of Würzburg, 97074 Würzburg Organic light-emitting diodes (OLEDs) based on thermally activated delayed fluorescence (TADF) are becoming increasingly important due to their advantages over OLEDs of earlier generations as they enable access to triplet excitons via reverse intersystem crossing (rISC) without the need of resources-limited rare metal complexes. However, TADF OLEDs have yet to reach commercial viability, as an efficient and durable blue OLED remains to be found. A promising design for a blue host-dopant system is N7,N7,N13,N13,5,9,11,15-octaphenyl-5,9,11,15-tetrahydro-5, 9,11,15-tetraaza-19b, 20b diboradinaphtho[3,2,1-de:10, 20, 30-jk]pent-acene-7,13-diaminel (v-DABNA). This system belongs to the multiresonant TADF compounds, represented typically by narrow band emission, high photoluminescence quantum yield (PLQY) and a small singlet-triplet gap  $\Delta E_{ST}$ . In order to characterize its optical properties we examined the steady state photoluminescence (PL), transient photoluminescence (trPL) and PLQY. Furthermore, we used different host systems to survey the behavior of v-DABNA in a host-emitter system. With these optical characterization methods we are able to better understand the promising candidate of TADF OLEDs with high efficiencies and color purity.

## CPP 12.78 Mon 18:00 P1

Towards efficient blue perovskite lead-halide nanocrystal light emitting diodes — •TASSILO NAUJOKS¹, ADRIAN HOCHGESANG², CHRISTO-PHER KIRSCH³, MARCUS SCHEELE³, MUKUNDAN THELAKKAT², and WOLF-GANG BRÜTTING¹ — ¹Institut für Physik, Universität Augsburg, Germany — ²Universität Bayreuth, Germany — ³Institut für Physikalische und Theoretische Chemie, Universität Tübingen, Germany

The research focus for affordable solution-processed light-emitters has been shifted towards quantum-dot materials in recent years. High quantum yields (QY) even with inorganic nanocrystals (NC) capped by organic ligands have been achieved. One prominent, particularly highly luminescent type of NC is lead-halide perovskite with tunable colour by halide composition achieving near-unity QY.

While for red and green emitting NCs the quantum efficiency in the resulting LEDs is engineered to a satisfactory level, blue perovskite NCs are still underperforming. One issue with blue and therefore wider bandgap NCs lies in the very deep valence level. With that, hole injection into the NCs is significantly impaired. Here we present two approaches to enhance hole-injection into blue LHP NCs. The use of carbazole moieties either within the ligand on the NC surface or as a TCTA-doped polyvinyl-carbazole (PVK) polymeric hole transport layer increases the efficiency in perovskite NC LEDs. We propose that the carbazole group effectively blocks electrons, while its deep HOMO facilitates the injection into the similarly deep valence level of the blue perovskites.

#### CPP 12.79 Mon 18:00 P1

Photoinduced metastable and trapped charge-carrier pairs in neat amorphous films of OLED host materials — SEBASTIAN LULEI¹, JEANNINE GRÜNE¹, ANDREAS SPERLICH¹, •VLADIMIR DYAKONOV¹, ANDREI STANKEVYCH², ANDREY KADASSHCHUK², and ANNA KÖHLER² — ¹Experimental Physics 6, Julius Maximilian University of Würzburg, 97074 Würzburg — ²Soft Matter Optoelectronics and Bavarian Polymer Institute (BPS), 95448 Bayreuth

We discuss light-induced ESR (LESR) transients, PL-detected magnetic resonance (PLDMR), and thermally-stimulated luminescence (TSL) in neat amorphous thin films of 3',5-di(9H-carbazol-9-yl)-[1,1'-biphenyl]-3-carbonitrile (mCBP-CN), which is commonly used as a host material for blue emitters based on thermally activated delayed fluorescence (TADF) in OLED devices. While the half-field LESR signal associated with triplet excitations shows fast saturation being comparable with the triplet lifetime, the full-field LESR featured extremely slow kinetics of both growth and decay at T=10K. The latter implies very slow accumulation and subsequent recombination of the photogenerated charge carriers due to shallow charge trapping at such low temperatures. These results are in good agreement with the observation of a long isothermal afterglow lasting up to thousands of seconds at 5K. Further, the persistent LESR signal is detected in the same temperature range as the TSL emission, implying that both are caused by the same trapped carriers. Finally, PLDMR showed signals from closed-by triplet states, emitting through fluorescence.

CPP 12.80 Mon 18:00 P1

Graphene nanoribbons synthesized on Au(111) and Au(788) in ultra-high vacuum conditions and by atmospheric pressure chemical vapor deposition method — • VASILII OSIPOV, YI HAN, PHILIPP WEITKAMP, MAX REIMER, DIRK HERTEL, and KLAUS MEERHOLZ — Chemistry department, University of Cologne, Germany

Graphene nanoribbons (GNRs) are an interesting class of materials due to their tunable width- and edge-type-dependent electronic structure. The state-of-theart methods of GNRs synthesis are bottom-up processes involving polymerization of precursor molecules at catalytic surfaces, and are typically performed ei-

## CPP 13: Charged Soft Matter, Polyelectrolytes and Ionic Liquid

CPP 13.1 Tue 9:30 H38 Insights into degradation mechanisms in Li-based batteries and advantages of polymer coatings — •NEELIMA PAUL — Heinz Maier-Leibnitz Zentrum (MLZ), TU München, Lichtenbergstr. 1, 85748 Garching, Germany

Lithium-ion batteries are present in portable electronics, electric vehicles and grid-scale energy storage and are an inherent part of our daily life. They offer high energy density, high power density, stable temperature performance, and are safe. However, they eventually suffer from capacity fade due to some intrinsic degradation mechanisms, and thus have a limited cycle life. To increase their lifetime, knowledge of the responsible degradation/aging mechanism is crucial and most beneficial if determined without destructive disassembly of the battery. I will demonstrate how parameters responsible for aging such loss of mobile Li inventory, active material degradation, metallic Li plating, can be monitored and quantified using both operando and post-mortem neutron techniques. Thereafter, I will describe the main degradation mechanism in Li-metal batteries and show how this can be overcome by applying viscoelastic polymer coatings with a specific mechanical strength to the anode surface.

CPP 13.2 Tue 10:00 H38 Electrostatically Cross-Linked Reversible Gels - Effects of pH and Ionic  $Strength - Roman Staňo^{1,4}$ , •Peter Košovan¹, Andrea Tagliabue², and CHRISTIAN HOLM $^3 - {}^1$ Faculty of Science, Charles University, Prague, Czechia -  2 Universitá degli Studi dell Insubria, Como, Italy-  3 Institute for Computational Physics, University of Stuttgart, Germany-  4 University of Vienna, Austria

Mixing of oppositely charged macromolecules can lead to the formation of electrostatically cross-linked coacervate gels. In this simulation study, we determine the conditions under which four-armed star copolymers with charged endblocks are able to form such coacervate gels. The cationic charged blocks consist of quenched charges, whereas the anionic blocks contain pH-responsive weak acid groups. We used the Grand-reaction method to determine the phase stability, equilibrium composition, and structural properties of these systems in equilibrium with a supernatant solution at various pH levels and salt concentrations. Depending on the pH and hence on the charge state of the polyanion blocks, we observed the emergence of three regimes: a solution, a sol of isolated star clusters, and a gel*percolating network of stars. Moreover, we demonstrate that the charge state of the stars in the gel phase can be well described by the ideal Henderson-Hasselbalch (HH) equation, despite the presence of strong interactions violating ideality. We can explain this surprising result by cancellation of two stongly non-ideal effects. This observation explains why various experiments on coacervate gels can be well described by the HH equation, although its assumption of ideality is violated.

### CPP 13.3 Tue 10:15 H38

Temperature Dependence of PSS diffusion in multilayers of entangled **PDADMA: more than one diffusion constant** — •ANNEKATRIN SILL¹, PE-TER NESTLER², PETER THRAN¹, and CHRISTIANE A. HELM¹ - ¹University of Greifswald, Institute of Physics, D-17489 Greifswald, Germany - ²ZIK HIKE-Biomechanics, University of Greifswald, D-17489 Greifswald, Germany

Layer-by-layer assembly is a widely used tool for engineering materials and coatings, but the dynamics of the constituent polymer chains remain poorly understood. Using neutron reflectivity, the vertical diffusion of polyanion PSS (Mw(PSS) = 75.6 kDa) within PSS/PDADMA (Mw(PDADMA) = 72.1 kDa) multilayers is probed while annealing in 1 M NaCl solution at different temperatures. The observed diffusion could not be described by a simple diffusion model. Instead, two different PSS fractions (one mobile and one almost immobile, i.e. different diffusion constants) are the simplest model to describe the time dependence of the scattering length density profiles. Increasing the annealing temperatures (20 - 50 °C) increases the diffusion constant of both the fast and slow PSS ther in ultra-high vacuum (UHV) conditions or by atmospheric pressure chemical vapor deposition (AP-CVD) technique. Despite leading to GNR layers of reduced quality, the AP-CVD method possesses advantages of simplicity and better scalability compared to the UHV one, which make it a promising option for developing routes for synthesis of new types of GNRs. We present results of AP-CVD synthesis of GNRs from different precursors and their comparison to GNRs of corresponding types obtained by UHV method, using Raman spectroscopy. Particularly, degree of GNRs growth geometrical anisotropy, induced by using Au(788) growth substrate instead of Au(111), is investigated by observing the polarization-angle-dependent Raman intensity. This should eventually contribute to better understanding of the processes of GNRs synthesis and to development of technologies for functional (templating) materials for organic electronics.

Location: H38

fraction. Additionally, the fraction of fast PSS molecules is increased. We suggest that an immobile or nearly immobile fraction of polyelectrolytes is always present when the polymer length is beyond the entanglement limit and the sticky reptation model fails.

## CPP 13.4 Tue 10:30 H38

Ratcheting charged polymers through symmetric nanopores using pulsed fields: Designing a low pass filter for concentrating DNA - •LE QIAO and GARY W. SLATER - Department of Physics, University of Ottawa, Ottawa, Ontario K1N 6N5, Canada

Size-based separation of DNA molecules is crucial for molecular analyses such as genome sequencing. To date, gel electrophoresis is the most commonly used separation method in the laboratory. However, due to poor resolution for larger molecules and difficult sample recovery, it cannot meet the goal of bulk separation. Alternatively, micro/nanofluidics offers a relatively inexpensive, label-free, and continuous separation with high throughput. In this talk, I will present a new proof-of-concept idea for the separation of DNA by contour length using a nanofluidic ratchet by combining nanopore translocation and pulsed fields. Using Langevin dynamics simulations, we show that it is possible to design pulsed fields to ratchet semiflexible molecules such that only short chains are successfully translocated, effectively turning the nanopore process into a molecular lowpass filter. The process itself can be performed with many pores in parallel, and it is possible to integrate it directly into nanopore sequencing devices, increasing its potential utility.

## CPP 13.5 Tue 10:45 H38 Tuning water-in-salt electrolytes: impact of concentration and anion structure on local and long-ranged dynamics probed by NMR — • Dominik Gappa, ELISA STEINRÜCKEN, MANUEL BECHER, and MICHAEL VOGEL — TU Darmstadt, Institut für Physik kondensierter Materie, Darmstadt, Germany

Water-in-salt electrolytes (WiSE) are highly concentrated aqueous solutions of (Li-)salts. Newly developed WiSE, as they are nonflammable, nontoxic, have a high lithium-ion density and a wide electrochemical stability window (ESW), are promising materials for applications as lithium-ion electrolytes. Due the high amount of the solute and, thus, strong electrostatic interactions between the components they show complex molecular dynamics. A full understanding of interaction mechanism, e.g. the impact of the concentration and anion structure on the dynamics is still elusive. We investigate LiTFSI, which has a wide ESW for different salt concentrations in water. In particular, we exploit the isotope selectivity of Nuclear Magnetic Resonance (NMR) to observe the behavior of the constituents of LiTFSI-H2O mixtures with various concentrations separately via  $^1\mathrm{H},\,^7\mathrm{Li}$  and  $^{19}\mathrm{F}$  NMR. The anion structure is modified by extending one side group of the originally symmetric TFSI anion, leading to increasingly heterogeneous dynamics. Local dynamics are investigated by spin-lattice relaxation, including field-cycling NMR, and long-ranged transport by diffusion experiments. Rotational correlation times and diffusion coefficients are extracted to scruntinize the validity of the Stokes-Einstein relation.

## CPP 13.6 Tue 11:00 H38

Tuning the Electronic and Ionic Thermoelectric Transport Properties in Polymer Electrolytes by Carbon Based Additives — • $MAXIMILIAN FRANK^1$  and JENS PFLAUM^{1,2} — ¹Experimental Physics VI, University of Würzburg, 97074 Würzburg — ²ZAE Bayern, 97074 Würzburg

Ionic transport constitutes a key process in organic-based electrochemical energy storage media. As such, it also offers intriguing possibilities for the utilization of these materials in thermoelectrics (TE) to recuperate waste heat into electrical power. In this work we present our results on the electrical and thermoelectrical characterization of a methacrylate based solution processable solid polymer electrolyte. By means of impedance spectroscopy over a broad frequency

## Chemical and Polymer Physics Division (CPP)

regime from 100 mHz up to 500 kHz and in a technologically relevant temperature range between 263 K and 363 K we investigate the dynamics of charge carriers in the solidified electrolyte. Furthermore, we demonstrate that the electronic and ionic transport properties can be efficiently varied by the ratio between Lithium-salt and carbon-based additives, in this case, carbon nanotubes. Even more, we can reverse the sign of the occurring thermovoltage, which allows for different TE operational modes depending on ambient temperature. A proof-of-concept all organic TEG verifies the functionality of our approach and, thereby, substantiates the potential of mixed ionic and electronic materials for future TE applications.

# CPP 14: Emerging Topics in Chemical and Polymer Physics, New Instruments and Methods

Time: Tuesday 9:30-11:15

## CPP 14.1 Tue 9:30 H39

Where is the Water? — •MAXIMILIAN FUCHS^{1,2}, EDUARDO MACHADO Charry^{1,2}, Gregor Böhm^{1,2}, Roland Resel¹, and Karin Zojer^{1,2} — ¹Institute of Solid State Physics, NAWI Graz, Graz University of Technology, Austria —  2 Christian Doppler Laboratory for Mass Transport through Paper, Graz University of Technology, Austria

The take up of liquid water by paper is a complex interplay between capillary transport and swelling of cellulose-lignin-based fibers. Though paper is a convenience product used every day, little is known how swelling affects the pore space between fibers and the subsequent transport within it. We used X-ray microcomputed tomography to monitor the spread of water in-situ. The sequence of 3D-images, segmented by a neural network, traces the time-dependent progression of swelling and liquid transport up to one hour after the application of water. We find that water not only swells the fiber walls, but also expands the pore space between the fibers. Even more remarkable is that there is no liquid water in the pores between the fibers of the examined paper. Rather, liquid water was found exclusively in the fiber lumen.

CPP 14.2 Tue 9:45 H39 Rational Design of Novel Photoswitches with Generative Models - • ROBERT STROTHMANN, CHRISTIAN KUNKEL, JOHANNES T. MARGRAF, and KARSTEN REUTER — Fritz-Haber-Institut der MPG, Berlin, Germany

The sheer vastness of chemical spaces poses a daunting challenge to molecular discovery through high-throughput screening based on exhaustive sampling. Generative models (GMs) are an emerging machine learning (ML) approach that enables a more guided discovery. Implicitly learning chemical design rules from large reference data sets and suitable descriptors of a targeted functionality, GMs directly propose promising, yet diverse candidates.

Here we explore the use of GMs for the design of novel molecular photoswitches. In order to guarantee the desired functionality in the generated molecules, we specifically employ scaffold decoration methods that append chemically meaningful side-groups to a predefined photochromic core. In a second step, the creation process needs to be conditioned towards performant switching capabilities. In the absence of sufficient corresponding experimental reference data, this conditioning is based on synthetic first-principles data. To this end, we discuss computationally efficient descriptors assessing addressability and robustness.

#### CPP 14.3 Tue 10:00 H39

Transferable hidden variables in sequence space learned by transencoder neural networks — • MARCO WERNER — Institut Theorie der Polymere, Leibniz-Institut für Polymerforschung Dresden, Germany

The relation between chemical sequences and the properties of polymers is investigated using artificial neural networks with a bottleneck layer of neurons. By training such AutoEncoder networks to translate between sequence and property (TransEncoder¹), one may identify variables that control the physical relationship behind. Here, networks were trained to predict the effective free energy landscape of a copolymer interacting with a lipid membrane depending on its sequence of hydrophilic and hydrophobic monomers. TransEncoders that were split into separate encoder-decoder channels have learned to decompose the free energy into independent components that were physically meaningful. For instance, they reflect theoretical concepts such as solutions of the Edwards equation. Sequence-complete data sets for training were obtained via Rosenbluth sampling of single chains in a given density field. It is demonstrated that once the sequence patterns were learned based on the large data set for chain length N = 14, a small number of ~ 20 examples was sufficient to transfer-learn the prediction to a more detailed simulation model with explicit lipids and solvent (accuracy  $0.5k_BT$ ). The results open a perspective to physics-informed inverse searches, for instance, for copolymer sequences leading to the smallest translocation time through a membrane. [1] M. Werner, ACS Macro Lett. 10, 1333 (2021).

## CPP 14.4 Tue 10:15 H39

Improved virtual orbitals for the calculation of X-ray absorption spectra for organic molecules — •ROLF WÜRDEMANN¹ and MICHAEL WALTER^{2,3} — ¹Freiburger Materialforschungszentrum, Freiburg, Germany – ²Freiburger Zentrum für interaktive Werkstoffe und bioinspirierte Technologien, Freiburg, Germany — ³Fraunhofer-Institut für Werkstoffmechanik, Freiburg, Germany

X-ray absorption spectroscopy (XAS) is an element specific local probe used for the analysis of materials. One way to compare and interpret experimentally measured spectra is to perform ab initio calculations of XAS spectra for molecules in given geometries. This opens a way to distinguish between different isomers and gain a deeper understanding of the bonding situation.

Common ways to calculate XAS spectra by density functional theory (DFT) either utilize fractional charges in the frozen cores or restrict the state-space of linear time-dependent DFT. In our contribution we examine the possibility to utilize the combination of range-separated functionals (RSF) with Huzingas improved virtual orbitals to calculate XAS spectra. This combination has been successful in the calculation of charge transfer excitations[1].

#### CPP 14.5 Tue 10:30 H39

Transport of organic volatiles through paper: physics-informed neural networks for solving inverse and forward problems - •ALEXANDRA Serebrennikova^{1,4}, Raimund Teubler^{2,4}, Lisa Hoffellner^{2,4}, Erich Leitner^{2,4}, Ulrich Hirn^{3,4}, and Karin Zojer^{1,4} — ¹Institute of Solid State Physics, TU Graz, Petersgasse 16, Graz, 8010, Austria — ²Institute of Analytical Chemistry and Food Chemistry, TU Graz, Stremayrgasse 9/II, Graz, 8010, Austria — ³Institute of Bioproducts and Paper Technology, TU Graz, Inffeldgasse 23, Graz, 8010, Austria – ⁴Christian Doppler Laboratory for mass transport through paper, Petersgasse 16, Graz, 8010, Austria

Transport of volatile organic compounds (VOCs) through porous media with active surfaces takes place in many applications, e.g., in cellulose-based materials for packaging. To date, mathematical models proposed in literature for this complex process are scarce and have not been systematically compiled together with experimental data.

Based on a model for water-vapor transport through paper (Ramarao et al. (2003)), we propose to describe transport of VOCs via diffusion in pores and sorption to fibers. It is key to determine the necessary material parameters for the model. Using experiments for that is challenging, as the related system of non-linear PDEs does not offer analytical solutions.

We demonstrate for dimethyl sulfoxide and n-tetradecane, how combining experimental concentration data with physics-informed neural networks yields these parameters as solution of an inverse problem.

CPP 14.6 Tue 10:45 H39

**STED-Inspired Sub Diffractional Cationic Lithography** – •SOURAV ISLAM¹, MARCO SANGERMANO², and THOMAS  $KLAR^{1} - {}^{1}Institute$  of Applied Physics, Johannes Kepler University Linz, 4040 Linz, Austria — ²Department of Applied Science and Technology, Politecnico Di Torino, Torino, Italy

Cationic polymerization has come out as a low cost, efficient, bio-compatible alternative to radical polymerization because of lower toxicity of the monomers, lower shrinkage stress, no oxygen inhibition. Although the mechanism of cationic polymerization is well understood(1), the knowledge about twophoton induced cationic polymerization is still insufficient. In our work, we try to fill the void in the knowledge of two photon induced cationic polymerization and the scope of STED-inspired (2) sub diffractional lithography. 3,4-Epoxycyclohexylmethyl 3,4 epoxycyclohexanecarboxylate (CE) was used as monomer and Triarylsulfonium hexafluoroantimonate salts and 2-Isopropylthioxanthone (ITX) were used as onium salt and photo-sensitizer, respectively. 110fs laser pulses of 780nm wavelength were used to write twophoton polymer lines with a feature size of 315nm. Furthermore, 60% suppression of polymerization was achieved using an additional 660nm continuous beam overlapped with 780nm beam. To obtain further reduction of the feature size, a donut shaped beam profile was produced by installing a 2-pi phase plate in the 660 nm beam path. This way, lines of 195 nm feature size were achieved. 1.M. Sangermano Pure and Applied Chemistry, 84, 2089 (2012). 2.Fischer, Wegener, Opt. Mat. Exp. 1, 614 (2022)

CPP 14.7 Tue 11:00 H39 Photoluminescence spectroscopy for the detection of microplastics - the Nile Red approach — • SRUMIKA KONDE, STEFAN BRACKMANN, MARINA GERHARD, and MARTIN KOCH - Department of Physics and Material Sciences Center, Philipps-University of Marburg, Germany

For the detection and classification of microplastics, most researchers commonly use FTIR or Raman spectroscopy. These state-of-the-art methods are, how-

Tuesday

Location: H39

## Chemical and Polymer Physics Division (CPP)

ever, laborious, cost-intensive, and time-consuming. To establish a less arduous and inexpensive approach, we propose photoluminescence-based multispectral imaging. Based on the parallel research in our workgroup, we have found that the autofluorescence of plastics lies predominantly in the UV region. To accommodate the identification in the visible region we use a solvatochromic dye called Nile Red. PLE/PL spectra of stained plastics and stained natural materials have been analyzed to determine the right excitation and emission windows for building an imaging system. This analysis has been performed using LDA (linear discriminant analysis). Based on our analysis we propose a system consisting of a blue excitation LED, an RGB camera, and two bandpass filters which would yield about 98% accuracy in isolating plastics from natural materials.

Simulation of vapour flow through aperture arrays for quantifying gravimetric mass loss measurements — •RIKO KORZETZ, LENNART SCHULTE, and AN-DRÉ BEYER — Bielefeld University

Gravimetric mass loss measurements are frequently employed to investigate the permeative behaviour of 2D membranes with respect to vapours of different solvents. Due to constraints in these measurements, insufficient circulation causes the build-up of concentration gradients in the vapour phase, which is known as concentration polarization. This leads to a seemingly non-intuitive permeation behaviour, which complicates the evaluation of the measured data.

Here, we present finite-element simulations that were employed to investigate this effect with respect to different types of membrane supporting apertures and aperture arrays. Both open orifices as well as membranes with different permeance values have been modelled to achieve a quantitative understanding of the relevant effects in mass loss measurements.

We found that for open orifices and apertures with highly permeable membranes, the diffusion from the bulk towards the membrane is the rate-limiting step. This results, for example, in a linear dependence between the permeation rate and the edge length of single open orifices. On the other hand, a dependence on the free-standing area occurs in the case of membranes with a sufficiently low permeance. We devised a phenomenological model to describe the permeation rate in dependence of the membrane permeance as well as support geometry, which allows correction of these effects when evaluating such measured data.

#### CPP 17.2 Tue 11:00 P2

Preparation and characterization of photosensitive nanomembranes — •VERENA MÜLLER¹, MARIA KÜLLMER¹, FLORIAN KÜLLMER^{1,2}, HANS-DIETER ARNDT², and ANDREY TURCHANIN¹ — ¹Friedrich Schiller University Jena, Institute of Physical Chemistry, Lessingstraße 10, 07743 Jena, Germany — ²Friedrich Schiller University Jena, Institute of Organic Chemistry and Macromolecular Chemistry, Humboldtstraße 10, 07743 Jena

Carbon nanomembranes (CNMs) are two-dimensional (2D) organic materials with a molecular thickness that are synthesized by low-energy electron irradiation of aromatic self-assembled monolayers (SAMs). Using the molecular design, CNMs can be prepared with tunable physical and chemical properties and employed on their own, e.g. as separation membranes or in combination with other 2D materials in hierarchically assembled van-der-Waals heterostructures. Here we present the engineering of photosensitive nanomembranes *via* postfunctionalization of  $\sim 1$  nm thick amino-terminated CNMs with azobenzene molecules. We characterize their properties using surface science techniques including X-ray photoelectron spectroscopy (XPS) and compare the obtained characteristics with the azobenzene-based SAMs.

CPP 17.3 Tue 11:00 P2

Selective Diffusion of CO₂ and H₂O through Carbon Nanomembranes in Aqueous Solution as Studied with Radioactive Tracers — RAPHAEL DALPKE¹, ANNA DREYER², RIKO KORZETZ¹, •LENNART SCHULTE¹, ANDRÉ BEYER¹, and KARL JOSEF DIEZ² — ¹Faculty of Physics, Bielefeld University — ²Faculty of Biology, Bielefeld University

A well-known approach of improving membrane separation processes is the attempt to utilize 2D materials. In particular, carbon nanomem- branes (CNMs) are promising candidates due to their extremely high areal pore density. Specifically, CNMs made from terphenylthiol (TPT) exhibit a very high water permeance while blocking ions as well as many gases and vapours. Here, we present permeation measurements of TPT-CNMs utilizing radioactive tracer molecules to characterize diffusion of  $[{}^{3}H]H_{2}O$ ,  $[{}^{14}C]NaHCO_{3}$ , and  $[{}^{32}P]H_{3}PO_{4}$  in aqueous solution. For full consideration of concentration polarization and outgassing effects a mathematical model was developed and verified using finite-element simulations. The experiment shows that water and carbonate can pass through the CNM while phosphate ions are completely blocked. Considering ion conductivity measurements, the obtained diffusion coefficients indicate that the permeation across the membrane primarily occurs by transport of neutral species.

## CPP 17.4 Tue 11:00 P2

**Dipolar Molecular Rotors in Surface-Anchored Metal Organic Frameworks** – •XIANGHUI ZHANG¹, SEBASTIAN HAMER², RITESH HALDAR³, DANIEL REUTER⁴, FLORIAN PANEFF¹, DIRK VOLKMER⁴, PETER LUNKENHEIMER⁴, AN-DRÉ BEYER¹, IAN HOWARD³, and RAINER HERGES² – ¹Faculty of Physics, Bielefeld University, 33615 Bielefeld – ²Otto-Diels-Institute for Organic Chemistry, Christian-Albrechts-University of Kiel, 24098 Kiel – ³Karlsruhe Institute of Technology (KIT), 76344 Karlsruhe – ⁴Institute of Physics, Augsburg University, 86135 Augsburg, Germany

Molecular rotors arranged in the surface-anchored metal-organic frameworks (SURMOF) were investigated. The rotating part of each linker molecule consists of a fluorine-substituted phenyl group connected with acetylene linkages to the Cu clusters. Dielectric spectroscopy was used to investigate the rotation dynamics of molecular rotors in a parallel capacitor assembly. We determined an activation energy of 10 kJ/mol for one SURMOF type consisting of 3-[4-(2-carboxyethynyl)-2,3-difluoro-phenyl]prop-2-ynoic acid (C12H4F2O4) as dipolar linkers and 1,4-diazabicyclo(2.2.2)octane (DABCO) as pillars, at temperatures above 170 K. A smaller barrier of about 2 kJ/mol was found for the corresponding SURMOFs without any pillars. The analog made from the non-polar linker was used as a control system and showed no dielectric relaxation processes down to 20 K. The observed activation energy barriers are consistent with ab initio DFT modelling and classical dipole-dipole interaction calculations.

## CPP 17.5 Tue 11:00 P2

Design, fabrication and nano-scale characterization of novel SEI layers – •ZHUIJUN XU¹, YANJUN CHENG², YONGGAO XIA², and PETER MÜLLER-BUSCHBAUM^{1,3} – ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching, Germany – ²Ningbo Institute of Materials Technology and Engineering, Chinese Academy of Sciences, 315201, Ningbo, China – ³MLZ, TU München, 85748 Garching, Germany

Rechargeable lithium metal batteries have been recognized as one of the most promising energy storage devices due to their superior energy density. However, serious safety concerns and poor cyclability are challenges originating from an uncontrolled lithium dendrite growth and an unstable solid electrolyte interface (SEI) layer. One strategy to suppress dendrite growth is a surface modification with amphiphilic block copolymers, such as PDMS-b-PAA, which bear some clear advantages including absorbing mechanical stress, conducting lithium ion and controlling the lithium dendrite growth process. With ex-situ scattering techniques or in-situ scattering studies, the structures of the surface modified lithium metal anodes and structure formation processes are studied. In particular, by applying GISAXS, the horizontal structures and vertical structures of the polymer films on the lithium metal surfaces are investigated.

#### CPP 17.6 Tue 11:00 P2

In situ GISAXS printing of inorganic-organic hybrid nanostructures based on biopolymer templating — •LINUS F. HUBER¹, STEPHAN V. ROTH³, KUN SUN¹, MANUEL A. REUS¹, and PETER MÜLLER-BUSCHBAUM^{1,2} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²MLZ, TU München, 85748 Garching — ³Deutsches Elektronen-Synchrotron (DESY), Notkestr. 85, 22607 Hamburg, Germany

Inorganic-organic hybrid nanostructures are interesting for the energy conversion through the thermoelectric effect. Thermoelectric generators based on abundant, environmentally friendly and affordable materials have historically had low effitiencies. The electrical conductivity, the Seebeck coefficient and the thermal conductivity need to be individually improved, to significantly enhance the thermoelectric figure of merit. Nanostructuring can improve these parameters and maximize the performance of thermoelectric materials. Betalactoglobulin is a bovine whey protein that is used as a template during sol-gel synthesis. Different titania thin film morphologies can be achieved by changing the pH-value and the beta-lactoglobuline concentration. To investigate the different titania morphologies, in situ GISAXS, GIWAXS and SEM are used. In situ GISAXS printing enables a time resolved investigation of the structure formation, domain sizes and domain distances. UV-Vis and Pl are used to analyze differences in the optical properties of the thin films. These structural and optical changes are then correlated with measurements of the Seebeck coefficient and the electrical conductivity.

## CPP 17.7 Tue 11:00 P2

**Two-step nucleation in confined geometry on a lattice gas model** — •JACOB HOLDER, RALF SCHMID, and PETER NIELABA — Physics Department University of Konstanz, Konstanz, Germany

We deploy a degenerated Ising model to describe nucleation and crystallization from solution in a confined two-component system. The free energy is calculated using Metadynamics simulation. With nudged elastic band simulation we calculate the minimum energy path and give properties of the crystallization path. From the parameters and setup we find necessary conditions for the occurrence of two-step nucleation in our system.

## CPP 17.8 Tue 11:00 P2

Nucleation patterns in polymer crystallization analyzed by machine learning — •ATMIKA BHARDWA)^{1,2}, MARCO WERNER¹, and JENS-UWE SOMMER^{1,2} — ¹Leibniz-Institut für Polymerforschung Dresden e. V., Hohe Str. 6, Germany 01069 — ²Technische Universität Dresden (TUD)

Today, many efforts seek to link machine learning (ML) algorithms to the concepts of theoretical physics. Our work focuses on developing ML tools to derive meaningful interpretations from the data generated through molecular dynamics simulations. We aim to find and quantify the nucleation patterns in polymer crystallization. The transition dynamics occurring under-cooled polymer melt is a local environmental phenomenon rather than a property of individual particles (or monomers), and depends on subtle conformation patterns such as entanglements between the chains. Our first objective is to define a set of fingerprint parameters to capture the crucial information in the local conformation and a monomer's environment and to quantify the degree of crystallinity. We use selfsupervised auto-encoders to contain those local fingerprints. The second objective is to recognize the precursors or nucleation sites that stimulate crystal growth before the occurrence of such growth. We are currently working on both convolutional neural networks and recurrent neural networks to investigate the spatial and temporal patterns of the precursors.

#### CPP 17.9 Tue 11:00 P2

Laser control over crystallization and morphology of tetracene thin films — •Stefan Kowarik¹, Andika Asyuda², Linus Pithan³, and Andreas Opitz⁴

¹Physical Chemistry, University of Graz, Austria — ²Institute for Physical Chemistry, Universität Heidelberg, Germany — ³Institut für Angewandte Physik, Universität Tübingen, Germany — ⁴Institut für Physik, Humboldt-Universität zu Berlin, Germany

Nucleation and crystallization in thin-film growth are notoriously difficult to steer, but optical control offers exciting new possibilities for selecting specific polymorphic forms [1] or aligning the crystallite orientation in thin films [2]. Here we report an increase in crystallite size in vacuum-deposited tetracene thin films under illumination with a wavelength tuned to a specific absorption band of tetracene crystals. The morphological changes are induced with linearly and circularly polarized light and the larger crystallite size is accompanied by higher photoluminescence of tetracene. We propose a mechanism based on optical heating of specifically oriented crystals during growth, which leads to enhanced surface migration processes in these crystals and consequently larger crystals via Oswald ripening effects. The light-induced temperature effects are distinct from substrate heating both for linearly and circularly polarized light. Laser il lumination, therefore, is a novel control parameter of growth and enables high crystallinity even for low substrate temperature deposition.

[1] L. Pithan, et al., Crystal Growth & Design 15.3 (2015): 1319-1324. [2] L. Pithan, et al., Advanced Materials 29.6 (2017): 1604382.

CPP 17.10 Tue 11:00 P2

Synthesis of Hard-Carbon Microspheres with Binary Size Distribution via Hydrothermal Carbonization of Trehalose — •MARTIN WORTMANN¹, WALDEMAR KEIL², MICHAEL WESTPHAL¹, ELISE DIESTELHORST³, JAN BIEDINGER¹, BENNET BROCKHAGEN³, GÜNTER REISS¹, CLAUDIA SCHMIDT², KLAUS SATTLER⁴, and NATALIE FRESE¹ — ¹Bielefeld University, Bielefeld, Germany — ²Paderborn University, Paderborn, Germany — ³Bielefeld University of Applied Sciences, Bielefeld, Germany — ⁴University of Hawaii, Honolulu, USA

Hard Carbon microspheres (HCS) were synthesized via hydrothermal carbonization (HTC) of trehalose and subsequent pyrolytic post-carbonization at 1000°C. It was found that HTC of trehalose, in contrast to other saccharides, results in a distinctly binary sphere diameter distribution with monodisperse small spheres and polydispers large spheres. Pore formation, as visualized by charge-compensated helium ion microscopy, results in a strong increase in BET surface area. The chemical composition and crystallinity were examined before and after pyrolysis using a variety of spectroscopic methods. Strong compositional similarities were found to other saccharide-derived hydrochars, with a cross-linked furan-based polymer-structure before, and nano-crystalline carbon structure after pyrolysis. The binary size-distribution and large BET surface area make trehalose-derived HCS a highly promising material for applications in energy storage or catalysis.

#### CPP 17.11 Tue 11:00 P2

**Physics of supersaturated, agitated sucrose solutions: Crystal nucleation and growth** — •HANNAH M. HARTGE and THOMAS A. VILGIS — Max Planck Institute for Polymer Research, Mainz, Germany

Supersaturated sucrose solutions that have been sufficiently cooled without nucleation constitute a meta-stable system in which agitation promotes fast crystallization. Applications of this physically interesting process can be found for example in the production of fondant in confectionery. While just water and sucrose are present, the system goes through complex thermodynamic processes during crystallization, which are highly dependent on composition, temperature, and agitation.

In this work, we investigate how temperature and concentration affect nucleation, crystal growth and final particle size distribution of highly supersaturated sucrose solutions under agitation. To do so, the torque was measured during kneading of the samples at controlled temperature, followed by light microscopy and corresponding image analysis. When crystallization times were compared to classical nucleation theory, variations were found to be related to temperature and supersaturation in the same way as indicated by induction time models of statistical physics. Additionally, size distributions of the resulting crystal phases showed a strong dependence on temperature during agitation, sucrose content and according initial supersaturation.

## CPP 17.12 Tue 11:00 P2

**Following the directed self-assembly of crystallizable block co oligomers via in situ AFM** — •ALEXANDER MEINHARDT and THOMAS F. KELLER — Centre for X-ray and Nano Science (CXNS), Deutsches Elektronen-Synchrotron DESY, Hamburg, Germany

Bottom up nanofabrication utilizing the molecular self-assembly of block cooligomers with sub-10 nm domain sizes are widely discussed as a promising route for next generation photolithography. Double crystalline co-oligomers can be used to create well defined, high-fidelity nanostructures by controlling the competing driving forces microphase separation and crystallization. We report on the surface nanostructure formation and its temporal evolution during annealing of thin films of an amphiphilic double crystalline polyethylene-blockpoly(ethylene oxide) co-oligomer (PE-b-PEO) on planar and patterned surfaces. Directing the self-assembly of such systems with physical or chemical guiding patterns can enable the formation of defined, large scale amphiphilic nanostructures, which could be of interest for various applications, e.g., biomaterials, photonics, and nanotechnology. However, there still remain several challenges regarding the characterization, defect density, pattern fidelity, and post processing of such block copolymer nanopatterns. By investigating the directed selfassembly (DSA) of the PE-b-PEO using AFM in situ, we aim to tune the balance of the involved driving forces and in turn create optimized nano-templates.

## CPP 17.13 Tue 11:00 P2

Influence of the surface roughness and surface chemistry to understand slide electrification — •BENJAMIN LEIBAUER, WERNER STEFFEN, and HANS-JÜRGEN BUTT — Ackermannweg 10 55128 Mainz

In the last few years a lot of studies have shown that by contact electrification between water droplets and hydrophobic surfaces, it is possible to generate electricity in an environmentally friendly way.[1] The physical processes are still being discussed today and to extend the understanding Stetten et al.[2] have established an experimental setup that allows the drop charge of individual drops. In the work presented here we have studied with this setup the influence of the surface roughness and the chemistry of the substrates on hydrophobic to superhydrophobic substrates. We found that for the drop charge both parameters have an influence on at least the same order of magnitude.

## CPP 17.14 Tue 11:00 P2

**Dewetting dynamics and equilibrium droplet shapes for of visco-elastic substrates** — •KHALIL REMINI¹, LEONIE SCHMELLER², DIRK PESCHKA², BARBARA WAGNER², and RALF SEEMANN¹ — ¹Experimental Physics, Saarland University, Saarbrücken, Germany — ²Weierstrass-Institute, Berlin University, Berlin, Germany

In our study we are interested in the dewetting of liquid polymer layers (Polystyrene 18 kg/mol) with about 100 nm thickness from visco-elastic polydimethylsiloxane surfaces with elasticity ranging E = 1.2 MPa for Sylgard 184 to E = 3 kPa for Cy52-276. When heating the samples to temperatures where PS is liquid, holes nucleate in the initially uniform PS film. These holes grow during dewetting, coalesce and eventually form sessile droplets of a few micrometers in diameter sitting on the PDMS surface. Due to the particular situation of the adaptive PDMS substrate, we observe characteristic qualitative and quantitative differences in rim shapes, (dynamic) contact angles and dewetting velocities which are indicating differences in the underlying energy dissipation but might result also from potential phase separation of liquid and cross linked PDMS close to the three-phase contact line. To shed light on the impact of viscous and elastic properties and potential phase separation at the three phase contact line, we aim at a quantitative comparison of sessile (equilibrium) droplets on substrates having different elasticities and thus elastocapillary lengths.

#### CPP 17.15 Tue 11:00 P2

Messung von Kräften zwischen Tropfen und bewegten Oberflächen — •MARISA FISCHER, SIMON SCHUBOTZ, JENS-UWE SOMMER, ANDREAS FERY und GÜNTER AUERNHAMMER — Leibniz-Institut für Polymerforschung Dresden e.V., 01069 Dresden, Germany

Um einen Tropfen über eine Oberfläche zu bewegen, wird eine Kraft benötigt, die von deren Eigenschaften abhängt. Das zur Messung dieser Kraft entwickelte Drop Adhesion Force Instrument (DAFI) erlaubt die freie Wahl der Geschwindigkeit der Drei-Phasen Kontaktlinie und der Größe des Tropfens [1]. Die Kraftmessung erfolgt mittels des Hookschen Gesetzes, indem die Auslenkung einer im Tropfen befindlichen Glaskapillare gemessen wird.

Ein von der Bewegung des Tropfens aufgenommenes Video wird mit einem von uns entwickelten Analyseprogramm ausgewertet. Für die Übertragung größerer Kräfte wird ein Glasplättchen am Kapillarende befestigt, welches die Adhäsion zwischen Tropfen und Kapillare erhöht.

Mit dem entwickelten Aufbau wurden die Kräfte zwischen Wassertropfen und Polydimethylsiloxan (PDMS) sowie Poly(N-isopropylacrylamide) (PNiPAAm) Polymerbürsten untersucht. Dabei zeigte sich ein Zusammenhang zwischen dem Zustand der Oberfläche und der Kraft.

#### CPP 17.16 Tue 11:00 P2

In-situ Monitoring of Hard-Core Soft-Shell Microgels During Monolayer Drying — •JULIAN RINGLING, KEUMKYUNG KUK, and MATTHIAS KARG — Heinrich-Heine-Universität, Düsseldorf, Germany

Hard-core soft-shell (HCSS) microgels are interesting colloids with the potential to be used as model systems to understand crystallization and melting processes [1]. They spread at the air/water interface and self-assemble into 2D monolay-

ers in which the cores do not touch directly due to shell-shell repulsion. Compression of such a monolayer allows control over the inter-particle distance by compressing the soft and deformable shell [2]. After transferring a compressed monolayer to a substrate, various structures can be observed [3]. Understanding and controlling the formation of those structures is essential for the use of the system as a model for crystallization.

Previously our group discovered a difference in monolayer structure at the air/water interface in comparison to the dried monolayer after transfer onto a substrate when using micron-sized silica-poly(N-isopropylacrylamide) HCSS microgels. To understand the phase transition/structural change occurring, we have monitored this phase transition/structural change using fluorescence and light microscopy. Here we present results from in-situ observations of drying 2D colloidal monolayers focussing on the effect of different parameters on drying and assembly behaviour.

CPP 17.17 Tue 11:00 P2

**Investigation of Cononsolvency Phase Transition of Poly(sulfobetaine)based Diblock Copolymer Thin Films** — •PEIXI WANG¹ and PETER MÜLLER-BUSCHBAUM^{1,2} — ¹Technische Universität München, James-Franck-Straße 1, 85748 Garching, Germany — ²Heinz Maier-Leibnitz Zentrum (MLZ), Lichtenbergstr. 1, 85748 Garching, Germany

Co-nonsolvency occurs if a mixture of two good solvents causes the collapse or demixing of polymers into a polymer-rich and solvent-rich phase in a certain range of compositions of these two solvents. The nonionic thermoresponsive polymer, poly(N-isopropylmethacrylamide) (PNIPMAM), which features a lower critical solution temperature (LCST) in aqueous solution, has been widely used to investigate its collapse transition behavior in a mixture of two competing good solvents. However, co-nonsolvency response of its block copolymer containing the zwitterionic poly(sulfobetaine)s, especially poly(4-((3-methacrylamidopropyl)dimethyllammonio)butane-1-sulfonate))

(PSBP)*which exhibits an lower upper critical solution temperature (UCST) and shows a strong swelling transition in aqueous media, is newly studied. We focus on the co-nonsolvency behavior of PSBP-b-PNIPMAM thin films in water/acetone mixtures by in situ time-of-flight neutron reflectometry (TOF-NR) and spectral reflectance (SR). Furthermore, Fourier transform infra-red (FTIR) spectroscopy is applied to investigate the interactions between the polymer thin film and water/co-solvent, which is closely related to their deuteration level.

#### CPP 17.18 Tue 11:00 P2

**Core-shell microgels synthesized in continuous flow: Deep insight into shell growth by temperature-dependent FTIR spectrocopy** — •PASCAL FANDRICH¹, MARCO ANNEGARN¹, LARS WIEHEMEIER¹, INA EHRING¹, TILMAN KOTTKE², and THOMAS HELLWEG¹ — ¹Physical and Biophysical Chemistry, Bielefeld University, 33615 Bielefeld, Germany — ²Biophysical Chemistry and Diagnostics, Bielefeld University, 33615 Bielefeld, Germany

While core-shell microgels have been intensively studied in their fully synthesized state, the formation mechanism of the shell growth has not been completely understood. Such insight is decisive for a customization of microgel properties for applications. In a novel approach, we synthesized microgels based on a N-isopropylmethacrylamide (NiPMAM) core and a N-n-propylacrylamide (NnPAM) shell in a continuous flow reactor. The shell growth is studied depending on the solution's time of residence inside the reactor. PCS experiments reveal a significant decrease of the volume phase transition temperatures of the core and the shell respectively, with increasing residence time. At early stages, a decreased swelling capacity is found before a discrete NnPAM shell is formed. Temperature-dependent FTIR spectroscopy shows that the decreased swelling capacity originates from a pronounced interpenetrated network between NnPAM and NiPMAM. AFM images resolve a raspberry-like structure after 3 min, pointing to an aggregation of NnPAM domains before the distinct shell forms.

## CPP 17.19 Tue 11:00 P2

How ultrasound accelerates microgel adsorption kinetics — •LUCA MIRAU¹, SEBASTIAN STOCK¹, AMIN RAHIMZADEH¹, SONJA WISMATH², MATTHIAS RUTSCH², MARIO KUPNIK², and REGINE VON KLITZING¹ — ¹Department of Physics, TU Darmstadt, Hochschulstr. 8, 64289 Darmstadt — ²Measurement and Sensor Technology, TU Darmstadt, Merckstraße 25, 64283 Darmstadt

Poly-N-isopropylacrylamide (PNIPAM) based microgels (MGs) are surfaceactive and offer great opportunities as stabilizers of emulsions and foams. Due to their thermosensitive response, the MGs enable also destabilization on demand. However, emulsion formation implies energy input by stirring or ultrasonication. To understand this formation process, it is important to understand the interfacial adsorption of the MGs. A fast trigger to affect the adsorption process is given by ultrasonication. The present study shows the effect of ultrasound on the adsorption kinetics of PNIPAM MGs at the water-oil interface monitored by drop shape tensiometry. The adsorption kinetics of MGs accelerates with increasing ultrasonication intensity. The variation of different parameters, such as ultrasonic frequency, MG crosslinker density, concentration and phase composition, indicates that both acoustic streaming as well as ultrasound induced deswelling of MGs due to breakage of hydrogen bonding cause this acceleration.

#### CPP 17.20 Tue 11:00 P2

Interaction of soft microgel with solid silica particles at the air-water interface — •CARINA SCHNEIDER, SEBASTIAN STOCK, KEVIN GRÄFF, FRANZISKA JAKOB, and REGINE VON KLITZING — Departement of Physics, TU Darmstadt, Hochschulstraße 8, 64289, Darmstadt

Emulsions stabilized by multiple particle systems are interesting in various research fields, e. g., in the food industry or interfacial catalysis. The interaction of two or more nano-particle systems of different properties at liquid interfaces is important for the coalescence behavior of emulsion droplets stabilized by these particle mixtures. For instance, a mixture of hydrophilic microgel particles (MGs) and hydrophobic silica nano-particles (SiNP) is able to stabilize water in oil emulsions, which is not possible with MGs alone. Therefore, it is of special interest to understand the interaction of those particles at the interface. In this context, their lateral compression may simulate the droplet interfaces under coalescence conditions. For this purpose, we spread mixtures of poly-NIPAM MGs and spherical SiNPs at the air-water interface of a Langmuir trough and determined the compression isotherms. For deeper insights into the lateral structure formation, the particle layers were transferred onto Silicon wafers and scanned by atomic force microscopy. For low compressions, the elastic MG network dominates the isotherm while SiNP are situated between the MGs with low impact. For higher compressions, the inelastic SiNP structures are pushed onto the MGs and take over the resistance to the outer pressure.

#### CPP 17.21 Tue 11:00 P2

Adsorption kineticts of microgel particles at the air/water interface — •KAI LUCA SPANHEIMER, DANIEL JÄGER, SEBASTIAN STOCK, and REGINE VON KLITZ-ING — Department of Physics, TU Darmstadt, Hochschulstraße 8, 64289 Darmstadt

Interest in microgel particles (MGs) based on poly-N-isopropyl acrylamide (PNIPAM) as surface-active material remains high. The nano- to micrometer sized, cross-linked polymer particles are able to adsorb to water/air or water/oil interfaces spontaneously. Combined with their ability to act as carriers for drugs, recent studies showed, that they may act as transport vehicles for amphiphilic catalysts to the interface, resulting in improved interfacial catalysis, e. g., in Pickering emulsions. Despite much research on the interaction of MGs with various low and higher molecular weight material, the adsorption of MG/catalyst complexes at the interface is not yet well understood. In the presented work, the adsorption kinetics at the air/water interface is measured via change in surface tension over time by drop shape analysis. In order to disentangle different effects in case of MG/catalyst complexes the adsorption kinetics of pure MGs and mixtures of MGs with simple anionic and cationic surfactants as model systems for the catalysts is studied and compared with the adsorption of MG/catalysts complexes.

## CPP 17.22 Tue 11:00 P2

A molecular dynamics approach to understand and control the catalyst enrichment at the IL/vacuum interface in SILP systems — MATTIA LIVRAGH1¹, CHRISTIAN WICK^{1,2}, •DAVID MATTHEW SMITH^{1,3}, and ANA-SUNČANA SMITH³ — ¹PULS Group, Institute for Theoretical Physics and Interdisciplinary Center for Nanostructured Films (IZNF), Friedrich-Alexander Universität Erlangen-Nürnberg (FAU), 91058 Erlangen, Germany — ²Competence Unit for Scientific Computing (CSC), FAU, 91058 Erlangen, Germany — ³Group of Computational Life Sciences, Division of Physical Chemistry, Ruder Bošković Institute, 10000 Zagreb, Croatia

Supported Ionic Liquid Phase Catalysis (SILP) improves the catalytic turnover by smearing a thin IL layer onto a support material, reducing the need for slow reactant transport inside viscous ILs. Next generation SILP technology will rely on confining the catalyst to the vacuum interface, spatially localising the chemical reaction. This will require a deep understanding of the interface enrichment and structuring of the individual chemical components. We investigated ionic liquids made of iodide and polyehtylene glycol imidazolium cations. Therefore, we parameterized atomic charges for the new ILs using multiple conformations during the RESP fitting procedure, compatible with the GAFF force field, and validated our simulations against experimental data. The (also newly parameterized) catalysts are Nickel(II) coordination compounds with task-specific carbene ligands. We investigate the influence of the structures of the ligands and the IL's chain on controlling the catalyst's distribution in and affinity for the IL-vacuum interface.

## CPP 17.23 Tue 11:00 P2

Morphology control of titania thin films in a low temperature process — •GUANGJIU PAN¹, SHANSHAN YIN¹, NIAN LI¹, TIANFU GUAN¹, RENJUN GUO¹, SUZHE LIANG¹, YUQIN ZOU¹, CAROLINE EHGARTNER², NICOLA HÜSING², and PETER MÜLLER-BUSCHBAUM^{1,3} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching, Germany — ²Materialchemie,

Chemie und Physik der Materialien, Universität Salzburg, 5020 Salzburg, Austria-  $^3\rm MLZ,$  TU München, 85748 Garching, Germany

A low-temperature routine to realize inorganic electron-transport layers (ETLs) is important for the commercialization of perovskite solar cells. Fabricating ETLs at low temperature is energy saving and compatible with flexible substrates. In this work, titania thin films are synthesized at low temperature (below 100 Celsius degree) with a polymer template sol-gel method based on the amphiphilic diblock copolymer polystyrene-b-polyethylene oxide (PS-b-PEO), in combination with selective incorporation of the titanium precursor ethylene glycol-modified titanate (EGMT). Tailoring titania film morphology in the lowtemperature process is achieved by managing phase separation of the polymer template. The ratio of polymer, precursor, solvent, and catalyst for the sol-gel solution is varied to tune the thin film morphologies. The surface morphologies of titania films are probed via scanning electron microscopy and GISAXS. The optical properties of the films are examined with ultraviolet-visible spectroscopy.

### CPP 17.24 Tue 11:00 P2

**Soft Matter Food Physics: Oat Drink Foams** — •JUDITH HEGE, ANTONIA-LOUISA SCHLICHTING, JANA REEH, and THOMAS A. VILGIS — Max Planck Institute for Polymer Research, Mainz, Germany

For various applications, oat drink needs to provide a capacity to form stable, creamy, homogeneous foams. Such macroscopic foam properties are based on molecular interactions at the air-water interfaces and protein kinetics within the lamellae. However, the underlying structure-function relationships between molecular interactions and macroscopic foam properties are not yet fully understood, especially for multicomponent systems like plant-based drinks. Therefore, this study probed foams formed by an oat drink containing only water, oats, canola oil and salt.

Investigations focused on the influence of enzyme treatment, canola oil addition, heat treatment and homogenization parameters on foam properties. Accordingly, time-dependent foam height measurements were performed and supported by light microscopy, photography, and particle size measurements to compare the findings on the macroscopic scale with bubble size evolution and oil droplet distribution.

This study showed that protease treatment resulted in a higher foaming capacity, but lower foam stability and that heat treatment lessened the foam stability. Furthermore, addition of small contents of canola oil increased the foaming capacity, however, higher canola oil contents reduced foam stability. Furthermore, a longer duration and higher speed of homogenization treatment caused a more homogeneous emulsion and increased foaming capacity as well as foam stability.

#### CPP 17.25 Tue 11:00 P2

**Spatial resolution of particle transport at interfaces** – •Kevin Höllring¹, ANDREAS BAER¹, DAVID M. SMITH², and ANA-SUNČANA SMITH^{1,2} – ¹PULS Group, FAU Erlangen-Nürnberg, Germany – ²Group for Computational Life Sciences, Ruđer Bošković Institute, Zagreb, Croatia

Confined geometries play an important role in various applications, where it is generally important to be able to predict particle transport and mobility. Commonly used techniques like the Einstein-approach using the Mean Square Displacement (MSD) as well as Auto-correlation-function (ACF) related techniques rely on strong assumptions about spatial isotropy and homogeneity tied to conditions on local symmetry, that are not satisfied in these confined geometries, making it especially hard to resolve interface-orthogonal particle dynamics. Still other techniques like jump-diffusion are only able to approximate relative mobility and require calibration for each system.

We propose a theoretical model for resolving absolute interface-perpendicular diffusion based on the time particles spend within subspaces of confined systems that accurately predicts diffusion for simple point-like particles like water. In addition, we also present an extension to that model taking into account internal deformational degrees of freedom that can affect the observed particle lifetime.

By application of the proposed models to water as well as Imidazolium-based ionic liquids, we confirm their accuracy and versatility in the analysis of complex particle dynamics thus also proving their applicability to confined geometries.

#### CPP 17.26 Tue 11:00 P2

**In-situ investigation during gold HiPIMS deposition onto polymers** — •YUSUF BULUT^{1,2}, KRISTIAN RECK³, MATTHIAS SCHWARTZKOPF¹, JONAS DREWES³, SUZHE LIANG², TIANFU GUAN², THOMAS STRUNKUS³, FRANZ FRAUPEL³, PETER MÜLLER-BUSCHBAUM^{2,4}, and STEPHAN V. ROTH^{1,5} — ¹DESY, 22607 Hamburg — ²TU München, Physik Department, Lehrstuhl für Funktionelle Materialien, 85748 Garching — ³CAU, Chair for Multicomponent Materials, Faculty of Engineering, 24143 Kiel — ⁴MLZ, TU München, 85748 Garching — ⁵KTH Royal Institute of Technology, Department of Fibre and Polymer Technology, SE-100 44 Stockholm

Gold deposition via high power impulse magnetron sputtering (HiPIMS) allows to coat thin metal layers on heat sensitive materials such as polymers allowing for increased adhesion and density. HiPIMS allows deposition at a lower total deposited thermal energy in comparison to conventional magnetron sputtering, but this energy is delivered in a very short pulse exhibiting very high power and ionization. The consequences for the nucleation and growth processes during HiPIMS deposition are not sufficiently known. Therefore, we investigate the morphology evolution of thin gold layers on four polymer templates, namely polystyrene (PS), polyvinylalcohol (PVA), polystyrene sulfonicacid (PSS) and poly-4-vinylpyridin (P4VP). These polymers show different functional moieties and thus are expected to influence the growth of the gold layer. We present first results of our in situ investigations combining grazing-incidence small angle X-ray scattering (GISAXS), grazing incidence wide angle X ray scattering (GIWAXS).

#### CPP 17.27 Tue 11:00 P2

**High-concentration Lithium-ion Electrolyte Overcomes the Challenges of High-temperature Lithium Batteries** — •TIANLE ZHENG¹, YAJUN CHENG², and PETER MÜLLER-BUSCHBAUM¹ — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²Ningbo Institute of Materials Technology & Engineering, Chinese Academy of Sciences, Ningbo, 315201, Zhejiang Province, P. R. China

Traditional Li-ion batteries, on the other hand, are severely constrained in high-temperature applications due to the low thermal stability of the electrolyte/electrode interface and electrolyte decompositions in the cell. Herein, we demonstrate a new electrolyte that achieves an excellent stable long-term cycling at 100°C, well beyond the typical 60°C limits of normal conventional Li-ion batteries. The high concentrated lithium oxalyldifluoroborate (LiODFB) is selected as the only lithium salt with a carefully designed high thermal stability solvent group. As a result, this unique high-concentration electrolyte can promote to form a stable and inorganic solid electrolyte interface (SEI) layer on the electrode at elevated temperature, leading to improved performance in MCMB/Li and lithium iron phosphate (LFP)/Li half-cells, and achieve reversible capacities of 160 and 350 mA h/g, respectively, with Coulombic efficiencies (CEs) > 99.3%. Subsequently, we further investigate the mechanism of high concentration Li-ODFB electrolytes by molecular dynamics (MD) simulations and XPS characterization techniques, exploring a new way for future high-temperature electrolytes for Li-ion batteries.

CPP 17.28 Tue 11:00 P2

Sol-gel based tailored lithium-ion battery electrodes — •Ivana Pivarníková^{1,2}, Ralph Gilles¹, and Peter Müller-Buschbaum^{1,2} — ¹MLZ, TU München, 85748 Garching — ²TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching

Silicon based materials have been considered as one of the most promising candidates for the next-generation lithium-ion battery anodes, thanks to its low cost, non-toxicity and high theoretical gravimetric capacity (4200 mAh/g). One of the concepts for a suitable application is to design the mesoporous Si-based material via copolymer assisted sol-gel synthesis. This wet chemical method consists of the formation of the organic-inorganic composites by a self-assembly mechanism, where the organic phase (PEO-b-PPO-b-PEO non-ionic triblock copolymer) serves as a template for the inorganic structure (SiOx). The tetraethoxysilane (TEOS) is used as a Si precursor. The solution mix is spin-coated onto the cleaned Si substrates and the removal of the template is done by calcination at high temperature (400 °C). The properties of the thin films can be tuned by adjusting the synthesis conditions such as concentration of the reaction compounds, choice of the deposition technique, choice of the final calcination step or choice of additives. The aim is to reach the desired thickness, porosity, conductivity and mechanical stability for a successful Li-ion battery anode application. The produced thin films are characterized by scanning electron microscopy (SEM), grazing incidence small-angle X-ray scattering (GISAXS), profilometry and ellipsometry measurements.

# CPP 17.29 Tue 11:00 P2

Silicon-germanium based coating of anodes for Lithium-ion batteries — •KEXIN Wu¹, CHRISTIAN L. WEINDL¹, and PETER MÜLLER-BUSCHBAUM^{1,2} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²MLZ, TU München, 85748 Garching

Lithium-ion batteries (LIBs) have received increasing attention over several decades as an indispensable role in energy storage. The application of silicon anodes is hindered by their volumetric expansion after full lithiation, which causes collapse with three failure mechanisms including electrode pulverization, disconnection between the electrode and current collector, and continuous breaking and re-growth of the solid electrolyte interface (SEI) layer. To tackle this critical issue, the construction of hierarchical structures is a promising way to increase the stability of active materials. In our studies, Si/Ge hierarchical structures are built by chemical templating of pre-nanostructure self-assembled polystyrene nanoparticles, using an amphiphilic polystyrene-block-polyethylene oxide (PS-b-PEO) diblock copolymer as structure-directing agent. The diblock copolymers undergo microphase separation, which is further modified by solvent vapor annealing with dichloromethane (DCM) and SiCl4. By pyrolysis, mesoporous thin films are achieved. The desirable morphological and crystallographic studies are accomplished by GISAXS) SEM, AFM, and GIWAXS) The study is completed by galvanostatic cycling tests and impedance spectroscopy.

## CPP 17.30 Tue 11:00 P2 Modeling of Nano-Porous Electrode Systems via Molecular Dynamics —

•PHILIPP STÄRK — SC Simtech, Uni Stuttgart, Germany We use grand canonical Monte Carlo combined with atomistic-level MD to simulate open electrode systems at a constant potential. Using a multi-scale approach, our aim is to aid in the design of energy storage devices/electrocatalysis applications. In order to achieve this goal, we use different constant potential approaches to characterise the atomistic mechanisms behind charging and electro-

catalytic product transport.

#### CPP 17.31 Tue 11:00 P2

Charging of dielectric surfaces in contact with aqueous electrolyte – the influence of  $CO_2$  – •PETER VOGEL¹, NADIR MÖLLER¹, PRAVASH BISTA², STE-FAN WEBER², HANS-JÜRGEN BUTT², BENNO LIEBCHEN³, and THOMAS PALBERG¹ – ¹Institut für Physik, Johannes Gutenberg Universität, 55128 Mainz (Germany) – ²Max Planck Institut für Polymerforschung, 55128 Mainz (Germany) – ³Institut für Physik kondensierter Materie, Technische Universität Darmstadt, 3 64289 Darmstadt (Germany)

The charge state of dielectric surfaces in aqueous environments is of fundamental and technological importance. We use super-heterodyne light scattering in a custom-made cell to study the influence of dissolved CO₂ on the charging of three, chemically different surfaces. We compare an ideal, CO₂-free reference state to ambient CO₂ conditions. Systems are conditioned under conductometric control at different low concentrations of NaCl. As expected for constant charge densities,  $\zeta$ -potentials drop upon increasing the salt concentration in the reference state. Presence of CO₂ leads to an overall lowering of  $\zeta$ -potentials. Moreover, for the inorganic dielectric, the salt dependent drop is significantly weakened, and it is inversed for the organic dielectrics. We suggest that at ambient conditions, the charge state of dielectric surfaces is related to dielectric charge regulation caused by the salt concentration dependent adsorption/desorption of CO₂.

### CPP 17.32 Tue 11:00 P2

**Characterization of Nd complexes and processing of photonic crystal structures** — •MIRIAM GERSTEL¹, MUHAMMAD SHAHARUKH¹, INGO KÖHNE², PAUL MERTIN³, RUDOLF PIETSCHNIG², BERND WITZIGMANN³, JOHANN PETER REITHMAIER¹, and MOHAMED BENYOUCEF¹ — ¹Institute of Nanostructure Technologies and Analytics (INA) — ²Institute of Chemistry — ³Institute of Computational Electronics and Photonics, CINSaT, University of Kassel, Germany

Lanthanide (Ln) ions are unique for applications in lighting, sensing, and display technologies. In our approach, we investigate the potential of using Ln(III) complexes as attractive luminescent materials due to its characteristics of narrow emission bands and wide emission spectrum. Two different types of Nd(III) complexes are investigated: Nd complexes with phosphonate ligands with varying aromatic residues and complexes where the Nd ion is incorporated in a polyoctahedral silsesquioxane cage. Optical properties of Nd complexes are determined by photoluminescence (PL) spectroscopy, which reveals three emission bands of Nd(III) ions in the NIR region. To achieve a lowdensity molecular distribution on the sample surface, the complexes are dissolved in dichloromethane and drop-casted on a flat surface. For light enhancement, molecules will be immobilized on photonic crystal cavities (PhCs). The fabrication of PhCs by electron-beam lithography, inductively coupled plasma reactive ion etching and selective wet etching techniques is discussed. This work is supported by the state of Hesse in the frame of LOEWE priority project SMolBits.

#### CPP 17.33 Tue 11:00 P2

Fabrication of photonic crystals for integration of molecules — •ÖZLEM URCAN¹, RANBIR KAUR¹, MUHAMMAD SHAHARUKH¹, INGO KÖHNE², RUDOLF PIETSCHNIG², JOHANN PETER REITHMAIER¹, and MOHAMED BENYOUCEF¹ — ¹Institute of Nanostructure Technologies and Analytics (INA), Kassel, Germany — ²Institute of Chemistry, Kassel, Germany

The control of light-matter interaction is an enabling technique for many emerging quantum technology applications. Photonic crystals (PhCs) are of particular interest since they can confine light in small mode volumes producing a strong interaction between light and emitters located in or near the cavity. Emitters such as lanthanide (Ln) molecules offer the potential of scalable quantum systems due to their characteristic narrow linewidth and wide emission spectrum.

This work focuses on the fabrication of PhCs by electron-beam lithography, inductively coupled plasma reactive ion etching and selective wet etching techniques and investigating different process parameters influencing the quality of PhCs. The morphological and optical properties of PhCs are characterized by scanning electron microscopy and micro-photoluminescence spectroscopy. In order to enhance the light emission, Ln molecules will be immobilized on the processed PhC cavities.

This work is supported by the state of Hesse in the frame of LOEWE priority project SMolBits

CPP 17.34 Tue 11:00 P2

Propandehydrierungskatalysatoren mit den Eisen(III)oxid-Nanopartikeln — •Irina Belova — Moscow, Russia

Propylen ist ein sehr wichtiger Industrierohstoff, aber das Wachstum seiner Produktion hat mit dem Wachstum des Verbrauchs nicht Schritt gehalten. Das größte Potenzial im Bereich der Propylenherstellung haben die Reaktionen der direkten und oxidativen Dehydrierung von Propan. Wir haben versucht, einen Propan-Dehydrierungskatalysator als Eisen-Nanopartikeln auf Aluminiumoxid zu erhalten. Um Nanopartikel zu bilden, griffen wir auf die Bildung von Eisenkomplexen mit Phenanthrolin zurück. Bei der Reaktion der direkten Propandehydrierung gibt es bei diesen Katalysatoren eine geringe Selektivität. Dabei schreitet Cracken schreitet aktiv voran. Es gibt jedoch immer noch eine Propandehydrierung . Wir planen, mit Sauerstoff gemischtes Propan benutzen. Wir erwarten, dass die *milde* Oxidation von Propan mit Sauerstoff besser verläuft.

CPP 17.35 Tue 11:00 P2 Polydisperse curved polymer brushes - •Marios Giannakou and FRIEDERIKE SCHMID — University of Mainz

In the past, polymer brushes have been investigated in the monodisperse limit or in flat geometries. These circumstances however aren*t as experimentally relevant, as monodisperse brushes are difficult to construct and brushes are found in curved geometries most of the times. Here, we attempt to resolve this issue by extending the already established mean-field theory describing polymer brushes developed by Cates et.al.. We develop a numerical method that allows us to investigate cylindrical and spherical geometries for arbitrary polydispersities. We then explore the uniform, Schulz-Zimm and monodisperse polymer distributions, and comment on the results.

CPP 17.36 Tue 11:00 P2 Temperature-dependent conformation behavior of isolated Poly(3hexylthiopene) chains — •SANWARDHINI PANTAWANE and STEPHAN GEKLE — Biofluid Simulation and Modeling Theoretische Physik VI Universität Bayreuth 95440 Bayreuth Germany

We use atomistic as well as coarse-grained molecular dynamics simulations to study the conformation of a single Poly(3-hexylthiopene) chain as function of temperature. We find that mainly bundle and toroid structures appear with bundles becoming more abundant for decreasing temperatures and even more after adding solvent (THF), leading to a prominent swelling of the molecular size at a temperature of about 220K. This swelling is in close agreement with the interpretation of recent spectroscopic experiments (Panzer et al. J Phys Chem Lett 8, 114 (2017)). We further relate the temperature dependence of P3HT to that of simple Lennard-Jones model polymers in vacuum.

## CPP 17.37 Tue 11:00 P2

Dynamic Origin of the Entropic Force on a Semi-Confined Chain -•Rodrique Badr¹, Lama Tannoury², and Leonid Klushin³ – ¹Johannes Gutenberg University, Mainz, Germany — ²Martin Luther University, Halle-Wittenberg, Germany — ³American University of Beirut, Beirut, Lebanon Thermodynamics predicts that the free energy of confinement

 $F = B\frac{L}{D}$  for a chain confined in a tube with thin and thick walls is the same in both cases. This equivalence implies that the force acting to eject the chain from semi-confinement is also the same. Thermodynamics, however, does not explain the dynamical origin of the force, but one can understand the force as originating from contacts with the surface of the boundary. Intuition suggests that the thin boundary should amount to fewer contacts and thus lead to a smaller ejection force when compared to the case of a thick boundary. Using coarse-grained molecular dynamics (MD) simulations, we support and validate the thermodynamic prediction that the magnitude of the ejection force is the same for different thicknesses of the boundary.

The forces are also found to be in good agreement with the scaling laws predicted by the thermodynamic approach. Finally, the results from our MD simulations provide an explanation of the origin of this equivalence of entropic forces, through the analysis of the radial distribution of contributions from the boundary to the ejection force.

#### CPP 17.38 Tue 11:00 P2

Computational study of the rheology of nanoparticle-polymer composites -•LEON HILLMANN, NIKLAS BLAGOJEVIC, and MARCUS MÜLLER — Institute for Theoretical Physics, Georg-August-Universität Göttingen, Germany

Matrix-filler interactions in nanoparticle-polymer composites play a crucial role in the manufacturing process as well as the properties of the final material. Therefore, understanding the interplay between the parameters, such as shape, concentration, and size, is paramount for the design process of new composites. Computer simulations of these materials, however, pose several challenges due to the vast differences in the length scales involved, ranging from atomistic forces up to large-scale self-assembling structures. Here, a single nanoparticle embedded in polymer melt, represented by a highly coarse-grained, Gaussian, bead-spring model, is studied by dissipative particle dynamics (DPD) simulations. The nanoparticle-polymer interaction is adjusted with iterative Boltzmann inversion to match predictions of the density profile from atomistic simulations. Measurements of the nanoparticle's velocity autocorrelation function are then used to determine the memory kernel in a generalized Langevin equation. To what extent does the motion of the nanoparticle provide information about the viscoelastic properties of the surrounding melt? To this end, a numerical solution of the corresponding inverse problem is presented, which arises from a reformulation of the problem as the inversion of a triangular Toeplitz matrix. The results are finally compared with the predictions made by the Rouse model for unentangled polymer melts.

#### CPP 17.39 Tue 11:00 P2

Anomalous Diffusion of Diisocyanate in Cross-linked Silicone – •MARTIN WORTMANN¹, KLAUS VIERTEL², NATALIE FRESE¹, WALDEMAR KEIL³, CLAUDIA SCHMIDT³, and BRUNO HÜSGEN² – ¹Bielefeld University, Bielefeld, Germany –  2 Bielefeld University of Applied Sciences, Bielefeld, Germany —  3 Paderborn University, Paderborn, Germany

In industrial applications of polyurethane vacuum casting, silicone casting molds are used to replicate complex three-dimensional master patterns for prototypes and small series production. The undesired diffusion of isocyanate from the casting resin into the silicone causes gradual degradation of the casting molds. In this contribution, we present mathematical models for the anomalous diffusion process and a comprehensive description of the underlying chemical and physical mechanisms. The polymerization of the isocyanate with residual moisture to polyurea within the silicone matrix leads to a time dependence of both the surface concentration and the diffusion coefficient. The resulting concentration distribution over time and cross-section is modelled by analytical solutions to the diffusion equation.

CPP 17.40 Tue 11:00 P2

Molecular Dynamics Simulation of Free chain Diffusion into a Regular Network — •JUDE ANN VISHNU¹ and FRIEDERIKE SCHMID² — ¹Johannes Gutenberg University, Mainz, Germany — ²Johannes Gutenberg University, Mainz, Germany

Thermo-sensitive hydrogels have attracted considerable attention in the field of bio chemistry and bio-medicine. Earlier works show that microfluidics can be used to create core-shell particle with decoupled elasticity and surface adhesiveness. However these experiments could not achieve proper control over the coreshell interconnectivity. We use MD simulations to understand and quantify the diffusive interpenetration of these shell polymers into a core gel. The simulation uses a Regular network to model the gel which is diffusively invaded via a polymer solution. We look into the interfacial profile and the ways to control this core-shell connectivity. The density profiles show a clear dependence of penetration on shell polymer concentrations. This is also seen in the degree of interfacial integration and diffusion depths. Finally the analysis of diffused free chain within the gel shows the emergence of large clusters leading to percolation. These results give us insight into how the factors like the core-shell polymer contact time, shell polymer concentration, etc can help us fine tune the core-shell connectivity in experiments.

#### CPP 17.41 Tue 11:00 P2

Nucleation of separating liquid phases in elastic polymer networks -•CHARLOTTA LORENZ, CARLA FERNÁNDEZ-RICO, and ERIC DUFRESNE — Soft and Living Materials, ETH Zurich, Zurich, Switzerland

Arrested phase separation is a key mechanism used by living systems to create well-controlled nanostructures. One of the most salient examples is structural color as present in some bird and insect species. Besides fascinating optical properties, phase-separating composite systems can have astonishing mechanical properties: For example, liquid inclusions can stiffen polymer networks. These mechanical properties have been less studied compared to the optical properties. To study the mechanical properties we use a sample system of a polymer network made of PDMS and fluorinated oil. We aim to control mechanical properties by tuning the structure of the phase-separated domains. Structure of the phase separating domains can be influenced by their nucleation. We vary typical parameters which could determine the nucleation such as the mesh size of the polymer network and total liquid fraction. We employ small-angle Xray scattering, tensile tests and indentation experiments to study nucleation and mechanical properties of phase-separating samples. Our studies can result in mechanically highly flexible, self-assembled materials, which are comparatively fast and easy to produce.

## CPP 18: Complex Fluids and Colloids, Micelles and Vesicles (joint session CPP/DY)

Time: Tuesday 11:30-13:00

**Invited Talk** CPP 18.1 Tue 11:30 H38 How X-rays can reveal waters mysteries — •KATRIN AMANN-WINKEL — Max-Planck-Institut für Polymerforschung, Mainz, Germany - Johannes Gutenberg Universität Mainz, Institut für Physik, Mainz, Germany - Stockholm University, Department of Physics, Stockholm, Sweden

Water is ubiquitous and the most important liquid for life on earth. Although the water molecule is seemingly simple, various macroscopic properties of water are most anomalous, such as the density maximum at 4°C or the divergence of the heat capacity upon cooling. Computer-simulations suggest that the anomalous behaviour of ambient and supercooled water could be explained by a two state model of water. An important role in this ongoing discussion plays the amorphous forms of water [1]. Since the discovery of two distinct amorphous states of ice with different density (high- and low density amorphous ice, HDA and LDA) it has been discussed whether and how this phenomenon of polyamorphism at high pressures is connected to the occurrence of two distinct liquid phases (HDL and LDL). X-ray scattering experiments on both supercooled water [2] and amorphous ice [3] are of major importance for our understanding of water. In my talk I will give an overview on our recent experiments on supercooled water and amorphous ices. [1] K. Amann-Winkel et al., Waters controversial glass transition, Rev. Mod. Phys. 88, (2016) [2] K.H. Kim, et al., SCIENCE 358, 1589 (2017) [3] K.H. Kim, et al., SCIENCE 370, 6519, 978 (2020)

 $Electrostatic\ Shielding\ Behavior\ of\ Keggin\ Anions\ in\ Aqueous\ Solution\ -$ •THOMAS TILGER and REGINE VON KLITZING — Department of Physics, Technische Universität Darmstadt, Darmstadt, 64289, Germany

Natural colloidal dispersions have accompanied mankind in the form of blood or milk ever since. Besides this, artificial systems have gained a significant importance for our daily life during the last decades.

Therefore, it is of special interest to gain an understanding of which interparticle forces govern the stability of colloidal dispersions and how this stability can be tailored. In electrolyte solutions, the classical DLVO theory describes these interactions. Whilst this description provides a good agreement with experimental data for 1:1 electrolytes, larger deviations appear for systems of higher valency. For a detailed examination of the van der Waals and electrostatically dominated regimes, we directly measure the forces between colloidal silica particles in aqueous solutions by the colloidal probe AFM (atomic force microscopy) technique.

Varying the concentration of monovalent salts and acids allows us to demonstrate the transition from the double layer to the van der Waals dominated regime and to determine the pH dependence of the colloidal probes double layer potential. Similar measurements for phosphotungstic (PTA, a 1:3 system) and silicotungstic acid (STA, a 1:4 system) - both nanometer-sized anions of the Keggin type - can still be described with the DLVO theory, but reveal significant deviations between the calculated and measured ionic strengths.

## CPP 18.3 Tue 12:15 H38

Influence of the imbibition of colloids through the morphology of porous **CNF layers** — •Constantin Harder^{1,2}, Marie Betker^{1,3}, Alexakis E. Alexakis³, Andrei Chumakov¹, Benedikt Sochor¹, Elisabeth Erbes^{1,4}, Marc Gensch^{1,2}, Qing Chen¹, Calvin Brett^{1,3}, Jan Rubeck¹, Matthias Schwartzkopf¹, Eva Malmström³, Daniel Söderberg³, Peter Müller-Buschbaum^{2,5}, and Stephan V. Roth^{1,3} — ¹DESY, 22607 Hamburg, Germany - ²TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching, Germany — ³KTH Royal Institute of Technology, 10044 Stockholm, Sweden — ⁴Institute for X-ray Physics, Goettingen University, 37077 Goettingen, Germany – ⁵MLZ, TU München, 85748 Garching, Germany

Functionalization of porous materials in terms of optical, chemical, and mechanical properties is readily achieved by applying colloidal layers. Our goal is to functionalize porous cellulose nanofibril (CNF) templates by applying tailored core-shell colloids with specific surface properties. The colloidal layer formation influencing the surface properties can be tuned by the deposition conditions and subsequent annealing. Therefore, we applied colloidal inks (poly(butyl methacrylate) and poly(sobrerol methacrylate) in aqueous dispersion) with different glass transition temperatures  $T_q$  as the colloidal layers on the CNF templates. During the deposition, the colloids partially enter the CNF layer to fill the CNF voids and remain on the CNF surface, leading to complex drying processes. The morphology of the mixed CNF / colloidal thin film changes when  $T_a$  of the colloids is exceeded.

CPP 18.4 Tue 12:30 H38

Elastic core-shell materials and their deformational behavior - JANNIS KOLKER¹, •LUKAS FISCHER², ANDREAS M. MENZEL², and HARTMUT LÖWEN¹ ¹Institut für Theoretische Physik II, Heinrich-Heine-Universität Düsseldorf, Düsseldorf, Germany — ²Institut für Physik, Otto-von-Guericke-Universität Magdeburg, Magdeburg, Germany

Elastic materials consisting of an inner part, a core, and an outer part, a shell, of possibly different material properties can be found from planetary scales down to the colloidal microscale. We here describe a situation amenable to analytical theory, namely the linear elastic deformation of a spherical core-shell system in response to an equatorial load in form of a force line density [1]. The relevance of this setup lies in, e.g., functionalized microgel particles absorbed to fluid-fluid interfaces or macroscopic illustrative show-and-tell objects.

Situations of different elastic properties and sizes of core and shell are analyzed to study their influence on the deformational response of the whole system. For example, tuning the two Poisson ratios allows to adjust the relative degree of oblate or prolate deformations and change in volume between core and shell. Due to the overall spherical shape and the two-component structure, the stress and strain distributions become rather inhomogeneous. Using different core and shell materials in colloidal microgel particles allows for inner functionalization while simultaneously adjusting the outer wetting properties.

## CPP 19: Perovskite and Photovoltaics 2

Time: Wednesday 9:30-11:00

## Invited Talk

CPP 19.1 Wed 9:30 H38 Elucidating the role of antisolvent polarity on the surface chemistry and optoelectronic properties of lead-halide perovskite nanocrystals — • ROBERT HOYE - Department of Materials, Imperial College London, Exhibition Road, London SW7 2AZ, United Kingdom

Lead-halide perovskites (LHPs) have emerged as highly-promising contenders for light-emission applications, particularly in the form of nanocrystals (NCs), owing to their advantages of high photoluminescence quantum yield (PLQY), along with tunable, sharp emission peaks. Achieving high-quality NCs critically depends on the purification process, which often makes use of an antisolvent. Despite its important role, the mechanism by which the antisolvent influences the surface properties of the NCs is not well understood. In this talk, we examine

the influence of the polarity of the antisolvent on the properties of the model NC system CsPbBrxI3-x. The antisolvents we compare are (in order of increasing polarity): methyl acetate, acetone and butanol. We find that as the polarity of the antisolvent increases, there is a greater blue-shift in the photoluminescence peak, owing to the removal of iodide. Through detailed nuclear magnetic resonance measurements, we find that this occurs due to more polar antisolvents having a higher propensity to induce a condensation reaction between the oleic acid and oleylamine ligands on the NCs, leading to their removal in the form of amides, which leads to the removal of surface iodides. This work shows that minimising surface damage to LHP NCs requires the selection of low polarity antisolvents.

## CPP 19.2 Wed 10:00 H38

Simulation of the impact of processing conditions on the perovskite film morphology — •MARTIN MAJEWSKI, OLIVIER RONSIN, and JENS HARTING — Forschungszentrum Jülich GmbH, Helmholtz Institute Erlangen- Nürnberg (IEK-11), Dynamics of Complex Fluids and Interfaces, Cauerstraße 1, 91058 Erlangen, Germany

The solution-processed perovskite layer forms complex structures during drying. This morphology of the dry film heavily influences the efficiency of the final solar cell. The impact of the physical mechanisms on the morphology, like for example nucleation and evaporation rate, in a drying, crystallizing wet film is not really understood yet. Therefore a better understanding of the interplay of these phenomena is needed.

We will present phase field simulations which are capable to describe the main physical processes like: evaporation, diffusion, spontaneous nucleation, crystal growth and advection, to investigate the impact of processing conditions on the final morphology of the perovskite film. Comparisons of the simulation to the theory will be presented. First simulations of drying solutions, including all physical phenomena, will be shown and compared to experiments.

## CPP 19.3 Wed 10:15 H38

Influence of crystallization on the structural and optical properties of lead-free Cs2AgBiBr6 perovskite crystals — •MELINA ARMER¹, JULIAN HÖCKER², CARSTEN BÜCHNER¹, SOPHIE HÄFELE¹, PATRICK DÖRFLINGER¹, MAXIMILIAN T. SIRTL³, KRISTOFER TVINGSTEDT¹, THOMAS BEIN³, and VLADIMIR DYAKONOV¹ — ¹Experimental Physics VI, Julius Maximilian University of Würzburg, 97074 Würzburg — ²Ludwigs Maximilian University München, 80539 München — ³Ludwigs Maximilian University München

As conventional perovskite solar cells contain lead and therefore suffer from toxicity issues, finding stable lead-free materials for the application in perovskite photovoltaics has become an essential problem to be solved. In this work, leadfree Cs2AgBiBr6 single crystals have been synthesized by slowly evaporating organic solvents and by using the well-known controlled cooling technique. The evaluation of solubility curves showed that slow evaporation enables crystal growth in a wide range of temperatures. We further used the controlled cooling technique as a reference to the slow evaporation method to grow crystals at different temperatures. The quality of the synthesized crystals was characterized by X-ray diffraction (XRD) and energy dispersive X-ray (EDX) measurements. Furthermore, photoluminescence excitation (PLE) and absorption measurements were conducted to investigate the relationship between Urbach energy and the growth method and temperature. As a result, we found that growth temperatures significantly impact the amount of tail-states present in the perovskite crystals. CPP 19.4 Wed 10:30 H38

Real-time texture and phase evolution tracking of the annealing process of slot-die coated perovskite by in situ GIWAXS — •MANUEL A. REUS¹, LENNART K. REB¹, ALEXANDER F. WEINZIERL¹, CHRISTIAN L. WEINDL¹, RENJUN Guo¹, TIANXIAO XIAO¹, MATTHIAS SCHWARTZKOPF², ANDREI CHUMAKOV², STEPHAN V. ROTH², and PETER MÜLLER-BUSCHBAUM^{1,3} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²DESY, 22607 Hamburg — ³MLZ, TU München, 85748 Garching

In perovskite solar cell material research the thin-film morphology determines the quality of the absorber material and consequently device performance. To scale up material deposition towards, e.g., roll-to-roll compatible techniques, the influence of the deposition method on morphology needs to be known to control the process. Here, we apply in situ grazing-incidence wide-angle x-ray scattering (GIWAXS) on the annealing process of slot-die coated lead iodide and slot-die coated methylammonium iodide, that react to perovskite under heat. We track the conversion in real-time and extract relevant parameters concerning texture and phase evolution. As a reference, we show GIWAXS data of spin-cast equivalent systems and show the resulting morphology and kinetics differences traced back to the deposition method.

#### CPP 19.5 Wed 10:45 H38

**Temperature-reduced and rapid growth of hybrid perovskite single crystals** — •JULIAN HÖCKER^{1,2}, FELIX BRUST¹, MELINA ARMER¹, and VLADIMIR DYAKONOV¹ — ¹Experimental Physics VI, Julius Maximilian University of Würzburg, 97074 Würzburg, Germany — ²Experimental Physics - Soft Condensed Matter, Ludwig Maximilian University of Munich, 80539 Munich, Germany

Organolead trihalide perovskite single crystals are gaining more and more interest in the field of semiconductor research since they can be used for a variety of technical applications, like photodetectors or solar cells. To date, exclusively solution-processed perovskite crystals have been used for the fabrication of such device prototypes. A supersaturated perovskite solution is caused either by a temperature change, solvent evaporation, chemical reaction, or a combination of the methods. The aim of the various processes is to achieve rapid growth of crystals with controlled structure, size, shape, and yield. In addition, the crystalline components must exhibit high physical and chemical qualities to be applied as semiconducting components. However, these high requirements and numerous criteria cannot always be fully met by standard techniques like inverse temperature crystallisation. In order to grow large-sized OLTP single crystals in a controlled and simple manner from solution in the shortest possible time, we developed a crystallisation process based on primary alcohols. As a result, the blends based on perovskite precursor solution and alcohols lead to a significant reduction in their retrograde solubility and enable a temperature-reduced crystallisation pathway to grow single crystals.

## CPP 20: General Session to the Symposium: Interplay of Substrate Adaptivity and Wetting Dynamics from Soft Matter to Biology (joint session CPP/DY)

CPP 20.1 Wed 9:30 H39

Adaptive two capacitor model to describe slide electrification in moving water drops — •PRAVASH BISTA¹, AMY Z. STETTEN¹, WILLIAM S.Y WONG¹, HANS-JÜRGEN BUTT¹, and STEFAN A.L. WEBER^{1,2} — ¹Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany<br/> -  $^2 {\rm Johannes}$  Gutenberg University, Department of Physics, Staudingerweg 10, 55128 Mainz, Germany Slide electrification is a contact-charge separation where neutral water drops slide over a neutral hydrophobic surface, accumulating and leaving behind a net charge. The accumulated drop charge for successive sliding drops decreases and eventually reaches a steady state. On hydrophobic and hydrophilic mixed surfaces, even a polarity flipping of drop charge depending on a drop rate was observed. Here, we describe this effect in terms of a voltage generated at the threephase contact line. This voltage moves charges between capacitors, one formed by the drop combined with the solid surface and one on the solid-surface. By introducing an adaptation of the voltage upon water contact, we can model drop charge experiments on different surfaces, including more exotic ones with droprate-dependent charge polarity. Thus, the adaptive two capacitor model enables new insights into the molecular details of the charge separation mechanism.

**Memory effects of PNiPAAm brushes in different atmospheres** — •SIMON SCHUBOTZ, MARISA FISCHER, JENS-UWE SOMMER, PETRA UHLMANN, ANDREAS FERY, and GÜNTER AUERNHAMMER — Leibniz-Institut für Polymerforschung Dresden e.V., 01069 Dresden, Germany

Some polymer brushes show a co-nonsolvency effect: They collapse in a mixture of two good solvents at some specific mixing ratio. In contrast to previous studies we concentrate on partial wetting of co-nonsolvent polymer brushes, i.e., on

the dynamics of a three-phase contact line moving over such brushes.

We found that Poly(N-isopropylacrylamide) (PNiPAAm) brushes experiences a memory effect when consecutively depositing drops at the same position. Previously deposited drops adapt the brush and changes the wetting behavior (advancing contact angle) of subsequent drops.

We measure water drops in an ethanol-saturated atmosphere on PNiPAAm brushes. The measurements show that the memory effect is strongly effected by an ethanol-enriched atmosphere. At the three-phase contact line, due to evaporation from the drop, the composition of the atmosphere and probably also the brush will transition from an ethanol-rich state to a water-enriched state. Thus, the brush might pass through the co-nonsolvency regime. On large time scales the ethanol enriched gas phase and the water drop will become mixtures of ethanol and water. We present strategies to counter this mixing effect.

**Fast contact lines on soft solids** — •HANSOL JEON^{1,2} and STEFAN KARPITSCHKA¹ — ¹Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — ²Georg-August-Universität Göttingen, Göttingen, Germany

When a droplet is resting on a soft surface, the capillary forces deform the surface into a sharp wetting ridge. The amplitude of the wetting ridge is determined by elasto-capillary length, but the angles by which the interfaces meet at the ridge tip only depend on the balance of surface tensions, the so-called Neumann balance. For moving contact lines, dissipation in the wetting ridge leads to viscoelastic braking. In recent literature, various effects that could alter Neumann balance and viscoelastic braking have been suggested, ranging from free, extractable oligomers to point forces emerg-ing from bulk viscoelasticity. We visualize moving wetting ridges at high spatio-temporal resolution and determine the tip geometry for various liquids and PDMS substrates. We observe an increase of the ridge opening angle at large speeds, even for very mild deformations caused by the low surface tension of a fluorinated oil. We also find no significant change in ridge rotation and opening angle for gels with different fractions of cross-linked and free chains, nor for different bulk rheological properties. These findings highlight the need for a non-trivial surface constitutional relation that is different from the bulk.

CPP 20.4 Wed 10:15 H39

Mixed grafted homopolymer and diblock copolymer functional brush layers upon humidity alterations: nanoscale morphology and transformations -•Apostolos Vagias¹, Theodore Manouras², Eleftherios Koufakis^{2,3}, Peixi Wang⁴, Marcell Wolf¹, Fabian A. C. Hellas, Institute of Electronic Structure and Laser,700 13 Heraklion, Crete, Greece — ³Department of Materials Science and Technology, University of Crete, 700 13 Heraklion, Crete, Greece — ⁴Physik-Department, Lehrstuhl für Funktionelle Materialien, Technische Universität München, 85748 Garching, Germany — ⁵Elettra Sincrotrone Trieste S.C.p.A., Basovizza, 34149 Trieste, Italy Using in situ grazing-incident small-angle X-ray scattering (GISAXS) measurements during water vapor uptake, we study the nanostructure morphology in the dry state, during vapor swelling and in the fully swollen state, for thin (<100nm) films of poly(2-(dimethylamino)ethyl methacrylate) (PDMAEMA) and poly(fluoroalkyl methacrylate) (POFPMA) homopolymer and PDMAEMAb-POFPMA block copolymer dual functional, bactericidal and antifouling, brushes. Our surface energy and swelling studies, stress on the role alkyl chain length, charged groups and brush topology in morphology, for the brush functionality.

## CPP 20.5 Wed 10:30 H39

Steering droplets on substrates with periodic wettability patterns and deformations — •JOSUA GRAWITTER and HOLGER STARK — Technische Universität Berlin, Institut für Theoretische Physik, Straße des 17. Juni 135, 10623 Berlin Droplets are set in motion on substrates with a spatio-temporal wettability pattern as generated, for example, on light-switchable surfaces. To study such cases, we implement the boundary-element method to solve the governing Stokes equations for the fluid flow field inside and on the surface of a droplet and supplement it by the Cox*Voinov law for the dynamics of the contact line. Our approach reproduces the relaxation of an axisymmetric droplet in experiments, which we initiate by instantaneously switching the uniform wettability of a substrate quantified by the equilibrium contact angle.

First, we investigate a droplet on substrates with planar-wave-like wettability profile by varying the speed an wave length of the pattern. When the profile moves slowly, it moves the droplet moves steadily forward. Above a critical pattern speed the droplet performs steady oscillations, the effective (time-averaged) velocity of which decreases with the square of the pattern speed. Wednesday

Second, we investigate a droplet on substrates which deform periodically according to a planar-wave profile. We analyze the effective velocity again as a function of wave speed and length and investigate specifically the influence of curvature changes on droplet motion.

CPP 20.6 Wed 10:45 H39

Spontaneous charging affects the motion of sliding drops — XIAOMEI LI¹, PRAVASH BISTA¹, RÜDIGER BERGER¹, STEFFEN HARDT², HOLGER MARSCHALL³, HANS-JÜRGEN BUTT¹, and •STEFAN A.L. WEBER^{1,4} — ¹MPI for Polymer Research, Ackermannweg 10, Mainz, Germany — ²Institute for Nano- and Microfluidics, Technische Universität Darmstadt, Darmstadt, Germany — ³Computational Multiphase Flows, Technische Universität Darmstadt, Darmstadt, Darmstadt, Germany — ⁴Institute of Physics, Johannes Gutenberg University Mainz, Mainz, Germany

The motion of water drops on surfaces is still far from being fully understood. Previous understanding is that drop motion is dictated by viscous dissipation and activated dynamics at the contact line. To accurately measure the forces experienced by moving drops, we imaged their trajectory when sliding down a tilted surface, and applied the relevant equations of motion [1]. We found that drop motion on low-permittivity substrates is substantially influenced by electrostatic forces. Our findings confirm that electrostatics must be taken into consideration of the description of the motion of water, aqueous electrolytes and ethylene gly-col on hydrophobic surfaces. Our results are relevant for improving the control of drop motion in many applications, including printing, microfluidics, water man agement and triboelectric nanogenerators. [1] Li, X. et al. Spontaneous charging affects the motion of sliding drops. Nat. Phys. (2022).

CPP 20.7 Wed 11:00 H39

**Dynamic mesoscopic model for two-component compound drops** — •JAN DIEKMANN and UWE THIELE — Westfälische Wilhelms-Universität, Münster, Deutschland

We consider a mesoscopic model for two immiscible fluids forming two-layer liquid films or compound drops on a rigid solid substrate. The earlier macroscale description [1,2] is connected to our mesoscopic approach (building on [3]) via consistency conditions. Thereby we relate macroscale and mesoscale versions of the Young and Neumann relations at the liquid 1/solid/gas and liquid 1/liquid 2/gas contact lines, respectively. Furthermore, we employ the mesoscale model to investigate selected dewetting and coarsening processes for physically realistic parameters. The steady compound drops emerging from the time simulations are related to bifurcation scenarios determined via macroscale and mesoscale descriptions.

CPP 26.1 Wed 11:30 H38

Large Area Semitransparent Near-Infrared Organic Photodetectors — YAZHONG WANG¹, •TIANYI ZHANG¹, LOUIS CONRAD WINKLER¹, DONATO SPOLTORE², JOHANNES BENDUHN¹, and KARL LEO¹ — ¹Dresden Integrated Center for Applied Physics and Photonic Materials, Technische Universität Dresden, Dresden, Germany — ²Department of Mathematical, Physical and Computer Sciences, University of Parma, V.le delle Scienze 7/A, 43124 Parma, Italy

Organic photodetector (OPD) is a promising technology for several sensing applications. With advances in material synthesis and device engineering, OPDs can rival their inorganic counterparts due to their tunable absorption, lightweight, facile fabrication, low cost, and comparable performance. Here, we demonstrate a semi-transparent large area (256 mm²) near-infrared OPD. Through vacuum deposition and optimization of the thickness of the back metal contact layer, a promising average visible transmittance up to 34.6% is achieved while maintaining 36.0% of external quantum efficiency at 790 nm. Judicious design for combining wide-optical gap buffer layers with semi-transparent electrodes results in the remarkable specific detectivity of  $1.4 \times 10^{13} (6.44 \text{ mm}^2)$  and  $1.1 \times 10^{12}$  (large area) Jones, respectively. Those performances are comparable with commercial silicon photodiodes. To the best of our knowledge, our device is the best see-through, large-area, near-infrared OPD, which enables a higher level of photon detection and integration into image sensors. The transparency and good stability of these OPDs make them excellent candidates for various biomedical sensing applications and the internet of things.

#### CPP 26.2 Wed 11:45 H38

**Exploring Highly Ordered Rubrene**: $C_{60}$  Heterojunctions for Organic Photodetectors — •Anna-Lena Hofmann¹, Lucy Winkler¹, Max Herzog¹, Eva Bittrich², Jakob Wolansky¹, Martin Kroll¹, Johannes Benduhn¹, and Karl Leo¹ — ¹Institute of Applied Physics, Technische Universität Dresden, Nöthnitzer Str. 61, 01187 Dresden, Germany — ²Leibniz-Institut für Polymerforschung Dresden e.V., Dresden, Germany

Rubrene can form highly ordered phases, demonstrating an unusually high charge carrier mobility for holes (>  $10 \text{ cm}^2 \text{V}^{-1} \text{s}^{-1}$ ) even in thin films. Therefore it is a promising material for high-performance organic photodetectors (OPDs). To study the impact on OPDs, crystalline triclinic rubrene is compared to amorphous rubrene. Planar heterojunctions (PHJs) and bulk heterojunctions (BHJs) are fabricated for both material systems. For the latter, rubrene is doped with 2, 5, and 10 wt% of C₆₀. Linearly polarized microscopy is used to get the first insight into the morphology, which is then completed by ellipsometry, atomic force microscopy (AFM), and x-ray diffraction (XRD). For the electrical characterization, the external quantum efficiency (EQE) and IV characteristics are obtained, where an additional crystalline sample with a neat C₆₀ layer is investigated. The neat layer of C₆₀ achieves an enormous improvement of the EQE. This makes the PHJ a more favourable device architecture. Even though triclinic rubrene reaches a higher EQE and has a broader spectral response, it does underperform in optimized OPDs concerning the specific detectivity since the dark current is three magnitudes higher than the amorphous counterpart.

#### CPP 26.3 Wed 12:00 H38

Hybrid Energy Harvester based on Triboelectric Nanogenerator and PbS Quantum Dot Solar Cell — •TIANXIAO XIAO¹, WEI CHEN¹, WEI CAO¹, and PETER MÜLLER-BUSCHBAUM^{1,2} — ¹Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²MLZ, TU München, 85748 Garching

Developing clean energy lies in the heart of the sustainable development of human society. Triboelectric nanogenerators (TENGs) originating from Maxwell's displacement current is a new type of energy harvester for harnessing ambient mechanical energy based on the coupling of triboelectrification and electrostatic induction effect. Compared with other counterparts, owing to the light-weight, low-cost, and easy fabrication TENGs become one of the most promising candidates in the replacement of conventional fossil fuels and attract worldwide attention in the past years. However, to further increase the energy harvesting efficiency and broaden application fields, integrating the TENG with other kinds of energy harvesters in one device is a possible way to meet these needs. In the present work, a TENG based hybrid energy harvester is designed and fabricated on the flexible polyethylene terephthalate (PET) substrate. This hybrid device consists of a single-electrode mode TENG component and a PbS quantum dot (QD) based solar cell component, which can harness both mechanical and solar energy from ambient environment to directly generate electricity. CPP 26.4 Wed 12:15 H38

In Situ and In Operando KPFM Studies on OFET Based on Hexadecafluoro-Copper-Phthalocyanine ( $F_{16}PcCu$ ) to Access Energy Level Alignment and Electrical Contact Resistance — •PASCAL SCHWEITZER, CLEMENS GEIS, and DERCK SCHLETTWEIN — Justus-Liebig-Universität Gießen, Institut für Angewandte Physik

Contact resistances are considered a show-stopper for organic field effect transistors (OFET). Perfluorinated copper-phthalocyanine  $(F_{16}PcCu)$  is a promising chemically stable n-conductor to build complementary logical circuits with established p-conductors. A reasonably high charge carrier mobility  $\mu_{ext} \approx$  $2 \times 10^{-3} \text{cm}^2/\text{Vs}$  was estimated from device performance affected, however, by neglected contact resistances. In this work, we used in operando Kelvin probe force microscopy under high vacuum to study the influence of contact resistances at the source and drain electrodes on the OFET performance. Noncontact potentiometry at different applied external voltages revealed relevant voltage drops at the electrode interface and in the adjacent contact region. Based on these voltage drops and measured device currents significant contact resistances were calculated. Correcting for such parasitic voltage drops, contact-free  $\mu_{ch}$  was obtained, substantially higher than  $\mu_{ext}.$  The growth mode of  $F_{16}PcCu$ on application-relevant polycrystalline gold substrates and shifts of the energy levels were studied by in situ KPFM and an injection barrier was confirmed. From these results, we conclude that the model of thermionic emission, often used for contact resistances, is not completely sufficient to describe the present case.

#### CPP 26.5 Wed 12:30 H38

Thin films of electron donor-acceptor complexes: characterisation of mixedcrystalline phases and implications for electrical doping — •ANDREAS OPITZ¹, GIULIANO DUVA², MARIUS GEBHARDT³, HONGWON KIM³, EDUARD MEISTER³, TINO MEISEL¹, PAUL BEYER¹, VALENTINA BELOVA², CHRISTIAN KASPER⁴, JENS PFLAUM⁴, LINUS PITHAN^{4,5}, ALEXANDER HINDERHOFER², FRANK SCHREIBER², and WOLFGANG BRÜTTING³ — ¹Institut für Physik, Humboldt-Universität zu Berlin, Germany — ²Institut für Angewandte Physik, Universität Tübingen, Germany — ³Institut für Physik, Universität Augsburg, Germany — ⁴Experimentelle Physik VI, Julius-Maximilians-Universität Würzburg, Germany — ⁵European Synchrotron Radiation Facility, Grenoble Cedex 9, France

Electron donor-acceptor (EDA) complexes are of interest as low-band gap molecular semiconductors and as dopants for molecular semiconducting matrices. Our recent work establishes a link between optical, structural and vibrational properties of EDA complexes as well as the electrical doping by them. [1] Here, we report on optical and electrical properties of EDA complexes. All studied donor:acceptor systems form mixed crystalline structures and the EDA complex is characterised by the complex-related absorption, which cross the neutralto-ionic boundary. Our measurements reveal an exponential relation between electrical conductivity and activation energy of transport for all complex-doped systems related to the separation of Coulombically bound charges. [1] A. Opitz *et al., Mater. Adv.* **3** (2022). DOI: 10.1039/D1MA00578B

CPP 26.6 Wed 12:45 H38 Effect of phenylation vs. functionalization for tetracene-based electron transport materials — •MARYKE KOUVATE SEBASTIAN HUTSCH and FRANK OPT-

port materials — •MARYKE KOUYATE, SEBASTIAN HUTSCH, and FRANK ORT-MANN — Technical University of Munich, Munich, Germany

In analogy to the tetracene/rubrene system, new electron transport materials (ETMs) are designed by modifying the outer benzene rings of tetracene with electron-withdrawing groups and attaching four phenyl groups to the modified backbone. Subsequent crystal structure prediction and charge transport calculations provided further insights in the structural effect of tetra-phenylation on tetracene based systems and the impact on charge transport properties. A strong effect of core-end modification on the molecular packing and charge transport properties for molecules without phenylation is revealed. These structures differ significantly from the known crystal structure of tetracene. Tetra-phenylation, on the other hand, reduces the impact of core-end modification and crystal structures close to the high-mobility orthorhombic rubrene structure are obtained, suggesting a considerable steric effect of the bulky phenyl-groups. We finally compare the charge-transport properties between the tetracene/rubrene reference systems and ETMs with and without phenyl functionalization.

## CPP 27: Composites and Functional Polymer Hybrids

Time: Wednesday 11:30-13:00

## CPP 27.1 Wed 11:30 H39

**Polymer - Organic Metal Composites for Waste Heat Recovery** — •MARIE SIEGERT¹ and JENS PFLAUM^{1,2} — ¹Experimental Physics VI, University of Würzburg, 97074 Würzburg — ²ZAE Bayern, 97074 Würzburg

The interest in organic thermoelectrics has greatly gained traction over the last decade due to its great potential in waste heat recovery based on sustainable, lowcost materials. For instance, polymers can be solution processed on industrial scale and display aptly low thermal conductivity, but lack high electrical conductivity due to their inherent disorder. Organic molecular metals, on the other hand, exhibit superior electrical conductivity over a wide temperature range, but the complexity of preparation currently limits scalable applications [1]. Here, we report on an approach utilizing suitable polymers in combination with the p-type organic metal TTT₂I₃ and the n-type Cu(DCNQI)₂, thus exploiting the benefits of both material classes. As demonstrated by our preliminary experimental data, these composite materials do not only allow for a controlled variation of the thermoelectric properties via the respective amount of organic metal additive but also show significant improvements with respect to their mechanical integrity upon thermal treatment. The related thermoelectric properties of the composites will be evaluated with regard to their application in thin film based organic thermolectric generators for waste heat recovery. The Deutsche Bundesstiftung Umwelt (DBU) is acknowledged for financial support.

Mesoporous hematite (Fe2O3) thin films with high surface-to-volume ratios show great potential as photoelectrodes or electrochemical electrodes in energy conversion and storage. In the present work, with the assistance of an up-scalable slot-die coating technique, highly ordered Fe2O3 thin films are successfully printed based on the amphiphilic diblock copolymer poly (styrene-b-4-vinyl pyridine) (PS-b-P4VP) as a structure-directing agent. Pure PS-b-P4VP films are printed under the same conditions for comparison. The micellization of the diblock copolymer in the solution, the film formation process of the printed thin films, the homogeneity of the dry films in the lateral and vertical direction as well as the morphological and compositional information of the calcined hybrid PS-b-P4VP/FeCl3 thin film are investigated.

Location: H39

## CPP 27.4 Wed 12:15 H39

Morphology transformation pathway of block copolymer- directed cooperative self-assembly of ZnO hybrid films monitored in situ during slot-die coating — •TING TIAN¹, SHANSHAN YIN¹, SUO TU¹, CHRISTIAN L. WEINDL¹, KERSTIN S. WIENHOLD¹, SUZHE LIANG¹, MATTHIAS SCHWARTZKOPF², STEPHAN V. ROTH^{2,3}, and PETER MÜLLER-BUSCHBAUM^{1,4} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²DESY, 22607 Hamburg — ³KTH, Department of Fibre and Polymer Technology, 10044 Stockholm, Sweden — ⁴MLZ, TU München, 85748 Garching

Co-assembly of diblock copolymers (DBCs) and inorganic precursors that takes inspiration from the rich phase separation behavior of DBCs can enable the realization of a broad spectrum of functional nanostructures with the desired sizes. In a DBC assisted sol*gel chemistry approach with polystyrene-blockpoly(ethylene oxide) and ZnO, hybrid films are formed with slot-die coating. In situ GISAXS measurements are performed to investigate the self-assembly and co-assembly process during the film formation. Combining complementary ex situ characterizations, several distinct regimes are differentiated to describe the morphological transformations from the solvent-dispersed to solidified films. The comparison of the assembly pathway evidences that the key step in the establishment of the pure DBC film is the coalescence of spherical micelles toward cylindrical domains. Due to the presence of the precursor, the formation of cylindrical aggregates in the solution is crucial for the structural development of the hybrid film.

#### CPP 27.5 Wed 12:30 H39

Programmable Luminescent Tags: Utilizing the interplay of room temperature phosphorescence and oxygen as an information storage device —  $\bullet$ Tim Achenbach, Max GMELCH, HEIDI THOMAS, and SEBASTIAN REINEKE — Technische Universität Dresden, Germany

By utilizing the interaction between molecular oxygen and the room temperature phosphorescence of organic materials, continuous-wave-readable and subsecond programmable luminescent tags (PLT) can be realized. They are transparent, flexible and provide a resolution of up to 700 dpi. Information is imprinted by illuminating the PLT with UV light through a shadow mask. By heating the PLT, the information can be erased and a new writing cycle can be started again.

The device consists of two layers on a substrate. The functional layer comprises an organic biluminescent emitter doped into a polymer. The second layer is an oxygen barrier layer. After wet processing in air, molecular oxygen is present in the functional layer of the device, quenching the phosphorescence of the emitter. As energy is transferred to the oxygen during this interaction, it is excited to its highly reactive singlet state and binds to its environment. Over time, all molecular oxygen in the illuminated areas undergoes this photoconsumption process, and a phosphorescent pattern in shape of the mask becomes visible. The oxygen barrier becomes more permeable at elevated temperatures, allowing an oxygen refill of the functional layer by heating the device. This resets the device and it can be rewritten after a short cooling phase.

#### CPP 27.6 Wed 12:45 H39

Spatio-temporal Imaging of Programmable Luminescent Tags reveals Planar Oxygen Diffusion Properties in Polymer Films — •RICHARD KANTELBERG, TIM ACHENBACH, ANTON KIRCH, and SEBASTIAN REINEKE — Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute for Applied Physics, Technische Universität Dresden, Germany

Programmable Luminescent Tags based on oxygen quenched organic room temperature phosphorescence show application potential in UV sensing and rewritable labelling. This work demonstrates, that the concept can also be exploited to resolve oxygen diffusion properties in thin polymer films, which are essential in everyday applications from medical encapsulation to industrial packaging. In contrast to many established methods, the investigated principle comes without the need of complex pressure sensitive setups or vacuum technology and potentially allows high spatial accuracy. The time-resolved tracking of a twodimensional phosphorescent pattern reveals the in-plane oxygen diffusion coefficient and considers the photoconsumption of oxygen during the measurement. The diffusion coefficients are determined at the representative case of polystyrene glasses with molecular weights between 13 000 and 350 000 g/mol.

## CPP 28: Perovskite and Photovoltaics 3

Time: Wednesday 15:00-17:15

CPP 28.1 Wed 15:00 H38

Optically-Induced Long-lived Chirality Memory in the Color Tunable Chiral Lead-Free Semiconductor (R)/(S)-CHEA4Bi2BrxI10-x (x = 0 - 10) — •SHANGPU LIU¹, MARKUS HEINDL¹, NATALIE FEHN², SEBASTIÁN CAICEDO-DÁVILA¹, SILVA KRONAWITTER², GREGOR KIESLICH², DAVID EGGER¹, ARAS KARTOUZIAN², and FELIX DESCHLER¹ — ¹Walter Schottky Institute and Department of Physics, TUM, Garching, Germany — ²Catalysis Research Center, TUM, Garching, Germany

Hybrid organic-Inorganic networks that incorporate chiral molecules have attracted great attention due to their potential in semiconductor lighting applications and optical communication. Here we introduce the chiral organic molecules (R/S)-CHEA into bismuth-based structures with an edge-sharing octahedral motif, to synthesize chiral (R/S)-CHEA4Bi2Brx110-x crystals and thin films. Using single-crystal X-ray diffraction measurements and densityfunctional theory calculations, we identify crystal and electronic band structures. We investigate the material optical properties and find circular dichroism, which we tune by the bromide-iodide ratio over a wide wavelength range from 300-500 nm. Further, we employ transient absorption spectra and timecorrelated single photon counting to investigate charge carrier dynamics, which show long-lived excitations with unexpected optically-induced chirality memory up to 10s of nanosecond timescales. Our demonstration of chirality memory in a color-tunable and chiral lead-free semiconductor opens a new avenue for the discovery of high-performance spintronic materials with optical functionalities.

#### CPP 28.2 Wed 15:15 H38

**Time-Resolved Microwave Conductivity on ionic liquid doped Lead Halide Perovskites** — •PATRICK DÖRFLINGER¹, VALENTIN SCHMID¹, YONG DING², MO-HAMMAD KHAJA NAZEERUDDIN², and VLADIMIR DYAKONOV¹ — ¹Experimental Physics VI, Julius Maximilian University of Würzburg, 97074 Würzburg — ²Group for Molecular Engineering of Functional Materials, Institute of Chemical Sciences and Engineering, EPFL Valais, Sion 1950, Switzerland

In the past decade, perovskite solar cells evolved to one of the most promising photovoltaic materials with steadily rising power conversion efficiencies, now exceeding 25%. Nonetheless, Organolead Halide Perovskites suffer from insufficient long-term stability. Especially the stability under thermal stress is crucial towards commercialization. Ionic liquids as an additive into the precursor solution are candidates to overcome this issue. Besides the increased resistivity against higher temperatures, alterations of important material properties like mobility and lifetime are expected. Therefore, we used Time-Resolved Microwave Conductivity (TRMC) to determine the mobility and lifetime of photogenerated charge carriers in the perovskite layer. In addition, with Steady-State Microwave Conductivity (SSMC) we can provide insights into the predominating recombination pathways. Combined, we investigated the influence of the ionic liquids on the perovskite material properties and gain deeper understanding of the charge carrier dynamics.

#### CPP 28.3 Wed 15:30 H38

Hidden interfaces: How ferroelastic domain walls affect the charge diffusion in perovskite solar cells — •ILKA M. HERMES^{1,2}, ANDREAS BEST², KALOIAN KOYNOV², HANS-JÜRGEN BUTT², and STEFAN A. L. WEBER² — ¹Leibniz Institute for Polymer Research Dresden e.V., Dresden, Germany — ²Max Planck Institute for Polymer Research, Mainz, Germany

Ferroelastic domains form during phase transitions that change the crystal system. By arranging in domains with alternating unit cell orientation, the material lowers its overall strain. The walls that separate ferroelastic domains typically feature some structural anomalies, which can affect the electronic properties of the crystal by increasing the defect concentration, introducing dopants or forming a local electric polarization via the flexoelectric effect. Here, we explored the implications of ferroelastic domain walls for the photo-carrier transport in methylammonium lead iodide, a solar cell light absorber used in perovskite solar cells. Via correlative spatial and time-resolved photoluminescence microscopy and electromechanical atomic force microscopy, we could link the presence of domain walls to the occurrence of an anisotropic charge diffusion, where charges move faster parallel to domain walls than perpendicular. Moreover, the ferroelastic nature of the domains promises a targeted engineering of the domain wall arrangement using the application of external stress or heat treatments across the material's cubic-tetragonal phase transition: a perpendicular alignment of the domain walls with respect to the extraction layer interfaces should facilitate faster and more efficient charge extraction.

Degradation mechanisms of perovskite solar cells under vacuum and one atmosphere of nitrogen — •RENJUN GUO¹, WEI CHEN¹, LENNART K. REB¹, MANUEL A. SCHEEL¹, MATTHIAS SCHWARTZKOPF², STEPHAN V. ROTH², and PETER MÜLLER-BUSCHBAUM¹ — ¹Technische Universität München, Garching, Germany — ²Deutsches Elektronen-Synchrotron, Hamburg, Germany

Extensive studies have focused on improving the operational stability of perovskite solar cells. Only a few studies survey the fundamental degradation mechanisms related to the device performance, and these studies were executed under various experimental conditions. Thus, we investigate the degradation mechanisms of high-efficiency perovskite solar cells under vacuum and a nitrogen atmosphere, as based on the International Summit on Organic Photovoltaic Stability protocols. We use synchrotron radiation-based operando grazing-incidence X-ray scattering methods. Unlike what was seen in previous reports, we find that the perovskite lattice can also experience a lattice shrinkage under operation. Moreover, we reveal that the atmosphere has a paramount influence on phase segregation, lattice distortion, and morphology deformation during operation of mixed cation lead mixed halide perovskite solar cells. This, in turn, degrades the performance of the respective perovskite solar cells. Our discoveries emphasize the importance of different types of inert atmospheres as critical parameters, which must be considered in future scientific studies and the industrial screening of longevity for photovoltaic modules.

#### CPP 28.5 Wed 16:00 H38

Determination of the Optimum Dead Area Width of Laser-Patterned, Series-Interconnected Perovskite Solar Cells — •NICOLAS OTTO¹, CHRISTOF SCHULTZ¹, GUILLERMO FARIAS BASULTO², JANARDAN DAGAR³, MARKUS FENSKE¹, RUTGER SCHLATMANN^{1,2}, EVA UNGER³, and BERT STEGEMANN¹ — ¹HTW Berlin - University of Applied Sciences, Wilhelminenhofstr. 75A, D-12459 Berlin — ²HZB für Materialien und Energie, PVcomB, Schwarzschildstr. 3, D-12489 Berlin — ³HZB für Materialien und Energie, Young Investigator Group Hybrid Materials Formation and Scaling, Kekuléstraße 5, D-12489 Berlin, Germany

Based on recent work on minimizing the interconnection width of laser patterned perovskite solar cells the optimum dead area width was determined. In order to use the largest possible aperture area, the dead area width should be as small as possible while still providing full electrical functionality. For this purpose the width between the P2 and the P3 scribes was variated ranging from overlapping to pattering with safety area. By also reducing the P1/P2 spacing an optimum dead area width can be achieved. The detailed scribe line characterization was done by optical microscopy imaging, electrical j-V measurements and compositional analyses. Minimodules with three in series connected cells were then produced. The results show that overlapping scribe lines as well as included safety areas cause avoidable electrical losses. Consequently, an optimum is achieved for arranging the scribe lines as closely as possible. In our study an optimal scribe line width of about 230 micrometres was realized.

#### CPP 28.6 Wed 16:15 H38

**Performance of Perovskite and Organic Solar Cells in Space** – •LENNART REB¹, MICHAEL BÖHMER², BENJAMIN PREDESCHLX¹, SEBASTIAN GROTT¹, LUKAS SPANIER¹, CHRISTIAN WEINDL¹, GORAN IVANDEKIC¹, RENJUN GUO¹, CHRISTOPH DREISSIGACKER³, JÖRG DRESCHER³, ROMAN GERNHÄUSER², ANDREAS MEYER³, and PETER MÜLLER-BUSCHBAUM^{1,4} – ¹TU München, Physik-Department, Lehrstuhl für Funktionelle Materialien, Garching, Germany – ²TU München, Physik-Department, Zentrales Technologielabor, Garching, Germany – ³Deutsches Zentrum für Luft- und Raumfahrt (DLR), Institut für Materialphysik im Weltraum, Köln, Germany – ⁴Heinz Maier-Leibnitz-Zentrum, Garching, Germany

Perovskite and organic solar cells have become a hot research topic in the last few years. The lightweight thin-film solar cells exhibit an exceptional power per mass that exceeds their inorganic counterparts by magnitudes, particularly interesting for space applications. Recently, we launched perovskite and organic solar cells to space on a suborbital rocket flight for the first time [1, 2]. The perovskite and organic solar cells operate in space conditions and produce reasonable power per area of up to 14 and 7 mW cm-2, respectively. Here we derive, with a detailed solar irradiation reconstruction, the irradiation-dependent solar cell performance parameter evolutions, and conclude the solar cell efficiency under strong AM0 irradiation. ## CPP 28.7 Wed 16:45 H38

Quantum Efficiency Enhancement of Lead-Halide Perovskite Nanocrystal **LEDs by Organic Lithium Salt Treatment** — •ROSHINI JAYABALAN¹, TASSILO NAUJOKS¹, Christopher Kirsch², Fengshuo Zu³, Mukundha Mandal⁴, Jan Wahl², Martin Waibel¹, Andreas Opitz³, Norbert Koch^{3,5}, Denis ANDRIENKO⁴, MARCUS SCHEELE², and WOLFGANG BRÜTTING¹ — ¹Universitiät Augsburg, 86135 Augsburg, Germany — ²Universität Tübingen, 72076 Tübingen, Germany — ³Institüt für Physik & IRIS Adlershof, Humboldt-Universität zu Berlin, Germany — ⁴Max Planck Institut für Polymerforschung, 55128 Mainz, Germany — ⁵Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, 12489 Berlin, Germany

Owing to large specific surface area in lead halide perovskite nanocrystals, surface passivation using ligands is crucial to attain high photoluminescent quantum yield (PLQY). With respect to device fabrication, such passivation methods must also enable balanced charge injection to achieve high efficiency and operational stability. In this regard, this talk will discuss on the results of postpassivation treatment of CsPbBr3 nanocrystals with LiTFSI, an organic lithium salt. The results from such treatment have proven to be propitious for the nanocrystals - yielding higher PLQY, longer exciton lifetime and improved light outcoupling. Consequently, a significant improvement is observed in the devices fabricated using such post post-treated nanoparticles. Lastly, photoelectron spectroscopy and density functional theory modelling is employed to understand the impact of LiTFSI post-treatment on the performance of a perovskite based LED.

CPP 28.8 Wed 17:00 H38 Tunable mesoporous and optoelectronics properties of zinc titanate films using sol-gel technique — •YANAN LI¹, NIAN LI¹, APOSTOLOS VAGIAS², and PE-TER MÜLLER-BUSCHBAUM¹ — ¹Physics Department, Technical University of Munich, 85748 Garching, Germany — ²Heinz Maier-Leibnitz Zentrum (MLZ), Technische Universität München, 85748 Garching, Germany

Mesoporous films consisting of zinc titanate have high potential applications in photocatalysis, solar cells, and sensors due to tailoring their semiconductive properties. In the present work, we investigate the morphologies of mesoporous zinc titanate films obtained by changing the ratio of two inorganic precursors after calcining hybrid films consisting of organicinorganic materials. The amphiphilic diblock copolymer poly(styrene)-bpoly(ethyleneoxide) PS-b-PEO self-assembles into core-shell micelles in a mixture of N,N-dimethylformamid/hydrogen chloride playing the role as structure directing template. The inorganic precursors, zinc acetate dehydrate and titanium tetraisopropoxide, are loaded in the micellar shell due to hydrogen bonds between PEO and precursors. We use slot-die and spin-coating methods to prepare hybrid films, and investigate the influence of the different deposition methods on the film morphologies. Moreover, we investigate how mesoporous structures and crystal phases depend on calcination temperatures. The morphologies of the hybrid films are characterized using grazing incidence small-angle X-ray scattering (GISAXS) and scanning electronic microscopy (SEM).

organized by Stephan Förster (FZ Jülich), Thomas Gutberlet (FZ Jülich), Peter Müller-Buschbaum (TUM) and Walter Richtering (RWTH Aachen)

Time: Thursday 9:30-11:15

**Invited Talk** CPP 33.1 Thu 9:30 H38 Cooperative and non-Gaussian dynamics of entanglement strands in polymer melts — •MARGARITA KRUTEVA¹, MICHAELA ZAMPONI², INGO HOFFMANN³, JÜRGEN ALLGAIER¹, LUTZ WILLNER¹, ANDREAS WISCHNEWSKI¹, MICHAEL MONKENBUSCH¹, and DIETER RICHTER¹ — ¹Forschungszentrum Jülich GmbH, Jülich Centre for Neutron Science (JCNS-1: Neutron Scattering and Biological Matter), 52425 Jülich, Germany — ²Forschungszentrum Jülich GmbH, Jülich Centre for Neutron Science at MLZ, Lichtenbergstraße 1, 85748 Garching, Germany — ³Institut Laue-Langevin (ILL), B.P. 156, F-38042 Grenoble Cedex 9, France

We report neutron spin echo investigations on the motion of short tracer chains in highly entangled melts [1,2]. The tracers were found to undergo sub-diffusion behavior. Unexpectedly the sub-diffusion is limited by a distance very close to the tube diameter of the respective highly entangled host. The cross-over distance to Fickian diffusion, thereby, is independent of the tracer's length. The Fickian

diffusivity agreed with the macroscopic results. We found that the Rouse dynamics of the tracers is strongly non-Gaussian with a related segment displacement distribution narrower than the Gaussian counterpart. These results were understood as a consequence of highly cooperative motion of the tracers with the host that mirrors the host dynamics within the tube. The phenomena were found both in a polyolefin (polyethylene) as well as in a polyether (polyethylene-oxide) indicating their generality. (1) Zamponi, M. et al. Phys. Rev. Lett. 2021, 126 (18), 187801. (2) Kruteva, M. et al. Macromolecules 2021, accepted.

Grafting polymer chains on nanoparticles prevents their undesired aggregation leading to improved properties. Whereas, grafting induces inevitable alteration in the dynamics of polymer chains, which affects macroscopic properties e.g. viscoelasticity. It has been established that the polymer chain dynamics is retarded in grafted chains. However, literature lacks consensus on whether the segmental dynamics of grafted chains is accelerated or retarded. We study the segmental dynamics of polyisoprene grafted on spherical nanoparticles using neutron backscattering. The analysis of relaxation times led to the conclusions: (i) Low molecular weight (MW) grafted polymer display reduced local relaxation (ii) At high MW and equal grafting density faster segmental dynamics than the free polymer is observed. We prove that these conflicting results are seemingly artifacts of the traditional analysis method. We invoke an elegant methodology and show that the underlying physics of grafted polymer is unchanged. However, spatial variation of the relaxation times across the grafted chain causes the average dynamics to transition with molecular weight.

#### CPP 33.3 Thu 10:15 H38

Structure and Dynamics of Polymer Brushes and Microgels at Interfaces measured with Neutron Scattering — •OLAF HOLDERER¹ and STEFAN WELLERT² — ¹Jülich Centre for Neutron Science at MLZ, Forschungszentrum Jülich GmbH, 85748 Garching, Germany - ²Department of Chemistry, Technische Universität Berlin, 10623 Berlin, Germany

It is an experimental challenge to access structural and dynamic properties of brushes and microgels at the solid liquid interface [1]. Neutron scattering techniques such as Grazing Incidence Small Angle Neutron Scattering (GISANS) for structural investigations and Grazing Incidence Neutron Spin Echo Spectroscopy (GINSES) provide a means of studying structural and dynamic properties on molecular length scales at the interface. Simulations of the experimental conditions in the framework of the Distorted Wave Born Approximation help interpreting the static and dynamic scattering signals [2]. Examples of thermoresponsive microgels with different architecture and brushes at the interface are presented to illustrate the possibilities and challenges of this type of interface studies.

## CPP 33.4 Thu 10:30 H38

In-situ neutron reflectometry measurements of polyelectrolyte diffusion in Layer-by-Layer films in aqueous solution at ILL - •ANNEKATRIN SILL¹, HEIKO AHRENS¹, OLAF SOLTWEDEL², PHILIPP GUTFREUND³, and CHRISTIANE A. HELM¹ — ¹University of Greifswald, Institute of Physics, D-17489 Greifswald, Germany — ²Technische Universität Darmstadt, Institute for Condensed Matter Physics, D-64289 Darmstadt, Germany — ³Institut Laue-Langevin, F-38042 Grenoble, France

Up to now, we measured vertical polyelectrolyte diffusion in Layer-by-Layer films by immersing the film for a defined amount of time in the annealing solution. Then the film was dried, and a snapshot was taken. With the snapshot method, one can get good results, but we wanted to develop an improved method. For the first time, the dynamics of our films were studied in-situ at the Institut Laue-Langevin (ILL) on instrument D17. This neutron reflectometer with horizontal scattering geometry is suitable for in-situ measurements, using wavelengths from 2 to 27 Å with great flexibility in resolution. We used the slab architecture with selective polyanion deuteration to study vertical polyanion diffusion. As polycation linear PDADMA was used, PSS/PSSd was the polyanion. Each film consisted of a protonated and a deuterated slab. Varied were the salt concentration and the temperature of the annealing solution. The diffusion constant was determined and compared to the snapshot measurements in air.

## CPP 33.5 Thu 10:45 H38

Kinetics of mesoglobule formation and dissolution in solutions of thermoresponsive polymers after fast pressure jumps — BART-JAN NIEBUUR¹, Leonardo Chiappisi², Alfons Schulte³, and •Christine M. Papadakis¹ — ¹Technical University of Munich, Physics Department, Garching, Germany —  2 Institut Laue-Langevin, Grenoble, France —  3 University of Central Florida, Department of Physics and College of Optics and Photonics, Orlando FL, U.S.A. The thermoresponsive polymer poly(N-isopropylacrylamide) (PNIPAM) features lower critical solution temperature behavior in aqueous solution with the cloud point depending on pressure [1]. Fast pressure jumps across the coexistence line in combination with time-resolved small-angle neutron scattering elucidate the pathways of mesoglobule formation and disintegration over a wide range of length scales with a time resolution of 50 milliseconds. Varying the start and target pressures gives insight into the role of thermodynamic and kinetic factors governing mesoglobule formation [2,3]. For disintegration, the osmotic pressure of the solvent within the mesoglobules is the decisive factor for the mechanism and the time scales [4]. These results are of importance for applications of thermoresponsive polymers as switches. 1. B.-J. Niebuur et al., ACS Macro Lett. 6, 1180 (2017). 2. B.-J. Niebuur et al., ACS Macro Lett. 7, 1155 (2018). 3. B.-J. Niebuur et al., Macromolecules 52, 6416 (2019). 4. B.-J. Niebuur et al., RSC Nanoscale 13, 13421 (2021).

CPP 33.6 Thu 11:00 H38 Simultaneous SAXS/SANS method: A novel nanoanalytical tool - $\bullet Ezzeldin \, {\rm Metwalli}^1, {\rm Klaus} \, {\rm G{\"o}tz}^1, {\rm Tobias} \, {\rm Zech}^1, {\rm Christian} \, {\rm B{\ddot{a}r}}^1, {\rm Anne}$  ${\tt Martel}^2, {\tt Lionel Porcar}^2, {\tt and Tobias Unruh}^1-{}^1 {\tt Institute for Crystallogrammatical constraints}$ phy and Structural Physics (ICSP), Friedrich-Alexander-Universität Erlangen-Nürnberg, Staudtstr. 3, 91058 Erlangen, Germany — ²Institut Laue-Langevin, 71, Avenue des Martyrs, Grenoble, 38042, France

Exploiting X-ray and neutron beams at the same sample volume enables unprecedented investigations of nanomaterials using small angle scattering (SAS) technique. A portable small angle X-ray scattering (SAXS) instrument with a proper geometrical dimension was successfully designed, constructed and implemented at D22 zone of Institut Laue Langevin (ILL) in France for simultaneous SAXS/SANS experiments. Compared with an independent experimental approach, the simultaneous SAXS/SANS experimental approach ensures the exactness of the probed samples, especially for time-resolved studies. The SAXS/SANS experimental setup will indispensably permit to instantaneously analyse and understand the complicated correlated nanostructures of two different types of nanoscale components in the same sample volume. For instance, a temporal structural cross-correlation between organic stabilizing agent (cetyltrimethylammonium bromide; CTAB micelles) and gold seeds, which cooperate in the formation of different size/shape of large stabilized gold nanorods during the synthesis process [1] was successfully probed. ## CPP 34: Hydrogels and Microgels

Time: Thursday 9:30-10:15

## CPP 34.1 Thu 9:30 H39

Simulations explain the Swelling Behavior of Hydrogels with Alternating Neutral and Weakly Acidic Blocks - •DAVID BEYER¹, PETER KOŠOVAN², and Christian  $\operatorname{Holm}^1 - {}^1$ Institute for Computational Physics, University of Stuttgart, D-70569 Stuttgart, Germany  $- {}^2$ Department of Physical and Macromolecular Chemistry, Charles University, Prague, Czechia

We use computer simulations to study a coarse-grained model of a weak (pHresponsive) polyelectrolyte hydrogel which consists of a covalent, regular tetrafunctional network of four-armed neutral and acidic stars, coupled to a reservoir of small ions. A similar system consisting of tetrapoly-(acrylic acid) and tetrapoly(ethylene glycol) was recently investigated experimentally by the Sakai group. To model the ionization equilibrium of the weak groups and the exchange of small ions with the reservoir, we make use of the recently developed Grand-Reaction Monte-Carlo method (G-RxMC). We determine the free swelling equilibrium for different salt concentrations and pH values of the reservoir. The results for the swelling ratio are in good agreement with the experimental data for high and intermediate pH values. We obtain titration curves which display a significant deviation from the ideal Henderson-Hasselbalch equation due to charge correlations and Donnan partitioning. Contrary to a previous conjecture, our results show that counterion condensation does not explain the observed swelling behavior. Finally, we investigate the gel structure and observe that the swelling is dominated by the stretching of the acidic blocks.

CPP 34.2 Thu 9:45 H39

Importance of pH in Synthesis of pH-Responsive Cationic Nano- and Microgels — •MARCO ANNEGARN, MAXIM DIRKSEN, and THOMAS HELLWEG — Department of Physical and Biophysical Chemistry, Bielefeld University, Universitätsstraße 25, 33615 Bielefeld, Germany

While cationic nano- and microgels are potentially useful for transfection of cells or the immobilization of biomacromolecules, their synthesis often has certain drawbacks regarding size, polydispersity, yield and incorporation of the cationic comonomer. Since many cationic comonomers like primary or secondary amines are pH-responsive, their charge relies on the surrounding pH. Therefore, a range of poly(N-isopropylacrylamide) (PNIPAM) microgels with

#### Chemical and Polymer Physics Division (CPP)

the primary amine *N*-(3-aminopropyl)methacrylamide hydrochloride (APMH) as the cationic comonomer were synthesized at different reaction pH. The microgels were analyzed with respect to their size, thermoresponsive swelling behavior, synthesis yield, polydispersity and APMH-incorporation.

The results show that the reaction pH has a strong influence on on all the mentioned parameters and can be utilized to tailor the microgels properties. While the influence of the pH on such microgels has been examined repeatedly after synthesis, the influence of the reaction pH during synthesis is mostly ignored. Hence, a precise pH-control during the synthesis of microgels with pH-responsive moieties is crucial to gain reproducible and comparable results.

#### w. Considering the size of the MNG and typical time and velocity scales involved

in their nanofluidics, experimental characterisation of the system is challenging. In this work, we perform molecular dynamics (MD) simulations combined with the Lattice-Boltzmann (LB) scheme aiming at describing the impact of the shear rate on the shape, magnetic structure and motion of an MNG.

microfluidic systems, one of which can be modelled as a channel with a given

We find that in a shear flow, the centre of mass of an MNG tends to be in the centre of a channel and to move, preserving the distance to both walls. The MNG monomers along with translation are involved in two more types of motion, they rotate around the centre of mass and oscillate with respect to the latter. It results in synchronised tumbling and wobbling of the whole MNG accompanied by its volume oscillates. We show that the volume oscillations and rotations are two faces of the same periodic process whose frequency is a growing function of the shear rate and depends on strength of magnetic interaction between magnetic nanoparticles. We demonstrate that the oscillations of the volume lead to the periodic changes in MNG magnetic energy.

## CPP 37: Interfaces and Thin Films and Responsive and Adaptive Systems

Time: Thursday 10:30-13:00

Invited TalkCPP 37.1Thu 10:30H39Non-equilibrium Properties of Thin Polymer Films — •GÜNTER REITER¹ andSIVASURENDER CHANDRAN² — ¹Physikalisches Institut, Albert-Ludwigs Universität Freiburg — ²Department of Physics, Indian Institute of Technology Kanpur,Uttar Pradesh 208016, India

Rapid industrial processes often freeze polymers in non-equilibrium conformations, which, in turn, cause material properties that are significantly different from the predictions of equilibrium theories. Thus, by choosing appropriate processing pathways, we potentially can control macroscopic properties and performance of polymers. However, due to our current lack of fundamental understanding of the behavior of non-equilibrated polymers, we have to rely on empirical knowledge, imposing trial-and-error approaches for achieving desired properties. Considering these aspects, we discuss recent studies on polymer films revealing that quantitative relations exist between properties and processing pathways, suggesting possible relations for processing-induced deviations in chain conformations. These relations propose that long-living and long-ranged correlations between polymers have been induced by processing, as indicated by the observation of relaxation times much longer than known for equilibrated polymers. We present an example where control of processing conditions for thin films allowed to translate the molecular relaxations during equilibration into a predictable lifting of macroscopic loads.

#### CPP 37.2 Thu 11:00 H39

Water Induced Polymer Reorientation at a Polystyrene/ Polyacrylic Acid Surface — XIAOMEI LI¹, MIRELA ENCHEVA², KALOIAN KOYNOV¹, HANS-JÜRGEN BUTT¹, ELLEN BACKUS², and •RÜDIGER BERGER¹ — ¹Max Planck Institute for Polymer Research, 55128 Mainz, Germany — ²University of Vienna, Währinger Straße 42, 1090 Vienna, Austria

Polymers are capable of undergoing adaptation phenomena triggered by exposure to liquids. Here we study the adaptation of copolymer films formed by polystyrene and polyacrylic acid (PS/PAA) after water exposure. We measured the dynamic advancing and receding contact angles (CA) of water drops sliding down a PS/PAA film. We associate the gradual increase in advancing CA with drop velocity to the adaptation process to water. By applying adaptation theory, we estimated the time constant of this adaptation process to be much smaller than 1 s. The changes in contact angles may be caused by swelling of the copolymer and/or by a reorientation of the hydrophilic segments (PAA) towards the surface. Therefore, we performed vibrational sum frequency generation (SFG) spectroscopy which is surface sensitive. SFG experiments before and after exposing the copolymer to water reveal a decrease in intensity of the vibrational band representing the PS segments, suggesting a reorientation of the polymer groups at the surface upon contact with water. 15 min. break

CPP 37.3 Thu 11:30 H39

Tailoring the Optical Properties of Sputter-Deposited Gold Nanostructures on Nanostructured TiO2 Templates based on in situ GISAXS Determined Growth Laws — •SUZHE LIANG¹, WEI CHEN¹, SHANSHAN YIN¹, SI-MON J. SCHAPER¹, JONAS DREWES², NIKO CARSTENS², THOMAS STRUNSKUS², FRANZ FAUPEL², MARC GENSCH^{1,3}, MATTHIAS SCHWARTZKOPF³, STENPHAN V. ROTH^{3,4}, YA-JUN CHENG⁵, and PETER MÜLLER-BUSCHBAUM^{1,6} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²LS Materialverbunde, Institut für Materialwissenschaft, CAU, 24143 Kiel — ³DESY, 22607 Hamburg — ⁴Department of Fibre and Polymer Technology, KTH, SE-100 44 Stockholm, Sweden — ⁵NIMTE, CAS, 315201 Ningbo, China — ⁶MLZ, TU München, 85748 Garching

Au/TiO2 nanohybrid materials have attracted significant attention due to the outstanding optical, photocatalytic and photovoltaic performance. We use customized polymer templating to achieve TiO2 nanostructures with different morphologies. Au/TiO2 hybrid thin films are fabricated by sputter deposition, meanwhile in situ GISAXS during the deposition process is applied to in-depth understand the Au morphology on the TiO2 templates. The resulting Au nanostructure is largely influenced by the TiO2 template morphology. Based on the detailed understanding of the Au growth process, characteristic distances can be selected to achieve tailored Au nanostructures at different Au loadings. For selected sputter-deposited Au/TiO2 hybrid thin films, the optical response with a tailored localized surface plasmon resonance is demonstrated.

CPP 37.4 Thu 11:45 H39

**Investigations of ultra-thin film behavior of polycarbonate on inorganic surfaces** — •HASSAN OMAR, PAULINA SZYMONIAK, and ANDREAS SCHÖNHALS — Bundesanstalt für Materialforschung und -prüfung (BAM), Berlin, Germany Thin polymer films are of vital importance due to their low production costs and wide range of applications in sensors, electronics, and coatings. Their geometry is ideal for the study of confinement effects on the thermodynamic properties and segmental dynamics of polymers. However, there is little research into these effects for main chain polymers such as polycarbonate (PC). PC has important applications due to its improved mechanical, optical, and thermal stability compared to other polymers. For this investigation, films of PC ranging from 200 nm to 7 nm were prepared on both glass and silica substrates to measure the dielectric and calorimetric behavior. The methodology consisted of broadband dielectric spectroscopy (BDS), ellipsometry, atomic force microscopy (AFM), and sum frequency generation (SFG). Using ellipsometry, the glass transition was shown to increase with decreasing film thickness. This was further proved by BDS for glassy dynamics for thin films employing different sample geometries (crossed electrode and nanostructured capacitors). The properties and influence of the adsorbed layer on the molecular mobility was also addressed by a combination of AFM, SFG and BDS.

CPP 37.5 Thu 12:00 H39 Fabrication and Characterization of Hydrophobic Porous Metallic Membranes for High-Temperature Applications — SARA CLARAMUNT¹, •MUHAMMAD KHURRAM², WALTHER BENZINGER¹, MANFRED KRAUT¹, and ROLAND DITTMEYER¹ — ¹Institute for Micro Process Engineering, Karlsruhe Institute of Technology, 76131 Karlsruhe, Germany — ²Institute for Physics, University of Greifswald, 17489 Greifswald, Germany

Hydrophobic porous metallic membranes can be integrated into a microreactor for in-situ separation of steam at high temperatures. This study investigates the fabrication and characterization of hydrophobic coatings on metallic substrates. Two different coating methods were explored: (1) plasma enhanced-chemical vapor deposition to form amorphous carbon silicon-doped a-C:H:Si:O thin films and (2) direct immersion in fluoroalkyl silane (FAS-13) solution using dip coating to form self-assembled monolayers. The results on wettability as well as SEM images and Energy Dispersive Spectroscopy/Wavelength Depressive Spectroscopy analyses indicate that the coated sintered stainless-steel membranes are adequate as hydrophobic surfaces, maintaining the porosity of the substrate and withstanding high temperatures. Especially the FAS-13 coating shows very good resistance to temperatures higher than 250°C. These findings are of special significance for the fabrication of porous metal membranes for the separation of steam in high-temperature applications.

## CPP 37.6 Thu 12:15 H39

Superlatice deformation via uniaxial strain and its impact on photoluminescence in PbS quantum dot thin films — •JULIAN E. HEGER¹, WEI CHEN¹, HUAYING ZHONG¹, TIANXIAO XIAO¹, CONSTANTIN HARDER^{1,2}, FABIAN A. C. APFELBECK¹, ALEXANDER WEINZIERL¹, REGINE BOLDT³, LUCAS SCHRAA³, ERIC EUCHLER³, ANNA K. SAMBALE³, KONRAD SCHNEIDER³, MATTHIAS SCHWARTZKOPF², STEPHAN V. ROTH^{2,4}, and PETER MÜLLER-BUSCHBAUM^{1,5} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²DESY, 22607 Hamburg — ³Leibniz-Institut für Polymerforschung IPFDD, 01069 Dresden — ⁴Royal Institute of Technology KTH, 100 44 Stockholm — ⁵MLZ, TU München, 85748 Garching

Colloidal lead sulfide quantum dots (PbS CQDs) show high potential for the application in flexible electronics, as they are solution processible with tunable optoelectronic properties. In thin films, PbS CQDs form a superlattice morphology that tailors these optoelectronic properties. For instance, electronic coupling between adjacent PbS CQDs is dependent on the inter-dot distance in the super-lattice. In this work, we investigate the superlattice deformation during applied

Fluorinated Acenes: Controlling Molecular Electronic Levels, Crystalline Phases and Optoelectronic Properties — •DANIEL BISCHOF¹, PHILIPP E. HOFMANN², MATTHIAS W. TRIPP², MARC ZEPLICHAL³, SEBASTIAN ANHÄUSER¹, TOBIAS BREUER¹, SERGEI I. IVLEV², MARINA GERHARD¹, ANDREAS TERFORT³, ULRICH KOERT², and GREGOR WITTE¹ — ¹Fachbereich Physik, Philipps-Universität Marburg — ²Fachbereich Chemie, Philipps-Universität Marburg — ³Goethe Universität Frankfurt

Acenes serve as prototypical molecular materials to study structure-property relationships. Here, we systematically analyze the influence of the acene length and the degree of fluorination on their structure and optoelectronic properties [1-3]. Our results show that the optical gap decreases with increasing acene length, while the degree of fluorination determines the precise energy levels of the frontier orbitals HOMO and LUMO, whereas the optical gap is barely affected upon fluorination. Partial fluorination also influences the molecular electrostatic potential (MEP) and leads to a change in the molecular packing from herringbone packing for pristine and perfluorinated acenes to a planar stacking motif. These structural changes also affect the photoluminescence properties and induce a red-shifted PL for the stacked molecules due to excimer formation. The presented insights are not limited to acenes, but can be extended to other  $\pi$ -conjugated systems.

external strain. For this, PbS CQDs thin films are prepared on flexible PDMS substrates. The samples are investigated with in situ GISAXS and photoluminescence measurements at different levels of strain to correlate the deformation-induced morphological changes to the optoelectronic performance.

CPP 37.7 Thu 12:30 H39

**The surface of electrolyte solutions is stratified** — •YAIR LITMAN, KUO-YANG CHIANG, TAKAKAZU SEKI, YUKI NAGATA, and MISCHA BONN — MPI for Polymer Research, Mainz, Germany.

The electrical-double layer (EDL) model has been used during the last two decades to describe the behaviour of ions at the water/air interface, and also as a framework to analyze and interpret several types of surface-selective experimental measurements. In this work, we present a combination of surface-sensitive heterodyne-detected vibrational sum frequency generation (VSFG) and *ab initio* based molecular dynamics simulations to study the liquid/air interface of different aqueous electrolyte solutions. Our VSFG measurements clearly demonstrate that the EDL model is an incomplete microscopic picture to understand the interface of NaCl, NaBr and NaCl aqueous solutions and it is completely inappropriate for the NaOH and CsF cases. Based on our simulations, we propose that the surface of electrolytes solutions is stratified into two water layers, one depleted and the other enriched with ions, creating an effective liquid-liquid interface buried a few Å inside the solution.

## CPP 37.8 Thu 12:45 H39

A purely ionic voltage effect soft triod — •ELALYAA MOHAMED, SABINE JOSTEN, and FRANK MARLOW — Kaiser-Wilhelm-Platz 1, 45470 Mülheim an der Ruhr Iontronics is a concept of connecting ionic transport, storage and reactions with electronics. As ions are the language of nature and electrons are the language of man-made information processing, connecting both may lead to more understanding of nature as well as to new computational systems which might be called neuromorphic. In the last decade, many iontronic devices were invented and studied. However, developing of iontronics requires the invention of more flexible devices. In our lab we developed a purely ionic voltage effect soft triode (IVEST) based on interfacial ion adsorption and redox oxidizer depletion. The IVEST was built with no need of sophisticated or expensive materials. This device is an electrochemical micro-cell, which consists of a top electrode and two bottom electrodes. The basic idea of this device is to control the concentration and diffusion of ions by the voltage applied on the top electrode. In different electrical circuit configurations, it can show amplification or memory effects. The device had an electrical current amplification reaching 52 and memory effects in the electrical resistance lasting for up to 6 h. These values were achieved by tuning an electrode interface, the electrolyte and diffusion properties. They might be promising for neuromorphic applications.

#### CPP 39.2 Thu 11:45 H38

Time-resolved spectroscopy study of the dynamics of charge transfer processes in strongly interacting organic donor/acceptor compounds — •NICO HOFEDITZ¹, CHRISTOPH P. THEURER², JULIAN HAUSCH², KATHARINA BROCH², WOLFRAM HEIMBRODT¹, and MARINA GERHARD¹ — ¹Department of Physics, Philipps-Universität Marburg, Germany — ²Institut für Angewandte Physik, Universität Tübingen, Germany

Doping of organic semiconductors with strong acceptor molecules is an effective way to tailor their electronic properties. Here, we investigate the photoexcitation dynamics of blends of tetracene and the strong acceptor F4-TCNQ to better understand how acceptors alter the transport of charge carriers and excitons. The mixtures feature a phase of relatively pure tetracene as well as an intimately mixed phase. In the mixed phase donor and acceptor molecules for charge transfer complexes that efficiently quench excitons from the pure phases. That leads to faster photoluminescence dynamics in the blends with respect to neat tetracene. We investigate the low temperature photoluminescence through global analysis and find constrained dynamics in the blends which we attribute to localization effects and energetic disorder in the tetracene domains.

## CPP 39.3 Thu 12:00 H38

Ultrafast excited states dynamics of two orthogonal molecular photoswitches •TANJA SCHMITT¹, LI-YUN HSU², EVA BLASCO², and PETRA TEGEDER¹ ¹Physical Chemistry, Ruprecht-Karls-Universität Heidelberg – ²Organic Chemistry, Ruprecht-Karls-Universität Heidelberg

Molecular photoswitches are widely used in physics, chemistry, biology and material sciences. The use of multiple photoswitches at one time opens diverse opportunities for further improved and more complicated systems. This requires orthogonal addressability of the photoswitches and ideally reversible processes. Herein, we report a mixture of two reversible and orthogonal photoswitches which could potentially be used in four-dimensional printing. We report the first study of their ultrafast excited state dynamics when they are addressed orthogonally as well as simultaneously to gain insight in their interaction. In addition, the environmental influence of the excited state dynamics of the orthogonal photoswitches is examined using different solvents as well as films.

#### CPP 39.4 Thu 12:15 H38

Charge Transfer and Singlet Fission in Pentacene/Acceptor thin films -•MARTIN RICHTER¹, CHRISTOPH THEURER², DEBKUMAR RANA^{1,3}, KATHARINA BROCH², and PETRA TEGEDER^{1,3} – ¹Physikalisch-Chemisches Institut, Universität Heidelberg, Im Neuenheimer Feld 253/229, 69120 Heidelberg, Germany  $-^2$ Institut für Angewandte Physik, Universität Tübingen, Auf der Morgenstelle 10, 72076 Tübingen, Germany $-^3$ Centre for Advanced Materials, Universität Heidelberg, Im Neuenheimer Feld 225, 69120 Heidelberg, Germany

Singlet fission (SF) is a process where a singlet excited state is converted into two triplet excited states. Since SF is exothermic in pentacene (PEN), it is an excellent material to investigate charge transfer (CT) interactions with electron acceptors. Here, stacked bi-layers of PEN either with 2,3,5,6-tetrafluoro-7,7,8,8-tetracyanoquinodimethane (F4-TCNQ) or 2,2'-(perfluoronaphthalene-2,6-diylidene)dimalononitrile (F6-TCNNQ) were investigated with transient absorption spectroscopy. The experiments show formation of triplet pairs, due to the SF process with a slightly slower time constant compared to the pure PEN. Subsequently a separation of the correlated triplet pair can be observed, a process that has been identified also in PEN thin films. A drastic reduction of the triplet lifetime is extracted with both acceptors. Further, evidence for diffusion of excitons to the interface followed by charge formation is found for layers with F4-TCNQ, supported by the shifting of an absorption band, caused by electric fields.

## CPP 39.5 Thu 12:30 H38

Understanding charge transfer excitations in Bacteriochlorophyll dimers from first principles — •ZOHREH HASHEMI¹, MATTHIAS KNODT¹, and LINN LEPPERT^{1,2⁻} - ¹Institute of Physics, University of Bayreuth, Germany ²MESA+ Institute for Nanotechnology, University of Twente, Netherlands

Bacteriochlorophyll (BCL) molecules are the main pigments driving the primary excitation and charge transfer processes in photosynthetic bacteria. They are organized in highly coordinated multichromophoric complexes, embedded in protein, guaranteeing an efficient transfer of excitation energy from the light harvesting antennae to the reaction center where a charge transfer excitation triggers. In this contribution we focus on the electronic and excited state structure of BCL monomers and dimers found in the reaction center and light harvesting apparatus of the purple bacterium Rhodobacter sphaeroides. We asses the accuracy of ab initio GW+Bethe-Salpeter equation approach for BCL monomers considering a wide range of excitation energies, and find excellent agreement with experimental data and correlated wavefunction-based approaches. We also discuss notable differences to results from state-of-the-art time-dependent density functional theory, which can be traced back to the treatment of electron-hole interactions in both methods [1]. For dimeric systems we show that the energy and character of charge transfer excitations is strongly affected by distance and orientation of the BCL molecules, providing an intuitive understanding for the role of these excitations in different parts of the photosynthetic apparatus.

#### CPP 39.6 Thu 12:45 H38

Temperature Dependent Optical Transition in Zinc Phthalocyanine Single **Crystals** — •LISA SCHRAUT-MAY¹, SEBASTIAN HAMMER¹, KILIAN FRANK², BERT NICKEL², and JENS PFLAUM^{1,3} — ¹Experimental Physics VI, Julius Max-imilian University, 97074 Würzburg — ²Department of Physics and Center for Nano Science, Ludwig Maximilian University, 80539 Munich — ³Bavarian Center for Applied Energy Research, 97074 Würzburg

By its various polymorphs, Zinc Phthalocyanine (ZnPc) serves as an excellent model system to study the interplay between molecular packing on microscopic length scales and the resulting photophysical properties [1]. Here, we address the dependence of the excitonic coupling on the underlying crystal structure of the thermodynamically stable ZnPc  $\beta$ -phase. For this purpose, we conducted complementary temperature dependent X-ray diffraction as well as polarisation dependent photoluminescence (PL) studies on ZnPc single crystals. By means of the PL signals spectral characteristics we observed a continuous transition from a J- into an H-aggregated state between 300 K and 100 K. Remarkably, below 100 K an exceptionally sharp PL peak evolves being indicative for the formation of a superradiant J-aggregate. As there is no indication for a discrete structural phase transition, we interpret the resulting PL signal in this temperature range by a model of vibronically coupled excitons steered by the gradual anisotropic thermal contraction of the crystal lattice [2]. We thank the Bavarian research network SolTech for financial support. [1] Hammer et al., Appl. Phys. Lett. (2019) [2] Hestand et al., Chem. Rev. (2018)

## **CPP 40: Organic Electronics and Photovoltaics 3**

Time: Thursday 15:00-17:45

#### Invited Talk

CPP 40.1 Thu 15:00 H38 Computational Design of Organic Semiconductors - •HARALD OBERHOFER - Chair for Theoretical Physics VII, Universität Bayreuth - Chair for Theoretical Chemistry, Technische Universität München

Organic electronics-in the form of field effect transistors, light emitting diodes, or solar cells—are slowly finding their use in everyday consumer devices. To date, most of the employed materials have been discovered by structural tuning of a promising compound family, thereby relying on intuition, experience, or simply trial and error. While sometimes quite successful, such incremental changes only lead to a local exploration of the vast chemical space of possible molecules, potentially overlooking many interesting materials.

In contrast, modern data-driven strategies allow the extraction of general design rules through the systematic of the available design space. Often, these take the form of a computational funnel, where large databases are searched by computing relevant properties, so-called descriptors, for each element of the database. While this can point towards promising yet so-far overlooked theoretical and experimental design routes for organic electronics materials such an approach is limited by the employed database, not really allowing any insight beyond. Therefore, we trained machine-learned surrogate models for the most important organic semiconductor properties. These form the basis for an active machine learning scheme that allows us to sample the, in principle, unlimited space of organic molecules searching for materials not considered so far.

#### CPP 40.2 Thu 15:30 H38

Reorganization energies of flexible organic molecules as a challenging target for machine learning enhanced virtual screening — •Ke CHEN^{1,2}, CHRISTIAN KUNKEL^{1,2}, KARSTEN REUTER^{1,2}, and JOHANNES T. MARGRAF^{1,2} — ¹Technische Universität München, Garching, Germany — ²Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany

The molecular reorganization energy  $\lambda$  strongly influences the charge carrier mobility of organic semiconductors and is therefore an important target for molecular design. Machine learning (ML) has the potential to accelerate this process by providing accurate surrogate models in design space. Unfortunately,  $\lambda$  poses a significant challenge for ML-models as it simultaneously depends on the neutral and ionized potential energy surfaces of the molecule.

In this contribution, we address the questions of how ML models for  $\lambda$  can be improved and what their benefit is in high-throughput virtual screening (HTVS). We find that, while improved predictive accuracy with respect to a semi-empirical baseline model is achieved, the benefits for molecular discovery are actually somewhat marginal. In particular, ML-enhanced HTVS is more effective in identifying promising candidates but leads to a less diverse sample set.

CPP 40.3 Thu 15:45 H38

Protonation-Induced Charge Transfer and Polaron Formation in Organic Semiconductors Doped by Lewis Acids - •FABIAN BAUCH, CHUAN-DING DONG, and STEFAN SCHUMACHER - Physics Department and CeOPP, Paderborn University, Germany

Organic electronics rely crucially on doping to enhance the conductivity of organic semiconductors (OSC). Lewis acid doping of OSC is currently of great interest as an alternative to typical molecular p-type doping. Recently, the underlying process was understood to be based on the electron transfer (ET) from a neutral polymer to the protonated polymer [Nat. Mater. 18, 1327 (2019)]. In this work, we provide insight into the microscopic process by investigating the influence of protons on the electronic properties of the copolymer PCPDT-BT using DFT calculations. [1] We find that a single proton on the backbone can give rise to a polaron coupled to the proton position. Two protons on the same polymer backbone can induce a long range intrachain ET, resulting in a polaron decoupled from the proton positions, more fit to act as charge carrier. We also demonstrate the possibility of ET between a neutral polymer and a doubly protonated polymer. The experimental data on the doping of PCPDT-BT via Lewis acid BCF agree well with our simulated vertical excitation spectra for an ensemble of protonated species with increasing amounts of protons. Our results highlight the important role of multiple protonation of the OSC backbone in completing the mechanistic picture of Lewis acid doping. [1] F. Bauch, C. Dong, and S. Schumacher, RSC Advances 12, 13999 (2022).

# $CPP \ 40.4 \quad Thu \ 16:00 \quad H38$ Adsorption layers of diketopyrrolopyrrole acceptor blocks on graphite: Self-assembly and structure in all-atom modelling — MOUFDI HADJAB¹ and •OLGA GUSKOVA² — ¹Boudiaf University of M'Sila, 28000 M'Sila, Algeria — ²IPF Dresden, 01069 Dresden, Germany

In this computational work, we investigate the adsorption layers of electrondeficient N-unsubstituted difuran-diketopyrrolopyrroles (DPP). Three conformational states differing in the mutual orientation of the central DPP unit and furan flanks are distinguished: cis-cis, trans-trans, and cis-trans. The adsorption layers are obtained during in-silico self-assembly on graphite surface through intermolecular hydrogen bonding in all-atom MD simulations. The experimental process for the construction of the adsorption layers, called the droplet deposition technique, is reproduced in the modeling. In all simulated systems, the formation of stable supramolecular polymers is observed which build the ordered carpets on the surface. However, the binding energetics and strength and the type of hydrogen bonding are highly sensitive to the molecular conformation. We quantify each of these characteristics and provide a molecular picture of difuran-DPP layers relevant for organic field-effect transistor applications. OG thanks DFG (project GU1510/5-1) for financial support.

## CPP 40.5 Thu 16:15 H38

Understanding Phonon Properties and the Thermal Conductivity of Crystalline Polymers — •Lukas Reicht, Lukas Legenstein, Tomas Kamencek, SANDRO WIESER, and EGBERT ZOJER — Graz University of Technology, Austria Disordered polymers are characterized by a very low thermal conductivity on the order of 0.1 W/mK. In contrast, recent studies have shown that aligned (crystalline) polymers can have thermal conductivities comparable to those of metals. Given these prospects, it is interesting to understand, how the thermal conductivity of a polymer depends on its chemical structure. A crucial step in that context is to investigate phonons and their influence on thermal transport. For simulating the phonons, we relied on density-functional theory (DFT) calculations combining phonopy and the Vienna Ab initio Simulation Package (VASP). In a second step, anharmonic force constants and thermal conductivities were calculated with phono3py and hiPhive. Additionally, we explored the capabilities of on-the-fly machine learned force fields (ML-FF), trained on DFT data, as implemented in VASP. These approaches were tested and benchmarked for polyethylene as a comparably simple model system. The final goal of our work is to then apply the above methodology to other polymers, systematically varying the structure of the backbone, thereby finding structure-to-property relations. These polymers include poly(p-phenylene), polythiophene, polyfuran, polyselenophene, poly(3-hexylthiophen-2,5-diyl) (P3HT) and Poly(p-phenylene vinylene) (PPV).

## 15 min. break

## CPP 40.6 Thu 16:45 H38

Assessing Crystal Structure Prediction Based on Density Functional Tight Binding and Evolutionary Algorithms — •SEBASTIAN HUTSCH and FRANK ORTMANN — Department of Chemistry, Technical University of Munich The prediction of crystal structures for organic molecules is a computationally expensive task due to the large number of atoms in the unit cell and the associated number of possible configurations. The computational load can be compensated by the use of classical force fields, which however lack transferability to new molecules and necessitate an extensive training for complex molecules. Here, we study an approach to crystal structure prediction based on evolutionary algorithms and a combination of Density Functional Tight Binding (DFTB) and Density Functional Theory (DFT). This combination allows us to efficiently compute crystal structures for new materials on a high level of accuracy. A comparison of the calculated crystal structures with experimentally known structures will be made.

## CPP 40.7 Thu 17:00 H38

Singlet Fission search in polyacene molecules in gas-phase and on raregas clusters using ab initio methods — •SELMANE FERCHANE¹, ALEXANDER EISFELD², and MICHAEL WALTER^{1,3,4} — ¹Institute of Physics, University of Freiburg, Germany — ²Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — ³FIT Freiburg Center for Interactive Materials and Bioinspired Technologies, University of Freiburg, Germany — ⁴Fraunhofer IWM, Freiburg, Germany

Singlet fission (SF), is a spontaneous photo-excited splitting phenomenon. Where an organic chromophore dimer, converts its singlet exciton into a pair of triplet excitons. A great promise for future photon-to-current conversion of solar energy using organic materials with high efficiency. To get more insight into these processes of SF, we employed different ab initio theories and approaches in our investigation, namely, density functional theory (DFT), TD-DFT, MCTDH, and CASPT2/CASSCF. Since the spatial orientation is crucial to whether the molecule will go SF and the rate of it due to the orbital coupling of both molecules, based on recent studies. We calculate the most favorable orientation of the chromophores with the binding energies in the gas phase and adsorbed on Argon and Neon surfaces. Then we calculate the lowest-lying excited states that contribute to the singlet and triple transition plus the search for the possible conical intersection that crosses the surface potential energies.

#### CPP 40.8 Thu 17:15 H38

Materials design based on theoretical characterization: Improving open-shell organic molecules for electronic applications — •SEBASTIAN SCHELLHAMMER¹ and FRANK ORTMANN² — ¹Dresden Integrated Center for Applied Physics and Photonic Materials (IAPP) and Institute for Applied Physics, Technische Universität Dresden, Dresden, 01187 Germany — ²Department of Chemistry, Technische Universität München, Lichtenbergstr. 4, 85748 Garching b. München

In recent years, organic molecules with stable open-shell ground states have attracted growing interest due to their outstanding properties, i.e. responsive spin structures, high-spin ground states, two-photon absorption, or small band gap. Although a growing number of interesting materials has appeared, molecules often lack thermal stability impeding their application in electronic devices. In this presentation, we will highlight routes but also dead ends in the quest for highspin configurations in hydrocarbons. We benchmark a computational approach for the characterization of open-shell organic structures, which combines predictability with appropriate simulation resources. For polycyclic heteroaromatic hydrocarbons containing a benzoisoindole core, we explain why a supposedly open-shell material does not provide the desired characteristics. On the contrary, we discuss the promising characteristics of stable polycyclic hydrocarbon diradicaloids as well as related tetraradicaloids. Based on these analyses, design rules for optimized material properties are extracted, which helps to exploit the full potential of promising material groups.

CPP 40.9 Thu 17:30 H38 Simulation organic semiconductors with tensor network techniques —  $\bullet$ SAM MARDAZAD¹, YIHE XU², XUEXIAO XANG², MARTIN GRUNDNER³, ULRICH SCHOLLWÖCK³, HAIBO MA², and SEBASTIAN PAECKEL³ — ¹Heriot-Watt University, Edinburgh — ²School of Chemistry and Chemical Engineering, Nanjing University — ³Department of Physics, Arnold Sommerfeld Center of Theoretical Physics, University of Munich

Organic solar cells provide the possibility to enhance the efficiency and to overcome the Shockley-Queisser limit. In this talk we present results for the simulation of quantum transport effects in a tetracene para dimers, a large organic molecule modelled by a Frenkel-exciton Hamiltonian. We account for the full quantum dynamics going beyond the Born-Oppenheimer approximation. For that purpose we use a new numerically unbiased representation of the molecule's wave function enabling us to compare with experiments, exhibiting good agreement. With this powerful approach we map out a phase diagram aiming and determining the experimental sweet spot yielding the highest charge carrier production rate. Furthermore, we develop a physical picture indicating that the coherent time scale in which most of the yield is generated is driven by a renormalization of the bare modes and make suggestions on how to manipulate this for the development of more efficient organic solar cells.

## CPP 41: Crystallization, Nucleation and Self-Assembly

Time: Thursday 15:00-17:30

Invited Talk CPP 41.1 Thu 15:00 H39 Interface-induced crystallization in polymers: From model systems to applications for semiconducting polymers — Muhammad Tariq¹, Robert Kahl¹, Mukundan Thelakkat², Thomas Thurn-Albrecht¹, and •Oleksandr Location: H39

DOLYNCHUK¹ — ¹Experimental Polymer Physics, Martin Luther University Halle-Wittenberg — ²Applied Functional Polymers, University of Bayreuth Crystallization is usually initiated at interfaces. Understanding the physical process underlying interface-induced crystallization (IIC) is of fundamental inter-

est and is relevant for material applications. IIC of liquids can occur either by heterogeneous nucleation (HN) or by the equilibrium phenomenon of prefreezing. First, we present a combined theoretical and experimental study of the effect of the substrate-material interactions on the thermodynamics of prefreezing and on the kinetics of HN in model polymers on various substrates. Second, the acquired knowledge about IIC elucidates the role of interfaces for crystal orientation in films of conjugated polymers, which is important for device performance. Using polythiophenes as model conjugated polymers, we show that different crystal orientations can be formed at the interfaces to a substrate and vacuum as a result of two competing interfacial interactions. Our results demonstrate that increasing the polarity of polythiophene side chains influences the interactions at the interfaces, resulting in a change of crystal orientations. Thus, we disclose the crucial role of the interfacial interactions for crystallization kinetics, thin film morphology, and control of molecular orientation in films of model and semiconducting polymers.

#### CPP 41.2 Thu 15:30 H39

Determination of Morphologically Tailored Chirality in Supramolecular Nanostructures by X-ray Scattering — •ASENA CERHAN HAINK¹, FELIX WENZEL², KLAUS KREGER², HANS-WERNER SCHMIDT², RICHARD HILDNER³, and EVA M. HERZIG¹ — ¹Dynamik und Strukturbildung-Herzig Group, Universität Bayreuth, Universitätsstr.30, 95447 Bayreuth, Germany — ²Makromolekulare Chemie I, Universität Bayreuth, Universitätsstr.30, 95447 Bayreuth, Germany — ³Zernike Institute for Advanced Materials, University of Groningen, Nijenborgh 4, 9747 AG Groningen, Netherlands

Designed supramolecular nanostructures allow control over their optical and electronic properties which make them promising candidates for lightharvesting applications. Recently, we presented long-range ( $\mu$ m) transport of excitation energy in supramolecular nanofibres based on a carbonyl-bridged triarylamine (CBT). Here, we study supramolecular CBT building blocks with chiral side groups, which result in a distinct circular dichroism (CD) signal from self-assembled nanofibres. For bundles of supramolecular nanofibres, we observe an inversion in the CD signal as a function of temperature. To understand the origin of this effect, we performed morphological characterisation using temperature-dependent Wide Angle X-ray Scattering on the CBT-based bundles. We demonstrate systematic temperature-dependent variations in the  $\pi$ - $\pi$ stacking and the column-column distances, which indicates that the CBT-based bundles have thermoelastic behaviour and change chirality at the critical temperature.

## CPP 41.3 Thu 15:45 H39

Learning the Crystallisation Behaviour of Bidisperse Branched Model Polymers using Coarse-Grained Molecular Dynamics Simulations - • WILLIAM Fall¹, Joerg Baschnagel¹, Olivier Lhost², and Hendrik Meyer¹ -¹Institut Charles Sadron, 23 rue du Loess, 67034 Strasbourg Cedex, France. — ²TotalEnergies One Tech Belgium, Zone Industrielle C, 7181 Feluy, Belgium Model polymer systems allow fundamental questions about polymer crystallisation to be tackled precisely. Molecular dynamics (MD) simulations can provide insights but studying large lamellar structures is challenging. Meyer and Muller-Plathe set the stage for molecular dynamics (MD) simulations of large lamella structures, by demonstrating that reproducing local crystalline structures is unimportant when large crystalline and amorphous regions dominate properties. Here, the role of short chain branches (SCBs) (C4) on the melt and crystalline properties of monodisperse polyethylene systems (C400) is investigated, using CGMD simulations. SCBs are grown into the melt to minimise computational expense, providing access to large systems. Cooling and heating cycles reveal the crystalline morphology depends strongly on both cooling rate and number of branches. Bidisperse mixtures of ultra-long C4000 and C400 are also studied, with different branch distributions, which mimic industrial PE morphologies. Via self-seeding, well aligned lamella are grown and morphological features, i.e. tie chains analysed. We begin to address how these features influence crystalline structure and material properties. We thank TotalEnergies for funding and GENCI/IDRIS (Orsay) and CAIUS/HPC centre.

## CPP 41.4 Thu 16:00 H39

**Aggregation and ordering in small alkane systems** — •TIMUR SHAKIROV and WOLFGANG PAUL — University of Halle, Halle, Germany

Ordering of small alkanes differs drastically from the bulk one. The difference is not only quantitative but also qualitative: short-chain single alkanes fold at low temperatures into non-trivial structures [1] in contrast to fully-stretched-chain lamellae in bulk. For the few chain systems we demonstrate the leading role of torsional stiffness in the ordered structure formation and investigate the corresponding conformations, which vary from spirals to tilted lamellae. For the fully stretched chain lamellae we find a two-step ordering, the indications of which remain at least up to 16 chain aggregates. In contrast to the low-temperature ordering, the aggregation or liquid-vapor transition leads to similarly disordered structures for all system sizes, which allows correction of size effects and extrapolation of the estimated aggregation/boiling temperatures at normal pressure are in good agreement with experimental data. The presented equilibrium results are based on Wang-Landau-type Monte Carlo simulations [2,3] of a chemically realistic united atom model [4].

CPP 41.5 Thu 16:15 H39

How the competition between crystal growth and intracrystalline chain diffusion determines the lamellar thickness in semicrystalline polymers — MARTHA SCHULZ, MAREEN SCHÄFER, KAY SAALWÄCHTER, and •THOMAS THURN-ALBRECHT — Institut für Physik, Martin-Luther-Universität Halle-Wittenberg, 06099 Halle

The non-equilibrium thickness of lamellar crystals in semicrystalline polymers varies significantly between different polymer systems and depends on the crystallization temperature  $T_c$ . There is currently no consensus on the mechanism of thickness selection. Previous work has highlighted the decisive role of intracrystalline chain diffusion (ICD) in special cases, but a systematic dependence of lamellar thickness on relevant timescales such as that of ICD and stem attachment has not yet been established. Studying the morphology by small-angle X-ray scattering and the two timescales by NMR methods and polarization microscopy, we present data on poly(oxymethylene), a case with relatively slow ICD. It fills the gap between previously studied cases of absent and fast ICD, enabling us to establish a quantitative dependence of lamellar thickness on the competition between the noted timescales.

CPP 41.6 Thu 16:45 H39 The Crucial Role of Solvation Forces in Inter-Nanoplatelet Interactions and Stack Formation — •NANNING PETERSEN, MARTIN GIRARD, ANDREAS RIEDINGER, and OMAR VALSSON — Max Planck Institute for Polymer Research, Ackermannweg 10, D-55128 Mainz

Cadmium selenide nanoplatelets show the tendency to form stacks in apolar alkane solvents. This effect is very similar to the stack formation of micron-sized discs, which can be induced by depletion forces. However, the interplay of the various forces leading to stack formation of nanoplatelets remains unclear. Solvation forces are in their origin and behaviour very similar to depletion forces.

Here, we use coarse-grained molecular dynamics simulations of nanoplatelets in octane solvent to investigate the role of solvation forces in nanoplatelet interactions. We demonstrate that solvation forces resulting from solvent layering are sufficiently strong to stabilize nanoplatelet stacks. We examine the dependence of solvation forces on the nanoplatelets' ligand shell, size, and other parameters. In particular, we demonstrate that for sufficiently large nanoplatelets, solvation forces are proportional to the interacting facet area, and their strength is intrinsically tied to the softness of the ligand shell. The solvation forces exhibit an oscillatory nature; increases in their strength leads to a stronger attraction between close nanoplatelet facets and in addition to an increase in the kinetic barriers.

## CPP 41.7 Thu 17:00 H39

In situ small-angle X-ray scattering and total scattering to study CuPd nanoparticle growth and self-assembly — •KILIAN FRANK¹, DAVIDE DERELLI², DOROTA KOZIEJ², and BERT NICKEL¹ — ¹Faculty of Physics and Center for Nanoscience (CeNS), Ludwig-Maximilians-Universität, Geschwister-Scholl-Platz 1, 80539 München, Germany — ²University of Hamburg, Institute for Nanostructure and Solid-State Physics, Center for Hybrid Nanostructures, 22761, Hamburg, Germany

Combining noble metals with abundant materials is a promising design strategy for new catalytic nanomaterials, e.g. for  $\rm CO_2$  reduction. Reliable synthesis routes of nanoparticles with a low size dispersity are required, but often an understanding of the formation pathway is lacking. Therefore, we investigated the entire synthesis of CuPd alloy nanoparticles using simultaneous small-angle X-ray scattering (SAXS) and the atomic pair distribution function obtained from total scattering (TS) to establish the sequence of structures from the atomic level to the nanoscale. We use a dedicated reaction cell for heating and stirring at the high-energy beamline PO7 (PETRA III, DESY), extending our previous studies on cobalt oxide nanoparticle formation (https://doi.org/10.1038/s41467-021-24557-z). We characterize the transformation of precursors and early nucleation by TS, and the subsequent particle growth and assembly by SAXS in a model-based analysis. Upon cooling, we observe a rich temperature-dependent phases behavior of particle assemblies. These can serve as a potential templating strategy for efficient particle-based catalysts.

CPP 41.8 Thu 17:15 H39

Ligand-stabilized gold nanorods as an ideal model system for anisotropic colloids — •MARCEL KRÜSMANN and MATTHIAS KARG — Physikalische Chemie I: Kolloide und Nanooptik, Heinrich-Heine-Universität Düsseldorf, Düsseldorf, 40225, Germany

Anisotropic colloidal particles have interesting optical, electronic and selfassembly properties. Yet the investigation of their phase behavior is often difficult due to limitations in quantity, monodispersity and colloidal stability for many particles. An additional challenge is the precise determination of particle number concentrations.

## CPP 42: Perovskite and Photovoltaics 5 (joint session HL/CPP/KFM)

Time: Thursday 15:00-16:30

See HL 32 for details of this session.

Time: Thursday 18:00-19:00

All members of the Chemical and Polymer Physics Division are invited to participate.

## CPP 44: Focus Session: Soft Matter and Nanocomposites: New Opportunities with Advanced Neutron Sources 2

organized by Stephan Förster (FZ Jülich), Thomas Gutberlet (FZ Jülich), Peter Müller-Buschbaum (TUM) and Walter Richtering (RWTH Aachen)

Time: Friday 9:30-11:15

# Invited Talk CPP 44.1 Fri 9:30 H38 Connecting dynamics and phase behavior of proteins: The neutron perspective - •FRANK SCHREIBER -- Universität Tübingen, Germany

We discuss the combination of various neutron scattering techniques to shed light on the dynamics of proteins in aqueous solution. This includes several processes, such as backbone and side-chain fluctuations, interdomain motions, as well as global rotational and translational (i.e. center of mass) diffusion. Since protein dynamics is related to protein function and essential transport processes, a detailed mechanistic understanding and monitoring of protein dynamics in solution is highly desirable. In particular, we connect it to the overall phase behavior in terms of clustering, crowding, crystallization, and phase separation [1], employing a combination of elastic, quasi-elastic, and inelastic scattering [2] as well as complementary techniques, such as X-ray photon correlation spectroscopy (XPCS) and simulations [3]. Finally, we comment on future perspectives with advanced neutron sources. Invaluable contributions by numerous collaborators are gratefully acknowledged.

Self-assembly of supramolecular magnetic polymers with monomers of different sizes — Ekaterina Novak¹, Elena Pyanzina¹, •Marina Gupalo¹, and Sofia Kantorovich^{1,2} — ¹Ekaterinburg, Russia — ²University of Vienna, Vienna, Austria

In this paper we studying the effect of polydispersity of magnetic particles on the self-assembly of supramolecular magnetic polymers. Magnetic polymers are widely used to create new magnetically controlled materials and represent an analogue of polymer chains, where polymer molecules serve as crosslinks, and magnetic particles replace monomers. We propose to consider the bidisperse model, which takes into account only two fractions of particles in size, which is enough to track the main influence of polydispersity on the self-organization of a magnetic polymer. Using the method of computer simulation of Langevin's dynamics, we study various structural parameters of an individual magnetic polymer of different configurations: a chain, a closed ring, an X-shaped and Y-shaped magnetic filament. For analysis of the qualitative changes in equilibrium properties with temperature were used radius of gyration and magnetic moment, the general microstates are also defined. It turned out that the considered new types of polymer configuration compared with the monodisperse model significantly affect the equilibrium properties. This work was supported by RSF grant 19-72-10033.

The easily scalable synthesis of gold nanorods gives access to monodisperse anisotropic colloids with a broad range of aspect ratios. The functionalization of gold nanorods with a polymer ligand increases the colloidal stability and removes the large excess of surfactant that is most often used in particle synthesis.

These anisotropic particles can now be studied with various methods. One of this methods is small-angle X-ray scattering for which gold has an excellent contrast. In combination with the good colloidal stability it is now possible to not only study the form factor but also the structure factor at high concentrations and/or during induced aggregation. The addition of absolute intensity measurements gives access to the particle number concentration, that can be related to measured extinction from spectroscopy.

 $\label{eq:constraint} CPP \ 44.3 \quad Fri \ 10:15 \quad H38$  Pathways of micellar collapse and swelling of PMMA-b-PNIPAM in aqueous solution after a rapid change of pressure — •PABLO A. ALVAREZ HERRERA¹, JOHANNES ALLWANG¹, FEIFEI ZHENG¹, CRISTIANE HENSCHEL², LEONARDO CHIAPPISI³, ALFONS SCHULTE⁴, ANDRÉ LASCHEWSKY², and CHRISTINE M. PAPADAKIS¹ — ¹TU München, Physik-Department, Garching, Germany — ²Institut für Chemie, Potsdam-Golm, Germany — ³Institut Laue- Langevin, Grenoble, France — ⁴University of Central Florida, Orlando, USA

In aqueous solution, diblock copolymers consisting of a permanently hydrophobic and a thermo-responsive block can self-assemble into different morphologies. In particular, poly (methyl methacrylate)- *b*-poly(*N*-isopropylacrylamide) (PMMA-*b*-PNIPAM) forms spherical micelles featuring a PMMA core and a thermo-responsive PNIPAM shell. At atmospheric pressure, the micellar shell dehydrates, and the collapsed micelles form aggregates when heating above the cloud point of PNIPAM [1]. This phase transition can be also induced by changing the pressure. In this contribution, we study the micellar collapse and their posterior aggregation by kinetic small-angle neutron scattering (SANS) in combination with rapid pressure jumps across the co-existence line. The disintegration of the aggregates and the micellar swelling are also investigated by performing the pressure jump in the opposite direction.

CPP 44.4 Fri 10:30 H38 Investigation of the Effect of Magnesium Salts with Chaotropic Anions on the Swelling Behavior of PNIPMAM Thin Films –  $\bullet$ JULIJA REITENBACH¹, CHRISTINA GEIGER¹, PEIXI WANG¹, ROBERT CUBITT², DIRK SCHANZENBACH³, ANDRÉ LASCHEWSKY³, CHRISTINE M. PAPADAKIS⁴, and PETER MÜLLER-BUSCHBAUM¹ – ¹TU München, Physik-Department, Lehrstuhl für Funktionelle Materialien, James-Franck- Str. 1, 85748 Garching – ²Institut Laue-Langevin, 71 Avenue des Martyrs, CS 20156, 38042 Grenoble Cedex 9, France – ³Universität Potsdam, Institut für Chemie, Karl-Liebknecht-Str. 24-25, 14476

Potsdam-Golm — ⁴TU München, Physik-Department, Physik weicher Materie, 85748 Garching Thermoresponsive polymer thin films have gained a lot of attention in the past decades due to their attractiveness for a wide range of applications. A variety of polymer showing LCST- or UCST-type behavior are known, and their transition temperatures can be influenced by various factors such as molar mass, end groups, copolymerization, or by the addition of salts. For polymers in aqueous solution, it was found that the folding of the polymer chains can be strongly influenced by the type of salt and this ability follows a trend called the Hofmeister series. While this effect is well known in solution, the influence on the swelling behavior of PNIPMAM thin films has yet to be investigated thoroughly. We aim

CPP 44.5 Fri 10:45 H38 Invited Talk Magnetic particle self-assembly at functionalized interfaces — •MAX WOLFF - Department for Physics and Astronomy, Uppsala University, Uppsala, Sweden Neutrons allow the study of buried interfaces and are directly sensitive to magnetic induction. This makes grazing incidence neutron scattering an ideal tool for the study of self-assembled magnetic particles.

In this talk I will discuss the self-assembly of monodisperse colloidal magnetite nanoparticles from a dilute water-based ferrofluid onto functionalized silicon

## CPP 45: Biopolymers, Biomaterials and Bioinspired Functional Materials (joint session CPP/BP)

Time: Friday 9:30-11:15

Invited Talk CPP 45.1 Fri 9:30 H39 New biobased material concepts using scattering techniques to elucidate and control nanoscale assembly — • DANIEL SÖDERBERG — KTH Royal Institute of Technology, Department of FIbre and Polymer technology, Stockholm, Sweden Cellulose, the most abundant biopolymer on earth, can be crucial in mitigating fossil-based resources to more sustainable solutions. It is used as an engineering material, e.g. sawn timber, pulp for papermaking or as a polymer as a basis for plastic materials.

Cellulose nanofibres (CNF) constitute the structural component of plants, it is a semi-crystalline, semi-flexible rod-like nanoparticle having cross-sections in the order of 4-5 nm and lengths around one micrometre. Based on technical developments during the last decades, it is today possible to extract the CNF in large quantities, which has promoted significant research efforts aiming at new material concepts and devices based on cellulose.

Small and wide-angle x-ray scattering have been used to understand nanoscale assembly during fibre spinning from a CNF dope using microfluidics, allowing the tuning of the hierarchical structure, resulting in 100% bio-based filaments with exceptional properties. Furthermore, to develop scalable engineering processes, an in-depth understanding of nanoscale diffusion and the effects of nanoparticle interaction in low-concentration crowded systems has been pursued by combining light-scattering, X-ray Photon Correlation Scattering and coarse-grain modelling.

## CPP 45.2 Fri 10:00 H39

A Semisynthetic Superparamagnetic Nanoprobe for Protein Targeting and Manipulation — •Andreas Neusch¹, Iuliia Novoselova¹, Nikolaos TETOS², MICHAEL FARLE², ULF WIEDLAND², and CORNELIA MONZEL¹ – ¹Heinrich-Heine University Düsseldorf, Germany – ²University of Duisburg-Essen, Germany

Probing and manipulating biological functions requires tools to target and modify the proteins involved in the respective process. In recent years Magnetogenetics emerged as an approach where magnetic nanoparticles (MNPs) and external magnetic fields are used to realize such manipulation (Lisse et al., Adv. Mater., 29, 1700189 (2017)). The advantages of this combination lies within the deep tissue penetration of magnetic fields and the possibility to apply stimuli on nanoscales leading to spatial redistribution, force application, or heat generation of proteins. However, a precise active perturbation requires MNPs to be monodisperse, biocompatible, tunable with regard to their magnetic properties, as well as exhibiting a modifiable molecular shell (Monzel et al., Chem. Sci. 8, 7330-7338 (2017)). Here, we synthesize a bioinspired semisynthetic MNP - Magnetoferritin (MFt) -, which fulfils these demands. MFt is based on the globular iron storage protein complex ferritin that converts iron ions to a ferrihydrite core but can be synthetically loaded with a magnetic iron oxide core (Novoselova et al., Nanomaterials, 11, 2267 (2021)). MFt was chemically, physically and magnetically characterized both in vitro and in vivo. We demonstrate how MFt can be used to target proteins on living cells as well as to spatially manipulate MFts in a single cell environment.

## CPP 45.3 Fri 10:15 H39

**Bioinspired electrodes for brain wave detection** – •Volker Körstgens¹, GÖKAY ERBIL¹, ANDREAS ZHENG¹, HSIN-YIN CHIANG², and PETER MÜLLER-Визснваим¹ — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²Cephalgo, 67000 Strasbourg, France

With increasing demands in brain computer interfaces (BCI) measuring biosignals non-invasively becomes more important. Applications like measuring brain waves via electroencephalography (EEG) with dry electrodes remains challenging as for a steady biosignal acquisition adhesion to the skin has to be maintained all the time. We present two different approaches inspired by nature for such electrodes. In our first approach we developed micro-structured dry adhesive electrodes based on polydimethylsiloxane (PDMS) with conductive fillers.

surfaces. The density of the layer adjacent to the substrate is determined by the interaction between the particles and the substrate. Dense layers form for chemical binding and magnetic substrates, while less dense and no layering is found for physisorption and repulsive interactions. Once adsorbed subsequent layers assemble due to magnetic dipolar forces. The layering gets more pronounced for larger dipole moments of the particles. Once formed the density and structure of the layers may be tuned by magnetic and/or shear fields.

Magnetic particles may also be used to self-assemble polymer micelles. Applied magnetic fields may result in a micro shear effect aligning the domains of micellar crystals. By stroboscopic reintegration this reorientation process may be followed on time scales down to ms and resonant enhancement may aid the identification of off-specular and grazing incidence small angle scattering.

Location: H39

The EEG-performance and adhesive properties of these electrodes will be discussed and compared to the concept of mussel-inspired hydrogels we follow in our second approach.

#### CPP 45.4 Fri 10:30 H39

Anionically functionalized glycogens efficiently encapsulate cationic peptides — Hanna Zhukouskaya¹, • Pablo M. Blanco², Zulfiya Černochová¹ LUCIE ČTVERÁČKOVÁ¹, ROMAN STAŇO³, EWA PAVLOVA¹, MIROSLAV VETRÍK¹, PETER ČERNOCH¹, MIROSLAV ŠLOUF¹, MARCELA FILIPOVÁ¹, MIROSLAV ŠTĚPÁNEK², MARTIN HRUBÝ¹, PETER KOŠOVAN², and JIŘÍ PÁNEK¹ — ¹Institute of Macromolecular Chemistry, Czech Academy of Sciences, Heyrovského nám. 2, 162 06 Prague 6, Czech Republic — ²Department of Physical and Macromolecular Chemistry, Faculty of Science, Charles University, Hlavova 8, 128 40 Prague 2, Czech Republic —  3 Faculty of Physics, University of Vienna, Kolingasse 14-16, 1090 Vienna, Austria

We developed and tested novel acid-functionalized glycogen conjugates as supramolecular carriers for efficient encapsulation and inhibition of a model cationic peptide melittin, which is the main component of honeybee venom. Systematic investigation of this model system allowed us not only to test its potential application as honeybee venom antidote but also to assess the role of the degree of substitution and solution pH in the interactions of these anionic carriers with multivalent cationic cargos. Our results demonstrate that the concept of electrostatically driven encapsulation by acid-functionalized glycogens should be applicable not only to the model case of melittin but also to other multivalent cationic biomolecules.

Dissipative Assembly: Controlling Changes of Membrane Topology by Reaction Cycles - • GREGOR IBBEKEN and MARCUS MÜLLER - Institut für Theoretische Physik, Georg-August Universität, Friedrich-Hund-Platz 1, 37075 Göttingen

Coupling a self-assembling system to a reaction cycle, we go beyond equilibrium self-assembly toward systems that dissipate energy and thus exhibit new, unique features of dynamic self- organization. We consider polymers which can switch between a hydrophilic and an amphiphilic state and in the latter self-assemble to form vesicles in aqueous solution. This can occur either by macromolecular or monomeric reactions. In both cases a precursor reacts with a fuel to a product, which itself can decay back to the precursor. We perform particle-based simulations using a soft, coarse grained model for polymers. For the macromolecular reactions we find two drastically different scenarios depending on the fuel volatility: (i) For high fuel volatility, the coupling of inactivated to activated polymers introduces a length scale which dictates the maximal vesicle size and prevents fusion beyond this. This results in an interplay between the architectureand the reaction-rate-determined length and time scales. (ii) For less volatile fuel, a fuel gradient arises in the system. This results in the compartments moving within the fuel gradient to approach the source. In doing so the moieties gain material over long times which drastically changes the formation mechanism of the vesicles. Finally, we show that the above reaction mechanism can be mimicked by monomeric reactions by the use of multiple, inhomogeneously distributed fuels.

Mechanical nanoscale polarization switching in ferroelectric polymer films •KATHRIN DÖRR, MARTIN KOCH, DIANA RATA, and ROBERT ROTH — MLU Halle-Wittenberg

Ferroelectric polymer films offer strong advantages like mechanical flexibility, biocompatibility, optical transparency and low-cost processing. However, their dielectric or piezoelectric performance is often inferior to that of oxide ferroelectric materials. Key to that is the electric dipolar order which is naturally lower in semicrystalline polymers than in crystalline ferroelectrics. We introduce the reorientation and alignment of the electric polarization in thin films utilizing the mechanical effect of an unbiased scanning force microscopy tip, providing a versatile tool for nanoscale domain writing [1]. Thin films (50 - 150 nm) of P(VDF-TrFE) (78:22) on graphite were prepared with dense (110)-oriented beta-phase lamellae randomly oriented in the film plane. Domain patterns with resolution down to 50 nm have been written with four (out of six possible) local polarization orientations. Written domains show excellent long-time stability. We discuss a ferroelastic origin of the mechanical polarization switching and make suggestions for how to utilize the domain patterns in thin film devices. [1] Adv. Electron. Mater. 2022, 2101416

CPP 48.2 Fri 11:45 H38

In-situ investigations of morphology degradation and oxidation level changes in EMIM DCA post-treated PEDOT:PSS thin films upon external influence — •Anna Lena Oechsle¹, Julian E. Heger¹, Nian Li¹, Shanshan Yin¹, Sigrid Bernstorff², and Peter Müller-Buschbaum^{1,3} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching -²ELETTRA, 34149 Basovizza TS, Italy — ³MLZ, TU München, 85748 Garching Nowadays thermoelectric generators are considered a promising technique for heat waste recovery as they enable a direct conversion of a temperature gradient into electrical power. Especially, organic thermoelectric polymers are attractive, owning some advantages like low cost, lightness and high mechanical flexibility, low or no toxicity, as well as a usually low thermal conductivity. In our work we show the positive effect of ionic liquid (IL) treatment on the thermoelectric properties, Seebeck coefficient and electrical conductivity, of semiconducting PEDOT:PSS thin films. Furthermore with different in-situ experiments like GISAXS (grazing incidence small angle x-ray scattering), UV-Vis, and conductivity measurements we examine the inner film morphology and oxidation level changes upon operation at different ambient conditions.

up to 4*10^3 S/m was found. A change in PDADMA molecular weight by almost a factor of ten does not affect the film thickness and electrical conductivity, only the film/air roughness is reduced. However, increasing CNT concentration in the deposition dispersion from 0.15 up to 0.25 mg/ml results in an increased thickness of a CNT/PDADMA bilayer (by a factor of three). The increased bilayer thickness is accompanied by a decreased CNT coverage and a decreased electrical conductivity (by a factor of four).

CPP 48.3 Fri 12:00 H38

Improvement of TE properties of PEDOT:PSS films via DMSO addition and DMSO/salt post-treatment resolved from a fundamental view -Tu¹, Ting Tian¹, Anna-Lena Oechsle¹, Shanshan Yin¹, Xinyu Jiang¹, Wei Cao¹, Nian Li¹, Manuel A. Reus¹, Lennart K. Reb¹, Shujin Hou², Ali-Aksandr S. Bandarenka², Matthias Schwartzkopf³, Stephan V. Roth³, and Peter Müller-Buschbaum^{1,4} - ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching - ²TU München, Physik-Department, Physik der Energiewandlung und -speicherung, 85748 Garching –  $^3\rm DESY,$  22607 Hamburg –  $^4\rm MLZ,$  TU München, 85748 Garching

The combination of DMSO-solvent doping and physical-chemical DMSO/salt de-doping in a sequence has been used to improve the thermoelectric PE-DOT:PSS films. The initial DMSO-doping treatment induces a distinct phase separation by facilitating the aggregation of the PEDOT molecules. At the same time, the subsequent DMSO/salt de-doping post-treatment strengthens the selective removal of the surplus non-conductive PSS chains. Substantial alterations in the oxidation level, chain conformations, PEDOT crystallites and their preferential orientation are observed upon treatment on the molecular level. At the mesoscale level, the purification and densification of PEDOT-rich domains enable the realization of inter-grain coupling by the formation of the electronically well-percolated network. Thereby, both electrical conductivity and Seebeck coefficient are optimized.

CPP 48.4 Fri 12:15 H38

Exciton dynamics in surface-mounted metal-organic frameworks: A femtosecond transient absorption study — •VIPILAN SIVANESAN¹, MARTIN Richter¹, Debkumar Rana¹, Ritesh Haldar², Christoph Wöll², and Pe-TRA TEGEDER¹ — ¹Physikalisch-Chemisches Institut, Universität Heidelberg, Germany —  $^2 \mathrm{Institute}$  of Functional Interfaces, Karlsruhe Institute of Technology, Germany

For the optimization of organic optoelectronic devices, it is important to understand the ultrafast electronically excited state dynamics in organic semiconductors after optical excitation. For instance, different molecular packing and relative orientations of the optically active chromophores can affect the excitonic coupling strength. This can be studied in crystalline molecular assemblies by integrating these chromophores into surface-mounted metal-organic frameworks (SURMOFs) as organic linkers. Varying the side-groups of the molecules enables to engineer the crystal structure to tune the excitonic coupling. To analyse the influence of this crystal engineering on the ultrafast dynamics we investigated thin films of chromophore functionalized Zn-SURMOF by means of femtosecond transient absorption.

Molecular Mobility and Physical Aging in Polymers of Intrinsic Microporosity (PIM-1) Revisited: A Big Glassy World — •FARNAZ EMAMVERDI, MARTIN BÖHNING, and ANDREAS SCHÖNHALS — Bundesanstalt für Materialforschung und -prüfung (BAM), Berlin, Germany

Polymers of Intrinsic Microporosity (PIMs) are promising candidates for the active layer in gas separation membranes because of their high permeability and reasonable permselectivity. However, PIMs suffer from a decrease in performance with time due to physical aging. The initial microporous structures approach a denser state via local rearrangements, leading to a reduction of the permeability. Hence a characterization of the molecular mobility in these materials can provide valuable information about physical aging. In this work, the dielectric behavior of PIM-1 films and their behavior upon heating (aging) were revisited during different heating/cooling cycles in a broad temperature range between 133 K and 523 K. In addition, the obtained results were compared with data of samples that were annealed at ambient temperatures for different time. Multiple dielectric processes were observed like different relaxations due to local fluctuations and a Maxwell-Wagner-Sillars polarization effects due to the microporosity. The temperature dependence of the rates of all the processes follows the Arrhenius law where the estimated activation energy depends on the process. The influence of the thermal history on the processes is discussed in detail.

#### CPP 49.2 Fri 11:45 H39

Orientation approach to the light-induced surface relief gratings formation in azopolymer materials - •NINA TVERDOKHLEB, BHARTI YADAV, and MA-RINA SAPHIANNIKOVA — Leibniz-Institut für Polymerforschung Dresden e. V., PF 120411, 01005 Dresden

The phenomenon of azopolymer deformation giving rise to surface relief gratings (SRG) under the influence of polarized light was discovered two and a half decades ago. Despite the numerous different theoretical approaches to this effect, an accurate representation that would interpret all peculiarities of this phenomenon is absent. At present, the light-induced orientation of polymer backbones looks like the most promising explanation [1]. With help of this orientation approach and the finite element modeling software ANSYS, we simulate the viscoplastic formation of sinusoidal protrusions produced by the applied lightinduced stress on the thin azopolymer films. We explain the difference in SRG height for irradiation with various interference patterns. It is found that the mechanical boundary conditions have a crucial impact on the output. The results of our viscoplastic modeling are in good agreement with recent experiments [2]. [1] B. Yadav et al. J. Phys. Chem. B 122 (2019) 2001-2009. [2] B. Yadav, N. Tverdokhleb et al. Macromol. Mater. Eng. (2022) 2100990.

CPP 49.3 Fri 12:00 H39 Measuring Volume Exclusion on Single Polymer Chains Diffusing in Solution — • TOBIAS THALHEIM and FRANK CICHOS — Peter Debye Institute for Soft Matter Physics, Leipzig University, Germany

Excluded volume effects in single polymer chains occur due to long-range interactions of distant segments in the chain which cannot pass through each other entailing a strong influence of the static as well as the dynamic behavior of the polymer. Various theoretical descriptions were thus devised to incorporate these effects in the interpretation of experimental outcomes. A theory by Schäfer and Krüger incorporating this real-polymer phenomenon predicts a distribution function which describes the total segment density about an individual polymer's center of mass. This distribution function augments the picture of an ideal Gaussian chain by correction functions that account for volume exclusion and which were derived in the framework of renormalization groups. Although this permits the assessment of the role of volume exclusion for single chains in contrast to usual accesses via scaling theories or ensemble measurements, this theory has never been tested before. We report on experiments including two types of freely-diffusing double-stranded DNA molecules that utilize Schäfer's and Krüger's theory to investigate these effects. We show that for short  $\lambda$ -DNA molecules volume exclusion is of minor importance, whereas long T4-DNA molecules exhibit prominent volume exclusion. Furthermore, we employ a thermophoretic trapping method to test this theory on single compressed polymers subjected to a virtual harmonic potential.

Dynamics in polymer-fullerene blends for photovoltaic applications studied with quasielastic neutron scattering — •DOMINIK M. Schwaiger¹, Wiebke Lohstroh², and Peter Müller-Buschbaum^{1,2} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching - ²MLZ, TU München, 85748 Garching

In organic photovoltaics, donor - acceptor bulk heterojunctions are of- ten used as active layer due to their superior performance compared to e.g. planar structured devices. In this optically active polymer layer, photons are absorbed, excitons are created, subsequently dissipated at a material interface and hence free charges are provided. A promising low-bandgap electron donor material is the conjugated polymer PTB7 that is often used in combination with the fullerene derivate PCBM. Besides a large number of studies on structure and electrical prop- erties, the level of knowledge about dynamics in this system is very limited. We investigated films of PTB7, PCBM and different blends of these two, prepared out of chlorobenzene solutions. Quasielastic neutron scattering experiments were performed to determine hydro- gen dynamics on a pico- to nanosecond timescale. In addition, two well established techniques for performance enhancement in organic photovoltaics, namely the addition of DIO to the casting solution and a methanol posttreatment of the active layer, are applied and their influence on the polymer dynamics is investigated.

CPP 49.5 Fri 12:30 H39

Equilibration of free-standing films of highly entangled polymer melts -•HSIAO-PING HSU and KURT KREMER - Max-Planck-Institut für Polymerforschung, Ackermannweg 10, 55128, Mainz, Germany

Equilibrating confined and free-standing films of highly entangled polymer melts is a challenge for computer simulations. We approach this problem by first studying polymer melts based on a soft-sphere coarse-grained model confined between two walls. The distance of the walls is compatible with the simulation box of bulk melts in equilibrium, while periodic boundary conditions in the directions parallel to the walls are kept. Then we successively insert more fine grained polymer representations until the underlying microscopic details of the bead-spring model are reached. Tuning the wall potential, the monomer density of confined polymer melts in equilibrium is kept at bulk melt density even near the walls. Switching to another recently developed variant of the bead-spring model we can study melts at zero pressure [1] and study free-standing polymer films [2]. Furthermore, this also allows us to study free-standing films under strain and analyze the influence of entanglements on the local film morphology. [1] H.-P. Hsu, K. Kremer, J. Chem. Phys. 150, 091101 (2019); 150, 159902

(2019)

Liquid flow through nanoporous media: non-linear response and blocking -•ROYA EBRAHIMI VIAND¹ and FELIX HÖFLING^{1,2} — ¹Department of Mathematics and Computer Science, Freie Universität Berlin, Germany — ²Zuse Institute Berlin, Germany

Directed fluid flow is a major transport mechanism in porous media that can either be generated by pumps or emerge in response to a pressure gradient. The pressure-flow relation and how it depends on the structure and geometry of the medium is investigated by non-equilibrium molecular dynamics (NEMD) simulations of a flow of dense liquids through regular bead packings as a model for nanoporous medium. Upon decreasing the porosity, we find a significant nonlinear response. The linear permeability varies over two orders of magnitude and vanishes beyond a critical porosity. Our simulations further exhibit a substantial increase in temperature inside the porous medium, which we attribute to the local balance of energy fluxes using fluid mechanical conservation laws. Finally, we show that a recent NEMD approach based on the adaptive resolution simulation (AdResS) technique can help to decrease the required simulation volume considerably [1,2]. This simulation approach is expected to be highly applicable for research on flow in porous as well as biological media.

## CPP 50: Nanostructures, Nanostructuring and Nanosized Soft Matter

Time: Friday 12:30-13:00

CPP 50.1 Fri 12:30 H38

The effect of solvent vapor annealing on diblock copolymer templated mesoporous Si/Ge/C thin films — •CHRISTIAN L. WEINDL¹, CHRISTIAN E. FAJMAN², MICHAEL A. GIEBEL², KERSTIN S. WIENHOLD¹, SHANSHAN YIN¹, TING TIAN¹, CHRISTINA GEIGER¹, LUCAS P. KREUZER⁵, MATTHIAS SCHWARTZKOPF³, STEPHAN V. ROTH^{3,4}, THOMAS F. FÄSSLER², and PETER MÜLLER-BUSCHBAUM^{1,5} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²TU München, LS Anorganische Chemie mit Schwerpunkt Neue Materialien, Chemie-Department, 85748 Garching — ³DESY, 22607 Hamburg — ⁴Royal Institute of Technology KTH, 100 44 Stockholm — ⁵MLZ, TU München, 85748 Garching

The latest research has revealed promising results for silicon (Si) and germanium (Ge) as anode materials for lithium-ion batteries. These two group 14 semiconductors are considered auspicious additives in graphite anodes due to their high specific capacity (Si) and electron mobility (Ge). This study aims to synthesize a mesoporous Si/Ge/C structure by using a wet chemical sol-gel approach with the structure-directing amphiphilic diblock copolymer PS-b-PEO and the Zintl cluster  $K_{12}Si_xGe_{17-x}$ . Furthermore, we investigate the structural changes on the spin-coated thin films upon exposure to a saturated toluene/butanol atmosphere. For morphological analysis, scanning electron microscopy will be combined with grazing-incidence small-angle x-ray scattering (GISAXS). Moreover, energy-dispersive X-ray spectroscopy, Raman spectroscopy and powder X-ray diffraction are used for further elemental and crystalline phase analysis.

Location: H38

CPP 50.2 Fri 12:45 H38

**The kinetics and free-energy landscape of grain-boundary motion incylinder-forming copolymers** — •NIKLAS BLAGOJEVIC and MARCUS MÜLLER — Universität Göttingen, Institut für Theoretische Physik

Block copolymers which self-assemble into a dense array of hexagonally-packed cylinders are promising canditates for filtering membranes with pore sizes in the nanometer range used to extract or to purify a substance. The cylinders act as selective transport channels and it is important to align the cylinders along the desired flux direction. A fundamental understanding on how to control the cylinder orientation in the processing of the membrane, however, is incomplete and successful applications have often relied on trial-and-error searches in the high-dimensional space of process parameters.

To gain fundamental understanding about orientation mechanisms of cylindrical copolymer phases, we employ large-scale computer simulations of a particle based model in a highly efficient GPU-parallel implementation with sophisticated free-energy techniques. With this, we study the kinetics of grain-boundary motion of cylindrical copolymer domains – resembling the (re-)orientation mechanisms – and the Minimum Free-Energy Path of the associated changes of the domain topology. The simulation study has provided direct insights into the kinetics and the free-energy landscapes of orientation mechanisms and ordering in the early and late stages.

## CPP 51: Overview Talk Claus M. Schneider (joint session O/CPP)

Time: Friday 13:15-14:00

See O 84 for details of this session.

## Thin Films Division Fachverband Dünne Schichten (DS)

Patrick Vogt Institut für Festkörperphysik Technische Universität Berlin Hardenbergstr. 36 10623 Berlin patrick.vogt@physik.tu-berlin.de

## **Overview of Invited Talks and Sessions**

(Lecture halls H14 and H17; Poster P3)

## **Invited Talks**

DS 2.1	Mon	9:30-10:00	H17	GaN-based power converters enabling talktive power — •MARCO LISERRE
DS 2.2	Mon	10:00-10:30	H17	Energy-efficient power electronics based on Gallium Nitride — •OLIVER AMBACHER
DS 2.4	Mon	10:45-11:15	H17	Potential of Aluminum Nitride for Vertical Power Electronics — • ANDREAS WAAG, KLAAS
				Strempel, Lukas Peters, Christoph Margenfeld, Samuel Faber, Friedhard Römer, Bernd Witzigmann
DS 6.1	Mon	15:00-15:30	H17	Novel high power device structures: Enabling compact and integrated power ICs —
				•Elison Matioli
DS 6.2	Mon	15:30-16:00	H17	Ab-initio investigations of V-pits and nanopipes in GaN — •LIVERIOS LYMPERAKIS, SU-
				Hyun Yoo, Jörg Neugebauer
DS 6.4	Mon	16:15-16:45	H17	Lateral and Vertical $\beta$ -Ga ₂ O ₃ Power Transistors for High-Voltage Applications –
				•Kornelius Tetzner, Michael Klupsch, Karina Ickert, Ralph-Stephan Unger, Zbig-
				niew Galazka, Ta-Shun Chou, Saud Bin Anooz, Andreas Popp, Joachim Würfl,
				Oliver Hilt
DS 14.1	Wed	9:30-10:00	H17	Facet dependence of reconstructions at quantum material interfaces — •EVA BENCKISER
DS 14.3	Wed	10:15-10:45	H17	Designing novel electronic phases at oxide interfaces from first principles — •ROSSITZA
				Pentcheva

## Invited Talks of the joint Symposium Frontiers of Orbital Physics: Statics, Dynamics, and Transport of Orbital Angular Momentum (SYOP)

See SYOP for the full program of the symposium.

SYOP 1.1	Mon	9:30-10:00	H1	Orbital degeneracy in transition metal compounds: Jahn-Teller effect, spin-orbit coupling and quantum effects — •DANIEL KHOMSKII

## DS 1: Thin Film Properties: Structure, Morphology and Composition (XRD, TEM, XPS, SIMS, RBS, AFM, ...) 1

Time: Monday 9:30-10:45

## DS 1.1 Mon 9:30 H14

**Low-energy ion channeling in nanocubes** — •SHIVA CHOUPANIAN¹, WOLFHARD MÖLLER², MARTIN SEYRING¹, and CARSTEN RONNING¹ — ¹Institute of Solid State Physics, Friedrich Schiller University Jena — ²Helmholtz-Zentrum Dresden-Rossendorf

Focused ion beam (FIB) processing with low-energy ions has become a standard technique for the manipulation of nanostructures. Many underlying ion beam effects that deviate from conventional high-energy ion irradiation of bulk systems are considered today; however, ion channeling with its consequence of significant deeper penetration depth has been only theoretically investigated in this regime. We present here an experimental approach to determine the channeling of low-energy ions in crystalline nanoparticles by measuring the sputter yield derived from SEM images taken after irradiation under various incident ion angles. Channeling maps of 30 and 20 keV Ga+ ions in Ag nanocubes have been identified and fit well with the theory. Indeed, channeling has a significant impact on the transport of energetic ions in crystals due to the large critical angle at low ion energies, thus being relevant for any FIB-application. Consequently, the obtained sputter yield clearly differs from amorphous materials; therefore, it is recommended not to rely only on, e.g., ion distribution depths predicted by standard Monte-Carlo (MC) algorithms for amorphous materials.

## DS 1.2 Mon 9:45 H14

Tuning the properties of thin films via disorder  $- \cdot$  ALESSANDRO TROGLIA¹, Jorik van de Groep², Anne de Visser², and Roland Bliem^{1,2} - ¹Advanced Research Center for Nanolithography (ARCNL), Science Park 106, 1098 XG Amsterdam, The Netherlands (NL) - ²Van der Waals-Zeeman Institute, University of Amsterdam, Science Park 904, 1098 XH Amsterdam, The Netherlands (NL) Structural disorder in thin films is often considered detrimental compared to the well-defined nature of epitaxial layers. However, some examples of amorphous thin films show superior properties such as better corrosion resistance, mechanical strength and catalytic performance. Here we investigate amorphous and crystalline CuZr thin films of identical composition. Grazing-incidence x-ray diffraction (GI-XRD) demonstrate that amorphous and crystalline CuZr thin films were achieved by varying the substrate temperature during deposition with pulsed laser deposition (PLD). The effect of disorder is clearly visible in the optical, transport and corrosion properties. The amorphous films are optically transparent in the visible, while polycrystalline films are dark and reflective. The temperature-dependent electronic transport changes its mode from a bad metal to a charge-hopping conductor with an increase in structural disorder. Moreover, we observe a higher oxidation resistance of amorphous CuZr thin films due to the absence of grain boundaries. These results pave the way to the synthesis of metallic thin films with superior and tunable properties via disorder for customizing materials properties to their technological applications.

#### DS 1.3 Mon 10:00 H14

**Faster and lower dose X-ray reflectivity measurements enabled by physicsinformed modelling and artificial intelligence co-refinement** — •DAVID MARECER¹, JULIAN OBERREITER¹, ANDREW NELSON², and STEFAN KOWARIK¹ — ¹Physikalische und Theoretische Chemie, Universität Graz, Graz, 8010, Austria — ²ANSTO, Locked Bag 2001, Kirrawee DC, NSW, 2232, Australia

We present an approach for analysis of real-time X-ray reflectivity (XRR) process data not just as a function of the reciprocal space vector q as is commonly done, but as a function of both q and time. We restrict the real-space structures extracted from the XRR curves to be solutions of a physics-informed growth model, and use state-of-the-art convolutional neural networks (CNNs) and differential evolution fitting to co-refine multiple time-dependent XRR curves R(q,t) of a Location: H14

thin film growth experiment. Thereby it becomes possible to correctly analyze XRR data with a fidelity corresponding to standard fits of individual XRR curves even if they are sparsely sampled with a 7-fold reduction of XRR datapoints, or if the data is noisy due to a 200-fold reduction in counting times. Our approach of using a CNN analysis and of including prior information through a kinetic model is not limited to growth studies, but can be easily extended to other kinetic X-ray or neutron reflectivity data to enable faster measurements with lower beam damage.

## DS 1.4 Mon 10:15 H14

Scattergram analysis and filtering of differential phase contrast STEM images — •JULIUS BÜRGER^{1,2}, MAJA GROLL^{1,2}, THOMAS RIEDL^{1,2}, and JÖRG K. N. LINDNER^{1,2} — ¹Nanostructuring, Nanoanalysis and Photonic Materials Group, Dept. of Physics, Paderborn University, Paderborn, Germany — ²Center for Optoelectronics and Photonics Paderborn (CeOPP), Paderborn, Germany

Differential phase contrast (DPC) in scanning transmission electron microscopy allows the imaging and quantification of electric fields in solid specimen by measuring the transferred (first) momentum perpendicular to the optical axis imposed on the beam by the specimen's electrostatic potentials. Owing to the high-resolution capability of modern Cs-corrected transmission electron microscopes, electric fields and charge densities can be revealed with sub-atomic resolution. However, the requirements are very high, since the field distributions being measured by a position sensitive detector are drastically influenced by numerous factors, such as the lens aberrations, dynamic diffraction effects, noises, and the detector response function. We demonstrate how these influences can be readily detected in a DPC image using the so-called scattergram, which is a two-dimensional histogram of all transferred momenta, and particularly focus on the effect of noise and detector rotation by comparing DPC measurements and simulations for Si [110] performed with a segmented annular quadrant detector. In this regard, we introduce a novel method, the scattergram filtering, revealing the position of characteristic features in DPC images.

## DS 1.5 Mon 10:30 H14

**Contrast modes in transmission experiments using broad and focussed keV ion beams** — •SVENJA LOHMANN^{1,2}, GREGOR HLAWACEK¹, RADEK HOLEŇÁK², NICO KLINGNER¹, DANIEL PRIMETZHOFER², and EDUARDO SERRALTA^{1,3} — ¹Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — ²Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden — ³Technische Universität Dresden, Germany

The helium ion microscope (HIM) is an instrument for high-resolution imaging, composition analysis, and materials modification at the nanoscale. Ion transmission experiments could further improve the analytical capabilities of this technique, and multiple contrast modes are possible. We explore the latter at keV ion energies using a HIM in a scanning transmission approach as well as a broad beam in combination with a time-of-flight (ToF) set-up. Both systems employ position-sensitive detectors allowing for analysis of angular distributions.

In the ToF-system, we find a strong trajectory-dependence of the measured specific energy loss attributed to charge-exchange events in close collisions [Phys. Rev. Lett. 124 (2020), 096601]. Channelling and blocking of transmitted ions allows for mapping of intensity as well as different energy loss moments [Ul-tramicroscopy 217 (2020), 113051]. In the HIM we demonstrate different contrasts, e.g., due to orientation of nanocrystals, channelling in single-crystalline membranes and material contrast for layered films [Beilstein J. Nanotechnol. 11 (2020), 1854].

## DS 2: Focus Session: Innovative GaN-based High-power Devices: Growth, Characterization, Simulation, Application 1

Organizers:

Bernd Witzigmann, University Erlangen-Nürnberg Frank Bertram, Magdeburg University

The transition to globally sustainable energy generation requires a further significant rise of sharing electrical energy. Power electronics is a key technology enabling efficient distribution, conversion, and use of these large amounts of electrical energy. Thanks to the advances in semiconductor materials with solid-state properties, power electronics research remains a focal point. The remarkable progress in wide-bandgap semiconductor materials such as Gallium Nitride (GaN) allows for power devices reaching switching speeds an order of magnitude above the state of the art, with significantly reduced ohmic and dynamic losses, and improved thermal properties. GaN-based devices and circuits therefore enable the design of highly compact power-electronic systems with highest efficiencies. Considerable energy savings are possible, e.g. with energy and vehicle technology alone, a previously unused potential of up to 35% can be exploited. This not only offers economic advantages, but also significantly reduces the  $CO_2$ equivalents associated with the applications.

Time: Monday 9:30-11:15

## **Invited Talk**

DS 2.1 Mon 9:30 H17 GaN-based power converters enabling talktive power - •MARCO LISERRE -Kiel University, Kiel, Germany

GaN power semiconductors with their extremely fast switching characteristics enable not only electrical energy conversion which is almost free from switching losses but also to bridge for the first time two fields which have been developing separately for more than 70 years: energy and information transfer. This contribution will start from the physical characteristics of GaN power semiconductors to show what they allow in power conversion and how they can lead to realize power exchange which carries also information.

DS 2.2 Mon 10:00 H17 Invited Talk Energy-efficient power electronics based on Gallium Nitride - •OLIVER AMBACHER — Sustainable Systems Engineering (INATECH), Albert-Ludwigs-Universität, Freiburg

Around 40% of the energy converted worldwide by technical systems is already provided in the form of electricity. This share is expected to increase to around 60% in 2040. These enormous amounts of energy not only have to be generated in a way that conserves resources and the environment, but also distributed and used efficiently. The power electronics required for this is an *emerging field* of electrical engineering, which makes it possible to provide electrical energy optimally adapted for a wide variety of applications. These applications include the integration of renewable energy sources into the electrical supply network, drive technology for electromobility, the power supply for data centers or the high-frequency network for mobile communications. Using the example of the development and use of particularly energy-efficient gallium nitride-based power electronic circuits, the presentation will illustrate the high potential for saving energy that further optimization of semiconductor materials and microelectronic components offers and how sustainable electronic systems can be realized from them. Based on a basic understanding of the *atomic building blocks*, functional material properties are derived and presented for the design of novel power electronic devices and components. These GaN-based components are demonstrated for high performance amplifiers and voltage converters that are characterized by particularly energy-efficient operation.

#### DS 2.3 Mon 10:30 H17

Influence of space-charge region on luminescence in a lateral GaN super**junction** — •Gordon Schmidt¹, Peter Veit¹, Frank Bertram¹, Jürgen Christen¹, Arne Debald², Michael Heuken^{2,3}, Thorsten Zweipfennig², HOLGER KALISCH², and ANDREI VESCAN² - ¹Otto-von-Guericke-University Magdeburg, Magdeburg, Germany —  2 RWTH Aachen University, Aachen, Germany — ³AIXTRON SE, Herzogenrath, Germany

The superjunction concept, based on charge compensation in the drift region by fully balanced n- and p-regions, is intended to break the tradeoff between breakdown voltage and on-resistance in GaN-based power devices.

In this study, a lateral GaN p-n⁺ superjunction was investigated by scanning transmission electron microscope cathodoluminescence microscopy. The structure was grown on top of a GaN/sapphire template. After the growth of an AlGaN marker layer, the superjunction was epitaxially deposited composed of alternating 91 nm thick p-GaN with  $5\cdot 10^{18}$  cm⁻³ Mg doping and 23 nm thick n⁺GaN with  $1 \cdot 10^{19}$  Si doping. Finally, the structure was capped by a n⁺GaN layer. To probe the space charge region of the superjunction, the luminescence evolution across the pn⁺p junctions was investigated at T = 16 K. Donor-acceptor-pair recombination (DAP) is dominating the spectrum in the n-doped layers. In the near-band-edge region, bound exciton luminescence is observed in GaN:Mg. Both, excitons bound to an acceptor as well as to a donor exhibit reduced intensity in the space-charge region indicating exciton dissociation by the built-in electric field.

Potential of Aluminum Nitride for Vertical Power Electronics — •ANDREAS Waag^{1,2}, Klaas Strempel^{1,2}, Lukas Peters^{1,2}, Christoph Margenfeld^{1,2}, SAMUEL FABER³, FRIEDHARD RÖMER³, and BERND WITZIGMANN³ — ¹Institute of Semiconductor Technology, Technische Universität Braunschweig, Hans-Sommer-Straße 66, 38106 Braunschweig, Germany $-^2 \rm Laboratory$  for Emerging Nanometrology (LENA), Technische Universität Braunschweig, Langer Kamp 6, 38106 Braunschweig, Germany – ³Institute for Optoelectronics, Friedrich-Alexander Universität Erlangen-Nürnberg, Konrad-Zuse Str. 3/5, 91052 Erlangen, Germany

Owing to its excellent material properties, AlN is considered to be highly promising for power electronics. One of the main obstacles for AlN, however, is the poor availability of single crystal substrates. A particularly promising technique is the high temperature annealing (HTA) of sputtered AlN thin films on sapphire. AlN is one of the few compound semiconductors, which is curing its crystal lattice during HTA without thermal decomposition or evaporation if processed in a face-to-face configuration.

In addition to the material aspects, we discuss the design of AlN devices, supported by TCAD simulations, combining microscopic drift-diffusion currents with electron/hole continuity equations and the Poisson equation.

Scaling and confinement in ultrathin chalcogenide films as exemplified by GeTe — •PETER KERRES — 1st Institute of Physics "new Materials", RWTH Aachen University, 52066 Aachen, Germany

Chalcogenides such as GeTe, PbTe, Sb2Te3, and Bi2Se3 are characterized by an unconventional combination of properties enabling a plethora of applications ranging from thermo-electrics to phase change materials, topological insulators and photonic switches. Chalcogenides possess pronounced optical absorption, relatively low effective masses, reasonably high electron mobilities, soft bonds, large bond polarizabilities and low thermal conductivities. These remarkable characteristics are linked to an unconventional bonding mechanism characterized by a competition between electron delocalization and electron localization. Confinement, i.e. the reduction of the sample dimension as realized in thin films should alter this competition and modify chemical bonds and the resulting properties. Here, we demonstrate for crystalline films of GeTe pronounced changes of optical and vibrational properties, while amorphous films of GeTe show no similar thickness dependence. For crystalline films, this thickness dependence persists up to remarkably large thicknesses of 40 nm. x-ray diffraction and accompanying simulations employing density functional theory relate these changes to thickness dependent structural (Peierls) distortions, due to an increased electron localization between adjacent atoms upon reducing the film thickness. We expect a thickness dependence and hence potential to modify film properties for all chalcogenide films with a similar bonding mechanism .

**RuTPP thin films: morphology, dimerization and CO adsorption** — •JAKOB HAUNS¹, JOHANNES SEIBEL¹, ARTUR BÖTTCHER¹, LUKAS GERHARD², WULF WULFHEKEL², and MANFRED KAPPES¹ — ¹Institute of Physical Chemistry, KIT, 76131 Karlsruhe, Germany — ²Institute of Nanotechnology, KIT, 76344, Eggenstein-Leopoldshafen, Germany

Thin RuTPP-2H films were grown on HOPG under UHV conditions by applying the Low Energy Cluster Beam Deposition method, LECBD [1]. We used the mass-selected (RuTPP-2H)+ beam resulting from electron impact induced ionization and fragmentation of the effusive flux of RuTPP molecules. The morphology of the films grown here were systematically studied by means of STM, UPS, XPS and desorption spectroscopy. The temperature programmed desorption (TPD) spectra, taken for sub- and multilayers enable to determine the binding energies explaining the unique stability of the films. In particular this analysis revealed the thermally activated formation of stable desorbable dimers for layers thicker than one monolayer. By combining STM and UPS we found spectral markers for the monomers and dimers deposited on HOPG. XPS/UPS based study of the CO adsorption on RuTPP-2H submonolayers revealed pronounced modifications of the valence band. These findings are supported by extensive DFT calculations which enable to identify the major CO-(RuTPP-2H) binding sites.

Low-Temperature Atomic Layer Deposition of  $Al_2O_3$  Thin Films on Spin-Coated Carbon Nanomembranes — •Jan Biedinger, Natalie Frese, Raphael Dalpke, Bernhard Kaltschmidt, Martin Wortmann, Andreas Hütten, Armin Gölzhäuser, and Günter Reiss — Bielefeld University, Germany

Carbon nanomembranes are stable, carbon-based 2D sheets that have been investigated in recent years due to their wide range of potential applications, in nanofiltration, nanoelectromechanical systems, microelectronics or energy storage [1]. Atomic layer deposition relies on alternating self-limiting gas-surface

Location: H14

ing point ( $T_M$ ). These structural changes such as hillock formation and texture evolution can be followed by solid-state dewetting (SSD) in which capillary forces finally break up the film into isolated particles. Here, we investigate the microstructural evolution of  $\mathrm{Co}_x\mathrm{Cu}_{100-x}$  thin films with x equal to 15, 38 and 75 at.%. Films were deposited on (0001) sapphire and annealed below their  $T_M$ . Subsequently, characterization has been carried out using scanning and transmission electron microscopy (SEM, TEM), and X-ray diffraction (XRD). Upon annealing, Cu-rich hillocks form in all three compositions prior to voids at which dewetting initiates. The onset temperature of the formation of these hillocks depends on the composition of the film. Moreover, a phase separation of FCC Co and FCC Cu is observed. Finally, we show an orientation relationship of Cu (FCC) and Co (FCC)-rich isolated particles with sapphire:  $Cu/Co(111)\pm[1\bar{1}0] \parallel Al_2O_3(0001)[10\bar{1}0].$ 

DS 4.3 Mon 11:30 H14

Analysis of 3D check board pattern formation in NiCoMnAl shape memory alloys with alternating austenitic and martensitic layers — •DARIO STIERL, ANDREAS BECKER, LAILA BONDZIO, TAPAS SAMANTA, INGA ENNEN, and AN-DREAS HÜTTEN — Center for Thin Films and Physics of Nanostructures, Physics Department, Bielefeld University, 33615 Bielefeld, Germany

NiMnX (X=Al,Ga,Sn,In) magnetic shape memory Heusler alloys are considered as promising materials for magnetocaloric cooling applications due to their magnetoelastic coupling near room temperature. The thermal hysteresis could be reduced in NiCoMnAl thin films with alternating active transforming austenitic layers and martensitic intercalations. The stoichiometry of these two layers is chosen in such a way that their thermal hysteresis does not overlap. In addition, a 3D check board pattern becomes visible in HRTEM cross section images if the austenite active layers and martensite intercalations possess similar thicknesses.

In this contribution we aim for an improved understanding of the 3D check board pattern formation. Therefore, we varied the number of the alternating layers in one series and changed the ratio between the thicknesses of the two different layers in a different series. Furthermore, we analyzed the samples with XRD and temperature dependent magnetization measurements.

## Location: H17

reactions, resulting in smooth, conformal and defect-free coatings with precise thickness control [2]. In the presented work, carbon nanomembranes were coated with aluminum oxide ( $Al_2O_3$ ) via a thermal atomic layer deposition process at a substrate temperature of 60°C including the reactants trimethylaluminum and water. Structural and compositional investigations of these bilayer systems by atomic force, helium ion and transmission electron microscopy as well as depth profile X-ray photoelectron spectroscopy and energy dispersive Xray analysis, respectively, reveal a homogeneous and conformal coating of the entire sample, resulting in effective surface modification. In addition, gas permeation measurements were carried out to explore potential applications of such hybrid membranes, demonstrating atomic layer deposition offers a simple way of tuning carbon nanomembranes.

**Contact Primers: A new Approach to Reducing Contact Resistance in Organic Field-Effect Transistors** — •YURII RADIEV and GREGOR WITTE — Molekulare Festkörperphysik, Philipps-Universität Marburg, Renthof 7, 35037 Marburg, Germany

Methods to reduce contact resistance have long been of interest to researchers that aim to improve performance of organic electronic devices. Caused by the injection barrier at the metal-organic semiconductor interface, contact resistance was shown to be one of the main obstacles on the way to producing high-frequency organic field-effect transistors (OFETs), limiting the switching frequency of such transistors to well below gigahertz range [1]. In this work we report on the contact primer method [2] – a method that allows selective modification of the work function of the electrodes in a bottom gate-bottom contact OFET structure. The modified work function reduces the charge carrier injection barrier and improves the morphology of the subsequently deposited thin film on top. We demonstrate this effect for both p- and n-type OFETs by employing various organic contact primer materials to increase and reduce the work function of gold electrodes, respectively. Combining this device-oriented approximate the set of the subsequent of the subsequent of the work function of gold electrodes, respectively.

DS 4.1 Mon 11:00 H14

proach with a rigorous investigation of the employed material systems on model substrates, we are able to achieve deeper understanding of the phenomena that lead to a reduced contact resistance [3].

DS 5.4 Mon 12:15 H17

Patterned Growth of Organic Semiconductor Films by Electron Irradiation Induced F-Centers on Alkali Halide Substrates — •DARIUS GÜNDER¹, Valentin Diez-Cabanes², Andrea Huttner¹, Tobias Breuer¹, Vincent Lemaur², Jerome Cornil², and Gregor Witte¹ — ¹Molekulare Festkörperphysik, Philipps-Universität Marburg — ²Laboratory for Chemistry of Novel Materials, University of Mons

In this study, a new approach is introduced to control structural properties of organic films. Combining AFM, SEM and XRD we demonstrate that electron irradiation induced F-centers (halide vacancies) on KCl(100) surfaces strongly influence the molecular orientation and epitaxial alignment of dinaphtothienothiophene (DNTT) thin films. Due to electrostatic interactions between F-centers and interfacial DNTT molecules, as validated by DFT calculations, DNTT molecules adopt a recumbent molecular orientation and form elongated fibers instead of hexagonally shaped island with upright molecular orientation present on pristine KCl. Interestingly, both morphologies exhibit epitaxial alignments that are understood by higher-order commensurabilities. By inducing F-centers only at defined surface regions, this F-center controlled growth is utilized to achieve laterally patterned DNTT films that are even transferable to other substrates by a wet transfer process.

DS 5.5 Mon 12:30 H17 The Role of Molecular Packing in Strongly Coupled Metal-Organic Hybrid Structures — •MAXIMILIAN RÖDEL¹, POLINA LISINETSKAYA², MAXIMIL-IAN RUDLOFF¹, THOMAS STARK³, JOCHEN MANARA³, ROLAND MITRIC², and JENS PFLAUM^{1,3} – ¹Experimental Physics VI, University of Würzburg, 97074 Würzburg —  2 Institut für Physikalische und Theoretische Chemie, University of Würzburg, 97074 Würzburg — ³ZAE Bayern, 97074 Würzburg

The coupling between excited states in fluorinated zinc-phthalocyanine thin films ( $F_n$ ZnPc, with n = 0,4,8,16) and surface plasmons in gold layers underneath enables unique insights in the resulting exciton-plasmon polariton coupling phenoma and their energetics. In particular, the increase of the molecular van der Waals radii by the degree of fluorination offers an additional degree of freedom to analyze the role of molecular orientation and aggregation on the resulting dispersion curves. As such, we were able to identify up to four anticrossings in the layered Au/F_nZnPc samples which can be attributed to: 1) a coexisting F₁₆ZnPc  $\beta$ -polymorph, 2) monomers, preferentially located at the metal interface, and 3) aggregated  $\alpha$ -phase regions located within the F_nZnPc films. While energy and splitting of the monomer-related anticrossing are determined by the average tilting and the close proximity to the metal surface, the coupling associated with the aggregate can be consistently described by a change in F_nZnPc dipole density. Supported by structural data and TDDFT calculations in combinations with a Jaynes-Cummings model, Au/F_nZnPc bilayers proof to be a versatile platform to study the primary light-matter interactions.

#### DS 5.6 Mon 12:45 H17

Strong Quenching of Dye Fluorescence in Perylene Orange/TMDC Hybrid Structures — •TIM VÖLZER, ALINA SCHUBERT, ERIK VON DER OELSNITZ, INGO BARKE, SYLVIA SPELLER, TOBIAS KORN, and STEFAN LOCHBRUNNER — Institut für Physik, Universität Rostock, Albert-Einstein-Str. 23, 18059 Rostock

While monolayer transition metal dichalcogenides (1L-TMDCs) have emerged as 2D semiconductors with multiple applications in optoelectronics, their combination with dye molecules to form promising hybrid structures, since they should allow charge transfer after optical excitation as required for photodetectors or solar cells. Here, we discuss the preparation of such systems, i.e. the deposition of perylene orange (PO) onto substrates by means of spin coating, stamping, and thermal vapor deposition (TVD) and compare these methods regarding the quality of the dye layer and practicability of the process. For TVDfabricated 1L-TMDC/PO hybrid structures, we observe a drastic quenching of the dye fluorescence in terms of both intensity and lifetime reduction for all used TMDCs compared to hBN/PO references. This quenching is attributed to electron or hole transfer depending on the energy levels of the molecule and the specific TMDC, respectively.

Organizers:

Bernd Witzigmann, University Erlangen-Nürnberg Frank Bertram, Magdeburg University

Synopsis (see part I)

Time: Monday 15:00-16:45

## Invited Talk

DS 6.1 Mon 15:00 H17 Novel high power device structures: Enabling compact and integrated power ICs — •ELISON MATIOLI — EPFL, Lausanne, Switzerland

This talk will discuss new technologies to drastically reduce the sheet resistance in these semiconductors. Combined with a judicious design of the electric field distribution, based on nanostructures, this approach enables to concurrently reduce the on-resistance and increase the breakdown voltage of power devices, leading to figures of merit far beyond the state-of-the-art. To manage the large heat fluxes in power devices, I will present new technologies based on integrated microfluidic cooling inside the device. By co-designing microfluidics and electronics within the same semiconductor substrate, a monolithically integrated manifold microchannel cooling structure was produced with efficiency beyond what is currently available. Our results show that heat fluxes exceeding 1.7 kW/cm2 could be extracted using only 0.57 W/cm2 of pumping power. The proposed cooling technology should enable further miniaturization of electronics, and greatly reduce the energy consumption in cooling of electronics. Furthermore, by removing the need for large external heat sinks, this approach enables the realization of very compact power converters integrated on a single chip.

Invited Talk DS 6.2 Mon 15:30 H17 Ab-initio investigations of V-pits and nanopipes in GaN - •LIVERIOS LYMPERAKIS^{1,2}, SU-HYUN YOO², and JÖRG NEUGEBAUER² – ¹Department of Physics, University of Crete, Heraklion, Greece —²Computational Materials Design Department, Max-Planck-Institut für Eisenforschung GmbH, Düsseldorf, Germany

Dislocations in nitrides constitute a long-standing and controversial topic. Nevertheless, screw dislocations in GaN have recently attracted considerable inter-

## Location: H17

est due to their potential effect on power electronic devices' performance. An intriguing feature of these dislocations is that they trigger the formation of Vpits and nanopipes in GaN. However, a full understanding of their origin, size, and shape is still lacking. The nucleation and properties of these defects are governed by the complex interplay between dislocation's strain and core energies, surface energies, and oversaturation. In the present work, we combine density functional theory calculations with elasticity theory and we shed light on the aforementioned interplay. Based on these calculations we derive phase diagrams that describe the equilibrium size and shape of V-pits and nanopipes as a function of the ambient growth conditions, i.e., the Ga and H chemical potentials as well as the oversaturation. Our calculations indicate that under H-rich conditions, V-pits and nanopipes can spontaneously form due to the preferential decoration of the bounding surfaces by hydrogen. Based on these results we will further discuss their electronic properties as well as their potential to preferentially accommodate impurities/dopants.

#### DS 6.3 Mon 16:00 H17

Metal micro-contacts deposited by focused electron and ion beam: impact on electrical properties - •KONSTANTIN WEIN, GORDON SCHMIDT, FRANK BERTRAM, SILKE PETZOLD, PETER VEIT, CHRISTOPH BERGER, AN-DRÉ STRITTMATTER, and JÜRGEN CHRISTEN - Otto-von-Guericke-University Magdeburg, Magdeburg, Germany

In this study, we want to concentrate on the local deposition of platinum and tungsten as metal micro-contacts by electron- as well as ion-beam in a focused ion beam microscope (FIB). We are using a Thermo Fisher Scientific Scios 2 HighVac dual-beam with liquid gallium ion source. Either the focused electron beam or the ion beam are used to crack the precursor molecule bonds and induce the complex metal deposition process.

For the investigation of the electrical properties Pt/W stripes were deposited between macroscopic lithographic Au pads on top of insulating SiO₂/Si template. Parameters like Ga- and e-beam current, acceleration voltage, dwell time and pixel overlap were systematically investigated and optimized with regard to best electrical properties. The trade-off between efficient incorporation of conductive material and sputtering has to be determined. We observe almost insulating properties for layers deposited by electron beam radiation. On the other hand, the ion beam induced deposition layers behave ohmic and exhibit electrical conductivity up to  $4.6 \frac{10^5}{\Omega * m}$  for tungsten.

## DS 9: Thin Film Properties: Structure, Morphology and Composition (XRD, TEM, XPS, SIMS, RBS, AFM, ...) 3

Time: Tuesday 9:30-11:00

DS 9.1 Tue 9:30 H14

Structural properties of iron dichalcogenide thin films deposited by selenization process — •LUQMAN MUSTAFA¹, ANDREAS KREYSSIG¹, JILL FORTMANN², AURELIJA MOCKUTE², ALFRED LUDWIG², and ANNA E. BÖHMER¹ — ¹Institute for Experimental Physics IV, Ruhr-Universität Bochum, Germany — ²Materials Discovery and Interfaces, Institute for Materials, Ruhr University Bochum, Germany

Transition-metal dichalcogenides with marcasite structure have been extensively studied for their applications in light energy conversion and photoelectrochemical devices. Lately this structure type has also gained interest for its magnetic properties as a candidate for the newly-predicted altermagnetic order.

We report on the formation of  $(Fe,X)Se_2$ , (X=Co, Mn, Cr...) thin films by exsitu selenization of amorphous transition metal thin films. Using combinatorial deposition allowed to efficiently explore a wide range of substitution at the iron site with different transition metals (for example Co, Mn, Cr). The dependence of structural properties and phase stability on the selenization temperature and substitution level has been investigated. The process may be adapted for other transition metal dichalcogenides thin films, such as FeSb₂, and is therefore a unique tool to study a broad material family and its possible substitution ranges.

DS 9.2 Tue 9:45 H14 **Structural and elastic properties of Sc**_x**Al**_{1-x}**N** — •SASKIA MIHALIC¹, ARMIN DADGAR², NICLAS M. FEIL¹, CHRISTOPHER LÜTTICH², ANDRÉ STRITTMATTER², and OLIVER AMBACHER¹ — ¹Department of Sustainable Systems Engineering, University of Freiburg, Germany — ²Department of Semiconductor Epitaxy, Otto von Guericke University Magdeburg, Germany

The hexagonal compound alloy scandium aluminum nitride  $(Sc_xAl_{1-x}N)$  shows an enhancement of the piezoelectric module  $d_{33}(x)$  by more than 300 % compared to aluminum nitride (AlN). Therefore,  $Sc_xAl_{1-x}N$  is a highly promising material for the implementation of acoustic resonators for mobile communication systems, although usually a larger stiffness of the material is required. The direction-dependent elastic behavior of hexagonal  $Sc_xAl_{1-x}N$  crystals is represented by the reciprocal Young's modulus  $S^*_{11}(x)$  and aids in identifying the best trade-off between piezoelectric and elastic properties of anisotropic  $Sc_xAl_{1-x}N$ for microacoustic applications. To confirm the calculations with experimental results, thin films of  $Sc_xAl_{1-x}N(0001)$  and ScN(111) on Si-substrates were grown by reactive magnetron sputter epitaxy. The structural properties of thin films have been investigated by high-resolution X-Ray diffractometry (HRXRD) and high-resolution transmission electron microscopy (HRTEM). Furthermore, we will present a detailed comparison of theoretical and experimental results of Location: H36

Location: H38

the piezoelectric and stiffness coefficients achieved by the analysis of Sc_xAl_{1-x}N-based SAW resonators.

Kirchhoff-Straße 4, 12489 Berlin, Germany — ²Leibniz-Institut für Kristallzüch-

Beta gallium oxide ( $\beta$ -Ga₂O₃) with its ultra-wide bandgap of 4.8 eV has emerged

as a promising semiconducting material for the fabrication of next-generation

power electronic devices. The estimated dielectric strength of 8 MV/cm in com-

bination with the expected Baliga's figure of merit are promising indicators to

pave the way for the realization of power devices with even higher breakdown

voltages and efficiencies than their SiC and GaN counterparts. This presentation

will give an overview on the current status of lateral and vertical  $\beta$ -Ga₂O₃ power transistor devices with a special emphasis on results obtained at FBH and IKZ.

For both cases different concepts for bulk crystal growth, epitaxial layer struc-

tures and device designs suitable for reaching the targeted performance will be

discussed especially in terms of breakdown voltage and channel current density. In this regard, certain material and device related challenges are identified which need to be addressed perspectively in order to overcome current breakdown lim-

tung (IKZ), Max-Born-Straße 2, 12489 Berlin, Germany

DS 9.3 Tue 10:00 H14

Structural analysis of  $Sc_xAl_{1-x}N$  thin films — •Rebecca Petrich¹, Younes Slimi¹, Hauke Honig², Lorenz Steinacker², Katja Tonisch¹, Raphael Kuhnen³, Dietmar Frühauf³, and Stefan Krischok¹ – ¹TU Ilmenau, FG Technische Physik I, IMN MacroNano, 98693 Ilmenau $-\ ^{2}\mathrm{TU}$ Ilmenau, FG Werkstoffe der Elektrotechnik, IMN MacroNano, 98693 Ilmenau -³Endress+Hauser SE+Co. KG, TTD Technologieentwicklung, 79689 Maulburg The further and new development of functional materials is an important and constant research approach for the optimization of microelectromechanical systems. In the field of piezoelectric materials, AlN stands out due to its good piezoelectric properties and its CMOS compatibility, its very good thermal stability and high sound velocity. While the basic research for this material is considered to be largely completed, research for the scandium-based alloy Sc_xAl_{1-x}N is still in its infancy. The need for investigation is particularly high for alloys with scandium concentrations of more than x = 15%. For this purpose,  $Sc_xAl_{1-x}N$  thin films were deposited and analyzed using pulsed magnetron sputtering in a concentration range between x = 15% and 35%. Starting with the crystal orientation (X-ray diffractometry) and the layer composition (energy-dispersive X-ray spectroscopy) through to the surface roughness (atomic force microscopy), optical parameters for determining the layer thickness and dielectric function (spectroscopic UV-Vis ellipsometry) were also examined and compared to pure AlN. In addition, the homogeneity of the layer properties was examined over different radii on 4" Si wafers.

DS 9.4 Tue 10:15 H14

Phase behavior of dumbbell monolayers obtained via Langmuir-Blodgettlike Brownian dynamics simulations — •ANTON LÜDERS, ROUVEN STUCKERT, ELLEN ZANDER, ALEXANDER WITTEMANN, and PETER NIELABA — Universität Konstanz, Konstanz, Deutschland

We explore the structure formation and the phase behavior of thin films of dumbbell colloids. For this, we first determine empiric formulas for the microscopic diffusion coefficients of dumbbells using a bead-shell approach. These diffusion coefficients are used to perform two-dimensional Brownian dynamics (BD) simulations where the area fraction of the system is adjusted via movable barriers at the boundaries of the simulation box. The results of the simulations are compared to Langmuir-Blodgett experiments with dumbbell monolayers at the air/water interface. Using Voronoi diagrams and the Voronoi cell shape factor,

the influence of the area fraction on the structure of the monolayers is investigated. The simulations and the experiments show - in excellent agreement with each other - that an increase of the area fraction leads to a higher percentage of domains containing particles with six nearest neighbors. Especially in dense systems, these domains can consist of aligned particles with uniform Voronoi cells. Thus, the increase of the area fraction enhances the order of the monolayers. The remarkable qualitative agreement of the simulations and the experiments indicates a versatile way of characterizing colloidal monolayers by BD simulations which opens up perspectives for application to a broad range of nanoparticlebased thin film coatings.

## DS 9.5 Tue 10:30 H14

Thermal Laser Epitaxy of Refractory Metals — •LENA NADINE MAJER, HONG-GUANG WANG, WOLFGANG BRAUN, PETER A. VAN AKEN, JOCHEN MANNHART, and SANDER SMINK — Max Planck Institute for Solid State Research, Heisenbergstraße 1, 70569 Stuttgart, Germany

In thermal laser epitaxy, both the substrate and the individual evaporation sources are heated by high-power continuous-wave lasers. This method combines the advantages of MBE and PLD, allowing the efficient thermal evaporation and epitaxial deposition of practically any combination of elements from the periodic table. We demonstrate and discuss the epitaxial growth of refractory metals on c-cut sapphire. As examples we present Ru and Ta growth, because they are of particular interest for many technological applications. We have optimized the growth parameters to obtain epitaxial films of superior quality, which are apparently devoid of defects over large areas. The films have been characterized by AFM, RHEED, STEM, and X-ray analysis, revealing that the layers grow

single phase, with a low surface roughness and that the interface between the layer and the substrate is atomically sharp.

## DS 9.6 Tue 10:45 H14

Temperature-dependent C-AFM measurements on rhodium paddle-wheel coordination polymers — DANIEL STEINBACH, SOPHIE GERSDORF, and •FLORIAN MERTENS — Institute of Physical Chemistry, TU Bergakademie Freiberg, Germany

To overcome one of the disadvantages of most coordination polymers and metalorganic frameworks being insulators, conjugated coordination polymers are investigated regarding their electrical conductivity. To obtain a potentially conductive system paddle-wheel structures with a documented metal-metal bond, here rhodium derivates, were linked via conjugated organic molecules like pyrazine. Coordination polymers of this type were first synthesized as bulk materials, characterized using XRD, TG-DSC and XPS and then deposited as coatings on gold surfaces. Subsequently, the topography of the deposited layers was determined. The morphological properties of the coatings were correlated with the properties of the basic coordination polymer components.

The conductivity was investigated via temperature-dependent C-AFM measurements. As expected no conductivity is measurable for coordination polymers containing acetates based paddle-wheels even if they are linked with a tridentate conjugated ligand. For the  $[Rh_2(acam)_4(pyz)]_n$  (Hacam = acetamide) coordination polymer a strong temperature and field dependency of the conductivity was observed. From the corresponding measurements an arrhenius type activation energy of app. 0.3-0.4 eV was derived. In addition, various conduction mechanisms were discussed.

## DS 10: Gaede Prize Talks

Prize Talk	DS 10.1	Tue 9:40	H17					
Atomic-Scale Optical Spectroscopy at Surfaces — • TAKASHI KUMAGAI — Fritz								
Haber Institute, Berlin, German - Institute for Molecular Science, Okazaki,								
Aichi, Japan — Laureate of the Gaede-Prize 2020								

Light-matter interactions can be largely enhanced in the presence of optical near fields. Atomic-scale light-matter interactions in plasmonic "picocavities" has emerged as a new frontier of fundamental light science and technology [1]. However, the investigation of such light-matter interactions still involves significant challenges in both experiment and theory. A combination of plasmon-enhanced spectroscopy with low-temperature STM can provide a unique way to investigate intriguing physics resulting from the strong interaction between cavity-mode plasmon and matter even at atomic scales [2]. I will discuss our recent development toward atomic-scale optical spectroscopy in plasmonic STM junctions [3].

# Prize TalkDS 10.2Tue 10:20H17Slow highly charged ions as a tool for monolayer sensitive nano-engineering- •RICHARD WILHELM — TU Wien, Institute of Applied Physics, Vienna, Austria — Laureate of the Gaede-Prize 2021

Heavy ions in high charge states can be prepared with kinetic energies in the keV energy range. These slow ions interact with surface electrons upon impact of a material which leads to their neutralisation and consequently to the deposition of several ten keV of potential energy. Over the past 20 years it has been a puzzle how fast and consequently how surface sensitive this energy deposition is. With the use of freestanding two-dimensional materials we can now limit the interac-

Location: H17

tion time of the ions with a solid to the femtosecond regime. We find that most of the neutralisation of the ions takes place in a single atomic monolayer of material. In this contribution I will discuss recent advancements in the study of ion neutralisation dynamics inside of solids as well as the efficiency of potential energy driven sputtering of atoms. The latter depends on the type of material and can be confined to a single monolayer only, despite the high amount of deposited energy.

Prize TalkDS 10.3Tue 11:00H17Quantum Science with Single Atoms and Molecules on Surfaces — •PHILIPWILLKE — Karlsruhe Institute of Technology, Physikalisches Institut, Karlsruhe,<br/>Germany — Laureate of the Gaede-Prize 2022

The quantum nature of a physical system often emerges from its fundamental building blocks and demands a profound understanding to harvest its advantages for quantum devices. In this talk, I will introduce a new architecture for coherent control of spins on surfaces, by combining electron spin resonance (ESR) and scanning tunneling microscopy (STM) [1]. This technique allows to address single atoms and molecules on surfaces with unprecedented energy resolution. Thus, it can be used to sense the magnetic coupling between spin centers on the nanoscale [2]. In addition, when scanning the STM tip across the surface it permits to perform magnetic resonance imaging on the atomic scale [3]. The high energy resolution also grants access to the hyperfine interaction between the electron and nuclear spin of different atomic species [4]. Recently, we could extend this technique also to spin resonance on individual molecules [5]. Lastly, by employing pulsed ESR schemes, a coherent manipulation of the surface spin becomes possible, for instance in Rabi and Hahn echo schemes [6]. This opens up a path towards quantum information processing and quantum sensing using atomic building blocks, including atoms and molecules. [1] S. Baumann et al., Science 350 (2015) [2] T. ## DS 11: Focus Session: Quantum Properties at Functional Oxide Interfaces 1 (joint session HL/DS)

Modern oxide materials exhibit a rich variety of physical properties that lead to potential applications such as sensors and detectors, solar energy harvesting, transparent and power electronics. Understanding their quantum properties at surfaces and interfaces may play a decisive role for functionalities in high-electron-mobility transistors, quantum electronics or topological quantum computation. These typically require homo- or heteroepitaxial layers of high crystallinity and investigation methods designed to reveal the fascinating physics at (complex) oxide interfaces. This session sets a focus on growth of oxide interfaces, the experimental and theoretical investigation of their novel physical, in particular quantum properties as well as fabrication and characterization of demonstrator devices.

Organized by Martin Albrecht, Oliver Bierwagen, and Saskia F. Fischer

Time: Tuesday 9:30–12:45

See HL 14 for details of this session.

## DS 12: 2D Materials 4 (joint session HL/CPP/DS)

Time: Tuesday 9:30–12:00

See HL 15 for details of this session.

## DS 13: Thin Film Applications 2

Time: Wednesday 9:30-10:45

 $DS 13.1 \ Wed 9:30 \ H14$ Investigation of Production Techniques for Sputtered Tungsten Thin Films — •Tobias Ortmann¹, Andreas Erhart¹, Margarita Kaznacheeva¹, Angelina Kinast¹, Alexander Langenkämper¹, Luca Pattavina¹, Walter Potzel¹, Johann Riesch², Johannes Rothe¹, Nicole Schermer¹, Stefan Schönert¹, Raimund Strauss¹, Victoria Wagner¹, and Alexander Wex¹ — ¹Technische Universität München, Physik Department Lehrstuhl E15, James-Franck-Straße 1, D-85748 Garching — ²Max-Planck-Institut für Plasmaphysik, Boltzmannstraße 2, D-85748 Garching bei München

Cryogenic rare event searches like the CRESST and the NUCLEUS experiments use TES (Transition Edge Sensors) as phonon sensors to read out their target crystals. This type of sensors utilizes the superconducting phase transition of tungsten to measure the energy deposited in the absorbers. The most established method of production for these films is electron beam physical vapor deposition. For future large scale production the application of argon DC-magnetron sputtering is investigated in terms of film quality and reproducibility. The most recent results of these investigations are presented. The research was supported by the DFG through the Excellence Cluster ORIGINS and the SFB1258, and the BMBF: 05A17WO4 and 05A17VTA.

## DS 13.2 Wed 9:45 H14

**Preparation of RuVO**₂ alloy thin films and theirs uncooled infrared detection performance — •HAO LU^{1,2,3}, YUNBIN HE³, and PETER J. KLAR^{1,2} — ¹Institute of Experimental Physics I, Justus-Liebig-University, Giessen, Germany — ²Center for Materials Research (ZfM), Justus-Liebig-University, Giessen, Germany — ³School of Materials Science and Engineering, Hubei University, Wuhan 430062, China

Vanadium dioxide (VO₂) films are the most popular materials for sensing layers in uncooled IR detectors because of their high TCR of -2.0 %/K, low noise, low thermal conductivity. The monoclinic phase (M1) of VO₂ undergoes an insulator-to-metal transition at 341K which is accompanied by the crystal structure changing from tetragonal to rutile. The structural phase transition exhibits a thermal hysteresis, which reduces the sensitivity of the minimum temperature change detectable indicative for the IR intensify. So we focused on decreasing the thermal hysteresis width whilst increasing TCR, and carried out the following study: (022) oriented RuVO₂ alloy thin films were prepared on TiO₂ (110) substrates by pulsed laser deposition. It was found that the thermal hysteresis width of RuVO₂ (M1) for Ru content contents above 7% is smaller than for corresponding binary VO₂. The TCR of such RuVO₂ alloy films was -5.2%/K, and the thermal hysteresis was no longer observable from electrical properties. This work demonstrates the potential of VO₂ (M1) for the development of the IR detector.

## DS 13.3 Wed 10:00 H14

Tracking the evolution of polarization in BiFeO₃-based devices — •MARVIN MÜLLER¹, YEN-LIN HUANG², SAÜL VÉLEZ³, RAMAMOORTHY RAMESH², MANFRED FIEBIG¹, and MORGAN TRASSIN¹ — ¹Department of Materials, ETH Zurich, Switzerland — ²Department of Material Science and Engineering, University of California, Berkeley, USA — ³Department of Physics, Universidad Autónoma de Madrid, Spain

The integration of magnetoelectric multiferroics, hosting coexisting and coupled ferromagnetic and ferroelectric orders, into magnetoelectric spin-orbit logic devices holds promises for unprecedented performance and reduction of energy consumption by several orders of magnitude. While static properties such as the coercive electric field have been thoroughly studied and optimized, investigations on the evolution of the ferroic orders during electric-field switching cycles are sparse.

Here, we study the three-dimensional evolution of the net polarization in the technologically highly relevant magnetoelectric material  $La_{0.15}Bi_{0.85}FeO_3$ . Using optical second-harmonic generation microscopy, we access the polarization of the films integrated in capacitor heterostructures operando. We demonstrate that electric-field training results in a spontaneous domain ordering and a giant enhancement of the net in-plane polarization in  $La_{0.15}Bi_{0.85}FeO_3$ . Finally, we distinguish between the behavior of the in-plane and out-of-plane polarization during the electric poling. Our investigations thus give unprecedented insights into the polarization dynamics in integrated BiFeO₃-based devices.

#### DS 13.4 Wed 10:15 H14

Photoelectrochemical properties of CuBi2O4-based electrodes prepared via spin-coating for solar water splitting. — •FRANCESCO CADDEO, MARCO KRUEGER, SOPHIE MEDICUS, CARINA HEDRICH, ROBERT ZIEROLD, and DOROTA KOZIEJ — University of Hamburg, Institute of Nanostructure and Solid State Physics Luruper Chaussee 149, D-22761 Hamburg, Germany

Photoelectrochemical (PEC) water splitting is one of the most promising technologies for the conversion of solar energy into hydrogen gas, which can be stored and used on demand as a fuel with net-zero CO2 emissions. Copper bismuth oxide (CuBi2O4) is recently emerging as a promising metal-oxide to be used as a light harvesting material in the photocathode of a PEC cell and is attracting increasing attention due to its well-suited bandgap of ca. 1.8 eV, its conduction band position of -0.7 V vs RHE (Reversible Hydrogen Electrode) and its highly anodic onset potential of ca. 0.8 V vs RHE, which makes it an ideal material to be implemented in a tandem device for unassisted solar water splitting. In our labs, we have developed a spin-coating procedure that allows us to fabricate highly uniform CuBi2O4 films with pure crystalline phase and various thicknesses on top of fluorine-doped tin oxide coated glass (FTO) used as a support. During my presentation, I will talk about recent results on the synthesis, characterization and photoelectrochemical properties of CuBi2O4 based photo-electrodes protected with a uniform coating of TiO2 overlayer deposited using Atomic Layer Deposition (ALD).

#### DS 13.5 Wed 10:30 H14

**Growth and electrical properties of sputtered gallium oxide device** – •AMAN BAUNTHIYAL, MARCO SCHOWALTER, THORSTEN MEHRTENS, ANDREAS ROSE-NAUER, SEYED MAJID MAHDIAN, JON-OLAF KRISPONEIT, and JENS FALTA — Institute of Solid State Physics, University of Bremen, Germany

Due to the scalability limitations of conventional semiconductor based devices, there is a high demand for powerful memory devices. Resistive switching (RS) is a promising phenomenon especially for future resistance random access memories. In the last few years, gallium oxide has attracted the interest of researchers toward RS applications due to its very large breakdown voltage and concentration

Location: H34

Location: H36

sensitive to oxygen content. In this work, we present devices with RF sputtered gallium oxide on ultra smooth Ru/Al2O3 for non-volatile RAMs.

Sputter deposition of gallium oxide on Ru(0001)/Al₂O₃ at 400°C results in the good crystallinity with diffraction spots matching the  $\beta$ -Ga₂O₃ structure as confirmed by transmission electron diffraction (TED). For device completion, top electrodes (TE) were fabricated by depositing Al/Ag using the e-beam evaporation. X-ray photoelectron spectroscopy (XPS) confirmed a very large amount of

oxygen vacancies in gallium oxide film. A RS behaviour in Al TE devices with an ON/OFF ratio of more than 10⁴ is suggested to be related to formation/rupture of oxygen vacancies filaments. In the case of Ag TE devices, RS is assigned to electro-metallization of Ag electrode. The stable endurance cycle and long retention time of  $> 10^4$  seconds qualify these devices as a future prototype for non volatile ReRAMs.

## DS 14: Focus session: Quantum Properties at Functional Oxide Interfaces 2 (joint session DS/HL)

Time: Wednesday 9:30-11:00

Invited Talk

## DS 14.1 Wed 9:30 H17 Facet dependence of reconstructions at quantum material interfaces — • Eva

BENCKISER — Max Planck Institute for Solid State Research, Stuttgart, Germany Oxide heterostructures promise a rational design of quantum materials with specific, functional properties such as magnetism and superconductivity. Our research aims to gain a fundamental understanding of spin, orbital, charge and lattice reconstructions at complex transition-metal oxide interfaces, mainly using x-ray spectroscopy.

In my talk, I will focus on implications of the choice of the crystallographic facet of the interface by showing examples of two prototypical correlatedelectrons materials. In NdNiO3 epitaxial thin films we observe modifications of the metal-insulator transition, which we explain by the facet dependence of the bond-order instability in the system [1]. The choice of a specific interface facet, in turn, allows to manipulate the complex spin order in ultrathin NdNiO3 slabs [2]. In YVO₃ heterostructures, an artificial, layered orbital occupation pattern can be realized by the choice of the interface facet [3]. I have conducted the above-mentioned studies in collaboration with many scientists who are coauthors of the publications listed below.

[1] Y. E. Suyolcu, K. Fürsich et al., Phys. Rev. Materials 5, 045001 (2021). [2] M. Hepting et al., Nature Physics 14, 1097 (2018). [3] P. Radhakrishnan et al., Phys. Rev. B 104, L121102 (2021); Phys. Rev. B 105, 165117 (2022).

## DS 14.2 Wed 10:00 H17

A detailed interface and surface analysis of BaSnO₃ in LaInO₃/BaSnO₃ heterostructures — •Martina Zupancic¹, Wahib Aggoune², Daniel PFÜTZENREUTER¹, ZBIGNIEW GALAZKA¹, HOUARI AMARI¹, CLAUDIA DRAXL², JUTTA SCHWARZKOPF¹, and MARTIN ALBRECHT¹ — ¹Leibniz-Institut für Kristallzüchtung, Berlin, Germany — ²Institut für Physik and IRIS Adlershof, Humboldt-Universität zu Berlin, Berlin, Germany

LaInO₃/BaSnO₃ heterostructures have lately attracted a lot of interest due to the high electron mobility of ~300cm²/Vs in BaSnO₃ and the formation of a 2DEG at the interface. In LaAlO₃/SrTiO₃ system, the origin of the 2DEG is attributed to the polar discontinuity and an electronic reconstruction at the n-type LaO-TiO₂ interface. Controlling the interface termination is therefore crucial to accomplish heterostructures with desired properties. Here, we combine densityfunctional theory, atomic resolution transmission electron microscopy, energy dispersive X-ray spectroscopy, and electron energy loss spectroscopy (EELS) to study the LaInO₃/BaSnO₃ interface. Experiment and theory are in excellent agreement and show that free BaSnO3 (100) surfaces are BaO terminated, while the interface between BaSnO₃ and LaInO₃ is SnO₂ terminated. This finding indicates that during the growth of LaInO3 layer on BaSnO3 Ba atoms exchange from the subsurface to the surface. Preliminary EELS analysis of a few monolayer thick LaInO₃ grown on BaSnO₃ shows indications of Ba atoms on the LaInO₃ surface, confirming that atomic exchange in this system promotes the energetically favorable SnO2-LaO interface.

Designing novel electronic phases at oxide interfaces from first principles -•ROSSITZA PENTCHEVA — Department of Physics and Center for Nanointegration (CENIDE), University of Duisburg-Essen, Germany

Transition metal oxide interfaces exhibit a rich plethora of functional properties that are not available in the respective bulk compounds and open possibilities for electronics, spintronics and energy conversion applications. Over the past years several control parameters of novel behavior have been identified and systematically explored such as the symmetry breaking at the interface, the effect of strain, confinement and crystallographic orientation, the electrostatic doping at polar interfaces [1]. Based on the insight from density functional theory calculations including an on-site Hubbard term, I will address the formation of unanticipated charge, spin and orbital reconstructions in perovskite-derived superlattices and thin films with (001) and (111) orientation that can lead to e.g. metal-to-insulator transitions and/or topologically nontrivial states which are fascinating not only from a fundamental point of view but also potentially interesting for thermoelectric applications [2].

## DS 14.4 Wed 10:45 H17

Orbital engineering in vanadate heterostructures - •PADMA RADHAKRISHNAN¹, BENJAMIN GEISLER², KATRIN FÜRSICH¹, DANIEL PUTZKY¹, YI WANG¹, SVEN ILSE³, GEORG CHRISTIANI¹, GENNADY LOGVENOV¹, PETER Wochner¹, Peter van Aken¹, Eberhard Goering³, Rossitza Pentcheva², and Eva  ${\tt Benckiser}^1-{}^1{\tt Max}$  Planck Institute for Solid State Research, Heisenbergstrasse 1, 70569 Stuttgart, Germany — ²Department of Physics and Center for Nanointegration (CENIDE), Universität Duisburg-Essen, Lothastrasse 1, 47057 Duisburg, Germany - ³Max Planck Institute for Intelligent Systems, Heisenbergstrasse 3, 70569 Stuttgart, Germany

A promising approach for the manipulation of quantum states involves the epitaxial stabilization of certain orbital occupations, i.e. orbital engineering. Here we use resonant x-ray reflectometry to extract quantitative depth-dependent xray linear dichroism profiles of thin slabs of YVO3 embedded in a superlattice with LaAlO₃. Our data reveal an artificial, layered orbital polarization, where the average occupation of xz and yz orbitals at the interface is inverted compared to the central layers of YVO3. We attribute this effect to a combination of epitaxial strain and spatial confinement by LaAlO₃. Further, insights from ab initio calculations and scanning transmission electron microscopy indicate that the selection of a suitable spacer layer material, layer thickness of the transition metal oxide, facet of substrate, and sign of strain can together implement a desired orbital polarization pattern. Our study demonstrates the use of orbital engineering as a promising approach for the theory-guided rational design of quantum materials.

DS 16.1 Wed 11:00 H14

High Open-Circuit Voltage Cs2AgBiBr6 Carbon-Based Perovskite Solar Cells Via Green Processing of Ultrasonic Spray-Coated Carbon Electrodes from Waste Tire Sources — • FABIAN SCHMITZ and TERESA GATTI — Center for Materials Research, Justus Liebig University, Giessen, Germany

Although top-notch lead-based perovskite solar cells (PSCs) achieve power conversion efficiencies >25%, they are still hindered from commercial implementation by their low environmental stability, high toxicity and optimizable costs. The latter could be reduced by eliminating the metal back electrode as well as the hole-transport material by substituting both with a conductive carbon ma-

174

Location: H36

terial to create carbon-based PSCs (C-PSCs). Furthermore, the utilization of perovskite materials based on other metallic compounds could tackle the other two issues of stability and toxicity. A promising example that combines both high environmental stability and low toxicity is the double perovskite  $Cs_2AgBiBr_6$ .

In our work, we present the deposition of "green" carbon electrodes onto  $Cs_2AgBiBr_6$  thin films via high-throughput ultrasonic spray coating to prepare lead-free C-PSCs. For our sustainable approach, we started from a carbon material obtained from the hydrothermal recycling of waste tires and dispersed it in isopropanol. This additive-free ink worked as a precursor for the upscalable ultrasonic spray deposition method to fabricate carbon electrodes under ambient atmosphere and at a low substrate temperature. Through this procedure we obtained C-PSCs with record open-circuit voltages of >1.2 V.

#### DS 16.2 Wed 11:15 H14

Indirect band gap semiconductors for thin-film photovoltaics: Highthroughput calculation of phonon-assisted absorption — •JIBAN KANGSA-BANIK, MARK KAMPER SVENDSEN, ALIREZA TAGHIZADEH, and KRISTIAN S. THYGESEN — Technical University of Denmark, Denmark

Photovoltaics is one of the most promising ways towards meeting the everincreasing global energy demand in a sustainable and eco-friendly way. Thinfilm materials (GaAs, CdTe, InP, CIGS, MAPbI3, etc) are rapidly growing in terms of market share in recent times, showing comparable efficiencies to the current Si-based technology. Currently, these well-known thin-film materials possess some major drawbacks associated with low material abundance (In, Ga), toxicity (Cd, As, Pb), and long-term device stability (perovskites). As such, finding new materials with desirable physical attributes remains one of the key aspects in this area. Indirect bandgap semiconductors, which occupy a major portion of the semiconductor space are mostly ignored in recent material screening studies. Here, we propose a recipe to evaluate PV efficiency for indirect gap materials via calculating phonon-assisted absorption, which is high-throughput friendly. Using this recipe, we evaluate chemically stable unary and binary materials from the Open Quantum Materials Database for PV application. From our final screening, we identify well-known binary thin film materials (GaAs, CdTe, and InP) as well as a number of the emerging PV materials (PbS, SnS, Se, GeSe, etc). Additionally, we find a number of indirect gap materials with potential for thin-film PV device application.

## DS 16.3 Wed 11:30 H14

Physical unclonable function based on unsorted carbon nanotube random networks in multi-contact field-effect transistors — Jonas Schroeder¹, •JAMES W. BORCHERT¹, PATRICK SCHUSTER², PETER EDER², STEFAN HEISERER³, JOSEF BIBA³, GEORG S. DUESBERG³, ULRICH RÜHRMAIR^{2,4}, and R. THOMAS WEITZ¹ — ¹Georg-August Universität Göttingen, Göttingen, Germany — ²Ludwig-Maximilians-Universität München, München, Germany — ³Universität der Bundeswehr München, Neubiberg, Germany — ⁴University of Connecticut, Storrs CT 06269, USA

The standard practice in cryptography of using digital binary keys that are permanently stored on devices is prohibitively inefficient for some applications and open to both physical and software-based attacks. A promising alternative approach known as 'physical unclonable function' (PUF) instead uses the inherent random variation in fabrication to create physical 'keys' that produce unique randomized responses to defined challenges. Electrical PUF devices based on random networks of unsorted carbon nanotubes (CNTs) have shown promise, but so far have been limited in terms of scaling up the number of challengeresponse pairs (CRPs) that can be extracted. Here, we demonstrate how gating the CNT networks might be a useful method for expanding the number of CRPs, thus strengthening the scalability of the PUF. We show CNT networks implemented in modified field-effect transistors with up to 12 contacts. The output randomness and stability of the devices are investigated, and further routes for improvement are discussed.

#### DS 16.4 Wed 11:45 H14

**Redox-based Memristive Devices for Neuromorphic Systems** — •BENJAMIN SPETZLER, SEONGAE PARK, ANNA LINKENHEIL, TZVETAN IVANOV, and MARTIN ZIEGLER — Technical University Ilmenau, Ilmenau, Germany

Redox-based memristive devices have demonstrated promising properties for their application as synaptic elements in neuromorphic computing systems. The device characteristics are the product of a variety of complex mechanisms, and electronic and ionic processes need to be precisely tuned, which requires a deep understanding of the underlying physical mechanisms and control of the fabrication parameters. We present redox-based memristive elements and show how their properties can be tailored by systematic design variations for applications in neuromorphic computing architectures. In this context, the influence of different oxide layer systems and electrode materials on the device characteristics is analyzed to assess their properties for neuromorphic computing. The experimental findings are supported by a numerical device model, which connects the physical processes with technology parameters, and permits a deeper understanding of the origin of the current-voltage hysteresis. Furthermore, we discuss the system integration of memristive devices and present memristive device arrays.

This work was partially funded by the Carl-Zeiss Foundation via the Project MemWerk and the German Research Foundation (DFG) through the Collaborative Research Centre CRC 1461 "Neurotronics- Bio-Inspired Information Pathway".

## DS 17: 2D Materials 6 (joint session DS/CPP)

## DS 17.1 Wed 11:15 H17

Curvature-induced spin-orbit splitting in transition metal dichalcogenide nanotubes and wrinkles — MOHAMMADREZA DAQIQSHIRAZI and •THOMAS BRUMME — Theoretical Chemistry, TU Dresden

Strain engineering provides a powerful means to tune the properties of 2D materials. Homogeneous strain fields have been studied extensively, and there are standard techniques for altering properties of 2D materials even in industry. On the other hand, much less is known about how inhomogeneous strain affects the electronic properties of 2D materials. We employed DFT to understand the correlation between the atomic and the electronic structure in nanoscale wrinkles and nanotubes of the prototypical transition metal dichalcogenide WSe₂. Our research shows that the symmetry breaking in these structures lead to strong Rashba-like spin-orbit splitting of the bands at the  $\Gamma$  point and that they thus may be utilized in future tunable spintronics devices.

## DS 17.2 Wed 11:30 H17

Moiré-Bose-Hubbard model for interlayer excitons in twisted transition metal dichalcogenide heterostructures — •NICLAS GÖTTING, FREDERIK LO-HOF, and CHRISTOPHER GIES — Institute for Theoretical Physics, University of Bremen, Bremen

Introducing a twist between two superimposed TMD monolayers results in a new superlattice whose properties heavily depend on the twist angle. These so-called moiré structures of TMD materials like  $MOS_2/WS_2$  can host interlayer excitons (IXs) which perceive the varying atomic registry over the moiré unit cell as an effective moiré potential. In such structures, correlated states can emerge, in which the IXs are strongly localized to the potential minima due to exciton-exciton interactions.

We investigate the phases of these trapped moiré IXs by approximating them as bosonic particles and mapping the system onto a Bose-Hubbard model [1]. Our methods allow us to calculate the hopping and two-particle interaction terms of the Bose-Hubbard model for *n*-th nearest neighbors. To examine the strong impact of dielectrics surrounding the heterobilayer, we introduce a Keldysh potential to the calculation and thereby obtain first results of the twist-angle dependent phases of moiré IXs in twisted TMD heterobilayers.

## DS 17.3 Wed 11:45 H17

Enhanced Potassium Storage Capability of Two-Dimensional Transition-Metal Chalcogenides — •VINCENT HARTMANN and YONG LEI — Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany

Potassium-ion batteries (PIBs) have been considered a promising alternative to lithium-ion batteries due to their merits of high safety and low cost. Twodimensional transition metal chalcogenides (2D TMCs) with high theoretical specific capacities and unique layered structures have been proven to be amenable materials for PIB anodes. However, some intrinsic properties including severe stacking and unsatisfactory conductivity restrict their electrochemical performance, especially rate capability. Herein, a heterostructure of highcrystallized ultrathin MoSe2 nanosheet-coated multiwall carbon nanotubes was prepared and its electrochemical properties were investigated. In such a heterostructure, the constructive contribution of CNTs not only suppresses the restacking of MoSe2 nanosheets but also accelerates electron transport. Meanwhile, the MoSe2 nanosheets loaded on CNTs exhibit an ultrathin feature, which can expose abundant active sites for the electrochemical reaction and shorten the K+ diffusion length. Therefore, the synergistic effect between ultrathin MoSe2 and CNTs endows the resulting nanocomposite with superior structural and electrochemical properties. Additionally, the high crystallinity of the MoSe2 nanosheets further leads to the improvement of electrochemical performance.

175

## DS 17.4 Wed 12:00 H17

Single photon emission of quantum emitters in WSe2 monolayers and their temperature-dependent coherence properties — •MARTIN VON HELVERSEN¹, PAUL SCHLAUGAT¹, CHIRAG PALEKAR¹, CARLOS ANTÓN-SOLANAS², BÁRBARA ROSA¹, CHRISTIAN SCHNEIDER², and STEPHAN REITZENSTEIN¹ — ¹Institute for solid state physics, Technische Universität Berlin, 10623 Berlin, Germany — ²Institute for Physics, Carl von Ossietzky Universität Oldenburg, 26111 Oldenburg, Germany

Two-dimensional van der Waals monolayers have appeared as novel type of semiconducting materials, which provide a platform for the exploration of their highly interesting optical, electronic and structural properties. Within the transition-metal dichalcogenides, WSe2 has turned out to be the most promising platform for two-level single-photon emitters, generated either by applied strain to the monolayer-flake [1,2], or by defects in the material [2]. However, the quality of the generated photons still lacks behind other systems as for example semiconductor quantum dots. In this work, we study single emitters of a strained WSe2-monolayer showing linewidths around 100  $\mu$ eV at 4 K. In quasi-resonant pulsed optical excitation a second-order autocorrelation value down to g⁽²⁾(0)=0.037(5) is measured. We further study their temperature dependent first-order coherence properties via a scanning Michelson interferometer, which yields coherence times up to 48 ps.

#### DS 17.5 Wed 12:15 H17

 $\begin{array}{l} {\rm Spin-defect characteristics of single sulfur vacancies in monolayer MoS_2 } \\ {\rm \bullet Alexander Hötger^1, Tomer Amit^2, Julian Klein³, Katja Barthelmi¹, Thomas Pelini⁴, Alex Delhomme⁴, Sergio Rey⁵, Marek Potemski^{4,6}, Clément Faugeras⁴, Galit Cohen², Daniel Hernangómez-Pérez², Takashi Taniguchi⁷, Kenji Watanabe⁷, Christoph Kastl¹, Jonathan Finley¹, Sivan Refaely-Abramson², Alexander Holleitner¹, and Andreas Stier¹ \\ - ¹Walter Schottky Institute, Garching, Germany - ²Weizmann Institute of Science, Rehovot, Israel - ³Massachusetts Institute of Technology, Cambridge, USA - ⁴Laboratoire National des Champs Magnetiques Intenses, Grenoble, France - ⁵Technical University of Denmark, Lyngby, Denmark - ⁶University of Warsaw, Warszawa, Poland - ⁷National Institute for Materials Science, Tsukuba, Japan$ 

Single spin defects in 2D transition-metal dichalcogenides are natural spinphoton interfaces for quantum applications. Here we report high-field magnetospectroscopy from three emission lines of He-ion induced sulfur vacancies in monolayer  $MoS_2$ . The distinct valley-Zeeman splitting and the brightening of dark states necessitates spin-valley selectivity of the defect states and lifted spindegeneracy at zero field. Comparing our results to ab-initio calculations identifies the nature of the defect luminescence. Analysis of the optical degree of circular polarization reveals that the Fermi level is a parameter that enables the tunability of the emitter. These results show that defects in 2D semiconductors may be utilized for quantum technologies.

#### DS 17.6 Wed 12:30 H17

Probing excitonic population dynamics by nonlinear optical wave mixing in monolayer WSe2 — •JONAS M. BAUER, LIJUE CHEN, PHILIPP WILHELM, SEBAS-TIAN BANGE, JOHN M. LUPTON, and KAI-QIANG LIN — Department of Physics, University of Regensburg, 93053 Regensburg, Germany

Monolayer semiconductors are emerging platforms for strong nonlinear lightmatter interaction, due to their giant oscillator strength of tightly bound excitons. Recently, we reported the existence of a new excitonic species, the high-lying exciton (HX), in monolayer WSe2. The HX appears at around twice the energy of the band-edge A-exciton, forming a ladder-type excitonic three-level system. We demonstrate excitonic quantum interference in monolayers [1] and twisted bilayers [2]. Here, we apply time-resolved nonlinear spectroscopy to probe the excitonic dynamics. We find that a significant time difference between two light pulses is necessary for optimal sum-frequency generation (SFG) and four-wave mixing (FWM) if one of the pulses is in resonance with an excitonic transition. The experimental results are rationalized by numerical calculations based on a density-matrix approach and provide insights into coherent exciton dynamics on a femtosecond scale.

Characterization of 2D WSe2 by high-resolution STEM and Differential Phase Contrast STEM — •MAJA GROLL¹, JULIUS BÜRGER¹, IOANNIS CALTZIDIS², MARC SARTISON², KLAUS JÖNS², and JÖRG LINDNER¹ — ¹Nanostructuring, Nanoanalysis and Photonic Materials Group, Department of Physics, Paderborn University, Germany — ²Hybrid Quantum Photonic Devices, Department of Physics, Paderborn University, Germany

2D transition metal dichalcogenides (TMDs) are gaining attention as their optical and electronic properties differ from those of their bulk counterparts. In particular, layer thickness-dependent properties, such as the transition from an indirect to a direct band gap in monolayers, make these materials interesting for photonic and optoelectronic applications. At the same time 2D-TMDs are ideal materials for the advancement of new techniques in scanning transmission electron microscopy (STEM) like differential phase contrast (DPC)-STEM. Using a spherical aberration corrected STEM, this technique enables the quantification of atomic electric fields with sub-atomic resolution if the specimen is sufficiently thin. In order to examine the atomic electric fields of TMDs, we transferred mechanically exfoliated mono- and multilayers of tungsten diselenide (WSe2) to TEM grids. The atomic structure of WSe2 flakes and their thickness are studied using TEM, energy filtered TEM and STEM. STEM-DPC measurements are performed using an eight-fold segmented bright-field STEM detector measuring the beam deflection due to the internal fields. Results are presented for WSe2 flakes of different thickness and compared with simulations.

Simulation analysis of sneak paths effect in the memristor-based crossbar topology — •ZIANG CHEN^{1,2,3}, HAO CAI^{1,2,3}, CHRISTOPHER BENGEL⁴, FENG LIU⁵, XIANYUE ZHAO^{1,2,3}, HEIDEMARIE SCHMIDT^{1,2}, STEPHAN MENZEL⁵, and NAN DU^{1,2,3} — ¹1)*FSUJena, Jena, Germany — ²2)*IPHT, Jena, Germany — ³3)*TU Chemnitz, Chemnitz, Germany — ⁴4)*RWTH Aachen, Aachen, Germany — ⁵5)*FZJ, Juelich, Germany

The high demand for performance and energy efficiency poses challenges for computing systems. The memristor-based crossbar architecture is enthusiastically regarded as a potential competitor to traditional solutions. Nonetheless, due to the lack of a switching control per cell, the memristor-based crossbar architecture suffers from the sneak paths that limit the range of accurate operation of the crossbar array. In this talk, the memristor-based passive crossbar geometry is studied and different topological patterns-one word line pull-up (OneWLPU) and all word line pull-up (AllWLPU)-is presented. In the worst-case scenario of two crossbar topological patterns, the read margin is defined as an accurate estimation for the sneak paths effects. For suppressing the sneak paths effects, in the Cadence simulation of two crossbar topological patterns based on the mathematical memristor model, the relevance between the read margin and other functional elements in the crossbar topology, i.e. pull-up resistance, line resistance, On/Off ratio, is revealed and analyzed. This work offers a beneficial reference and feasible solutions for the future optimization of crossbar topology with the intention of diminishing sneak paths effects.

Mapping the local strain distribution of oxide membranes using polarizationdependent micro-Raman spectroscopy — •MATTHIAS T. ELM, ALEXANDER KONETSCHNY, MARCEL WEINHOLD, CHRISTIAN HEILIGER, and PETER J. KLAR — Justus-Liebig University, Gießen, Germany

Free-standing ceramic membranes are of great interest for miniaturized electrochemical devices, such as micro-solid oxide fuel cells, sensors or memory devices. Free-standing membranes exhibit residual strain, which alters the electrical conductivity and, thus, the performance of the device. Detailed knowledge of the local strain distribution in the membrane is therefore of paramount importance. Here, we show that the local strain state of the membrane can be monitored using polarization dependent micro-Raman mapping. Due to the residual strain the triply degenerate  $F_{2g}$  mode splits and the contribution of their Raman intensity to the overall Raman signal depends on the measurement geometry and the polarization of the incoming and scattered light. Varying the polarization of the incoming excitation light results in different averaging of the Raman-active modes. These results clearly demonstrate that polarization-dependent Raman measurements have the potential to yield additional insight into the local strain distribution in free-standing oxide membranes.

**Soft RIXS study of alumina-titania thin films heterostructure to reveal the nature of 2-dimensional electron system** — •DEOK-YONG CHO — Department of Physics, Jeonbuk National University, South Korea

Al2O3/TiO2 binary oxide heterostructure is a novel 2-dimensional electron system (2DES) compatible with mass production. The electronic structure of the 2DES was examined using resonant inelastic soft X-ray scattering. The TiO2 thickness-dependent evolution in the Ti L3-edge energy loss features unequivocally evidenced the presence of Ti3+ state at the interface and a substantial electron-phonon coupling effects. This suggests that the 2DES properties can be controlled via well-established TiO2 engineering so that the binary oxide heterostructure would be a promising candidate for 2DES-based device application.

This work was done in collaboration with Yu-Cheng Shao, Cheng-Tai Kuo, Xuefei Feng and Yi-De Chuang (Advanced Light Source, USA), and Tae Jun Seok, Ji Hyeon Choi and Tae Joo Park (Hanyang University, South Korea). DOI: 10.1002/adfm.202104430

DS 18.4 Wed 15:45 H14 Tuning the electrochemical properties of multifunctional CoO_x catalyst layers by plasma-enhanced atomic layer deposition — •MATTHIAS KUHL, GABRIEL GRÖTZNER, LAURA WAGNER, ALEX HENNING, IAN SHARP, and JO-HANNA EICHHORN — Walter Schottky Institute, Technical University of Munich, Munich, Germany

Artificial photosynthetic systems are often limited by the poor efficiency and material instability of photoelectrodes under harsh PEC conditions. One strategy towards stable and efficient systems is to interface the semiconductor light absorber with conformal and ultra-thin catalytic layers, which still permit interfacial charge transport and minimize losses due to parasitic light absorption. In this context, conformal, biphasic Co₃O₄/Co(OH)₂ catalyst layers were fabricated by means of plasma-enhanced atomic layer deposition (PE-ALD), which are simultaneously robust and electrochemically active. The nanocrystalline Co3O4 layer forms a durable interface to the substrate and the disordered Co(OH)₂ surface layer significantly improves the electrocatalytic oxygen evolution reaction activity. Here, we show that non-saturated oxidation reactions can be applied to tune catalytic activity, chemical stability, and physical properties of the PE-ALD layer by leveraging low plasma exposure time and low plasma power. Based on these insights, the  $CoO_x$  films are interfaced with polycrystalline semiconductor thin films to generate highly stable and efficient multilayer photoelectrode assemblies. Overall, this work highlights the use of PE-ALD as a promising approach for engineering catalyst/semiconductor interfaces to create efficient and stable photoelectrodes.

## DS 19.1 Wed 15:00 H17

Gate-Tunable Helical Currents in Commensurate Topological Insulator/Graphene Heterostructures — •JONAS KIEMLE^{1,2}, LUKAS POWALLA^{3,4}, KATHARINA POLYUDOV^{3,4}, LOVISH GULATI³, MAANWINDER SINGH^{1,2}, ALEXANDER HOLLEITNER^{1,2}, MARKO BURGHARD^{3,4}, and CHRISTOPH KASTL^{1,2} — ¹Walter Schottky Institut and Physics Department, Technical University of Munich, Garching, Germany — ²MCQST, München, Germany — ³Max-Planck-Institut für Festkörperforschung, Stuttgart, Germany — ⁴Institut de Physique, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

Van der Waals heterostructures made from graphene and three-dimensional topological insulators promise very high electron mobilities, a non-trivial spin texture and a gate-tunability of electronic properties. Here, we explore epitaxially grown interfaces between graphene and the lattice-matched topological insulator Bi₂Te₂Se. For this heterostructure, spin-orbit coupling proximity has been predicted to impart an anisotropic and electronically tunable spin texture. Polarization-resolved second-harmonic generation, Raman spectroscopy, and time-resolved magneto-optic Kerr microscopies are combined to demonstrate that the atomic interfaces align in a commensurate symmetry with characteristic interlayer vibrations. By polarization-resolved photocurrent measurements, we find a circular photogalvanic effect which is drastically enhanced at the Dirac point of the proximitized graphene. We attribute the peculiar gate-tunability to the proximity-induced interfacial spin structure.

Topological Invariant of Acoustic Phonons in 2D materials - •GUNNAR LANGE¹, ADRIEN BOUHON¹, BARTOMEU MONSERRAT^{1,2}, and ROBERT-JAN SLAGER¹ — ¹Cavendish Laboratory, University of Cambridge, UK — ²Department of Materials Science and Metallurgy, University of Cambridge, UK 2D materials that live in a 3D space display an unusual acoustic phonon mode: the flexural mode. This mode disperses quadratically away from the center of the acoustic Brillouin zone, and corresponds to a flexing of the material out-ofplane. This differs markedly from the linear dispersion displayed by the in-plane modes, and leads to an unusual triple degeneracy at the zone center. This triple degeneracy is enforced by the Nambu-Goldstone theorem, rather than symmetry, as will be discussed. Such band degeneracies frequently have associated topological invariants. For this triple degeneracy, the topological invariant turns out to generically be of quaternionic type (Euler topology), but reduces to a  $\mathbb{Z}_2$ invariant under fairly general assumptions. The invariant has important implications for 2D materials grown on a substrate, as it dictates how the bands are split due to the presence of the substrate. This will be discussed in the context of graphene, where the  $\mathbb{Z}_2$  invariant turns out to be non-trivial.

This talk is based on: Lange, G. F., Bouhon, A., Monserrat, B., and Slager, R.-J., "Topological continuum charges of acoustic phonons in two dimensions and the Nambu-Goldstone theorem" Phys. Rev. B **105**, 064301 (2022)

**Coupled Bilayer Graphene Quantum Dots** — •ANGELIKA KNOTHE^{1,2} and VLADIMIR FAL'KO^{2,3} — ¹Institute of Physics, Technische Universität Chemnitz, D-09107 Chemnitz, Germany — ²National Graphene Institute, University of Manchester, Manchester, UK — ³Henry Royce Institute for Advanced Materials, University of Manchester, Manchester, UK

Bilayer graphene quantum dots are promising for spin and valley qubits [1,2,3]. A functional quantum information architecture requires scalable multi-qubit systems. We theoretically study electrostatically confined double-dots and few-dot arrays in bilayer graphene. We quantify the inter-dot couplings for different dot parameters such as the field-induced gap, the confinement shape, and the inter-dot distance. This dependence on external parameters allows tuning the dot arrays into different regimes for which we study the extended Hubbard Hamiltonians and identify the spin and valley level structure. Our results will help to advance the use of bilayer graphene quantum dots for quantum technologies.

DS 19.4 Wed 15:45 H17

**Electron cavity optics in bilayer graphene** — LUKAS SEEMANN¹, •ANGELIKA KNOTHE¹, KLAUS RICHTER², and MARTINA HENTSCHEL¹ — ¹Institute of Physics, Technische Universität Chemnitz, D-09107 Chemnitz, Germany — ²Institut für Theoretische Physik, Universität Regensburg, 93040 Regensburg, Germany

Rapid developments in the field of 2D materials and their nanostructures make it possible to trap charge carriers with different dispersions in various confinement geometries with a high degree of control. This progress now allows studying 2D electron optics phenomena enriched by the charge carriers' different electronic and topological properties compared to the photonic case. Here, we theoretically investigate cavities in gapped bilayer graphene employing an approach based on ray-wave correspondence [1]. We identify the influence of the materials' trigonally warped band structure [2] on the fermion optics characteristics that we show to be conveniently tuneable by gate voltages. Similar considerations can be applied to electron optics in other 2D materials.

#### DS 20.1 Wed 16:00 P3

Thickness effect on ferroelectric domain formation in compressively strained K0.65Na0.35NbO3 epitaxial films — •YANKUN WANG^{1,2}, SAUD BIN ANOOZ¹, GANG NIU², MARTIN SCHMIDBAUER¹, LINGYAN WANG², WEI REN², and JUTTA SCHWARZKOPF¹ — ¹Leibniz-Institut für Kristallzüchtung, Max-Born-Str. 2, 12489 Berlin, Germany — ²Electronic Materials Research Laboratory, Xi'an Jiaotong University, Xi'an, China

Ferroelectrics are of increasing interest for a broad range of applications such as nonvolatile memory devices, transducers and MEMS sensors. Herein, the influence of thickness in epitaxial K0.65Na0.35NbO3 ferroelectric thin films grown on (110) TbScO3 substrate is systematically studied. By combining piezoresponse force microscopy and high-resolution x-ray diffraction, the occurrence of 90° stripe domains was demonstrated for the films with a thickness above 11 nm, while the domain periodicity is in good agreement with Kittel*s law. Furthermore, up to a thickness of 93 nm, elastic strain relaxation induced by the formation of ferroelectric domains is observed, whereas plastic strain relaxation plays only a minor role. With increasing film thickness three successive phases of ferroelectric domains were observed: i) Irregularly arranged orthorhombic c domains in the thinnest film, ii) periodically arranged 90° monoclinic MC domains up to a thickness of 25 nm and iii) flux closure vortex-like structure in thicker films to achieve the lowest equilibrium energy. These results demonstrate the importance of understanding the lattice relaxation mechanisms for intentional tuning of ferroelectric thin film properties.

#### DS 20.2 Wed 16:00 P3

X-ray characterization of an above-RT bi-stable sublimable molecular spincrossover Fe(II)-complex — •YAHYA SHUBBAK¹, MIGUEL GAVARA EDO², ARNO EHRESMANN¹, and EUGENIO CORONADO MIRALLES² — ¹Institute of Physics & Center for Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, D-34132 Kassel — ²Institute of Molecular Science (ICMol), University of València, S-46980 Paterna

Spin crossover (SCO) molecules are a promising type of material that can undergo reversible switching between low-spin (LS)- and high-spin (HS)states upon external stimuli (heat, light, pressure, etc.)[1], making them useful for information technology, data storage and optoelectronics[2]. However, most SCO molecules need to be cooled significantly for this transition to be observable. We have investigated the hitherto unknown electronic structure of the complex molecule bis[hydrotris(1,2,4-triazol-1-yl)borate]iron(II) ([Fe(HB(tz)3)2])[3] capable of above-RT transition by XPS and XAS measurements, since the distinct electronic structure in both spin-states unmistakably prove the transition between them.

#### DS 20.3 Wed 16:00 P3

Insights into the evaporation behaviour of FAI: material degradation and consequences for perovskite solar cells — MARTIN KROLL¹, SEREN DILARA ÖZ³, ZONGBAO ZHANG¹, RAN JI¹, •TIM SCHRAMM^{1,2}, TOBIAS ANTRACK¹, YANA VAYNZOF^{1,2}, SELINA OLTHOF³, and KARL LEO¹ — ¹Dresden Integrated Center for Applied Physics and Photonic Materials, IAPP — ²Center for Advancing Electronics Dresden, CFAED — ³Department of Chemistry, University of Cologne

Thermal co-evaporation is a promising method for large-scale uniform perovskite deposition. In this work, we look at the decomposition of formamidinium iodide (FAI) upon evaporation in high vacuum by tracking the composition of the residual gas with a mass spectrometer. We find that the precursor material degrades during the evaporation process into hydrogen cyanide (HCN) and sym-triazine (C3H3N3), leading to an increase in pressure, which is commonly observed during the deposition of FAI. Using optical characterization as well as x-ray photoelectron spectroscopy on co-deposited perovskite films, we demonstrate that this background pressure strongly affects the resulting film*s stoichiometry. Using two different vacuum setups, we are able to show that significant changes are imposed, e.g. on the optimized co-evaporation rates, by the specific vacuum chamber setup. Our results have important implications for the optimized evaporation of FA-based perovskites as they identify key issues related to the deposition of the FAI precursor. Location: P3

DS 20.4 Wed 16:00 P3

In situ surface X-ray diffraction studies at high temperatures of Co oxide model catalysts for electrochemical water splitting — •CARL HENDRIC SCHARF¹, CANRONG QIU¹, JOCHIM STETTNER¹, OLVIDO IRRAZÁBAL-MOREDA², MATHILDE BOUVIER³, FOUAD MAROUN³, and OLAF MAGNUSSEN¹ — ¹Institute of Experimental and Applied Physics, Kiel, Germany — ²European Synchrotron Radiation Facility (ESRF), Grenoble, France — ³Physique de la Matière Condensée, Ecole Polytechnique, Palaiseau, France

The development of low-cost electrocatalysts for electrochemical water splitting is of great interest for hydrogen technology. Among the best precious-metal-free electrode materials for the anodic oxygen evolution reaction (OER) in alkaline electrolysis are Co oxides such as  $Co_3O_4$  and CoOOH. It was shown previously that a sub-nm thick  $CoO_x(OH)_y$  skin layer is formed in the pre-OER potential range, which forms the active phase during OER. Furthermore, reversible and irreversible structural changes in the oxide bulk were detected in the pre-OER regime. So far the vast majority of publications on Co oxide OER electrolysis have been performed at room temperature. We present first results up to 60° C (typ. operating temperatures of commercial electrolysers). Using operando surface X-ray diffraction  $Co_3O_4$  and CoOOH epitaxial films electrodeposited on Au(111) were studied in 0.1M NaOH at Petra III, Desy. These data are correlated with the electrochemical properties, determined by Cyclic Voltammetry and Optical Reflectivity, in order to provide insights into the temperature-dependence of skin layer thickness, bulk lattice changes and the stability of the oxides.

#### DS 20.5 Wed 16:00 P3

Growth of CoO Thin Films for Application in Superconductor - Magnet Heterostructures — • AMY MCGLINCHEY — Trinity College Dublin, Ireland

Cobalt monoxide, CoO, is an antiferromagnet (AF) with a Néel temperature of 293K. It is utilised to pin the magnetisation of Co layers via exchange bias and is employed in magnetic heterostructures. The interaction between ferromagnet (F) and AF layers is predicted to generate long-range spin-triplet superconductivity in F-S-AF heterostructures [1]. CoO is a good candidate for the AF due to its strong magnetism, stability and low Neel temperature, which facilitates in-field cooling through the transition, improving magnetic uniformity. For the most part, CoO is synthesized by the oxidation of Co thin films. A fundamental understanding of how the Co phase (fcc or hcp) and oxidation environment influence the crystalline quality and surface morphology of the resultant CoO is lacking. In this work, we investigate the crystalline quality of the CoO as a function of Co phase and oxidation environment. As a second step towards a F-S-AF heterostructure, we also investigate the superconducting properties of superconducting Nb grown on the different CoO films. The properties of the niobium especially at low thickness relevant to heterostructures - will, in theory, be influenced by the CoO magnetic and surface structure. 1. L. G. Johnsen et al., Phys. Rev. B, 103, L060505 (2021).

#### DS 20.6 Wed 16:00 P3

Pseudo-2-dimensional Ga₂O₃ structures grown on Al₂O₃ using metaloxide catalyzed epitaxy (MOCATAXY) — •JUSTIN ANDREAS BICH¹, MARCO SCHOWALTER¹, TJARK LIESTMANN¹, SUSHMA RAGHUVANSY¹, JONATHAN MCCANDLESS², MANUEL ALONSO-ORTS¹, ANDREAS ROSENAUER¹, MARTIN EICKHOFF¹, and PATRICK VOGT¹ — ¹Institute of Solid-State Physics, Bremen University, Otto-Hahn-Allee 1, 28359 Bremen, Germany — ²School of Electrical and Computer Engineering, Cornell University, Ithaca, New York 14853, USA Ga₂O₃ has attracted attention as a new wide-bandgap semiconductor—which can be alloyed with Al₂O₃—for high-power applications. However, the growth of group-III sesquioxides by molecular-beam epitaxy differs substantially from other material systems, e.g., III-V materials.

In this work, we present the growth of ultra-thin  $\alpha$ -Ga₂O₃ (0001) on  $\alpha$ -Al₂O₃ (0001) in a controlled self-passivating manner. Using MOCATAXY, we observe the formation of this 'pseudo' 2-dimensional (2D)  $\alpha$ -Ga₂O₃ thin film and its growth passivation after reaching 2 nm thickness. This  $\alpha$ -Ga₂O₃ 2D thin film serves as a template for growing  $\alpha$ -Ga₂O₃/ $\alpha$ -Al₂O₃ quantum wells.

We present reflection-high energy electron diffraction, x-ray photoelectron spectroscopy, atomic force microscopy, x-ray diffraction, x-ray reflectivity, and transmission electron microscopy data, showing the existence and characteristics of this 'pseudo' 2D  $\alpha$ -Ga₂O₃ thin film grown by MOCATAXY, and explain our results using a kinetic and thermodynamic framework.

DS 20.7 Wed 16:00 P3

An unconventional octahedral metal: AgSnTe2 — •SOPHIA WAHL, CHRISTIAN TEICHRIB, CARL-FRIEDRICH SCHÖN, MARIA HÄSER, YUAN YU, and MATTHIAS WUTTIG — 1. Institute of Physics (Ia), RWTH Aachen University, Aachen, Germany

Phase-change materials (PCMs) provide a unique combination of properties. Switching from the amorphous to crystalline structural phase, their optical and electrical properties change significantly. While conventional PCMs undergo a change from covalent to metavalent bonding upon crystallization accompanied by a dielectric behavior in both phases [1], we observe a change from dielectric to metallic in the optical and electrical properties for the unconventional metal AgSnTe2 (AST).

We analyze the dielectric properties of amorphous and crystalline AST samples by employing optical spectroscopy from the infrared to UV/Vis range. Through a Kramers-Kronig analysis of the data, we can separate the contributions of the optical functions accordingly and yield insight into the nature of bonding. Transport measurements and the investigation of bond rupture in atom probe tomography support the findings and all imply a non-conventional bonding mechanism in crystalline AST.

This work is aiming to define a whole set of new plasmonic PCMs which are all located in one region of the materials bonding map[2].

### DS 20.8 Wed 16:00 P3

Structural and electronic investigations of Bismuth multilayers with DFT – •FABIAN TEICHERT¹, CHITRAN GHOSAL¹, UWE GERSTMANN², CHRISTOPH TEGENKAMP¹, and ANGELA THRÄNHARDT¹ – ¹Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany – ²Department of Physics, Paderborn University, Paderborn, Germany

Bismuth shows a variety of interesting properties as bulk material but also as thin film, e.g. it is a topological insulator, shows strong spin-orbit coupling effects and has a semimetal-semiconductor transition concerning film thickness. The focus of this presentation will be on density functional theory (DFT) calculations, which have been done for Bi(110) multilayers to get insights into the concrete structure and electronic states. We compare the results with Bi multilayers, which have been grown epitaxially on graphene substrate and where (110) slabs have been figured out. They are treated with scanning tunneling microscopy (STM) measurements for various slab thicknesses. We found an even/odd scheme concerning the number of monolayers as well as concerning the number of bilayers indicating a structural relaxation like the black phosphorus allotrope. Further calculations with graphene and highly oriented pyrolytic graphite (HOPG) substrate have be performed to figure out if structurally separated and electronically decoupled layers are present at the substrate interface. Concerning the electronic properties, we present the calculated bandstructures and density of states and comparisons with the measured differential conductance, which are in good agreement.

#### DS 20.9 Wed 16:00 P3

**Twisted bilayer antimonene** – •STEFAN WOLFF, ROLAND GILLEN, and JAN-INA MAULTZSCH — Department of Physics, Chair of Experimental Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, Staudtstr. 7, 91058 Erlangen, Germany

Antimony has proven to be a promising candidate for two-dimensional (2D) mono-elemental materials. In bulk form, it is a layered crystal comprising sheets of antimony atoms arranged in a hexagonal buckled honeycomb lattice called antimonene. The natural stacking order follows an ABC-pattern, in which each subsequent layer is shifted by one third. Other than many other 2D materials, the interlayer bonds in few-layer antimonene show partially covalent character. Due to this covalent character, changes of the local stacking order via rotation and translation may lead to new interesting features and properties of the material. Density functional theory (DFT) is used to simulate twisted bilayer antimonene structures with different rotation angels and to investigate their physical properties. Moiré patterns and local stacking orders can be found, which lead to a non-uniform bond length distribution. Additionally, our investigation of the charge density shows how the overlap of atomic orbitals in certain areas changes, depending on the proximity of atoms from neighboring layers. A comprehensive understanding of how the properties of twisted bilayer antimonene are modified compared to naturally stacked bilayer antimonene may lead to future applications making use of well-constructed, favorable stacking orders in layered materials.

## DS 20.10 Wed 16:00 P3

**Determination of circularly polarized light-triggered chiral excitons in organic light harvesting devices** — •OTGONBAYAR ERDENE-OCHIR, DIRK HER-TEL, and KLAUS MEERHOLZ — Chemistry Department, University of Cologne, Cologne, Germany

Organic-chiroptics have not been a focus of the research area due to the trace amount of circular dichroism (CD) nature has provided in most chiral molecules. However, aggregation of chiral prolinol functionalized squaraine offers giant intrinsic CD behavior. The CD effect is related not only to the difference of leftand right-handed circularly polarized (CP) light absorption for the organic chiral molecule, but also associated with their excitonic nature based on the formation of molecular aggregates. This work discusses the determination of the selective chiral excitons via direct right- and left-handed CP laser radiation. The enantiomer of squaraine derivative (S,S)-ProSQ-C16 is a strongly CD-active material featuring maximum absorbance at ca. 780 nm after thermal annealing of a thin film. We introduced (S,S)-ProSQ-C16 as a p-type active material in a planar heterojunction (PHJ) and bulk heterojunction (BHJ) blend for the photovoltaic devices, together with the fullerenes C60 and PCBM as acceptors, respectively. We used normal-incident transmission Mueller Matrix method to determine the intrinsic CD effects of the thin film. An electronic characterization of the chiral exciton within the PHJ and BHJ systems are quantified. The efficiency of the chiroptical response is estimated by the dissymmetry factor. A systematic correlation between optical and electronic dissymmetry factors will be discussed.

#### DS 20.11 Wed 16:00 P3

Molecular dynamics simulations of carbon nanomembranes (CNMs): Formation and mechanical properties — •LEVIN MIHLAN, JULIAN EHRENS, and JÜRGEN SCHNACK — Universität Bielefeld, Universitätsstrasse 25, D-33615 Bielefeld

CNMs are made by electron-induced crosslinking of aromatic self-assembled monolayers (SAMs) [1,2]. Their supposedly irregular internal structure cannot be adequately investigated by standard spectroscopic techniques, however, a determination of, e.g. Young's moduli is possible. In order to propose possible internal structures obtained from various initial configurations of the SAM and irradiation processes, we investigate the monolayers with respect to the Young's modulus in terms of classical molecular dynamics calculations using LAMMPS and compare to experimental values. We present three distinct methods to calculate the Young's modulus: Global scaling of all coordinates, stress-strain response from clamped straining and barostatted dynamics. Discrepancies among the methods with regard to vastly different outcomes will be discussed considering finite size effects. CNMs can be used for water filtration, a property that is closely related to the distribution of holes in the membrane [3]. With a hole-detection algorithm for our simulated CNMs we can investigate the hole distributions too and use this as a second observable for comparison with experimental data.

Microscopic theory of X-ray absorption spectroscopy — •JORIS STURM, DO-MINIK CHRISTIANSEN, MALTE SELIG, and ANDREAS KNORR — Institut für Theoretische Physik, Nichtlineare Optik und Quantenelektronik, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin, Germany

X-ray absorption near-edge spectroscopy (XANES) and extended X-ray absorption fine structure (EXAFS) are two widely used methods to investigate the structure of solid states. Unfortunately, for both techniques, mostly heuristic models are available [1,2,3].

In this contribution, we present the first self-consistent Maxwell-Bloch approach based on Heisenberg equation of motion formalism for the unified description of XANES and EXAFS for 2D solid-state materials and apply it to the exemplary material graphene. For XANES we reproduce the experimentally observed absorption peaks and polarization-dependent selection rules of the included orbitals. Furthermore, the rigorous treatment of the Bloch theorem allows us to calculate the Fourier transformed EXAFS spectrum [2] predicting so far uninterpreted features which have not been assigned within scattering theory [1].

**Confinement induced coherent phonon softening in Sb2Te3 thin films** — •JONATHAN FRANK¹, JULIAN MERTENS¹, FELIX HOFF¹, MOHIT RAGHUWANSHI², and MATTHIAS WUTTIG¹ — ¹1. Institute of Physics (IA), RWTH Aachen University, Aachen, Germany — ²Forschungszentrum Jülich, Jülich, Germany

Femtosecond reflection-type optical pump-probe experiments on a thicknessseries of MBE-grown Sb2Te3 thin films were carried out to study confinement effects of coherent optical phonons. Therefore, an isotropic detection scheme was applied to investigate the ultrafast dynamics of the LO-phonon mode of A1gsymmetry in Sb2Te3 thin films ranging from 1.3 to 55 nm. The ultrafast response of each thin film contains a distinct coherent feature uncovered by damped harmonic oscillations in the transient reflectivity traces. It is shown that coherent optical phonons are efficiently photoexcited in thin films of only a few quintuple layers. This finding supports the hypothesis that electron-phonon coupling in ultrathin sesqui-chalcogenide films does not fundamentally differ from bulk which is essential for the performance in strongly scaled applications as for example in topological insulators. Furthermore, a slight decrease in phonon-frequency accompanied by a more pronounced decrease in phonon-lifetime is observed in films smaller than ten nanometers; both quantities nearly monotonously decrease with film thickness. We ascribe this phonon softening to a decreased interlayer coupling in films of a few quintuple layers compared to a more bulk-like behavior observed in the thicker films.

## DS 20.14 Wed 16:00 P3

Characterization of layer systems by combination of X-ray reflectivity and hyperspectral imaging — •STEFFEN BIEDER¹, FLORIAN GRUBER², PATRICK SCHLENZ³, PHILLIPP WOLLMANN², CHRISTIAN ALBERS¹, SUSANNE DOGAN¹, MICHAEL PAULUS¹, NICOLA THIERING¹, CHRISTIAN STERNEMANN¹, and STEFFEN CORNELIUS³ — ¹TU Dortmund, 44227 Dortmund, Germany — ²Fraunhofer IWS, Winterbergstrasse 28, 01277 Dresden, Germany — ³Fraunhofer FEP, Winterbergstrasse 28, 01277 Dresden, Germany

Different thin film multilayers consisting of indium tin oxide, zinc tin oxide and silver deposited on flexible PET foils were studied using X-ray reflectivity and hyperspectral imaging aiming for an online quality control of the coatings' manufacturing process. The X-ray reflectivity data measured at beamline BL9 of the DELTA synchrotron radiation source provide detailed information on layer thickness with Angström resolution, roughness and electron density. These results are used to establish statistical models in order to analyze and interpret the data obtained from hyperspectral imaging. Latter is foreseen to be implemented into the foils' production line for in-situ detection of thickness changes during the production process.

The authors acknowledge funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 862055. We thank DELTA for providing synchrotron radiation.

#### DS 20.15 Wed 16:00 P3

Surface second harmonic generation in dielectric nanofilms — •FATEMEH AL-SADAT ABTAH1¹, PALLABI PAUL^{1,2}, SEBASTIAN BEER¹, ADRIANA SZEGHALIMI^{1,2}, STEFAN NOLTE^{1,2}, and FALK EILENBERGER^{1,2,3} — ¹Institute of Applied Physics, Friedrich-Schiller-University, Jena, Germany — ²Fraunhofer-Institute for Applied Optics and Precision Engineering IOF, Jena, Germany — ³Max Planck School of Photonics, Jena, Germany

Second-harmonic generation (SHG) is a second-order nonlinear optical process that is not allowed in media with inversion symmetry. However, due to the broken symmetry at the surface, surface SHG can still occur in such materials. We experimentally investigate the surface SHG in the periodic stacks of ultrathin dielectric layers. Uniform, dense and optically homogeneous multilayer stacks of SiO2/TiO2 were grown by Plasma Enhanced Atomic Layer Deposition (PEALD) on fused silica substrates. With this technique individual layers of a thickness of less than 2 nm can be fabricated, increasing the number of SHG-active surfaces substantially. Because of the material discontinuity, in each surface of this structure, the symmetry is broken and surface SHG will occur. By changing the Angle of Incidence (AOI) and having constructive interference between all fundamental/SHG signals from different surfaces, we are able to enhance the surface SHG. We experimentally show that under large angles of incidence > 20 degrees there is substantial SHG, well beyond the level, which can be expected for simple surfaces.

DS 20.16 Wed 16:00 P3 Surface-Enhanced Raman Spectroscopy and Transient Reflectivity of Strained LSMO Thin Films — •LEONARD SCHÜLER, TIM TITZE, STEFAN MATH-IAS, DANIEL STEIL, and VASILY MOSHNYAGA — I. Physikalisches Institut, Georg-August-Universität Göttingen

The effect of lattice strain on the structural and electronic surface reconstruction of epitaxial La_{0.7}Sr_{0.3}MnO₃/LaAlO₃ (LSMO/LAO) thin films has been studied by surface-enhanced optical measurements. Surface sensitivity is achieved by deposition of gold nanoparticles, in which the localized surface plasmon resonance enhances laser electric fields at the surface, enabling surface-enhanced Raman spectroscopy (SERS) and pump-probe reflectivity (SE-PPR) studies of the LSMO films. For this system, SERS reveals a structural surface reconstruction and signals an insulating surface state characterized by strong Jahn-Teller modes which are not present in the conventional Raman spectra of the ferromagnetic metallic LSMO/LAO films. Furthermore, a structural transition of the insulating surface is shown at T*=200-220 K possibly related to charge ordering (CO). SE-PPR indicates that it is possible to photoinduce a ferromagnetic metallic phase at the surface above the assumed CO transition temperature.

#### DS 20.17 Wed 16:00 P3

In-situ spectroscopic ellipsometry analysis of SiO2 on Si under different atmosphere and temperature — •XINYU ZHOU, YOUNES SLIMI, STEFAN KRISCHOK, and RÜDIGER SCHMIDT-GRUND — Technische Universität Ilmenau, Fachgebiet Technische Physik I, Weimarer Strafte 32, 98693 Ilmenau, Germany In-situ Spectroscopic ellipsometry has been applied to obtain optical constants and thin film thicknesses of SiO2 on Si under different atmospheres (nitrogen, dry air) and temperatures. We found changes in refractive index and thickness of the SiO2 layer under different conditions due to oxidation and material ablation. We further present our recent developments in building up an in-situ ellipsometry system for photo-electrochemical applications.

#### DS 20.18 Wed 16:00 P3

**Spectroscopic Ellipsometry of transition metal oxide thin films** — •NAHID AHMADIAN^{1,2}, TERESA I. MADEIRA^{1,2}, and DIETRICH R.T. ZAHN^{1,2} — ¹Chemnitz University of Technology, Chemnitz, Germany — ²Center for Materials, Architectures and Integration of Nanomembranes (MAIN), D-09107, Chemnitz, Germany

Transition metal oxides such as HfO₂ or TiO₂ with bandgaps of 5.3-5.9 eV and 3.0-3.4 eV, are transparent in the visible range of the spectrum, i.e. their extinction coefficient in this range is very low close to zero while the refractive index varies as a function of photon energy. In this work, we tested four dispersion models: Sellmeier, Cauchy, extended Cauchy, and Tauc-Lorentz aiming at understanding the mathematical and physical differences of these approximations, their robustness and limitations in addressing amorphous and crystalline phases of thin films of HfO₂ deposited by atomic layer deposition (ALD) on Si(100) and TiO₂ thin films prepared on Si(100) by magnetron sputtering and spin coating. The spectroscopic ellipsometry measurements were performed using a M-2000 T-Solar from J.A. Woollam. Spectra covering a range of energies 0.7 (IR) - 5 eV (UV) were taken in air at room temperature and analyzed using CompleteEASE. We conclude that multiple oscillators are required to treat the crystalline phases in comparison to the amorphous, and when very good solutions are obtained from all oscillators, the choice to use one or the other is based on complexity: the less the fit parameters the best.

DS 20.19 Wed 16:00 P3

Reaction of Tetrapyrrole Thin Films with Alkali Metals — •LEONARD NEUHAUS¹, STEFAN RENATO KACHEL¹, PETER SCHWEYEN², MARK HUTTER¹, MAIK SCHÖNIGER¹, FLORIAN MÜNSTER¹, LUKAS RUPPENTHAL¹, JAN HERRITSCH¹, MARIE-IRENE ALBUS¹, MARTIN BRÖRING², and J. MICHAEL GOTTFRIED¹ — ¹Fachbereich Chemie, Philipps-Universität Marburg, Germany — ²Institut für Anorganische und Analystische Chemie, Technische Universität Braunschweig, Germany

Tetrapyrroles such as porphyrins play an import role in living organism and for various modern technologies. While most previous publications related to tetrapyrrole thin films focus on transition metal complexes, we want to expand the field by exploring the reaction of various tetrapyrrole films with alkali metals. For this purpose, we prepared multilayer films of tetraphenylporphyrin and an octaalkylcorrol on a Au(111) surface and studied their reactions with Li and Cs, thus covering the extremes of the lightest and heaviest stable alkali metal. For all studied systems, X-ray photoelectron spectroscopy (XPS) showed, changes in the N 1s region that indicate formation of the corresponding tetrapyrrole metal complexes. Complementary studies with temperature programmed reaction (TPR) provided unambiguous mass spectrometric evidence for the formation of the metal complexes. TPR also showed that the number of alkali metal atoms at tached to a tetrapyrrole ligand can exceed the number of pyrrolic hydrogen atoms in the free-base tetrapyrrole.

#### DS 20.20 Wed 16:00 P3

**Thermoelectric Characterization of Polymer Thin Films with Ag-nanowire Additives** — •SOHRAAB SCHERZAD¹, MARIE SIEGERT¹, and JENS PFLAUM^{1,2} — ¹Experimental Physics VI, University of Würzburg, 97074 Würzburg — ²ZAE Bayern, 97074 Würzburg

Along the process of power conversion from primary energy carriers vast amounts of waste heat in the low and mid temperature range occur. A possible solution to recover this waste heat is offered by thermoelectric generators which rely on the Seebeck effect and are able to directly convert thermal into electrical energy. Polymeric semiconductors, operating in this temperature regime, offer a sustainable and low-cost alternative to inorganic thermoelectrics. Their characteristics include a sufficiently low thermal conductivity  $\kappa$ , but also a low electrical conductivity  $\sigma$ , due to the low charge carrier concentration and generic disorder. Here we report on composite thin films made of Ag-nanowires embedded in PEDOT:PSS polymer matrices, which lead to changes in the electrical conductivity compared to pure PEDOT:PSS. Ag-nanowires are considered to be a suitable additive for increasing  $\sigma$  of the resulting composite and its impact on  $\kappa$ will also be studied. First results on the thermoelectric properties of this material combination will be presented together with structural information obtained by X-ray diffraction and atomic force microscopy. Based on this complementary information we will critically discuss the potential of the presented approach for application in TEGs.

#### DS 20.21 Wed 16:00 P3

**Plasmonic-induced Thermoelectric Effects in Metal-organic Hybridstructures** — •LUCCA MACHER¹, PAUL HOPPSTOCK¹, MAXIMILIAN FRANK¹, MAX-IMILIAN RÖDEL¹, and JENS PFLAUM^{1,2} — ¹Experimental Physics VI, University of Würzburg, 97074 Würzburg — ²Bavarian Center for Applied Energy Research (ZAE Bayern), 97074 Würzburg

Local heat generation by plasmonic excitations in noble metal nanoparticles is of high technological interest for numerous applications such as photo-thermal chemistry or cancer therapy. In this work we utilize this approach to create a thermal gradient by the absorption of light in metal-organic hybrid structures. The latter are based on arrays of nanostructured gold and silver triangles in combination with solution processed p-type PEDOT:PSS films. As we can demonstrate, a defined temperature enhancement and thus, gradient evolves upon resonantly exciting local plasmons in the Au or Ag nanoparticle arrays. The amplitude of this enhancement amounts to  $\Delta T = 0.5$  K for an incident light power of 1.4 mW/mm². Accordingly, this plasmon-induced temperature gradient which is aligned along the PEDOT:PSS polymer layers results in a significant enhancement of the thermovoltage to  $V_T = 24 \ \mu V/K$  as compared to neat PEDOT:PSS ( $V_T = 12 \ \mu V/K$ ). An application-oriented approach was carried out as well, using arrays of nanostructured gold triangles covered by a transparent polymer-gel electrolyte PEGMA/BEMA in a window-like device architecture. A temperature gradient of  $\Delta T = 0.1$  K for an incident light power of 1.8 mW/mm² was determined along the PEGMA/BEMA layer.

#### DS 20.22 Wed 16:00 P3

Self-assembled monolayers of molecular spin-crossover (SCO) switches -•Fabian Streller¹, Stephen Goodner², Marat Khusniyarov², and Rainer  $FINK^1-{}^1Lehrstuhl für Physikalische Chemie II, Friedrich Alexander Universität Erlangen Nürnberg, Germany<math display="inline">-{}^2Lehrstuhl für Anorganische und Allge$ meine Chemie, Friedrich Alexander Universität Erlangen Nürnberg, Germany Spin-crossover (SCO) complexes are regarded as promising materials in applications such as spintronics, molecular electronics and ultra-high-density memory systems. They can be switched by external stimuli, e.g., change of temperature, pressure, or illumination with light. In the investigated complexes switching occurs between diamagnetic low-spin (LS) and paramagnetic high-spin (HS) species by either a simple SCO, or a valence tautomeric (VT) transition accompanied by a SCO. While the mentioned applications seem promising, one big challenge that needs to be overcome is the transfer of the systems from solution or bulk towards thin films or even monolayers on well-defined surfaces. Six-coordinate iron(II) complexes have been used as SCO materials, whereas six-coordinate Co complexes with redox active dioxolene ligands were chosen as VT materials. Both materials can be attached to the surface via a bidental phenanthroline ligand containing moieties suitable for bonding to the substrate. Here we report a step by step formation of single-layer films on Au(111) surfaces. The thus created specimens were characterized by atomic force microscopy (AFM), x-ray photoelectron spectroscopy (XPS) and near edge x-ray absorption fine structure (NEXAFS).

#### DS 20.23 Wed 16:00 P3

Chern number control in quantum anomalous Hall insulators by external fields — •YURIKO BABA^{1,2}, FRANCISCO DOMÍNGUEZ-ADAME¹, and RAFAEL A. MOLINA-FERÁNDEZ² — ¹GISC, Departamento de Física de Materiales, Universidad Complutense, E–28040 Madrid, Spain — ²Instituto de Estructura de la Materia, IEM-CSIC, E–28006 Madrid, Spain

Topological magnetic insulators have been discovered as a new platform for observing Quantum Anomalous Hall states with high Chern number C. In threedimensional structures of stacking layers of magnetically doped and undoped topological insulators of Bi2(Se,Te)3, the number of chiral edge channels can be controlled by the width and number of layers and by the doping concentration. This has been recently measured by Zhao et al. [1] in Cr doped samples, showing this feature up to C = 5.

In this theoretical work, we explore the possibilities of tuning the chiral channels of the aforementioned materials in the presence of electric fields in multilayered structures. The external field tunes the Chern number and changes the number of topological channels dynamically without the need of replacing the sample to modify the Chern number. The tuneability has a remarkable impact on the transport properties of pristine and disordered samples.

#### DS 20.24 Wed 16:00 P3

topological magnons and thermal hall conductivity in 2D magnets — •HAMID NOURI and HONGBIN ZHANG — Technical University of Darmstadt, 64287 Darmstadt, Germany

Two-dimensional (2D) materials provide a fascinating playground for emergent phenomena driven by enhanced thermal and quantum fluctuations, in particular the nontrivial topological phases with the associated dissipationless transport properties. For 2D magnetic insulators, magnons can also host Dirac and Weyl points with nonzero Berry curvature, leading to finite thermal Hall conductivities. In this work, based on the linear response spin-wave theory, we investigated a Hamiltonian formulated on 2D lattices comprising the Heisenberg exchange, Dzyaloshinskii-Moriya interaction (DMI) interactions, singleion anisotropy, external magnetic fields, and found that the gapped magnon bands exhibit nonzero Chern numbers of *1 due to finite DMI which acts like effective spin-orbit coupling. The thermal Hall conductivity is evaluated based on the Boltzmann transport theory, suggesting a novel approach to designing 2D thermal management materials. The realization of such Hamiltonians in experimentally available 2D materials will be discussed as well.

#### DS 20.25 Wed 16:00 P3

Bottom-up preparation of large area van-der-Waals heterostructures by the subsequent growth of 2D transition metal dichalcogenides layers — •DEVENDRA PAREEK¹, MARCO A. GONZALEZ¹, NEDAL GREWO¹, MARTEN L. JANSSEN¹, LEON A. GRÄPER¹, KUMARAHGIRI ARUNAKIRI¹, KAYODE. L. ALIMI¹, MARTIN SILIES^{1,2}, JÜRGEN PARISI¹, LEVENT GÜTAY¹, and SASCHA SCHÄFER¹ — ¹Ultrafast Nanoscale Dynamics, Institute of Physics, Carl von Ossietzky University of Oldenburg, Oldenburg, Germany — ²Institute for Lasers and Optics, University of Applied Sciences Emden/Leer, Emden, Germany

We report the preparation of as-grown two-dimensional transition metal dichalcogenides (2D-TMDC) heterostructures from a processing route employing a combination of atomic layer deposition of monolayer  $MoS_2$  and solution-based processing of ultrathin  $Mo(S/Se)_2$  and  $W(S/Se)_2$  films. Grown on centimeter-scale sapphire substrates, spatially uniform optoelectronic characteristics of the individual TMDC layers and heterostructures are demonstrated down to micrometer length scales using photoluminescence, Raman spectroscopy, and light-beam-induced current measurements. Preliminary observations on enhanced photogenerated currents in  $MoS_2-MoS_2/WS_2$  lateral heterostructures demonstrate the suitability of this approach for the preparation of functional devices on macroscopic length scales. Finally, we also discuss the possibilities to synthesize these compounds at temperatures below 400 °C, making them suitable for a broad range of substrate materials.

#### DS 20.26 Wed 16:00 P3

Twist-angle dependent proximity induced spin-orbit coupling in graphene/transition-metal dichalcogenide and graphene/topological insulator heterostructures — •THOMAS NAIMER¹, KLAUS ZOLLNER¹, MARTIN GMITRA², and JAROSLAV FABIAN¹ — ¹Uni Regensburg, Regensburg, Germany — ²Pavol Jozef Šafárik University, Košice, Slovakia

We investigate the proximity-induced spin-orbit coupling in twisted heterostructures of graphene/transition-metal dichalcogenides (MoS₂, WS₂, MoSe₂, and WSe₂) as well as graphene/topological insulators (Bi₂Se₃ and Bi₂Te₃) from first principles. To correct for strain induced band offsets, we apply a perpendicular electric field. The resulting corrected band structure is then fitted around the Dirac point to an established spin-orbit Hamiltonian, yielding the twist angle dependencies of the (Rashba and valley-Zeeman) spin-orbit coupling. This work was funded by the Elite Network of Bavaria, the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation), SFB 1277, SPP 2244 and by the European Union Horizon 2020 Research and Innovation Program under contract number 881603 (Graphene Flagship). M.G. acknowledges VEGA 1/0105/20.

#### DS 20.27 Wed 16:00 P3

Valley depolarization of excitons in encapsulated  $MOSe_2$ -WSe₂ heterostructures with controlled moiré potentials — •ANDREAS BEER¹, ANNA WEINDL¹, NICLAS MAIER¹, ANTONY GEORGE², ANDREY TURCHANIN², and CHRISTIAN SCHÜLLER¹ — ¹Universität Regensburg — ²Friedrich-Schiller-Universität Jena Our focus is the investigation of the temporal and spatial dynamics of interlayer excitons in MoSe₂-WSe₂ heterostructures with well-defined moiré potentials, based on CVD grown samples. The so called hot pickup method enables us to fabricate such heterostructures out of CVD grown triangulars in a controlled, dry, PDMS-free and easy way.

To understand the valley depolarization mechanism in TMDC monolayers and heterostructures we perform time resolved pump probe measurement. First measurements on twisted TMDC exfoliated heterostructures reveal twist-angledependent decay times of the interlayer exciton.

#### DS 20.28 Wed 16:00 P3

**Protection of QSHI indenene from air via intercalation** — •CEDRIC SCHMITT^{1,2}, JONAS ERHARDT^{1,2}, SIMON MOSER^{1,2}, and RALPH CLAESSEN^{1,2} — ¹Physikalisches Institut, Universität Würzburg, D-97074 Würzburg, Germany — ²Würzburg-Dresden Cluster of Excellence ct.qmat, Universität Würzburg, D-97074 Würzburg, Germany

In the search for new quantum materials, ultrathin metals are interesting as they push bulk properties to the 2D limit and foster novel quantum effects. Unfortunately, these systems are prone to oxidation in air, making them useless for quantum transport devices. Metal intercalation is a relatively new capping method, that utilizes graphene, an inert quantum material that can be easily produced by heating of a SiC substrate [1,2]. Hereby, the metal is intercalated between the SiC/graphene layer, thus forming freestanding graphene, which is believed to protect the intercalated layers against oxidation [3]. Hitherto studies focused mainly on identifying stable allotropes but lacking a detailed investigation of metal coverage and oxidation [3]. Here, we study the intercalation of indenene, a recently discovered QSHI on a triangular lattice [4]. First experiments indicate the indium layer to remain intact upon air exposure, indeed pointing to an effective protective function of the overlayer graphene.

Electronic Structure of  $[(SnSe)_{1+\delta}]_m(TiSe_2)_n$  investigated by Photoelectron Spectroscopy — •NIELS RÖSCH¹, FABIAN GÖHLER¹, DANIELLE M. HAMANN², DAVID C. JOHNSON², and THOMAS SEYLLER¹ — ¹Technische Universität Chemnitz, Institut für Physik, 09126 Chemnitz — ²University of Oregon, Department of Chemistry, Eugene OR 97401

The Modulated Elemental Reactants (MER) synthesis is a new method for producing multilayer heterostructures. A precursor is created in MER by using consecutive physical vapour deposition. The precursor's structure and composition can be deliberately changed to mimic the desired heterostructure. After that, the precursor is crystallized by annealing it at low temperatures in an inert environment. Low temperatures allow thermodynamically metastable films to form, albeit at the cost of turbostratic rotational disorder between layers. By systematically modifying the stacking sequence of individual layers, this approach can be used to create a succession of layered heterostructures.

X-ray photoelectron spectroscopy was used to investigate the electrical structure of a sequence of  $[(SnSe)_{1+\delta}]_m(TiSe_2)_n$  heterostructures [1]. It is demonstrated that electrons are transferred from the SnSe layers to the TiSe₂ layers. Understanding charge transfer in heterostructures is important for future applications, as controlled stacking of the heterostructure may allow for targeted doping.

#### DS 20.30 Wed 16:00 P3

Atomistic Simulations of Defects Production Under Ion Irradiation in Epitaxial Graphene on SiC — •MITISHA JAIN¹, SILVAN KRETSCHMER¹, KATJA HÖFLICH^{2,3}, JOAO MARCELO J. LOPES⁴, and ARKADY KRASHENINNIKOV¹ — ¹Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Bautzner Landstraße 400, 01328 Dresden, Germany — ²Ferdinand-Braun Institut gGmbH, Leibniz-Institut für Höchstfrequenztechnik, Berlin, Germany — ³Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Berlin, Germany — ⁴Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Berlin, Germany

In this work, using atomistic simulations at the analytical potential and densityfunctional theory (DFT) levels, we theoretically study defect production in EG on SiC by ion beams (He and Ne ions). We explicitly consider the effects of the substrate (bulk SiC) on the response of graphene to irradiation. Since the substrate affects the number of displaced carbon atoms and vacancy types in EG, we present information about the number, types and location of defects produced in each layer of EG to guide the experiment in tailoring the defect production. Motivated by the He FIB experiments (aiming at nucleation sites of h-BN growth, operating at 30 keV), our considerations apply to the typical ion energies used in HIM, that is 10-30 keV.

#### DS 20.31 Wed 16:00 P3

Low energy ion induced effects on core-shell nano particles — •JULIAN LISSON, SHIVA CHOUPANIAN, and CARSTEN RONNING — Institute of Solid State Physics, Friedrich Schiller University Jena, Max-Wien-Platz 1, 07743 Jena, Germany Ion irradiation can be used for manipulating the shape and properties of nanomaterials. However, the comportment of nano materials irradiated with energetic ions differs from bulk and thin films due to the mesoscopic properties of nanoparticles. The succeeding effects such as sputtering and ion beam mixing are strongly coupled and are dependent on the properties of the irradiated target. In this study, the effect of Ga+ ions with an energy range of 10-30 keV on different nanomaterials of Au, Ag, Au-Ag mix, and core-shell nanoparticles dispersed on Si substrates has been investigated. The sputter yield for each nanomaterial has been measured. Comparing the sputter yield and morphology changes of the nanoparticles, we observe that the ion beam mixing at the interface of the Au-Ag core-shell nano particles is prominent. The sputter yield dependence is changing when ion beam mixing is occurring and leads to dissimilar morphology changes of the core-shell nanoparticles due to preferential sputtering.

#### DS 20.32 Wed 16:00 P3

Lattice dynamics in tuneable thin films with Ruddlesden-Popper structure - •Veronica Goian¹, Natalie Dawley², Jingshu Zhang², Christelle Kadlec¹, Nathan D. Orloff³, Reinhard Uecker⁴, Steffen Ganschow⁴, DARRELL G. SCHLOM^{2,5}, and STANISLAV KAMBA¹ — ¹Institute of Physics ASCR, Prague, Czech Republic — ²Department of Materials Science and Engineering, Cornell University, Ithaca, NY, USA - ³National Institute of Standards and Technology, Boulder, CO, USA — ⁴Leibniz-Institut für Kristallzüchtung, Berlin, Germany — ⁵Kavli Institute at Cornell for Nanoscale Science, Ithaca, NY, USA In this work, we will compare the phonon dynamics of (SrTiO₃)₆SrO (SrRP6) thin film with (SrTiO₃)₅(BaTiO₃)₁SrO (BaRP6) and Sr_{5/6}Ba_{1/6}TiO₃ (SBT) thin films, all deposited on (110)DyScO3 substrates. The XRD measurements and the rocking curves prove the thin films are single phase and epitaxially grown on the substrates. The lattice dynamics of the thin films were determined using THz and IR spectroscopies down to 10 K. Many phonons exhibit anomalies near temperatures of the ferroelectric phase transitions. We found out that the 100 nm BaRP6 and SBT thin films have  $\mathrm{T}_{C}$  about 40-50 K higher than previously studied 50 nm thin films, which is due to slightly relaxed strain in the thin films. We will also compare the temperature behavior of the complex permittivity of BaRP6 and SBT thin films with behavior of  $Ba_x Sr_{1-x} TiO_3$  (x=0.1..0.6) ceramics and will discuss the reason for high tuneability of permittivity and low dielectric loss in strained thin films.

#### DS 20.33 Wed 16:00 P3

Stabilized ferromagnetism in LPCMO thin films by using buffer layers — •PIA HENNING¹, KAREN STROH¹, VITALY BRUCHMANN-BAMBERG¹, OLEG SHAPOVAL², and VASILY MOSHNYAGA¹ — ¹Erstes Physikalisches Institut, Georg-August-Universitat-Göttingen, Gottingen, Germany — ²IIEN, Academy of Sciences of Republic Moldova, Chisinau, Republic of Moldova

(La_{0.6}Pr_{0.4})_{0.7}Ca_{0.3}MnO₃ (LPCMO) is an A-site substituted perovskite manganite and is mostly known for the colossal magnetoresistance (CMR) effect. Relatively thick LPCMO films ( $d \approx 50-100$  nm) with a coupled ferro-to-paramagnet and a metal-to-insulator transition (MIT) and CMR can be heteroepitaxially grown on MgO(200) substrates, where a relaxed growth due to misfit dislocations is achieved. However, very thin LPCMO films with  $d \leq 20$  nm on MgO(200) do not show a MIT and CMR. On the alternative substrate SrTiO₃ (100), LPCMO grows coherently strained and with good surface morphology, but lacks an MIT and CMR even for  $d \leq 50$  nm.

To enable high-quality LPCMO thin film growth on  $SrTiO_3$  substrates, the introduction of a buffer layer to bridge the lattice mismatch of film and substrate is inevitable. Based on this, we investigate the growth of LaAlO₃ (LAO) buffer layers on  $SrTiO_3$  and the influence of LAO buffer layers on the growth of LPCMO in order to improve the magnetic and electric properties. Specifically, the interplay of buffer and film thickness is studied. It is demonstrated the possibility of high quality thin film growth of LPCMO on buffered STO and a stabilization of the ferromagnetic-metallic phase.

#### DS 20.34 Wed 16:00 P3

Electronic Reconstruction and Anomalous Hall Effect at the LaAlO₃/SrRuO₃ Interface — •MERIT SPRING¹, JI SOO LIM¹, MARTIN KAMP¹, LOUIS VEYRAT², PAVEL POTAPOV², AXEL LUBK², BERND BÜCHNER², MICHAEL SING¹, and RALPH CLAESSEN¹ — ¹Physikalisches Institut and Würzburg-Dresden Cluster of Excellence ct.qmat, 97074 Würzburg, Germany — ²Leibniz Institute for Solid State and Materials Research and Würzburg-Dresden Cluster of Excellence ct.qmat, 01069 Dresden, Germany

4d and 5d transition metal oxides are a promising class of materials for topological phases in the context of electron correlations. Recently, the ferromagnetic metal SrRuO₃ (SRO) grown on a SrTiO₃ (STO) (001) substrate has been reported to exhibit electronic-reconstruction induced interfacial charge pinning accompanied by a topological transition of its electronic bands when capped with a LaAlO₃ (LAO) layer [1]. LAO is a polar oxide and the electronic reconstruction in a heterosystem of LAO/STO caused by the polar discontinuity at the interface is well known. For the LAO/SRO system a similar behaviour is expected and charge is thought to be accumulated at the very interface giving rise to strong inversion-symmetry breaking and hence change in the momentum-space topology [1]. Here we show the observation of signatures of an anomalous Hall effect in 4uc SRO films capped with LAO but also with non-polar STO. We correlate these findings with angle-dependent XPS data that allow for depth-profiling the oxidation state of ruthenium in both systems.

#### DS 20.35 Wed 16:00 P3

Epitaxial growth of IrO2(110) thin films on TiO2(110) substrates by pulsed-laser-deposition — •TIM WALDSAUER¹, PHILIPP KESSLER¹, THEODORE PELLEGRIN¹, CHRISTOPHER REISER¹, RALPH CLAESSEN¹, VEDRAN JOVIC², and SIMON MOSER¹ — ¹JMU Physikalisches Institut, am Hubland, Würzburg, Germany — ²GNS National Isotope Center, Gracefield Rdd, Gracefield, New Zealand

Iridium dioxide (IrO2), a state-of-the-art catalyst for the electrocatalytic oxygen evolution reaction in water splitting, has recently been shown to exhibit exotic physical phenomena such as the inverse spin Hall effect. The latter is supposed to promote easy switching of its majority charge carriers. For both fundamental spectroscopic studies as well as device applications, IrO2 samples of high bulk and surface crystalline order are required. Here, we present a growth study of rutile IrO2(110) thin films on TiO2(110) substrates by pulsed-laser-deposition (PLD). Film characterization by AFM, RHEED and XPS shows stochiometric growth of thin films with high bulk crystallinity but a granular surface at higher thicknesses. Strategies to enhance the surface quality, e.g., through utilization of an oxygen plasma are outlined and first results are presented.

many — ³FZ Jülich GmbH, PGI-6, 52425 Jülich, Germany — ⁴PSI, Swiss Light Source, CH-5232 Villingen PSI, Switzerland — ⁵Institut für Theoretische Physik III, Ruhr-Universität Bochum, 44780 Bochum, Germany

Oxide interfaces play an important role in investigating phenomena like 2D electronic states which can feature properties like magnetism, superconductivity or the spin Hall effect. While 2DEGs have been reported for various oxide systems like LAO/STO or EuO/STO, the direct experimental evidence for the counterpart, the 2DHG, is still lacking. Using our UHV-MBE system, we grow high-quality oxide heterostructures to investigate these properties using synchrotron radiation. Here presented are the results of resonant photoelectron spectroscopy measurements that reveal the emergence of different 2DESs at Fe_xO_y/STO interfaces which suggests a dependence of the 2D interface properties on the oxidation state of Fe.

Stabilization of ferromagnetic metallic ground state in epitaxial  $(La_{1-y}Pr_y)_{0.7}Ca_{0.3}MnO_3$  /SrTiO₃ thin films by using buffer layers — •PIA HENNING¹, KAREN STROH¹, VITALY BRUCHMANN-BAMBERG¹, OLEG SHAPOVAL², and VASILY MOSHNYAGA¹ — ¹Erstes Physikalisches Institut, Georg-August-Universitat-Göttingen, Gottingen, Germany — ²IIEN, Academy of Sciences of Republic Moldova, Chisinau, Republic of Moldova

(La1-vPrv)0.7Ca0.3MnO3 (LPCMO) is an A-site substituted perovskite manganite, mostly known for the colossal magnetoresistance (CMR) effect. Relatively thick, d=50-100 nm, and stress-free LPCMO films with coupled ferro/paramagnetic and metal/insulator transition (MIT) and CMR  $\sim 10^4$ % can be heteroepitaxially grown by the metalorganic aerosol deposition technique on MgO(200) substrates, where strain relief occurs due to misfit dislocations. However, thin LPCMO films d<20 nm on MgO(200) do not show MIT and CMR. Alternatively, LPCMO/SrTiO3 (LPCMO/STO) films grow coherently strained and with smooth surface morphology, however lacking the MIT and CMR even for d>50 nm. To obtain epitaxial LPCMO films with optimal metal-insulator transition sharpness and temperature we have employed a strain-engineered LaAlO3 buffer layer to bridge the lattice mismatch of the LPCMO film and SrTiO₃(100) substrate. The influence of LaAlO₃ buffers on the magnetic and electric properties of epitaxial LPCMO films was studied. A high-quality growth of LPCMO/LAO/STO films and stabilization of the ferromagnetic-metallic phase for 10 nm thick LPCMO films were demonstrated.

#### DS 20.38 Wed 16:00 P3

Metal-insulator transition in  $AgSb_{1-x}Sn_xTe_2$  alloys — •Christian Teichrib and Matthias Wuttig — I. Physikalisches Institut (IA)

Metal-insulator transitions describe the localisation of charge carriers upon the change of a physical parameter. They can occur as a result of electron correlations (Mott transition) or disorder (Anderson transition) but a distinction between these two mechanisms is generally difficult and often both effects play a role in the transition. Phase change materials show a multitude of remarkable properties that make them suitable for the investigation of localisation phenomena. Their density of states at the Fermi level can be varied through chemical composition and disorder can be tuned through thermal annealing. This allows for the electrical resistivity to be modified over several orders of magnitude and a transition from a metallic to an insulating state to occur.

We present electrical transport and structural data for  $AgSb_{1-x}Sn_xTe_2$  alloys where a metal-insulator transition is observed upon variation of the stoichiometry. The nature of the transition is investigated using the temperature dependence of the resistivity, magnetoresistance data, and the Hall effect.

#### DS 20.39 Wed 16:00 P3

**Cryogenic Transport And Dielectric Properties Of Atomically Thin 2D-Polar Metals** — •Sven Bökemeier¹, Pierre-Maurice Piel¹, Jakob Henz¹, Mar-GAUX LASSUNIÈRe¹, JOSHUA ROBINSON², SIAVASH RAJABPOUR², ALEXANDER VERA² und URSULA WURSTBAUER¹ — ¹Physikalisches Institut, Westfälische Wilhelms-Universität, Münster, — ²MatSE; Center for 2DLM; Atomic; 2D Crystal Consort, PennState University, USA

2D layered materials are of great interest due to their electronic and optical properties that can be manipulated to a high degree. A novel class of atomically thin materials are 2D polar metals such as 2D Ga or 2D In and their ternary alloys that exhibit fascinating properties like strong nonlinear optical properties emerging by giant second harmonic generation [1], epsilon near zero behavior in the visible and NIR range [2] and alloy dependent superconductivity [3]. Intriguingly, 2D Ga exhibits a superconducting phase transition around 4K, while 2D In remains a metal down to < 800mK [3]. The 2D polar metals are prepared via confinement hetero-epitaxy (CHet) by intercalating metals between epitaxial graphene and the hosting SiC crystal resulting in atomically thin half-van der Waals materials [1]. We report on combined temperature dependent transport and spectroscopic ellipsometry experiments in order to a develop a better understanding of the alloy dependent emerging superconductivity of thin 2D Ga and 2D GaIn films. [1] M. A. Steves et al. Nano Lett. 2020, 20, 11, 8312*8318. [2] K. Nisi et al. Adv. Mater. 2021, 2104265 [3] S. Rajabpour et al. Adv. Funct. Mater. 2020, 2005977

Magnetic Field-Dependent Thermal Conductivity in Manganite Thin Films — •VITALY BRUCHMANN-BAMBERG, KAREN STROH, PIA HENNING, and VASILY MOSHNYAGA — I. Physik. Inst. Universität Göttingen, Friedrich-Hund-Platz 1, 37077 Göttingen

In perovskite manganites strong electron-phonon and spin-phonon coupling give rise to intriguing magneto-electric phenomena like colossal magnetoresistance (CMR), i.e. reduction of electrical resistivity by several orders of magnitude in an applied magnetic field of few Tesla. Since thermal conductivity of a solid contains both lattice and electronic contributions, a question of its manipulation by an external magnetic field can be addressed in CMR manganites.

Here we present temperature- and magnetic-field-dependent measurements of thermal conductivity by means of  $3\omega$ -technique in  $(La_{0.6}Pr_{0.4})_{0.7}Ca_{0.3}MnO_3$ -/MgO(100) thin films with a CMR ratio of  $[R(0T)-R(5T)]/R(5T)\approx 10^4$ %. The observed significant change of the thermal conductivity,  $\kappa$ , in magnetic field  $[\kappa(5T)-\kappa(0T)]/\kappa(0T) = 16\%$  close to  $T_C \approx 200K$  is caused by the electronic contribution in agreement with the Wiedemann-Franz law.

#### DS 20.41 Wed 16:00 P3

**Phonon-dominated energy transport in purely metallic thin films** — •MARC HERZOG¹, ALEXANDER VON REPPERT¹, JAN-ETIENNE PUDELL^{1,2}, CARSTEN HENKEL¹, MATTHIAS KRONSEDER³, CHRISTIAN BACK^{3,4}, ALEXEI MAZNEV⁵, and MATIAS BARGHEER^{1,6} — ¹Inst. f. Physik & Astronomie, Universität Potsdam, Germany — ²European XFEL, Schenfeld, Hamburg, Germany — ³Inst. f. Experimentelle & Angewandte Physik, Universität Regensburg, Germany — ⁴Fakultät f. Physik, Technische Universität München, Germany — ⁵Departent of Chemistry, MIT, Cambridge, USA — ⁶Helmholtz-Zentrum Berlin, Germany

In various branches of physical sciences it is assumed that electrons are the main carriers of thermal energy in metals. We use ultrafast x-ray diffraction to quantify the energy exchange among the metallic constituents in nanoscale thin films after laser excitation. Modeling the data with two-temperature models describing the energy exchange between non-equilibrium electrons and phonons provides clear evidence that phonons dominate the heat transport within gold films thinner than approx. 10 nm. Our fundamental experimental findings shifts the paradigm of energy being solely transported by electron in noble metals. These results may be relevant for the description of non-equilibrium thermal transport in diverse fields ranging from thermal management in nanoelectronics, spin-caloritronics and ultrafast spin dynamics to photothermal processes and plasmonic chemistry.

Combinatorial Synthesis of  $Pb_{1-x}Sn_xSe$  Films with Sputter Deposition — •THOMAS SCHMIDT, PETER KERRES, and MATTHIAS WUTTIG — RWTH Aachen University, Aachen, Germany

PbSe and SnSe are two chalcogenides with a wide range of applications of their properties, in particular as thermoelectrics. Interestingly, these two isoelectronic materials employ different bonding mechanisms. While at room temperature SnSe utilizes covalent bonds, PbSe is characterized by a more unconventional bonding mechanism, coined metavalent bonding. Therefore, we expect significant property changes upon crossing the border between those two bonding mechanisms. Such a change opens up the possibility to tailor material properties with sample stoichiometry. We have thus studied optical and electrical properties of Pb_{1-x}Sn_xSe films as a function of stoichiometry. Effective sample-production has been employed to facilitate this analysis. In this study the compositions around x=0.5, at which a structural transition is expected, are confocally sputtered and subsequently analyzed. The two targets PbSe (cubic structure) and SnSe (orthorhombic structure) were focused on the different ends of the 7.5 cm long Si-substrate. The resulting stoichiometry gradient in the sample was determined by energy dispersive X-ray spectroscopy and linked to the evolution of structure (X-ray diffraction) and optical properties (spectroscopic ellipsometry and reflectometry).

#### DS 20.43 Wed 16:00 P3

**Growth of Crystalline High-Entropy Alloy thin Films by Magnetron Sputtering** – •HOLGER SCHWARZ¹, THOMAS UHLIG², ERIC WONG¹, PETER HENNING¹, GUNTRAM WAGNER², and THOMAS SEYLLER¹ – ¹Institute of Physics, Faculty of Natural Sciences, TU Chemnitz, 09126 Chemnitz, Germany – ²Institute of Materials Science and Engineering, Faculty of Mechanical Engineering, TU Chemnitz, 09126 Chemnitz, Germany

Multicomponent alloys of at least four elements with near equimolar percentage were first reported and investigated by Cantor et al. in 2004 [1] and are nowadays often referred to as High-Entropy Alloys (HEAs) [2]. This group of materials has raised high attention in the field of material research due to its almost infinite possibilities of element combination and resulting physical properties. We demonstrate the fabrication of crystalline HEA thin films on MgO(100) and Al₂O₃(0001) single crystal substrates from homemade targets via magnetron sputtering. Low electron energy diffraction and X-ray diffraction experiments confirmed the formation of single phase crystalline HEA films. The surface elemental composition is investigated by X-ray photoelectron spectroscopy whereas the bulk stoichiometry is measured by energy dispersive X-ray spectroscopy. Angle resolved photoemission spectroscopy was used to investigate the band structure of the thin films.

Different approaches to deposit tungsten-doped vanadium dioxide by ionbeam sputter-deposition — •JILL KESSLER, SEBASTIAN LEONARD BENZ, IS-ABEL MÜLLER, MARTIN BECKER, and SANGAM CHATTERJEE — Institute for Exp. Physics I and Center for Materials Research (LaMa), Justus Liebig University Giessen, Germany

The complexity of the phase diagram of vanadium oxides makes the reproducible growth of thin films of defined phases by nonequilibrium techniques challenging. Here, we discuss thermochromic VO₂, which exhibits a significant change in optical transparency and reflectivity and, thus, is an ideal candidate for the use in smart windows. However, the bulk phase transition temperature of 68 °C is too high for useful applications. Doping VO₂ with tungsten drives the thermochromic key measures close to the desired range.

We present different approaches for tungsten doping of VO₂ based on ionbeam sputter-deposition. We employ tungsten screws that are inserted into the vanadium target. Furthermore, a pre-doped vanadium target is used. In another approach we employ two targets of vanadium and tungsten, respectively, to be sputtered simultaneously. Here, a compositional gradient allows for identification of the optimum doping concentration. The different approaches are compared regarding thin film properties and overall reproducibility of the growth process.

Raman spectroscopy and X-ray photoelectron spectroscopy provide structural and compositional analysis. UV/Vis/NIR spectroscopy yields the thermochromic performance.

#### DS 20.45 Wed 16:00 P3

Enhanced amorphization of Cu-Sn-I alloy thin films fabricated by reactive magnetron sputtering — •Christiane Dethloff, Sofie Vogt, Tillmann Stralka, Daniel Splith, Holger von Wenckstern, and Marius Grundmann — Universität Leipzig, Leipzig, Deutschland

CuI is a promising p-type semiconductor for optoelectronical applications due to various advantageous material properties such as transparency in the visible spectrum [1] and its earth abundant, cheap and non-toxic constituents. Growth of amorphous layers of CuI by solution processing has already been reported [2, 3]. The feasibility of deposition of the amorphous Cu-Sn-I alloy has not yet been demonstrated for a physical, scalable process, such as sputtering.

We present our investigations of the influence of the process parameters during the deposition of a Cu-Sn-I-alloy using reactive co-sputtering of Cu and Sn in a reactive iodine ambient. A dependence of the growth rate, the thin films morphology and the electrical properties on the process parameters i.e. the magnitude of the electrical power applied at the sputtering sources, the iodine partial pressure and the chamber pressure. A decrease of crystallinity was observed by XRD measurements for increasing sputtering power applied on the tin target as well as with increasing chamber pressure. LSM and AFM measurements yielded root-mean-square surface roughnesses below 10 nm.

#### DS 20.46 Wed 16:00 P3

**Overcoming the integration issues between 2D materials and waveguides** — •OSCAR CAMACHO IBARRA¹, IOANNIS CALTZIDIS¹, SELIM SCHARMER², SAMUEL GYGER², MARC SARTISON¹, and KLAUS D. JÖNS¹ — ¹HQPD lab, Department of Physics, Paderborn University, Germany — ²Quantum Nanophotonics, KTH Royal Institute of Technology, Sweden

To achieve fully operational quantum photonic integrated circuits, developing a scalable platform capable of supplying an efficient coupling between singlephoton emitters and photonic circuitry is essential. A hybrid approach is the most favorable to integrate single-photon emitters with other on-chip components since the advantages of each material platform are exploited. Singlephoton emitters hosted in 2D materials are emerging technologies and promising candidates for future scalable photonic circuits. However, the coupling of light from these emitters into waveguides remains challenging: In particular, higher coupling efficiency and reduction of spectral jitter are needed. Both issues can be simultaneously overcome by implementing a cavity in the photonic circuit. In this work, 1D photonic crystal cavities were designed and simulated for later integration of 2D emitters. These photonic crystal cavities are designed to be efficiently coupled to waveguide modes, and they possess high*quality factors and small mode volumes, resulting in prominent Purcell factors. Furthermore, the cavity geometrical structure can act as nucleation sites for strain*driven singlephoton emitters, allowing a self-alignment process between emitter and cavity.

DS 20.47 Wed 16:00 P3

**Propagation and manipulation of Bloch Surface Waves and Bloch Surface Wave Polaritons in ZnO** — •SEBASTIAN HENN, SIMON BRIESENICK, CHRIS STURM, and MARIUS GRUNDMANN — 1Universität Leipzig, Faculty of Physics and Earth Sciences, Felix Bloch Institute for Solid State Physics, Linnéstr. 5, 04103 Leipzig, Germany

In this contribution we demonstrate experimentally the control of the propagation of Bloch Surface Waves (BSW) in the transparent spectral range and Bloch Surface Wave Polaritons (BSWP) in the vicinity of excitonic transitions in ZnO. BSWP are bosonic quasi-particles originating from the strong coupling between BSW and excitons and exist along the ambient interface of a distributed Bragg reflector (DBR) with a thin ZnO top layer [1]. Using shallow optical diffraction gratings with sub-micron sized lattice constant, incident light is coupled into and out of the Bloch modes, which propagate along the surface interface between the gratings. Depending on the geometry of the sample and roughness of the surface layer the low-loss nature of evanescent BSW allows long-range lateral propagation of BSWP, on the order of micrometers, making this an interesting candidate for on-chip polaritonic devices. We determine the propagation lengths and test the coupling efficiency of the gratings, which are modelled using RCWA compuations.

DS 20.48 Wed 16:00 P3

**Improvement of the Architecture of Water-Based Dye-Sensitized Solar Cells** — •SARA DOMENICI, ANDREAS RINGLEB, and DERCK SCHLETTWEIN — Justus-Liebig-Universität Gießen, Institut für Angewandte Physik

Dye-sensitized solar cells (DSSCs) have emerged as a possible alternative technology for the conversion of sunlight into electrical energy. Aqueous electrolytes would considerably increase their sustainability. Aside from chemical instabilities, the power conversion efficiencies of aqueous DSSCs remain significantly lower compared to other DSSCs. One main problem which is dealt with in the present work, consist in low diffusion coefficients of appropriate redox couples. Aqueous DSSCs were assembled using screen-printed TiO₂ semiconducting layers sensitized with an organic dye, XY1b. The redox couple was TEMPO/TEMPO⁺ dissolved in aqueous LiClO₄ with MBI added as organic corrosion inhibitor. To improve the accessibility of the photoanodes for the redox couple, the size of TiO2 nanoparticles was varied. Further, this helps to add a scattering layer. In a second approach, the sealing method for the cells was adjusted. For instance, the distance between the working electrode and the counter electrode was tuned by using different sealant materials, such as hotmelt foils or UV glue, in order to allow short pathways for ion conduction. In this context, interactions of different sealant materials and the organic redox mediators have to be considered. The influence of the different approaches on cell efficiency will be discussed.

#### DS 20.49 Wed 16:00 P3

Development of a Transport Layer for the Integration of a TiO2-based Photoanode on a Silicon Wafer for Solar Water Splitting — •LUISA BUSCH, DENNIS BERENDS, and KAI GEHRKE — DLR Institut für Vernetzte Energiesysteme, Oldenburg, Germany

Recently, Segev et al. [1] proposed a three-terminal hybrid photoelectrochemical (PEC) / photovoltaic (PV) device for improved solar spectrum utilization. The concept integrates a TiO2 photoanode on an IBC silicon wafer in tandem configuration. To overcome the rather large bandgap of TiO2, which still limits the absorption of the solar spectrum and therefore the efficiency of the PEC, a sub-stochiometric TiO2 layer is advantageous. However, contacting the two semiconductors directly would result in a high recombination of the free charge carriers and thus low currents in the cell, due to band mismatch. By adding a transport layer between the two materials, for example a tunnel recombination junction, an improved current flow can be achieved. Within this work, the development of such a transport layer is presented in order to integrate a sub-stochiometric TiO2 photoanode on a Si wafer. For this purpose, the optoelectronic properties of the two semiconductor materials are characterized to select a suitable transport layer material by simulating the band alignment with AFORS-HET. Based on these results, a possible transport layer is developed and integrated into the tandem structure for electrochemical characterization.

[1] G. Segev et al., In: Nature materials, 17(12):1115-1121, 2018. doi: 10.1038/s41563-018-0198-y

#### DS 20.50 Wed 16:00 P3

Hybrid thin film for H2 evolution applications — •MORGAN LE D $\hat{v}^1$ , MANUEL ANDREE REUS¹, KUN SUN¹, ZERUI LI¹, CRISTIANE HENSCHEL², ANDRE LASCHEWSKY^{2,3}, SIGIRD BERNSTORFF⁴, and PETER MÜLLER-BUSCHBAUM^{1,5} — ¹TU München, Physik-Department, LS Funktionelle Materialien, 85748 Garching — ²Universität Potsdam, Institut für Chemie, 14476 Potsdam-Golm — ³Fraunhofer Institut für Angewandte Polymerforschung, 14476 Postdam-Golm — ⁴Elettra-Sincrotrone Trieste, Basovizza, 34149 Trieste, Italy — ⁵MLZ, TU München, 85748 Garching

Photocatalysis via water splitting reaction is a way to implement the sun to produce hydrogen-based energy. Recently, Pt loaded graphitic carbon nitride (gCN) has been found has a promising photocatalyst for H2 evolution under visible light. The aim of this work is to bring this material in a polymer thin film configuration to make it suitable for industrial purposes. Poly(N-isopropylacrylamide) exhibits good swelling capacity of water vapor and seems to be suitable for such a hybrid thin film system. A new isomer of PNIPAM, poly(N-vinylisobutyramide) (PNVIBAM) raised our attention due to its higher lower critical solution temperature (LCST) in aqueous solution ( $\approx 39^{\circ}C$ ) which makes it more stable in ambient environment. Spray coating has been chosen to be the deposition technique of PNVIBAM/g-CN/Pt hybrid films. A comparative study of the photocatalyst concentrations is presented. Grazing incident small angle x-ray scattering is the main tool of this work. G-CN/Pt blended polymer films structure is analysed under light irradiation condition.

#### DS 20.51 Wed 16:00 P3

Fabrication and electrochemical characterization of 2D membranes — •YOSSARIAN LIEBSCH — Universität Duisburg-Essen, AG Schleberger, Germany Membranes are critical components in widely used industrial and technical processes, *e.g.*, water filtration, desalination and energy storage and conversion. With their extreme thinness of only a few angstrom, two-dimensional (2D) materials have the potential to be used as highly efficient membranes, possibly outperforming conventional membranes by orders of magnitude. We fabricated two different types of 2D membranes: Membranes made of commercially available CVD-grown graphene and membranes made of self grown CVD MoS₂. The membranes were made by transferring the 2D material onto a 3  $\mu$ m micropore. Subsequently the membranes were plasma etched (graphene) or irradiated Thursday

by highly charged ions  $(MoS_2)$  in order to create nanopores. Raman and photoluminescence spectroscopy was used to analyse the membranes in terms of doping, stress and defects density. Additionally an electrochemical characterization of the membranes was done in a custom build membrane potential measurement stand. In case of the graphene membranes the measured membrane potentials were in good agreement to the well-known Theorell-Meyer-Sievers Theory. However for the  $MoS_2$  membranes no potential could yet be measured. In upcoming experiments with this electrochemical cell we aim to investigate the correlations between the pore creation mechanisms and intrinsic membrane properties like pore size, pore chemistry and surface charge density.

Surface-Diffusion Control Enables Tailored-Aspect-Ratio Nanostructures in Area-Selective Atomic Layer Deposition — •Philip Klement¹, Daniel Anders¹, Lukas Gümbel¹, Michele Bastianello¹, Fabian Michel¹, Jörg Schörmann¹, Matthias T. Elm^{1,2}, Christian Heiliger³, and Sangam Chatterjee¹ — ¹Institute of Experimental Physics I & Center for Materials Research (ZfM), Justus Liebig University Giessen, Giessen, Germany — ²Institute of Physical Chemistry, Justus Liebig University Giessen, Giessen, Germany — ³Institute of Theoretical Physics & Center for Materials Research (ZfM), Justus Liebig University Giessen, Germany

Area-selective atomic layer deposition is a key technology for modern microelectronics as it enables material deposition only in specific areas. Typically, the selectivity originates from surface modifications of the substrate that allow or block precursor adsorption. The control of the deposition process currently remains a major challenge as the selectivity of the no-growth areas is lost quickly. Here, we show that surface modifications of the substrate strongly manipulate the surface diffusion. The selective deposition of TiO2 on poly (methyl methacrylate) and SiO2 yields localized nanostructures with tailored aspect ratios. Controlling the surface diffusion allows to tune such nanostructures as it boosts the growth rate at the interface of the growth and no-growth areas. Kinetic Monte-Carlo calculations reveal that species move from high to low diffusion areas.

#### DS 21.2 Thu 9:45 H14

Molecular-beam epitaxy of Cd- and Nb-containing  $Bi_x Se_y$ -based compounds for novel topological materials — •Christoph Ringkamp¹, Abdur Rehman Jalil², Erik Zimmermann¹, Peter Schüffelgen¹, Thomas Schäpers¹, Gregor Mussler¹, and Detlev Grützmacher¹ — ¹PGI-9, Forschungszentrum Jülich — ²PGI-10, Forschungszentrum Jülich

Topological insulators (TIs) have gained a lot of interest in recent years because of their unique topologically protected surface states. Prominent examples of 3-dimensional topological insulators are Bi₂Te₃, Sb₂Te₃, and Bi₂Se₃ and alloys thereof. The combination of TI with superconductors and using the proximity effect to induce superconductivity in the TI is of fundamental interest in physics and may direct a possible avenue towards novel applications in the field of quantum computation. Here the successful deposition of Cd- and Nbcontaining Bi_xSe_y films by molecular beam epitaxy is reported. Carefully adjusting the growth parameter, single-crystal CdBi₂Se₄ and (BiSe)_{1.10}NbSe₂ thin films have been grown on sapphire substrates. For both materials, transmission electron microscopy images reveal the expected stacking sequences of atomic layers within the deposited films, indicating the presence of the anticipated stoichiometry. First data of the electrical transport of (BiSe)_{1.10}NbSe₂, films show superconducting behavior with a transition temperature of 0.4 K.

### DS 21.3 Thu 10:00 H14

Growth and Characterization of Epitaxial (Cr1-xMnx)2GaC MAX Phase Thin Films by Pulsed Laser Deposition — •IVAN TARASOV, HANNA PAZNIAK, MICHAEL FARLE, and ULF WIEDWALD — Faculty of Physics and Center for Nanointegration (CENIDE), University of Duisburg-Essen, 47057 Duisburg, Germany

Due to their nanolaminated structure, tunable chemistry, and high oxidation resistance, MAX phases (where M is an early transition metal, A is a main group element, and X is carbon or nitrogen) are interesting materials for a wide variety of applications. The partial substitution of M atoms is one of the ways to tailor their properties to specific applications. In this study, we grow (Cr1-xMnx)2GaC MAX phase films to fine-tune their magnetic response by stoichiometry variations for x = 0-1. High-quality epitaxial (Cr1-xMnx)2GaC MAX phase films (thickness 30 * 100 nm) are synthesized by pulsed laser deposition on MgO (111) substrates using (Mn50Cr50)66Ga34, Mn0.66Ga0.34, Cr66Ga34 and C targets. The combination of structural and morphological characterization reveals a strong competition between the (Cr1-xMnx)2GaC MAX phase and (Cr1xMnx)3GaC, (Cr1-xMnx)3Ga phases. We suppress the formation of side phases by variation of the growth temperature and the formation of seed layers. Vibrating sample magnetometry of the MAX phase reveals increasing magnetization and ordering temperature with increasing Mn content. Funding by the Deutsche Forschungs*gemeinschaft (DFG) within CRC/TRR 270, project B02 (Project-ID 405553726) is gratefully acknowledged.

#### DS 21.4 Thu 10:15 H14

**Optical Quantizing Structures in Al2O3/TiO2 Heterostructures by Plasma Enhanced Atomic Layer Deposition (PEALD)** — •PALLABI PAUL^{1,2} and ADRIANA SZEGHALMI^{1,2} — ¹Friedrich Schiller University Jena, Germany — ²Fraunhofer Institute for Applied Optics and Precision Engineering, Jena, Germany

Atomically thin heterostructures are promising candidates for various optoelectronic and photonic applications. Here we present on the properties of Al2O3/TiO2 nano-composites grown by PEALD. The growth, dispersion relation, optical bandgap and composition of such structures are systematically studied by means of UV/VIS spectrophotometry, ellipsometry, XRR, STEM, and XPS techniques. The refractive index and the indirect bandgap of the heterostructures depend on the ratio of the two oxides, while the bandgap is very sensitive to the thicknesses of the barrier and quantum well layers. A large blue shift of the absorption edge from 400 nm to 320 nm is obtained by changing the TiO2 (quantum well) thickness from 2 nm to 0.1 nm. PEALD unfolds the possibility of achieving optical quantizing effects within complex heterostructures enabling control of their structures down to atomic scale. Selected compositions are identified for applications in antireflection coatings at 355 nm wavelength. Interference multilayers of TiO2/Al2O3 composites as high refractive index material and SiO2 as the low refractive index show very low reflectance and optical losses at 355 nm wavelength with transmittance values of approximately 99%. Such heterostructures overcome the limitations of the low bandgap dielectric TiO2 for optical applications in the UV spectral range.

Calculation of Elastic Properties in Monolayer Covalent-Organic Frameworks — •David Bodesheim¹, Antonios Raptakis¹, Jonathan Heinze¹, AREZOO DIANAT¹, ROBERT BIELE¹, ALEXANDER CROY², and GIANAURELIO CUNIBERTI¹ — ¹TU Dresden, Dresden, Germany — ²FSU Jena, Jena, Germany Covalent-Organic Frameworks (COFs) are crystalline porous materials that are based on organic monomeric units, so called building blocks. Through recent experimental progress, mono- and few-layer COF materials have been synthesized, providing a new class of 2D materials.[1,2] From a computational point of view, however, accurately calculating properties of these materials is demanding as their unit cells are usually very big. In this work, we calculate elastic properties for a multitude of 2D COFs in a high-throughput manner. The calculations are based on classical force-fields and are compared with higher level of theory like density functional based tight binding (DFTB). We show how force-fields can be very useful for mechanical property calculation, how their accuracy can be improved, and typical fallacies for 2D COFs. Furthermore, we introduce models to predict mechanical properties from the properties of their monomeric building blocks.[3] This paves the way for accurate multiscale modeling, high-throughput calculations, and materials design with properties on demand.

Light-Matter Interaction in 2D Polar Metals — •MARGAUX LASSAUNIÈRE¹, WEN HE², KATHARINA NISI¹, SHRUTI SUBRAMANIAN³, SIAVASH RAJABPOUR³, ALEXANDER VERA³, NATHALIE BRIGGS³, SU YING QUEK², JOSHUA ROBINSON³, and URSULA WURSTBAUER¹ — ¹Institut of Physics, Münster University, Germany — ²Department of Physics, National University of Singapore, Singapore — ³MatSE; Center for 2DLM; ATOMIC; 2D Crystal Consort.; Penn State University, USA

Understanding and controlling the light-matter interaction in thin metal films is of high technological relevance. Here, we study the linear optical response of atomically thin 2D gallium, 2D indium as well as their alloys embedded in half-van der Waals heterostructures by spectroscopic imaging ellipsometry. The thin films are prepared via confinement heteroepitaxy (Chet). In a systematic study of the dielectric functions, we separate free and bound electron contributions to the optical response, with the latter pointing towards the existence of thickness-dependent quantum confinement phenomena and epsilon near zero (ENZ) behaviour [1]. The resonance energies of the observed ENZ behaviour are dependent on the number of atomic metal layers, materials, and alloying [2]. Their tunability makes 2D polar metals attractive for quantum engineered metal films, tunable (quantum-)plasmonics and nano-photonics.

Layer dependent anisotropic dielectric function of the magnetic semiconductor CrSBr — •PIERRE-MAURICE PIEL¹, MARGAUX LASSAUNIÈRE¹, JULIAN KLEIN², and URSULA WURSTBAUER¹ — ¹Institute of Physics, Muenster University, Germany — ²Department of Materials Science and Engineering, Massachusetts Institute of Technology, USA

The van der Waals (vdW) material CrSBr is a 2D magnetic semiconductor with ferromagnetic ordering within each layer. Adjacent layers, however, are coupled antiferromagnetically. As a vdw semiconductor with a direct band gap, the light matter interaction is determined by strong excitonic resonances that are highly anisotropic in the crystal plane. We experimentally determine the complex dielectric function in the near infrared to visible regime along the two main crystal directions by spectroscopic imaging ellipsometry (SIE) measurements and regression analysis to a multilayer model. Unlike other vdW semiconductors such as MoS2 or WSe2 [1], the rich excitonic signatures in the dielectric function are highly anisotropic and show only minor distinct dependence on the number of layers. Even more striking, we find that the excitonic resonance are better pronounced for multilayer compared to monolayer CrSBr with significantly reduced line-width even at room temperature. #### DS 22.4 Thu 10:15 H17

Tracing the Superconducting Phase Transition in Atomically Thin 2D Polar Gallium by Transport and Spectroscopic Ellipsometry — •JAKOB HENZ¹, MARGAUX LASSUNIÈRE¹, PIERRE-MAURICE PIEL¹, SIAVASH RAJABPOUR², ALEXANDER VERA², JOSHUA ROBINSON², and URSULA WURSTBAUER¹ — ¹Institute of Physics, Muenster University, Germany — ²MatSE; Center for 2DLM; Atomic; 2D Crystal Consort, PennState University, USA Location: H17

Half van der Waals 2D polar metals are a novel class of 2D materials, realized by confinement heteroepitaxial growth (CHet). Hereby, metal atoms such as gallium or indium are intercalated between graphene and a silicon carbide substrate. This results in large area, environmentally stable, 2D metals with a bonding gradient in z-direction ranging from covalent over metallic to vdW within only two to three atomic layers. The materials feature interesting properties such as superconductivity¹ and a large plasmonic response in the visible range². 2D gallium is studied by temperature dependent spectroscopic ellipsometry and transport measurements down to below 1K. We extract the dielectric function in the visible to near infrared range with a special focus on signatures across the phase transition from metallic to superconducting behavior unambiguously identified from the abrupt drop in the temperature dependent sheet resistance at the transition temperature  $T_C$  of about 3.5 K.

DS 22.5 Thu 10:30 H17

Epitaxial growth of  $Fe_{5-x}GeTe_2$  films with a Curie temperature above 300 K on graphene — Hua Lv¹, JENS HERFORT¹, JÜRGEN SCHUBERT², MICHAEL HANKE¹, MANFRED RAMSTEINER¹, and •JOAO MARCELO J. LOPES¹ — ¹Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V., Germany — ²Peter Grünberg Institut (PGI-9), Forschungszentrum Jülich, Germany

Synthesis of magnetic 2D materials exhibiting transition temperatures at or above 300 K is a crucial step towards the development of ultra-compact spintronic devices. Here, we report our recent progress on epitaxial growth of the 2D ferromagnet Fe_{5-x}GeTe₂ via MBE on graphene on SiC(0001). Thin films with a thickness of about 10 nm and different Fe concentrations were studied. Characterization performed with methods such as in-situ RHEED and grazing incidence X-ray diffraction confirmed the formation of epitaxial layers with good crystalline quality. Magneto-transport measurements and SQUID magnetometry were employed to assess the electrical and magnetic properties. They reveal that the MBE-grown Fe_{5-x}GeTe₂ exhibits a metallic behavior for all investigated Fe concentrations. In addition, composition-dependent magnetic anisotropies and Curie temperatures  $(T_C)$  were deduced. For the Fe content close to 5, a predominant easy out-of-plane orientation and  $\mathrm{T}_{\mathrm{C}}$  well above 300 K were measured. These results are relevant for the further development of wafer-scale fabrication of magnetic 2D materials aiming at the realization of multifunctional, atomically thin devices.

#### DS 22.6 Thu 10:45 H17

Antisymmetric magnetoresistance in a Fe₃GeTe₂-Fe₃GeTe₂ van der Waals ferromagnetic homojunction — •JAN BÄRENFÄNGER¹, KENJI WATANABE², TAKASHI TANIGUCHI², JONATHAN EROMS¹, DIETER WEISS¹, and MARIUSZ CIORGA¹ — ¹Institut für Experimentelle und Angewandte Physik, Universität Regensburg, 93040 Regensburg, Germany — ²NIMS, 1-1 Namiki, Tsukuba, Ibaraki 305-0044, Japan

The emergence of novel two-dimensional (2D) magnetic van der Waals (vdW) materials have breathed new life into the field of spintronics. The weak vdW interaction between layers of strong covalent bonds enables the exfoliation of these materials down to monolayers. Furthermore, vdW heterostructures can easily be fabricated by stacking them on top of each other like LEGO blocks, bringing a platform for novel spintronic devices. Here, we report an antisymmetric magnetoresistance (MR) in an Fe3GeTe2-Fe3GeTe2 (FGT) vdW homojunction. We attribute it to eddy currents emerging at the interface of the antiparallel, perpendicular-to-plane magnetized FGT flakes, due to the different sign of the anomalous Hall effect in both flakes. These eddy currents perturb the measured longitudinal resistance, resulting in the observation of a sign change of the MR when measuring the voltage drop along the opposite edges of the transport channel. This work highlights the potential for new spintronic applications using vdW ferromagnets.

#### DS 22.7 Thu 11:00 H17

Charge-transfer stabilization, modulation doping, and CDW phase in layered ferecrystal heterostructures — •FABIAN GÖHLER¹, SHRINIDHI RAMASUBRAMANIAN¹, SANAM K. RAJAK¹, NIELS RÖSCH¹, ADRIAN SCHÜTZE¹, SUSANNE WOLFF¹, MARISA CHOFFEL², DMITRI L. M. CORDOVA², DAVID C. JOHNSON², and THOMAS SEYLLER¹ — ¹Chemitz University of Technology, 09126 Chemnitz, Germany — ²University of Oregon, Eugene 97403, USA

A virtually unlimited number of metastable, layered heterostructures - called *fer*ecrystals due to the non-epitaxial alignment between layers - can be grown via the self-assembly of layered amorphous precursors. [1] In this contribution, we want to highlight recent investigations on the electronic structure and interlayer interactions in several series of compounds using photoemission spectroscopy (PES). In the Bi-Mo-Se system, the formation of the metallic 1T-polytype of  $MoSe_2$  is aided by charge transfer from rock-salt structured BiSe. By systematically stacking BiSe,  $Bi_2Se_3$ , and  $MoSe_2$ , the mechanisms which stabilize these structures can be understood. [2]

Compounds prepared from PbSe and  $VSe_2$  layers show charge transfer between layers as well, allowing to tune transport properties via modulation doping. Additionally, the emergence of a charge density wave in the  $VSe_2$  layers has been reported below 100 K [3], and was investigated by angle-resolved PES.

DS 22.8 Thu 11:15 H17

Impact of opto-electronic measurements on the properties of hexagonal boron nitride as a dielectric — •JO BERTRAM¹, LUCA KOTEWITZ¹, MANFRED ERSFELD¹, FRANK VOLMER¹, KENJI WATANABE², TAKASHI TANIGUCHI³, CHRISTOPH STAMPFER¹, and BERND BESCHOTEN¹ — ¹2nd Institute of Physics

and JARA-FIT, RWTH Aachen University, 52074 Aachen, Germany — ²Research Center for Functional Materials, National Institute for Materials Science, Tsukuba, Japan — ³International Center for Materials Nanoarchitectonics, National Institute for Materials Science, Tsukuba, Japan

Hexagonal boron nitride (hBN) serves as an atomically flat, insulating substrate for a large variety of 2D heterostructures. However, recent opto-electronic experiments showed that optically triggered leakage currents passing through hBN pose a serious bottleneck for reliable gating of 2D semiconductors [1]. Motivated by these observations, we report on photo-induced charge transport through hBN in graphite-hBN-graphite devices. Furthermore, we examine the impact of illuminating hBN employed as a gate dielectric on the charge carrier density of graphene Hall bar devices. Our results indicate that hBN exhibits optically active electronic states, which partially screen the gate electric field under light illumination. Interestingly, we observe a strong asymmetry of this effect for positive and negative electric fields showing that hBN does not behave as an ideal dielectric within the plate capacitor model especially in opto-electronic experiments. DS 23: Optical Analysis of Thin Films (Reflection, Ellipsometry, Raman, IR-DUV Spectroscopy, ...)

Time: Thursday 10:45-12:15

DS 23.1 Thu 10:45 H14 Raman characterisation of composite thin films of PEDOT:PSS and Cu2ZnSnS4 nanocrystals — •YEVHENII HAVRYLIUK^{1,2,3}, VOLODYMYR DZHAGAN³, OLEKSANDR SELYSHCHEV^{1,2}, and DIETRICH R.T. ZAHN^{1,2} — ¹Semiconductor Physics, Chemnitz University of Technology, Chemnitz, Germany — ²Center for Materials, Architectures, and Integration of Nanomembranes (MAIN), Chemnitz, Germany — ³V.E. Lashkaryov Institute of Semiconductor Physics NAS of Ukraine, Kyiv, Ukraine

The increasing demand for renewable energy sources powers the high research interest in the fields of photovoltaics and thermoelectrics. One of the materials promising in these fields are Cu2ZnSnS4 (CZTS) family compounds. CZTS nanocrystals (NCs) for third generation photovoltaics can be obtained by low-temperature "green" colloidal synthesis. Another material widely studied especially for thermoelectric applications is PEDOT:PSS. Usually these two materials are used as separate layers in devices. However, using them in a composite layer probably can reveal even more interesting properties. Therefore, we investigated such composite films with different polymer/NC ratios. Raman spectroscopy was used as a main characterization method. We detected the modification of the structure of PEDOT:PSS films upon incorporation of NCs and found that the formation of the CZTS NCs films using a drop-casting method occurs differently in the PEDOT:PSS/CZTS composite under intense laser irradiation, in comparison with the pure components, was also investigated.

#### DS 23.2 Thu 11:00 H14

dielectric function of Al(1-x)ScxN obtained by spectroscopic ellipsometry. — •YOUNES SLIMI¹, REBECCA PETRICH¹, RÜDIGER SCHMIDT-GRUND¹, HAUKE-LARS HONIG², CHRISTINA HELM³, HEIKE BARTSCH³, JENS MÜLLER³, PETER SCHAAF², and STEFAN KRISCHOK¹ — ¹Fachgebiet Technische Physik I, IMN Macro Nano, Technische Universität Ilmenau, 98693 Ilmenau — ²Fachgebiet Werkstoffe der Elektrotechnik, Institut für Werkstofftechnik und Institut für Mikro-und Nanotechnologien MacroNano, Technische Universität Ilmenau, 98693 Ilmenau — ³Fachgebiet Elektroniktechnologie, Technische Universität Ilmenau, IMN Macro Nano, 98693 Ilmenau

Scandium Aluminum Nitride alloy (ScxAl1-xN) thin films were prepared via the sputtering technique. The samples then were measured by spectroscopic ellipsometry (SE) and analysed to determine the sample's dielectric function (DE) by means of numeric b-spline and line shape model dielectric functions. We found a redshift of the bandgap (Eg) and an increasing refractive index with increasing Sc content. As AlN is hexagonal and ScN cubic, the birefringence also reduces when Sc is incorporated into the alloy. Therefore, the samples were measured with XRD and EDX to determine the crystal structure and lattice constant as a function of Sc percentage.

**Analysis of CVD coatings with Raman spectroscopy** — •MAXIMILIAN VON ROEDER, PETER J. KLAR, and SANGAM CHATTERJEE — Institute of Experimental Physics I, Giessen, Germany

The interphase between fibre and matrix is an important component in the preparation of ceramic matrix composites. The understanding of the nature of the coating is crucial for the optimization of CMC materials. Chemical vapour infiltration is the most frequent method of fibre coating. Homogenity, low error density and controlled thickness are the key properties that the coating has to satisfy. Most characterization methods for the coating are very local probes. We ap-

#### Location: H14

plied rough Raman mapping measurements together with principal component analysis to get a broader picture for a larger sample. We studied SiC Hi-Nicalon S fibres with BN/SiC and C coating prepared by chemical vapour infiltration. With a data filtering algorithm to erase the raman spectra of the background we were able to obtain a colour coded maps of the samples. We tested this method with different samples where we introduced errors of different magnitude to determine the sensitivity of the approach. This method provides a quick and easy way to examine a sample with the extensions up to a few centimeters. In this fashion it is possible to study a larger fraction of a prepared material which leads to a higher reliability in quality control.

#### DS 23.4 Thu 11:30 H14

**Time-resolved femtosecond ellipsometry** — •SHIRLY ESPINOZA — ELI Beamlines, Institute of Physics, Czech Academy of Science, Prague, Czech Republic The ellipsometry technique is well extend for the study of thin film material. Thanks to femtosecond pulse lasers, we developed a time-resolved femtosecond ellipsometry technique, where a pump beam from any wavelength between 200 nm and 2000 nm excite the material and second pulse, the probe beam, with a continuous spectrum from 350 nm * 750 nm measure the dielectric function of the material. The pump and the probe beam can be separated in time from femtoseconds until nanoseconds generating a time-scan of the relaxation of the material. The time-resolved ellipsometry technique is available to the scientific community at the user-oriented infrastructure ELI Beamlines located few kilometers from Prague, Czech Republic. Examples of successful experiments will be presented and the details of how to apply for beamtime will be shared.

#### DS 23.5 Thu 11:45 H14

Chalcogenides for Photonic Applications in the Visible - •FELIX HOFF¹, Carl-Friedrich Schoen¹, Maximilian Mueller¹, Yiming Zhou¹, Peter Kerres¹, Häser Maria¹, and Matthias Wuttig^{1,2,3} - ¹I. Institute of Physics (IA), RWTH Aachen University – ²Juelich-Aachen Research Alliance (JARA FIT and JARA HPC) — ³PGI 10 (Green IT), Forschungszentrum Juelich GmbH Due to its large bandgap, the chalcogenide phase-change material (PCM)  $\rm Sb_2S_3$ is interesting for photonic applications, such as photonic switches in the visible range. Recent publications report contradictory findings concerning the switching speed. Since this property is decisive for many applications, it is important to better understand the crystallization process. To understand glass dynamics and crystallization kinetics, calorimetric measurements were performed. In addition, the optical properties were measured by optical spectroscopy and Ellipsometry. Supporting density functional theory (DFT) calculations are used and a comparison with typical PCMs is made. Sb₂S₃ has significant optical contrast in the visible spectral range, but lower maximum contrast than typical PCMs. It has been shown that crystallization takes significantly longer and has a broader stochastic distribution than for typical PCMs. Furthermore, crystallization occurs from the undercooled liquid phase for a range of heating rates which span over six orders of magnitude, so the glass transition could be studied. Our observations can be explained by the covalent bonding of Sb₂S₃. They can be understood in the context of a quantum mechanical map, which can be utilized to design materials for photonic applications.

Visualization of metallic filament formation in rare-earth nickelates via optical microscopy — •THEODOR LUIBRAND¹, STEFAN GUÉNON¹, FARNAZ TAHOUNI-BONAB¹, JAVIER DEL VALLE², CLARIBEL DOMÍNGUEZ², WILLEM RISCHAU², LUCIA VARBARO², STEFANO GARIGLIO², RODOLFO ROCCO³, SOUMEN BAG³, MARCELO ROZENBERG³, JEAN-MARC TRISCONE², REINHOLD KLEINER¹, and DIETER KOELLE¹ — ¹Physikalisches Institut, Center for Quantum Science (CQ) an LISA⁺, Universität Tübingen, 72076 Tübingen, Germany — ²Department of Quantum Matter Physics, Université de Genève, 1211 Geneva, Switzerland — ³Université Paris-Saclay, CNRS, Laboratoire de Physique des Solides, 91405 Orsay, France

In recent years, there has been growing interest in resistive switching in strongly correlated materials. Resistive switching is at the core of memristive devices, which are considered as crucial elements in the emerging field of neuromorphic computing. However, in many systems, the details of the resistive switching mechanisms are elusive. We investigated the resistive switching of two types of rare-earth nickelate (NdNiO₃ and SmNiO₃) thin film devices. Both materials undergo insulator-to-metal transitions (IMT) from low-temperature antiferro-magnetic or paramagnetic insulating to high-temperature paramagnetic metallic phases. Current-voltage characteristics acquired at device temperatures near the IMT show jumps towards lower voltages indicating resistive switching. We find that these events are accompanied by the formation of spatially confined conducting filaments, which is revealed by a change in reflectivity in optical images.

#### DS 25.2 Thu 15:15 H14

Towards ultraclean correlated metal CaVO₃ - Electric Transport Measurements — •MAHNI MÜLLER¹, TATIANA KUZNETSOVA², ROMAN ENGEL-HERBERT^{2,3}, and SASKIA F. High-performance and cost-effective transparent materials are in great demand in the optoelectronic industry. The enhancement of the carrier effective mass through strong electron-electron interactions in correlated metals is a promising approach to achieve both high-optical transparency and high-electrical conductivity [1].

In this work we study the electric transport characteristics of CaVO₃ films with a thickness of 55 nm grown on LAO substrates. The films were deposited by hybrid molecular beam epitaxy with different partial pressures of the metalorganic vanadium oxytriisopropoxide precursor. Calcium was supplied through a solid state effusion cell. The optimal growth window estimated by X-ray diffraction was narrowed down by residual-resistance ratio (*RRR*) measurements. Temperature dependent resistivity and hall measurements were performed between 4.2 K and 300 K. The *RRR* was tripled compared to previous substrate [2]. Furthermore, the films with highest *RRR*  $\approx$  98 showed an increase of mobility with decreasing temperature with over 2000  $\frac{\text{CM}}{\text{CN}}$  at 4.2 K.

DS 25.3 Thu 15:30 H14 at the Insulator to Metal Transition in

Electro-Thermal Resistive Switching at the Insulator to Metal Transition in Strongly Correlated Materials — •STEFAN GUÉNON¹, MATTHIAS LANGE¹, YOAV KALCHEIM^{2,3}, THEODOR LUIBRAND¹, FARNAZ TAHOUNI¹, REINHOLD KLEINER¹, IVAN K SCHULLER², and DIETER KOELLE¹ — ¹Physikalisches Institut, Center for Quantum Science (CQ) and LISA⁺, Universität Tübingen, 72076 Tübingen, Germany — ²Department of Physics and Center for Advanced Nanoscience, University of California - San Diego La Jolla, CA 92093, USA — ³Department of Materials Science and Engineering, Technion - Israel Institute of Technology, Technion City, 32000 Haifa, Israel

Electro-thermal (Joule-heating driven) resistive switching devices are investigated in the emerging field of neuromorphic computing. In a bio-mimetic approach, the memristive properties of such devices are used to emulate neurons and synapses. This talk explains how the considerable resistance change at the insulator-to-metal transition leads to electro-thermal instability. A metallic filament forms above a certain threshold current due to current and temperature redistribution if a device is electrically biased in this unstable temperature regime. We will complement the explanation with experimental results from microscopic studies on  $V_2O_3$ -devices, in which photomicrographs were acquired during filament formation. Further, we will discuss how additional device properties like thermal hysteresis or structural phase separation affect electro-thermal resistive switching. The U.S. Department of Energy supported this work under Award # DE-SC0019273.

DS 25.4 Thu 15:45 H14

**Parallel field magnetoconductance in epitaxial bismuth quantum films** — •JULIAN KOCH¹, DOAA ABDELBAREY², PHILIPP KRÖGER², PRIYANKA YOGI², CHRISTOPH TEGENKAMP¹, and HERBERT PFNÜR² — ¹Institut für Physik, TU Chemnitz, Reichenhainerstr. 70, 09126 Chemnitz — ²Institut für Festkörperphysik, Leibniz Universität Hannover, Appelstraße 2, 30167 Hannover

The magnetoconductance (MC) of epitaxial Bi films on Si(111) (thickness 20-100 bilayers) was measured at T = 9 K in magnetic fields oriented in-plane parallel and perpendicular to the electric dc current *I*. Contributions to MC by weak antilocalization (WAL), by weak localization (WL) as well as by diffuse scattering were identified, which all turned out to be independent of the angle between *B* and *I*. In addition, only for  $B \perp I$  a contribution to MC was found that *increases* with increasing *B* and is, to first approximation,  $\propto B^2$ . It is ascribed to ballistic scattering between the Rashba-split interfaces that allow Umklapp scattering without spin flip.

At small thicknesses the MC curves are dominated by WAL originating from the surface/interface states. However, the coupling between the interfaces, necessary for the observation of WAL in an in-plane B-field, happens through quantized bulk states instead of tunneling. Moreover, the admixing of the quantized bulk states with increasing film thickness not only increases diffuse scattering, but also modifies the WAL component, effectively introducing a WL-like component, above 50 BL. Thus, our findings suggest an intriguing interplay in magnetotransport between 2D and quantized 3D states.

### DS 26: Thin Oxides and Oxide Layers 2

Time: Thursday 16:15-17:15

#### DS 26.1 Thu 16:15 H14

Studying the differences of Ga2O3 grown by conventional molecular-beam epitaxy (MBE) and suboxide MBE (S-MBE) — •SUSHMA RAGHUVANSY¹, JUSTIN A. BICH¹, TJARK LIESTMANN¹, JONATHAN MCCANDLESS², MANUEL ALONSO-ORTS¹, DARRELL G. SCHLOM³, MARTIN EICKHOFF¹, and PATRICK VOGT^{1,3} — ¹Institute of Solid-State Physics, Bremen University, Otto-Hahn-Allee 1, 28359 Bremen, Germany — ²School of Electrical and Computer Engineering, Cornell University, Ithaca, New York 14853, USA — ³Department of Materials Science and Engineering, Cornell University, Ithaca, New York 14853, USA

The growth of Ga2O3 by conventional MBE, i.e., when supplying elemental Ga and active O, is limited by the formation and subsequent desorption of its volatile suboxide, Ga2O. During suboxide MBE (S-MBE), a recently developed new MBE variant, suboxides (here: Ga2O) are supplied during growth, bypassing the reaction limiting steps experienced during conventional Ga2O3 MBE growth by conventional MBE, and extending its kinetic and thermodynamic limits. S-MBE enables the synthesis of Ga2O3 at much higher growth rates (> 1  $\mu$ m h-1) and displays improved crystallinity and surface morphology compared with Ga2O3 thin films grown by conventional MBE.

This talk presents a direct comparison of Ga2O3 thin films grown by conventional MBE versus Ga2O3 thin films grown by S-MBE. We will show the impact of both MBE variants on the crystallinity and surface morphology of Ga2O3/Al2O3 heterostructures.

#### DS 26.2 Thu 16:30 H14

**Comparative Study of a Ga2O3 nucleation layer and its impact on Ga2O3 growth on Al2O3 by molecular beam epitaxy** — •ALEXANDER KARG, ADRIAN MESSOW, MANUEL ALONSO-ORTS, STEPHAN FIGGE, PATRICK VOGT, and MARTIN EICKHOFF — Institute of Solid-State Physics, University Bremen, Bremen, Germany

Ga2O3 is a wide bandgap semiconductor and is seen as a promising candidate for e.g. future high-power electronics, and UV-detectors. The availability of single crystalline substrates makes the material attractive for device fabrication. Because of easier access, the majority of experiments were carried out by heteroepitaxy on e.g. Al2O3 substrates. In this study, the influence of the Al2O3 substrate on the nucleation and layer growth is investigated and compared with the use of a beta-Ga2O3 buffer layer to mimic homoepitaxial conditions. It was found that the effective Me to O ratio on the surface differs substantially and the amount of the available species (especially active oxygen) for growth could be estimated with respect to the different growth surfaces (0001) Al2O3 and (-201) beta-Ga2O3. This study was transferred to In2O3 growth to determine the different oxidation efficacies of the cations Indium and Gallium. Furthermore, the influence of the plasma power on the nucleation behavior of Ga2O3 and In2O3 as well as its influence on the growth kinetics itself and the layer properties will be discussed.

### Location: H14

DS 26.3 Thu 16:45 H14

The effect of post-growth annealing of titanium dioxide thin films prepared by a sol-gel process on the photocatalytic activity — •Lu He¹, Shuo Niu¹, DIETRICH.R.T. ZAHN^{1,2}, and TERESA I. MADEIRA^{1,2} — ¹Technische Universität Chemnitz, Semiconductor Physics, D-09107 Chemnitz, Germany — ²Center for Materials, Architectures and Integration of Nanomembranes (MAIN), Chemnitz University of Technology, 09107 Chemnitz, Germany

TiO2 thin films revealed competitive performance for photocatalytic applications[1,2]. Here, a set of TiO2 thin films are synthesized using a sol-gel process and spin coated on p-type Si(100) substrates with a native oxide layer. The asdeposited thin films are annealed at various temperatures from 400 to 800  $^{\circ}$ C for 3 hours in ambient conditions.

Characterization is performed using various methods[3] on phases (UV-Raman & X-Ray diffractometry), film thickness and optical constants (Spectroscopic ellipsometry), morphology(Atomic Force Microscopy). Photocatalytic results on photodegradation of acetone to CO2 are obtained in a self-designed gas (reactant)-solid (photocatalyst) reaction chamber. The decrease/increase of acetone/CO2 is monitored via in-situ Fourier Transform Infrared Spectroscopy.

Quantitative data analysis is performed and correlated to indicate the effect of post annealing on the optical and structural properties of the titanium dioxide thin films and their photocatalytic activities.

**Oxidation behavior of SMART alloys and MAX phases materials and applicability in solar receivers.** — •LEONARDO GUIMARÃES LEAL LEALDINI¹, ANDREY LITNOVSKY^{1,2}, and JESUS GONZALEZ-JULIAN^{1,3} — ¹Forschungszentrum, Jülich GmbH, 52425 Jülich, Germany — ²115409 Moscow, Russia — ³Institute of Mineral Engineering, RWTH Aachen University, 52064 Aachen, Germany

In the concept of materials for high-temperature application, two types of are being investigated: SMART alloys and MAX phase materials. W-Cr-Y SMART alloys were first designed for future fusion power plants. Studies suggests that SMART alloy containing Cr and Y is capable of forming a Cr2O3 layer and maintaining it at 1273K which avoids the generation of tungsten oxide. MAX Phase materials are able to provide great properties like oxidation resistance at high temperatures. Cr2AIC and Ti2AIC are two MAX phases that, in initial studies, provided a good oxidation response. Studies showed that Cr2AIC MAX phase and W-Cr-Y SMART alloy when exposed to 1273K and in humid atmosphere present good resistance to oxidation. Both were capable of withstand more than 20 hours in these conditions with a gain of mass lower than 0.3g/cm2. The main objective of this research is to evaluate the feasibility of both MAX phase materials and propose a new W-AI-Y SMART alloy, using them as solar receivers in concentrated solar power plants.

### DS 27: 2D Materials 10 (joint session HL/CPP/DS)

Time: Friday 9:30–12:00

See HL 42 for details of this session.

				Lina Jaurigue, Felix Köster, •Kathy Lüdge

### Invited Talks of the joint Symposium SKM Dissertation Prize 2022 (SYSD)

See SYSD for the full program of the symposium.

SYSD 1.1	Mon	10:15-10:45	H2	Charge localisation in halide perovskites from bulk to nano for efficient optoelectronic applications — •SASCHA FELDMANN
SYSD 1.2	Mon	10:45-11:15	H2	Nonequilibrium Transport and Dynamics in Conventional and Topological Supercon- ducting Junctions — •RAFFAEL L. KLEES
SYSD 1.3	Mon	11:15-11:45	H2	Probing magnetostatic and magnetotransport properties of the antiferromagnetic iron
SYSD 1.4	Mon	11:45-12:15	H2	oxide hematite — •Andrew Ross Quantum dot optomechanics with surface acoustic waves — •Matthias Weiss

### Invited Talks of the joint Symposium United Kingdom as Guest of Honor (SYUK)

See SYUK for the full program of the symposium.

SYUK 1.1	Wed	9:30-10:00	H2	Structure and Dynamics of Interfacial Water — • ANGELOS MICHAELIDES
SYUK 1.2	Wed	10:00-10:30	H2	A molecular view of the water interface — • MISCHA BONN
SYUK 1.3	Wed	10:30-11:00	H2	Motile cilia waves: creating and responding to flow — •PIETRO CICUTA
SYUK 1.4	Wed	11:00-11:30	H2	Cilia and flagella: Building blocks of life and a physicist's playground — •OLIVER BÄUM-
				CHEN

SYUK 1.5	Wed	11:45-12:15	H2	Computational modelling of the physics of rare earth - transition metal permanent mag-
				nets from SmCo ₅ to Nd ₂ Fe ₁₄ B — •Julie Staunton
SYUK 2.1	Wed	15:00-15:30	H2	Hysteresis Design of Magnetic Materials for Efficient Energy Conversion - •OLIVER
				Gutfleisch
SYUK 2.2	Wed	15:30-16:00	H2	Non-equilibrium dynamics of many-body quantum systems versus quantum technolo-
				gies — •Irene D'Amico
SYUK 2.3	Wed	16:00-16:30	H2	Quantum computing with trapped ions — •Ferdinand Schmidt-Kaler
SYUK 2.4	Wed	16:45-17:15	H2	Breaking the millikelvin barrier in cooling nanoelectronic devices — •RICHARD HALEY
SYUK 2.5	Wed	17:15-17:45	H2	Superconducting Quantum Interference Devices for applications at mK temperatures –
				•Sebastian Kempf

# Invited Talks of the joint Symposium Interplay of Substrate Adaptivity and Wetting Dynamics from Soft Matter to Biology (SYSM)

See SYSM for the full program of the symposium.

SYSM 1.1	Wed	15:00-15:30	H1	Statics and Dynamics of Soft Wetting — • Bruno Andreotti
SYSM 1.2	Wed	15:30-16:00	H1	Droplets on elastic substrates and membranes - Numerical simulation of soft wetting —
				•Sebastian Aland
SYSM 1.3	Wed	16:00-16:30	H1	Wetting of Polymer Brushes in Air — Lars Veldscholte, Guido Ritsema van Eck, Liz
				Mensink, Jacco Snoeijer, •Sissi de Beer
SYSM 1.4	Wed	16:45-17:15	H1	Elastocapillary phenomena in cells — • ROLAND L. KNORR
SYSM 1.5	Wed	17:15-17:45	H1	Active contact line depinning by micro-organisms spreading on hydrogels – MARC
				Hennes, Julien Tailleur, Gaëlle Charron, •Adrian Daerr

### Invited Talks of the joint Symposium Collective Social Dynamics from Animals to Humans (SYSO)

See SYSO for the full program of the symposium.

SYSO 1.1	Thu	9:30-10:00	H1	Capturing group interactions: The next frontier of modeling social and biological systems
				— •Frank Schweitzer
SYSO 1.2	Thu	10:00-10:30	H1	Modelling Individual Mobility Behavior — •Laura Maria Alessandretti
SYSO 1.3	Thu	10:30-11:00	H1	Validating argument-based opinion dynamics with survey experiments — • SVEN BANISCH
SYSO 1.4	Thu	11:15-11:45	H1	Self-organization, Criticality and Collective Information Processing in Animal Groups
				— •Pawel Romanczuk
SYSO 1.5	Thu	11:45-12:15	H1	Collective dynamics and physiological interactions in bird colonies — •HANJA BRANDL

### Invited Talks of the joint Symposium Complexity and Topology in Quantum Matter (SYQM)

See SYQM for the full program of the symposium.

SYQM 1.1	Fri	9:30-10:00	H1	The role of crystalline symmetries in topological materials: the topological materials database — •MAIA VERGNIORY
SYQM 1.2	Fri	10:00-10:30	H1	Microwave Bulk and Edge Transport in HgTe-Based 2D Topological Insulators — •Erwann Bocquillon, Matthieu C. Dartiailh, Alexandre Gourmelon, Hiroshi Kamata, Kalle Bendias, Simon Hartinger, Jean-Marc Berroir, Gwendal Fève, Bernard Plaçais, Lukas Lunczer, Raimund Schlereth, Hartmut Buhmann, Laurens Molenkamp
SYQM 1.3	Fri	10:30-11:00	H1	Spectral Sensitivity of Non-Hermitian Topological Systems — •JAN CARL BUDICH
SYQM 1.4	Fri	11:15-11:45	H1	Topological photonics and topological lasers with coupled vertical resonators — •SEBASTIAN KLEMBT
SYQM 1.5	Fri	11:45-12:15	H1	Spectroscopic Studies of the Topological Magnon Band Structure in a Skyrmion Lattice — •Markus Garst

Sessions

DY 1.1–1.3	Sun	16:00-18:30	H4	Tutorial: Stochastic Processes from Financial Risk to Genetics (joint session
				SOE/TUT/BP/DY)
DY 2.1–2.1	Mon	9:30-10:00	H18	Invited Talk Martin Oettel

# Members' Assembly of the Dynamics and Statistical Physics Division

Thursday 18:30-19:15 H19

### Sessions

- Invited Talks, Tutorials, Contributed Talks, and Posters -

### DY 1: Tutorial: Stochastic Processes from Financial Risk to Genetics (joint session SOE/TUT/BP/DY)

Macroscopic and microscopic models from Economy to Biology must account for stochasticity on various levels. While classical physics strives for deterministic descriptions through differential equations from fundamental level to thermodynamics, many physics-based models on higher level explicitely include stochasticity from various sources. Discrete and continuous stochastic processes then become the mathematical foundation of these models. This tutorial highlights classical as well as current methods and approaches of probabilistic models and stochastic processes in physics, biology as well as socio-economic systems, thereby bridging the risk to extinction in genetics with its economic counterpart. (Session organized by Jens Christian Claussen.)

Time: Sunday 16:00-18:30

See SOE 1 for details of this session.

### DY 2: Invited Talk Martin Oettel

Time: Monday 9:30-10:00

#### **Invited Talk**

DY 2.1 Mon 9:30 H18 Roughness growth modes in thin film growth — •MARTIN OETTEL — Uni Tübingen, Institut für Angewandte Physik

Thin film growth is one of the fundamental nonequilibrium processes in statistical physics and it is also very relevant for applications. In the past years, experimental attention has shifted from the growth of metallic films (with fairly isotropic particles) to growth of organic films with possibly very anisotropic particles. In view of applications, the film morphology (notably the film roughness) is a central object of interest. To study that, we employ simple lattice models for isotropic and anisotropic particles to elucidate principal film growth modes with a focus on the intermediate thickness regime. For isotropic particles we find 4 principal growth modes with fairly sharp transitions between them [1]. E.g., a dynamic layering transition separates layer-by-layer and island growth and can be viewed as a nonequilibrium counterpart of wetting/layering transitions. Anisotropy in the interactions between the lattice particles does not change the roughness growth modes but adds further orientational transitions [2]. Further, we have studied monolayer growth for lattice particles which are also anisotropic in their hard-core shape. There, the deposition process corresponds to trajectories in the space of macroscopic order parameters (density, orientation) which connect rather small equilibrium domains and which describe generalized nucleation and arrest processes.

### DY 3: Statistical Physics far from Thermal Equilibrium

Time: Monday 10:00-12:30

#### DY 3.1 Mon 10:00 H18

Relaxation to a parity-time symmetric generalized Gibbs ensemble after a quantum quench in a driven-dissipative Kitaev chain — •ELIAS STARCHL and LUKAS SIEBERER — Institute for Theoretical Physics, University of Innsbruck, Austria

After a quench, isolated thermalizing quantum many-body systems relax locally to an equilibrium state that is universally determined by conservation laws and the principle of maximum entropy. In contrast, open quantum systems, subjected to Markovian drive and dissipation, typically evolve toward nonequilibrium steady states that are highly model-dependent. However, focusing on a driven-dissipative Kitaev chain, we show that relaxation after a quantum quench can be described by a maximum entropy ensemble, if the Liouvillian governing the dynamics has parity-time (PT) symmetry. We dub this ensemble, which is determined by the biorthogonal eigenmodes of the adjoint Liouvillian, the PTsymmetric generalized Gibbs ensemble (PTGGE). Resembling isolated systems, thermalization becomes manifest in the growth and saturation of entanglement, and the relaxation of local observables. In contrast, the directional pumping of fermion parity represents a phenomenon that is unique to relaxation dynamics in driven-dissipative systems. We expect that our results apply rather generally to integrable, driven-dissipative bosonic and fermionic quantum many-body systems with PT symmetry.

#### DY 3.2 Mon 10:15 H18

Finite-time dynamical phase transition in non-equilibrium relaxation — •JAN Меївонм 1,2  and Massimiliano Esposito $^1 - {}^1$ Complex Systems and Statistical Mechanics, Department of Physics and Materials Science, University of Luxembourg, L-1511 Luxembourg, Luxembourg – ²Department of Mathematics, King's College London, London WC2R 2LS, United Kingdom

We uncover a finite-time dynamical phase transition in the thermal relaxation of a mean-field magnetic model. The phase transition manifests itself as a cusp singularity in the probability distribution of the magnetization that forms at a critical time. The transition is due to a sudden switch in the dynamics, characterized by a dynamical order parameter. We derive a dynamical Landau theory for the transition that applies to a range of systems with scalar, parity-invariant order parameters. Close to criticalilty, our theory reveals an exact mapping between the dynamical and equilibrium phase transitions of the magnetic model, and implies critical exponents of mean-field type. We argue that interactions between nearby saddle points, neglected at the mean-field level, may lead to critical, spatiotemporal fluctuations of the order parameter, and thus give rise to novel, dynamical critical phenomena.

#### DY 3.3 Mon 10:30 H18

Mori-Zwanzig formalism for general relativity: a new approach to the averag**ing problem**^{*} – •MICHAEL TE VRUGT¹, SABINE HOSSENFELDER², and RAPHAEL WITTKOWSKI¹ – ¹Institut für Theoretische Physik, Center for Soft Nanoscience, Westfälische Wilhelms-Universität Münster, D-48149 Münster, Germany -²Frankfurt Institute for Advanced Studies, D-60438 Frankfurt am Main, Germanv

Cosmology provides a coarse-grained description of the universe that is valid on very large length scales. However, the Einstein field equations are not valid for coarse-grained quantities since, due to their nonlinearity, they do not commute with an averaging procedure. Thus, it is unclear in which way small-scale inhomogeneities affect large-scale cosmology (backreaction). In this work [1], we address this problem by extending the Mori-Zwanzig projection operator formalism, a highly successful coarse-graining method from statistical mechanics, towards general relativity. This allows to derive a dynamic equation for the Hubble parameter in which backreaction is taken into account through memory and noise terms. Our results are linked to cosmological observations.

Synthetic horizons in 1D tight-binding model and thermalisation of the many-body groundstate — •LOTTE MERTENS^{1,2}, ALI G. MOGHADDAM^{2,3}, DMITRY CHERNYAVSKY², CORENTIN MORICE¹, JEROEN VAN DEN BRINK^{2,4}, and JASPER VAN WEZEL¹ — ¹Institute for Theoretical Physics and Delta Institute for Theoretical Physics, University of Amsterdam, 1090 GL Amsterdam, The Netherlands — ²Institute for Theoretical Solid State Physics, IFW Dresden, Helmholtzstr. 20, 01069 Dresden, Germany — ³Department of Physics, Institute for Advanced Studies in Basic Sciences (IASBS), Zanjan 45137-66731, Iran — ⁴Institute for Theoretical Physics and Wurzburg-Dresden Cluster of Excellence ct.qmat, Technische Universitat Dresden, 01069 Dresden, Germany

Open problems in general relativity have motivated the search for analogue gravitational systems in condensed matter implementations. In one such system, a 1D tight-binding model with position-dependent hopping, the possibility of realizing an analogue gravitational horizon has recently been demonstrated. Here, we introduce the concept of emergent temperature, inspired by Unruh radiation, and show that it arises naturally in tight-binding lattice models featuring a horizon. Despite finding many similarities between the emergent lattice temperature and the gravitational Unruh temperature, we show that the nature of the thermal spectrum in the lattice theory is radically different from that in the continuum limit. Additionally, we provide a detailed analysis of outgoing radiation showing the conditions under which the horizon behaves purely as a thermal source.

#### DY 3.5 Mon 11:00 H18

**Renormalized Fluctuation Expansion for Non-Equilibrium Disordered Networks** – •MICHAEL DICK^{1,2,3}, ALEX VAN MEEGEN^{1,4}, and MORITZ HELLAS^{1,5} – ¹Institute of Neuroscience and Medicine (INM-6) and Institute for Advanced Simulation (IAS-6) and JARA-BRAIN Institute I, Jülich Research Centre, 52425 Jülich, Germany – ²Department of Computer Science 3 - Software Engineering, RWTH Aachen University, Aachen, Germany – ³Peter Grünberg Institut (PGI-1) and Institute for Advanced Simulation (IAS-1), Jülich Research Centre, 52425 Jülich, Germany – ⁴Institute of Zoology, University of Cologne, 50674 Cologne, Germany – ⁵Department of Physics, Faculty 1, RWTH Aachen University, Aachen, Germany

It is frequently hypothesized that cortical networks display hallmarks of critical dynamics. Such critical dynamics are beyond the validity of a mean-field approximation because it inherently neglects fluctuations. Thus, a renormalized theory is necessary. We consider an archetypal neural network model which displays a magnetic as well as a chaotic transition. Based on the analogue of a quantum effective action, we derive self-consistency equations for the first two renormalized Greens functions. Their self-consistent solution reveals critical slowing down near the transition to the ferromagnetic state and an optimal level of disorder which favors collective behavior. The quantitative theory explains the shape of the single-unit autocorrelation function, featuring multiple temporal scales, and the population autocorrelation function.

DY 3.6 Mon 11:30 H18

Modeling flash sintering conditions with Boltzmann equations — •MAGDULIN DWEDARI, LOTHAR BRENDEL, and DIETRICH WOLF — University of Duisburg-Essen, Lotharstraße 1, 47057 Duisburg

In a flash sintering experiment, a suitable combination of electric field and furnace heating is applied to the sample, which makes it possible to sinter it in a matter of seconds and at significantly lower temperatures compared to conventional sintering. An established hypothesis that explains the key signatures of a flash sintering event, such as a surge in conductivity, is that the electric field causes a rapid generation of Frenkel defects in the sample. With molecular dynamic simulations it has been confirmed that a phonon proliferation at the Brioullin-Zone edge can cause a Frenkel defect concentration  $10^{15}$  times higher than the thermal concentration.

To study the effects of an electric field on the phonon distribution, we model the electron system governed by an electric field and the phonon system coupled to an external heat bath with two coupled Boltzmann equations. The key difference to previous work exciting the electron system via a laser pulse is that our excita-

tion term models the effects of the electric field and is therefore continuous and imposes a cylindrical symmetry.

**Barrier crossing in a viscoelastic bath** — •FÉLIX GINOT¹, JULIANA CASPERS², MATTHIAS KRÜGER², and CLEMENS BECHINGER¹ — ¹Fachbereich Physiks Universität Konstanz, 78457 Konstanz, Germany — ²Georg-August Universität Göttingen, 37073 Göttingen, Germany

The activated, i.e., fluctuation-assisted hopping of a Brownian particle across an energy barrier  $\Delta U$  is a fundamental process with important applications across science, such as in chemical reactions, protein folding, or drug absorption. Such processes can be rationalized using Kramers theory, which predicts the hopping rate  $v \propto \exp(-\Delta U/k_{\rm B}T)$  with  $k_{\rm B}T$  the thermal energy, in agreement with experimental observations. Many systems, however, cannot be described in terms of a single degree of freedom, notably when memory effects need to be taken into account. In this work we experimentally investigate barrier crossing of a Brownian particle in a double-well potential suspended in a viscoelastic solvent which exhibits non-Markovian behavior, i.e., memory. For potential barriers up to several  $k_{\rm B}T$  we find the hopping dynamics to be characterized not by a single but by two time scales which can differ by more than two orders of magnitude. While the long time scale increases exponentially with  $\Delta U$  (as in Kramers theory), the short one is almost unaffected by the barrier height. The latter results from elastic energy fluctuations of the viscoelastic bath due to excitations arising from the particle's hopping motion. Our results, which are in agreement with a simple model where the fluid is described as a Maxwell medium, have immediate consequences for the above examples, e.g., altering the interpretation and prediction of lifetimes.

Scalar Active Mixtures: The Nonreciprocal Cahn-Hilliard Model — •SUROPRIYA SAHA¹, JAIME AGUDO-CANALEJO¹, and RAMIN GOLESTANIAN^{1,2} — ¹Department of Living Matter Physics, Max Planck Institute for Dynamics and Self-Organization — ²Rudolf Peierls Centre for Theoretical Physics, University of Oxford

Pair interactions between active particles need not follow Newton's third law. In this work, we propose a continuum model of pattern formation due to nonreciprocal interaction between multiple species of scalar active matter. The classical Cahn-Hilliard model is minimally modified by supplementing the equilibrium Ginzburg-Landau dynamics with particle-number-conserving currents, which cannot be derived from a free energy, reflecting the microscopic departure from action-reaction symmetry. The strength of the asymmetry in the interaction determines whether the steady state exhibits a macroscopic phase separation or a traveling density wave displaying global polar order. The latter structure, which is equivalent to an active self- propelled smectic phase, coarsens via annihilation of defects, whereas the former structure undergoes Ostwald ripening. The emergence of traveling density waves, which is a clear signature of broken timereversal symmetry in this active system, is a generic feature of any multicomponent mixture with microscopic nonreciprocal interactions.

Quantum thermodynamics of nonadiabatically driven systems: The effect of electron-phonon interaction — •JAKOB BÄTGE¹, AMIKAM LEVY³, WENJIE DOU², and MICHAEL THOSS¹ — ¹Institute of Physics, University of Freiburg, Freiburg,Germany — ²Department of Physics, School of Science, Westlake University, Hangzhou, China — ³Department of Chemistry, Bar-Ilan University, Ramat-Gan, Israel

The development and optimization of quantum devices have increased the interest in dynamics and thermodynamics of systems on the scale of single atoms and molecules. In this contribution, we investigate the nonequilibrium quantum dynamics of a driven nanosystem with two different approaches. By comparing results from the numerically exact hierarchical equations of motion method [1] and a Markovian quantum master equation [2], we analyze non-Markovian effects in the system dynamics. Furthermore, we discuss nonadiabatic effects in thermodynamic quantities induced by electronic-vibrational coupling.

Lattice Boltzmann simulations of dense suspensions of soft particles with interface viscosity — •FABIO GUGLIETTA¹, OTHMANE AOUANE¹, FRANCESCA PELUSI¹, MARCELLO SEGA¹, and JENS HARTING^{1,2} — ¹Helmholtz Institute Erlangen-Nürnberg, Germany — ²Department of Chemical and Biological Engineering and Depart- ment of Physics, FAU Erlangen-Nüremberg, Germany

Interface viscosity (IV) plays a major role in the dynamics of single droplets and viscoelastic capsules by influencing their transient dynamics and steady-state deformation. For example, it has recently become clear that numerical models for red blood cells must include IV to account for their realistic description. Therefore, IV can be expected to play a significant role in determining also the dynamics and rheology of their dense suspensions. However, as no detailed inves-

tigation exists on the effects of IV in the dense suspensions of soft capsules, we aim to fill this gap by including it in computational fluid dynamics models. Here, we address this problem for the first time by performing numerical simulations in the framework of the immersed boundary - lattice Boltzmann method. This approach proved to be a valid numerical tool to provide a realistic description of soft particles immersed in Newtonian fluids. We employ a recent numerical model to account for IV by relying on the discretised Boussinesq-Scriven tensor, which provides a continuum description of a 2D viscous fluid. We show that the IV influences (a) the time it takes for particles to deform during the transient phase and (b) the final shape of the particles in the steady-state at different volume fraction values.

#### DY 4.2 Mon 10:15 H19

Wetting dynamics of droplets: an immersed boundary lattice Boltzmann approach — •FRANCESCA PELUSI¹, OTHMANE AOUANE¹, FABIO GUGLIETTA¹, MARCELLO SEGA¹, and JENS HARTING^{1,2} — ¹Helmholtz Institute Erlangen-Nürnberg, Germany — ²Department of Chemical and Biological Engineering and Department of Physics, FAU, Germany

Many applications in computational fluid dynamics require the immersed boundary (IB) method to couple the dynamics of well-defined structures with that of a surrounding fluid. If the latter is simulated with a lattice Boltzmann (LB) method, the resulting IBLB approach is known to be a very versatile tool, for example, in studying dense suspensions of red blood cells. However, little attention has been devoted so far to applying this approach to substrate wetting problems. Here, we report on an IBLB-based investigation of the wetting of droplets interacting with a solid surface. In our model, the droplet surface tension contributes to the force the droplet (structure) communicates to the surrounding fluid. We characterize Newtonian droplets' static and dynamic contact angles and show how surface/IB-nodes interaction tuning allows obtaining the desired wetting properties. Furthermore, the flexibility of the IBLB approach will enable us to model non-Newtonian surface rheology, opening the possibility of simulating the unusual wetting behavior of gallium droplets. Indeed, liquid gallium develops an oxide layer at the liquid surface when in contact with the oxygen, which affects its adhesive properties with significant consequences for its high-tech applications, such as catalysis.

#### DY 4.3 Mon 10:30 H19

Viscosity-induced Destabilization of a Liquid Sheet in Inertial Microfluidics — •KUNTAL PATEL and HOLGER STARK — Institut für Theoretische Physik, Technische Universität Berlin, Berlin, Germany

Lab-on-a-chip devices based on inertial microfluidics function between Stokes and turbulent regimes, which enables to achieve high throughput. In the present work, we study the motion of a liquid sheet of thickness  $t_s$  and viscosity  $\mu_1$  in a two-dimensional microchannel of width w, filled with a viscous fluid (viscosity  $\mu_2$ ,  $m = \mu_2/\mu_1 > 1$ ). At finite Reynolds number Re, a small perturbation at the interfaces separating the sheet from the surrounding fluid can result in a rapid destabilization of interfaces and may lead to a break-up. The present work gives a proof-of-concept of how viscosity-driven interfacial instability can be exploited for a controlled droplet production in inertial microfluidics. Such microfluidic droplets are utilized in food and pharmaceutical related applications and as chemical reactors in Lab-on-a-chip devices.

In our computational linear stability analysis based on the Orr-Sommerfeld equation, we observe that the growth rate of the fastest growing mode  $\xi^*$  increases with Re. Furthermore, the dependence of  $\xi^*$  on *m* and  $t_s$  is quantified by the scaling law  $\xi^* \propto m t_s^{2.5}$ , which is valid for thin sheets in moderate Re flows with relatively weak interfacial tension  $\Gamma$ . In the second part, our lattice Boltzmann simulations starting from a single-mode perturbation of wavelength  $\lambda$  reveal that the interfacial instability causes the liquid sheet to break up and ultimately to form droplets when  $\lambda \geq 0.5w$ . We also identify different interface breakup mechanisms leading to droplet formation.

Imaging, Analysis and Sorting in Microfluidic Systems: Correlative Multi-Contrast, Multi-Parameter Applications — •Tobias Neckernuss¹, Patricia Schwilling², Jonas Pfeil^{1,2}, Daniel Geiger¹, and Othmar Marti² — ¹Sensific GmbH — ²Institute for Experimental Physics, Ulm University

Droplet-based microfluidics is a promising approach in biology, pharmacy, medicine, and lab-on-a-chip applications. One remaining problem is the lack of a suitable fast image-based detection method that enables droplet- and contentbased analysis and sorting with rates fast enough to be sufficient for highthroughput measurements and to enable surveilled lab scale production. We demonstrate recent advances for high-speed, real-time, image-based analysis and manipulation of microfluidic systems. With rates of up to 3000 particles or droplets per second we show applications of our system in the field of dropletbased microfluidics. Here, we concentrate on droplet-content analysis and have a sneak look at further potential applications in biology and image-based cell analysis. We introduce new contrast types for image-based analysis like brightfield, darkfield, phase contrast, fluorescence and combinations thereof. Combining new cutting edge hardware technology with specifically tailored software and integration of external lab infrastructure enables us reach new dimensions in image based particle analysis and sorting.

DY 4.5 Mon 11:15 H19 the obstacle effect on soft sphere discharging in quasi-2D silo — •JING WANG¹, KIRSTEN HARTH^{1,2}, DMITRY PUZYREV¹, and RALF STANNARIUS¹ — ¹Institute of Physics, Otto von Guericke University Magdeburg, Universitätsplatz 2, D-39106 Magdeburg, Germany — ²Department of Engineering, Brandenburg University of Applied Sciences, Magdeburger Straße 50, D-14770 Brandenburg an der Havel, Germany

Soft smooth particles in silo discharge show their own characteristics, for example, non-permanent clogging and intermittent flow. We conduct experiment on soft, low-frictional hydrogel spheres compred with hard, frictional spheres in a quasi-2D silo. We introduce a competitive behavior of these spheres during their discharge by placing an obstacle in front of the outlet of the silo. High-speed optical imaging is applied to capture the process of discharge. By the method of particle tracking velocimetry (PTV), the fields of velocity, egress time, packing fraction, and kinetic stress are analysed in the study.

DY 4.6 Mon 11:30 H19

**Coalescence of isotropic and nematic droplets in quasi 2D liquid crystal films** — •CHRISTOPH KLOPP, ALEXEY EREMIN, and RALF STANNARIUS — Institute for Physics, Otto von Guericke University Magdeburg, Germany

Coalescence of droplets is ubiquitous in nature and modern technology. Various experimental and theoretical studies explored droplet dynamics in three dimensions (3D) and on two-dimensional (2D) solid or liquid substrates, e.g. [1-3]. Here, we demonstrate coalescence of isotropic and nematic droplets in quasi-2D liquids, viz. overheated smectic A freely suspended films. We investigated their dynamics experimentally and measured the shape deformation during the entire merging process using high-speed imaging and interferometry. This system is a unique example where the lubrication approximation can be directly applied, and the smectic membrane plays the role of a precursor film. Our studies reveal the scaling laws of the coalescence time depending on the droplet size and the material parameters. We also compared the dynamics of isotropic and nematic droplets and additionally analyzed the results based on an existing model for liquid lens coalescence on liquid and solid surfaces [4].

This study was supported by DLR and DFG within the OASIS and OASIS-Co projects WM2054 and STA 425/40.

Using feedback-controlled thermoviscous flows to precisely position microparticles — •Elena Erben, Antonio Minopoli, Nicola Maghelli, Ben-JAMIN SEELBINDER, ILIYA D. STOEV, SERGEI KLYKOV, and MORITZ KREYSING — Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany Optical positioning of microscale objects has proven key for advancing fundamental biological research and holds great potential for other disciplines as well. The most widely used among these methods are optical tweezers which enable the precise control and manipulation of multiple particles. However, they require probes of high refractive index contrast and low absorption and exclude the use of photosensitive samples. Here we present a novel optofluidic technique that leverages optical-control capabilities and the gentle nature of hydrodynamic flows, thus lifting the aforementioned constraints. Our approach is based on optically-induced thermoviscous flows generated by the repeated scanning of a moderately heating infrared laser beam [1]. We have combined thermoviscous flows with feedback control to confine micron-sized particles with a precision of up to 24 nm without exposing them directly to laser light [2]. Recently, we extended this approach beyond single-object manipulation to further enable simultaneous control of multiple particles. With this contribution, we furthermore discuss combinations with implicit force sensing [3] and the potential for future application in and beyond the life science sector.

Anomalous hydrodynamics and exact quantum scars in frustration-free Hamiltonians — •JONAS RICHTER and ARIJEET PAL — University College London, UK

We study the interplay between quantum scarring and weak Hilbert-space fragmentation in a class of one-dimensional spin-1 frustration-free projector Hamiltonians, known as deformed Motzkin chain. We show that the particular form of the projectors causes the emergence of disjoint Krylov subspaces, with an exact quantum scar being embedded in each subspace, leading to slow growth of entanglement and localized dynamics for specific out-of-equilibrium initial states. Focusing on infinite temperature, we unveil that spin transport is subdiffusive, which we corroborate by simulations of constrained stochastic cellular automaton circuits. Compared to dipole moment conserving systems, the deformed Motzkin chain belongs to a different universality class with distinct dynamical transport exponent and only polynomially many Krylov subspaces. Based on J. Richter and A. Pal, Phys. Rev. Research 4, L012003 (2022).

DY 5.4 Mon 10:45 H20 Influence functional of quantum many-body systems — •Alessio Lerose, MICHAEL SONNER, JULIAN THOENNISS, and DMITRY ABANIN — University of Geneva, Switzerland

Feynman-Vernon influence functional (IF) was originally introduced to describe the effect of a quantum environment on the dynamics of an open quantum system. We apply the IF approach to describe quantum many-body dynamics in isolated spin systems, viewing the system as an environment for its local subsystems. While the IF can be computed exactly only in certain many-body models, it generally satisfies a self-consistency equation, provided the system, or an ensemble of systems, are translationally invariant. We view the IF as a fictitious wavefunction in the temporal domain, and approximate it using matrix-product states (MPS). This approach is efficient provided the temporal entanglement of the IF is sufficiently low. We illustrate the versatility of the IF approach by analyzing several models that exhibit a range of dynamical behaviors, from thermalizing to many-body localized, in both Floquet and Hamiltonian settings. The IF approach offers a new lens on many-body non-equilibrium phenomena, both in ergodic and non-ergodic regimes, connecting the theory of open quantum systems theory to quantum statistical physics. DY 5.5 Mon 11:00 H20

**Transition from localized to uniform scrambling in locally hyperbolic systems** — •MATHIAS STEINHUBER, JUAN-DIEGO URBINA, and KLAUS RICHTER — University of Regensburg, Regensburg, Germany

A major signature of Quantum Chaos is the fast scrambling of quantum correlations, quantified by the exponential initial (pre-Ehrenfest time) growth of out-of-time-order correlators (OTOCs) and by their later saturation. As previously shown by [1] and [2], there is a significant difference in the short time dynamics of the OTOCs in integrable systems around hyperbolic fixed points depending on the initial state being localized or uniform (high-temperature). In these cases, the exponential regime is given respectively by twice the instability-exponent  $\lambda$  of the hyperbolic fixed point. We show that a local wave-packet can have a clear *dynamical* transition between these two reported exponential-regions within the pre-Ehrenfest-time regime. Thus, the question arises on how to decide, based on the properties of the hyperbolic fixed point which of the two scenarios applies in each particular situation.

**Optimal route to quantum chaos in the Bose-Hubbard model** — LUKAS PAUSCH^{1,2}, EDOARDO CARNIO^{1,2}, ANDREAS BUCHLEITNER^{1,2}, and •ALBERTO RODRÍGUEZ³ — ¹Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, Hermann-Herder-Straße 3, D-79104, Freiburg, Germany — ²EUCOR Centre for Quantum Science and Quantum Computing, Albert-Ludwigs-Universität Freiburg, Hermann-Herder-Straße 3, D-79104, Freiburg, Germany — ³Departamento de Física Fundamental, Universidad de Salamanca, E-37008 Salamanca, Spain

The dependence of the chaotic phase of the Bose-Hubbard Hamiltonian [1,2] on particle number N, system size L and particle density is investigated in terms of spectral and eigenstate features. We analyze the development of the chaotic phase as the limit of infinite Hilbert space dimension is approached along different directions, and show that the fastest route to chaos is the path at fixed density  $n \leq 1$  [3]. The limit  $N \rightarrow \infty$  at constant L leads to a slower convergence of the chaotic phase towards the random matrix theory benchmarks. In this case, from the distribution of the eigenstate generalized fractal dimensions, the ergodic phase becomes more distinguishable from random matrix theory for larger N, in a similar way as along trajectories at fixed density.

Observation of phase synchronization and alignment during free induction decay of quantum spins with Heisenberg interactions — •JÜRGEN SCHNACK¹, HEINZ-JÜRGEN SCHMIDT², CHRISTIAN SCHRÖDER³, and PATRICK VORNDAMME¹ — ¹Universität Bielefeld — ²Universität Osnabrück — ³Fachhochschule Bielefeld

Equilibration of observables in closed quantum systems that are described by a unitary time evolution is a meanwhile well-established phenomenon apart from a few equally well-established exceptions. Here we report the surprising theoretical observation that integrable as well as non-integrable spin rings with nearest-neighbor or long-range isotropic Heisenberg interaction not only equilibrate but moreover also synchronize the directions of the expectation values of the individual spins (New J. Phys. 23 (2021) 083038). We highlight that this differs from spontaneous synchronization in quantum dissipative systems. In our numerical simulations, we investigate the free induction decay (FID) of an ensemble of up to N = 25 quantum spins with s = 1/2 each by solving the time-dependent Schrödinger equation numerically exactly. Our findings are related to, but not fully explained by conservation laws of the system. The phenomenon very robust

against for instance random fluctuations of the Heisenberg couplings. Synchronization is not observed with strong enough symmetry-breaking interactions such as the dipolar interaction and is also not observed in closed-system classical spin dynamics.

DY 5.8 Mon 12:00 H20 Long-lived coherence in driven spin systems: from two to infinite spatial dimensions — •WALTER HAHN^{1,2,3} and VIATCHESLAV DOBROVITSKI^{2,4} — ¹Fraunhofer IAF, Fraunhofer Institute for Applied Solid State Physics, Freiburg, Germany — ²QuTech, Delft University of Technology, Lorentzweg 1, 2628 CJ Delft, The Netherlands — ³Institute for Quantum Optics and Quantum Information of the Austrian Academy of Sciences, Innsbruck, Austria — ⁴Kavli Institute of Nanoscience, Delft University of Technology, Lorentzweg 1, 2628 CJ Delft, The Netherlands

Long-lived coherences, emerging under periodic pulse driving in the disordered ensembles of strongly interacting spins, offer immense advantages for future quantum technologies but the physical origin and the key properties of this phenomenon remain poorly understood. We theoretically investigate this effect in ensembles of different spatial dimensionality, and predict existence of the long-lived coherences in all such systems, from two-dimensional to infinitedimensional, which are of particular importance for quantum sensing and quantum information processing. We explore the transition from two to infinite dimensions and show that the long-time coherence dynamics in all dimensionalities is qualitatively similar, although the short-time behavior is drastically different exhibiting dimensionality-dependent singularity

DY 5.9 Mon 12:15 H20

A Flow Equation Approach to Many-Body Localisation — •STEVEN THOMSON — Dahlem Centre for Complex Quantum Systems, Freie Universität Berlin Many-body localisation is a fascinating example of a scenario in which interacting quantum systems isolated from their environments can fail to thermalise, usually due to some form of disorder. Key to our understanding of this enigmatic phase of matter are emergent conserved quantities known as local integrals of motion (LIOMs, or l-bits), which prevent thermalisation from occurring. In this talk, I will present a powerful new numerical method known as the tensor flow equation technique ideally suited for computing LIOMs.

I will demonstrate how this method can be used to compute the integrals of motion in a variety of different systems, including disorder-free potentials and models of spinful fermions. I will show how this method gives an insight into the nature of many-body localisation in these different models, with LIOMs that retain a strong 'fingerprint' of the underlying potential, and will show that in some cases the method can also predict the onset of a delocalised phase. I will end by outlining promising future applications of the method, including to periodically driven and dissipative systems.

DY 5.10 Mon 12:30 H20

Towards a dictionary between JT gravity and periodic orbit theory — •TORSTEN WEBER, FABIAN HANEDER, JUAN-DIEGO URBINA, and KLAUS RICHTER — University of Regensburg, Germany

Periodic orbit theory is a far reaching development of the semiclassical methods where the most fundamental signatures of the quantum nature of closed systems, like the discreteness of their energy spectrum, emerges from interference between amplitudes constructed from the classical properties of periodic solutions [1]. This conceptual basis, leading to the celebrated Gutzwiller trace formula, has provided impressive achievements from quantum transport to atomic physics and multi-particle scattering. In particular, together with the necessary existence of periodic orbit bunching in ergodic systems, it has lead to an understading of the emergence of universal spectral correlations in chaotic systems, the BGS conjecture [2].

We report our progress in studying how a loss of information (characterized by a coarse graining of classical bunches of orbits) at the level of the trace formula implies the emergence of genus-like expansions with formally the same structure as the solution of JT quantum gravity found in [3]. Our work thus gives convincing hints toward a possible dictionary between quantum-gravitational and periodic orbit objects and concepts.

**Estimating covariant Lyapunov vectors from data** — •NAHAL SHARAFI, CHRI-STOPH MARTIN und SARAH HALLERBERG — Hamburg University of Applied Sciences, Hamburg, Germany

Covariant Lyapunov vectors characterize the directions along which perturbations in dynamical systems grow. They have also been studied as predictors of critical transitions and extreme events. For many applications, it is necessary to estimate these vectors from data since model equations are unknown for many interesting phenomena. We propose a novel approach for estimating covariant Lyapunov vectors based on data records without knowing the underlying equations of the system. In contrast to previous approaches, our approach can be applied to high-dimensional datasets. We demonstrate that this purely data-driven approach can accurately estimate covariant Lyapunpov vectors from data records generated by low and high-dimensional dynamical systems. Additionally we test for the robustness against noise in a low-dimensional dynamical system.

DY 8.2 Mon 15:15 H18 Extending the limits of Electrochemical Impedance Spectroscopy with Machine Learning and Digital Twins — •LIMEI JIN^{1,2}, FRANZ P. BERECK², CHRISTIAN H. BARTSCH², JOSEF GRANWEHR², RÜDIGER-A. EICHEL², KARSTEN REUTER¹, and CHRISTOPH SCHEURER¹ — ¹Fritz-Haber-Institut der MPG, Berlin, Germany — ²IEK-9, Forschungszentrum Jülich, Jülich, Germany Electrochemical impedance spectroscopy (EIS) is widely used to characterize electrochemical energy conversion systems. The traditional analysis with equivalent circuit models (ECM) has recently been augmented by a transform based distribution of relaxation times (DRT) analysis which allows one to reduce the ambiguity in the construction of ECMs and thus overfitting. Yet, DRT, just like most traditional analyses, is firmly based in the linear response regime as well as based on frequency sweeps on a logarithmic scale. The latter makes these approaches time-consuming, the first limits their scope severely. To develop novel experimental spectroscopic excitation schemes that address these limitations, a model space of sufficiently realistic systems is required that substitutes for time-consuming measurements in terms of a digital twin. We present a joint experimental and theoretical approach for the construction of such a target space for the case of battery cell performance and ageing behaviour.

DY 8.3 Mon 15:30 H18

Bayesian approach to anticipate critical transitions in complex systems — •MARTIN HESSLER^{1,2} and OLIVER KAMPS² — ¹Westfälische Wilhelms-Universität Münster, 48149 Münster — ²Center for Nonlinear Science, Westfälische Wilhelms-Universität Münster, 48149 Münster

Complex systems in nature, technology and society can undergo sudden transitions between system states with very different behaviour. In order to avoid undesired consequences of these tipping events, statistical measures as variance, autocorrelation, skewness and kurtosis have been proposed as leading indicators based on time series analysis. Under favourable conditions they can give a hint of an ongoing bifurcation-induced destabilization process. However, they suffer from their loose connection to complex system dynamics, sensitivity to noise

197

#### Location: H16

Location: H16

and sometimes misleading trends. Therefore, we want to present an alternative approach assuming the dynamical system being described by a Langevin equation. Starting from this stochastic description, we combine MCMC sampling, rolling window methods and Bayesian reasoning to derive the drift slope as an alternative early warning sign. The Bayesian approach enables us to define credibility bands which make it easier to distinguish random fluctuations from real trends that imply a less resilient system. Our investigations suggest that the estimation procedure is rather robust even under strong noise. Besides, the noise level of the system is computed to get insights into the probability of a noise induced transition. We want to present some of the results and discuss possible limitations and tasks of future research.

### DY 8.4 Mon 15:45 H18

Stochastic Interpolation of Sparsely Sampled Time Series by a Superstatistical Random Process and its Synthesis in Fourier and Wavelet Space — •JEREMIAH LÜBKE¹, JAN FRIEDRICH², and RAINER GRAUER¹ — ¹Institute for Theoretical Physics I, Ruhr-University Bochum, Universitätsstr. 150, 44801 Bochum, Germany — ²ForWind, Institute of Physics, University of Oldenburg, Küpkersweg 70, 26129 Oldenburg, Germany

A novel method is presented for stochastic interpolation of a sparsely sampled time signal based on a superstatistical random process generated from a Gaussian scale mixture. In comparison to other stochastic interpolation methods such as kriging, this method possesses strong non-Gaussian properties and is thus applicable to a broad range of real-world time series. A precise sampling algorithm is provided in terms of a mixing procedure that consists of generating a field  $u(\xi, t)$ , where each component  $u_{\xi}(t)$  is synthesized with identical underlying noise but covariance  $C_{\xi}(t, s)$  parameterized by a log-normally distributed parameter  $\xi$ . Due to the Gaussianity of each component  $u_{\xi}(t)$ , standard sampling algorithms and methods to constrain the process on the sparse measurement points can be exploited. The scale mixture u(t) is then obtained by assigning each point in time t a  $\xi(t)$  and therefore a specific value from  $u(\xi, t)$ , where  $\log \xi(t)$  is itself a realization of a Gaussian process with a correlation time large compared to the correlation time of  $u(\xi, t)$ . Finally, a wavelet-based hierarchical representation of the interpolating paths is introduced, which is shown to provide an adequate method to locally interpolate large datasets.

#### DY 8.5 Mon 16:00 H18

**Global sensitivity analysis of Monte Carlo models using Cramer-von Mises distance** – •SINA DORTAJ^{1,2} and SEBASTIAN MATERA^{1,2} – ¹Fritz-Haber-Institut der Max-Planck-Gesellschaft, Faradayweg 4-6, 14195 Berlin, Germany – ²Institute for Mathematics, Freie Universität Berlin, Arnimallee 6, 14195 Berlin, Germany

Typically, the parameters entering a physical simulation model carry some kind of uncertainty, e.g. due to the intrinsic approximations in a higher fidelity theory from which they have been obtained. Global sensitivity analysis (GSA) targets quantifying which parameters uncertainties impact the accuracy of the simulation results, e.g. to identify which parameters need to be determined more accurately.

We present a GSA approach on basis of the Cramers-von Mises distance. Unlike prevalent approaches it combines the following properties: i) it is equally suited for deterministic as well as stochastic model outputs, ii) it is free of gradients, and iii) it can be estimated from any suitable numerical quadrature (NQ) without further numerical tricks. Using Quasi-Monte Carlo for NQ and prototypical first-principles kinetic Monte Carlo models (kMC), we examine the performance of the approach. We find that the approach typically converges in a modest number of NQ points. Furthermore, it is robust against even extreme relative noise. All these properties make the method particularly suited for expensive (kinetic) Monte Carlo models, because we can reduce the number of simulations as well as the target variance of each of these.

Reproducible and transparent research software pipelines using semantic research data management and common workflow language — •ALEXANDER SCHLEMMER^{1,2,5}, INGA KOTTLARZ^{1,3}, BALTASAR RÜCHARDT^{1,5}, ULRICH PARLITZ^{1,3,5}, and STEFAN LUTHER^{1,4,5} — ¹Max Planck Institute for Dynamics and Self-Organization, Göttingen — ²IndiScale GmbH, Göttingen — ³Institute for the Dynamics of Complex Systems, Georg-August-Universität Göttingen — ⁴Institute of Pharmacology and Toxicology, University Medical Center Göttingen — ⁵German Center for Cardiovascular Research (DZHK), Partner Site Göttingen

Sustainable and well-documented scientific software is essential for effectiveness and reproducibility in data-intensive research. In practice, incompletely documented software hinders in many cases replicability, reproducibility and method comparison. In our terminology, documentation includes method and algorithm descriptions as well as human- and machine-readable representations of parameters, initial conditions and data, versions and dependencies and a welldefined software execution environment. We present an approach combining semantic data management with CaosDB and processing pipelines with Common Workflow Language (CWL), showing use cases from dynamical systems research. The CWL-based environment provides a transparent description of the process and includes metadata that can be searched within CaosDB. Input-/output-data and parameters can be directly linked to algorithms and software snapshots. The employment of containers simplifies reproducibility and interoperability.

**MDSuite:** A post-processing engine for particle simulations — •FABIAN ZILLS¹, SAMUEL TOVEY¹, FRANCISCO TORRES-HERRADOR², CHRISTOPH LOHRMANN¹, and CHRISTIAN  $HOLM^1 - {}^1Institute$  for Computational Physics, University of Stuttgart, Stuttgart, Germany —  2von  Karman Institute for Fluid Dynamics, Rhode-St-Genese, Belgium

Particle-based simulations are experiencing a rapid growth wherein system sizes in the hundreds of thousands or even millions are becoming commonplace. With this growth in system size comes the additional challenge of post-processing the simulation data.

In this talk, we introduce the Python package MDSuite. MDSuite is designed for the post-processing of particle-based simulation in an efficient manner and on modern hardware. Built on top of TensorFlow, MDSuite calculators are fully parallelised, gpu-enabled, and, due to the use of modern data pipe-lining methods, completely memory safe. Furthermore, the use of HDF5 and SQL database structures enables effective tracking of calcualtion parameters as well as a compressed trajectory storage medium. We present MDSuite as a standalone package for the storage, analysis, and comparison of large-scale simulation studies.

Distinguishing noise from high-dimensional chaos — •INGA KOTTLARZ^{1,2} and ULRICH PARLITZ^{1,2} — ¹Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany — ²Institute for Dynamics of Complex Systems, Georg-August-Universität Göttingen, Göttingen, Germany

The ordinal pattern-based Complexity-Entropy Plane is a popular tool in nonlinear dynamics for distinguishing noise from chaos. While successful attempts to do so have been documented for low-dimensional maps and continuous-time systems, high-dimensional systems have been somewhat neglected so far. To address the question in which way time series from highdimensional chaotic attractors can be characterized by their location in the Complexity-Entropy Plane we analyze data from the high-dimensional continuous-time Lorenz-96 system, the discrete generalized Hénon map and the Mackey-Glass equation as a delay system and discuss the crucial role of the lag and the pattern length or the ordinal pattern, and the length of the available time series.

#### DY 8.9 Mon 17:15 H18

The impact of the UEFA European Football Championship on the spread of COVID-19 — •JONAS DEHNING¹, SEBASTIAN B. MOHR¹, SEBASTIAN CONTRERAS¹, PHILIPP DÖNGES¹, EMIL IFTEKHAR¹, OLIVER SCHULZ², PHILIP BECHTLE³, and VIOLA PRIESEMANN^{1,4} — ¹MPI for Dynamics and Self-Organization, 37077 Göttingen — ²MPI for Physics, 80805 München — ³Physikalisches Institut, University of Bonn — ⁴Institute for the Dynamics of Complex Systems, University of Göttingen

Large-scale international events like the UEFA Euro 2020 football championship offer a unique opportunity to quantify the impact of match-related social gatherings on COVID-19, as the number of matches played by participating countries resembles a randomized trial. Moreover, soccer-related activities have a marked gender-imbalance that we can exploit for inference. In our work, we build a differentiable Bayesian SEIR-like model. Its parameters are inferred with Hamiltonian Monte-Carlo using the PyMC3 package. Our model simulates COVID-19 spread in each country using a discrete renewal process and gender-resolved case numbers. On average, 3.2% (95% CI: [1.3%, 5.2%]) of new cases in the 12 analyzed countries can be associated with the match-related social gatherings throughout our analysis period. Individually, England, the Czech Republic and Scotland showed a significant effect. Besides these insights on the spread of COVID-19 during large-scale events, our approach is an example of how modern Bayesian tools can be leveraged to gain insights on a complex dynamic process.

#### DY 8.10 Mon 17:30 H18

Recurrence-based analysis of instantaneous fractal characteristics of geomagnetic variability — •REIK V. DONNER^{1,2}, TOMMASO ALBERTI³, and DAVIDE FARANDA⁴ — ¹Hochschule Magdeburg-Stendal, Magdeburg, Germany — ²Potsdam Institute for Climate Impact Research, Potsdam, Germany — ³National Institute for Astrophysics, Rome, Italy — ⁴LSCE, Université Paris-Saclay, Gif-sur-Yvette, France

We employ two complementary approaches based on the concept of recurrences in phase space to quantify the local (instantaneous) and global fractal dimensions of the temporal variations of a suite of low (SYM-H, ASY-H) and high latitude (AE, AL, AU) geomagnetic indices and discuss similarities and dissimilarities of the obtained patterns for one year of observations during a solar activity maximum. Subsequently, we introduce bivariate extensions of both approaches, Dynamics and Statistical Physics Division (DY)

perspectives on the nonlinear dynamics and intermittent mutual entanglement of different parts of the geospace electromagnetic environment, including the netospheric quiescence and along with perturbations associated with geomagequatorial and westward auroral electrojets, in dependence of the overall state of netic storms and magnetospheric substorms, respectively. Our results open new the geospace system affected by temporary variations of the solar wind forcing.

Invited Talk DY 9.1 Mon 15:00 H19 Granular matter composed of non-convex grains — •RALF STANNARIUS -Otto-von-Guericke-Universität Magdeburg

The majority of granular matter studies so far has been devoted to hard, spherical grains. Recently, efforts have been increasingly focused on the investigation of shape-anisotropic and soft particle systems. We report experimental investigations of granular matter composed of non-convex particles. The random packing and orientational short-range order of flat crosses is studied in a twodimensional geometry, and the influence of the aspect ratio (arm length divided by arm length) is analyzed. With spatial crosses (hexapods), we perform shear experiments and report an unexpected phenomenon in split-bottom containers, a 'reversed Weissenberg effect' of granular matter. Secondary flow leads to convection rolls normal to the shear direction.

Measuring the coarsening dynamics of ferromagnetic granular networks under impact of a vertical magnetic field — MATTHIAS BIERSACK¹, OKSANA BILOUS², PEDRO SANCHEZ², SOFIA KANTOROVICH², and •REINHARD RICHTER¹ ¹University of Bayreuth, Experimental Physics V, 95447 Bayreuth, Germany ²Computational Physics, University of Vienna, 1090 Vienna, Austria

We are exploring in experiments the aggregation process in a shaken granular mixture of glass and magnetized steel beads, occuring in a horizontal vessel after the shaking amplitude is suddenly decreased. Then the magnetized beads form a transient network that coarsens in time into compact clusters, following a viscoelastic phase separation [1]. A homogeneous magnetic field oriented parallel to the system plane has been observed to "unknot" network structures orthogonal to the field [2]. Here we focus on the impact of a homogeneous magnetic field oriented in vertical direction. For certain field amplitudes we observe a threephase state, namely mobile glass beads, a grid of isolated steel beads and the coarsening network. Our results demonstrate that via dipole-dipole repulsion the field reduces the mobility of isolated steel beads, thus hindering the growth of the networks. The experimental results are compared with those of numerical simulations.

Dynamic light scattering from single macroscopic particles — • PHILIP BORN and LISA Dossow - Institut für Materialphysik im Weltraum, Deutsches Zentrum für Luft- und Raumfahrt (DLR), 51170 Köln, Germany

Here we present a methodology to extract information from the light intensity fluctuations that arise from motion of single granular particles. We first describe the experimental setup for dynamic light scattering measurements and the associated theoretical framework required to isolate contributions from the translational motion and from the rotational motion to the intensity autocorrelation function [1]. We subsequently present an approach to extract the angular velocity and the translational speed of the granular particles from the intensity autocorrelation. The approach is applied to a small ensemble of granular particles in an hour-glass-like experiment to determine the granular temperature with a dynamic light scattering measurement. The results indicate the next steps to be taken to eventually develop a thermometer for fluidized granular media based on dynamic light scattering.

Structural Analysis of Disordered Dimer Packings - •ESMA KURBAN and ADRIAN BAULE — School of Mathematical Sciences, Queen Mary University of London, Mile End Road, London E1 4NS, UK

Jammed disordered packings of non-spherical particles show significant variation in the packing density as a function of particle shape for a given packing protocol. Rotationally symmetric elongated shapes such as ellipsoids, spherocylinders, and dimers, e.g., pack significantly denser than spheres over a narrow range of aspect ratios, exhibiting a characteristic peak at aspect ratios of  $\alpha_{\rm max} \approx 1.4 - 1.5$ . However, the structural features that underlie this nonmonotonic behaviour in the packing density are unknown. Here, we study disordered packings of frictionless dimers in three dimensions generated by a gravitational pouring protocol in LAMMPS. Focusing on the characteristics of contacts as well as orientational and translational order metrics, we identify a number of structural features that accompany the formation of maximally dense packings as the dimer aspect ratio  $\alpha$  is varied from the spherical limit. Our results highlight that dimer packings undergo significant structural changes as  $\alpha$  increases up to  $\alpha_{max}$  manifest in the reorganisation of the contact configurations between neighbouring dimers, increasing nematic order, and decreasing local translational order. Remarkably, for  $\alpha > \alpha_{max}$  our metrics remain largely unchanged, indicating that the peak in the packing density is related to the interplay of structural rearrangements for  $\alpha < \alpha_{max}$  and subsequent excluded volume effects with unchanged structure for  $\alpha > \alpha_{max}$ .

DY 11.4 Mon 16:30 H19 The role of the particle aspect ratio in the discharge of a narrow silo – •Bo Fan^{2,4}, Tivadar Pongó^{1,2}, Dariel Hernández-Delfin^{1,5}, János TÖRÖK³, RALF STANNARIUS⁶, RAÚL CRUZ-HIDALGO¹, and TAMÁS BÖRZSÖNYI² - ¹Universidad de Navarra, Pamplona, Spain - ²Wigner Research Centre for Physics, Budapest, Hungary — ³Budapest University of Technology and Economics, Budapest, Hungary — ⁴Wageningen University, Wageningen, The Netherlands — ⁵Basque Center for Applied Mathematics, Bilbao, Spain — ⁶Otto von Guericke University, Magdeburg, Germany

The time evolution of silo discharge is investigated for different granular materials made of spherical or elongated grains in laboratory experiments and with discrete element model (DEM) calculations. For spherical grains, we confirm the widely known typical behavior with constant discharge rate (except for initial and final transients). For elongated particles with aspect ratios between 2 < L/d < 6.1, we find a peculiar flow rate increase for larger orifices, especially in the last third of the discharge process. While the flow field is practically homogeneous for spherical grains, it has strong gradients for elongated particles with a fast-flowing region in the middle of the silo surrounded by a stagnant zone. For large enough orifice sizes, the flow rate increase is connected to a gradual change in the character of the flow field, including a shrinkage of the stagnant zone and an increase in both the packing fraction and flow velocity near the silo outlet.

Excitation of Platonic bodies on a vibrating plate analyzed with smart IMUs - • Torsten Trittel, Dmitry Puzyrev, Niklas Dieckmann, and Ralf Stan-NARIUS — Otto-von-Guericke Universität Magdeburg

For the investigation of granular gases, i.e. large ensembles of macroscopic particles that interact via frequent mutual collisions, an initial or permanent exci-

#### Location: H19

Location: H19

tation of the ensembles is prerequisite. Typically, this excitation is realized by one or more vibrating plates (container walls). We investigate such a mechanical excitation of different Platonic bodies, e.g. icosahedra and cubes, and compare their dynamics with that of spherical particles. In earlier experiments with mechanically excited rods [1], the dynamic data were extracted from a huge amount of stereoscopic video data. This procedure is very complicated and time consuming. To overcome this problem, we equipped our particles with small IMUs (inertial measurement units) that are typically used for motion tracking [2]. From acceleration and rotation data, it is straightforward to calculate the rotational and translational energies of each jump. We present distributions of the energies on individual degrees of freedom and determine the efficiency of the excitation depending on vibration parameters. Finally, we compare the experimental findings with results obtained from numerical simulations.

DY 11.6 Mon 17:00 H19 **Rare Fluctuations in Sheared 2D LJ Fluids** — •DANIEL DERNBACH and JÜRGEN VOLLMER — Institut für Theoretische Physik, Universität Leipzig, Brüderstr. 16, D-04103 Leipzig, Germany

A distinguishing feature of sheared particulate flows are very large fluctuations in the dissipation, i.e. the product of the local velocity gradient and the local shear stress. At times, it even takes negative values (rare fluctuations). Surprisingly, the probability of rare fluctuations vanishes close to jamming [1], a far-fromequilibrium critical point where fluctuations are expected to be large.

Here, we compare this setting to the motion of classical fluids with attractive, elastic interactions. Specifically, we consider the transition from fluid to plastic flow in a two-dimensional (2D) Lennard-Jones (LJ) fluid subjected to a Nosé-Hoover thermostat.

Close to its critical rigidity transition this time-reversible sheared dynamics also features a drop of the probability of rare fluctuations. We will scrutinize the analogies and differences between the emergence of rare fluctuations in irreversible particulate flow and in time-reversible classical dynamics.

DY 11.7 Mon 17:15 H19

**Granular Gases of Mixtures of Rods in Microgravity** — •KIRSTEN HARTH^{1,2}, DMITRY PUZYREV³, TORSTEN TRITTEL³, and RALF STANNARIUS³ — ¹Fachbereich Technik, TH Brandenburg, Brandenburg an der Havel, Deutschland — ²MARS und MRTM, Otto von Guericke Universität Magdeburg, Deutschland — ³Institut für Physik und MARS, Otto von Guericke Universität Magdeburg, Deutschland

Granular gases consist of macroscopic particles in erratic motion, rarely colliding among each other. They are a comparatively simple, yet illustrative example of a non-equilibrium dynamical system. Numerous theoretical and numerical studies deal with their dynamics, however, the realization of 3D experiments is rare. It usually requires microgravity. Typical experiments are either performed under continuous external energy supply or they consider the process of collective kinetic energy decay by dissipation (granular cooling). It has been recently shown that both ensembles of rods and spheres follow the scaling predicted by Haff in 1983, however, with stark quantitative disagreement with the theory.

Here, we consider a bidisperse ensemble of 2 types of rods in a cuboid container. We track their positions and rotations in 3D. Expererimental data will be compared to validated numerical simulations of frictional rods under similar conditions. We extract kinectic energies in individual degrees of freedom and other statistical quantities.

DY 11.8 Mon 17:30 H19

**Pauling Structures in tribocharged Granular Media** — JAN HAEBERLE, MATTHIAS SPERL, and •PHILIP BORN — Institut für Materialphysik im Weltraum, Deutsches Zentrum für Luft- und Raumfahrt (DLR), Köln, Germany

Crystal-like arrangements of granular particles had been studied in the past for their mechanical properties or as a model system to study structure formation of equilibrium systems. These studies were limited to the formation of either hcp or fcc densest arrangements of monodisperse spheres. However, in most situations the hard core and the frictional contacts of the granular particles stabilize less dense disordered packings. Here we show that binary packings of granular particles with strong tribocharging spontaneouisly take BCC-like packing structures under suitable conditions [1]. We use a version of the bond-order parameter which is robust against noise to identify crystalline structures x-ray tomography reconstructions [2]. The observed BCC-like packing structures formed in incommensurate containers are, to large extent, in agreement with the prediction of Pauling's rules for ionic crystals, i.e. equilibrium structures of thermal ions.

Visualization of flow dynamics for Poly-dispersed dense granular suspension in various sections of pipe — •HIMANSHU P PATEL and GÜNTER K AUERNHAM-MER — Leibniz-Institut für Polymerforschung Dresden e. V., Germany

The study of flow dynamics in non-Newtonian media with polydispersed dense granular suspension, e.g., slurry, mud, concrete, still lacks quantification on the flow parameters linked to shear induced particle migration and insight about flow at center and at wall in closed pipes.

We developed transparent granular system that is a granular suspension of particles suspended in non-Newtonian media (particle volume fractions of 30% to 48%) [1]. The non-Newtonian granular system has yield stress and plastic viscosity and is well index matched. The rheological characteristics of the model system is tunable through its composition of additives.

We analyze gravity-assisted continuous flow of millimetric sized particles. We perform tracking of flow at different sections of pipe. The flow analysis revels understanding on the relaxation of such flow and the development of velocity profile within the length of pipe, we observe this using camera at entry and exit of pipe and later a 3D setup to observe flow at near end of pipe. This gives quantitative values into the particle migration to understand the effect of polydispersity and particle flow.

A phononic frequency comb from a single resonantly driven nanomechanical mode — •Eva WEIG — Department of Electrical and Computer Engineering, Technical University of Munich

Doubly-clamped nanostring resonators excel as high Q nanomechanical systems enabling room temperature quality factors of several 100,000 in the 10 MHz eigenfrequency range. Dielectric transduction via electrically induced gradient fields provides an integrated control scheme while retaining the large mechanical quality factor. Dielectrically controlled nanostrings are an ideal testbed to explore a variety of dynamical phenomena ranging from multimode coupling to coherent control. Here I will focus on the nonlinear dynamics of a single, resonantly driven mode. The broken time reversal symmetry gives rise to the squeezing of the string's fluctuations. As a result of the high mechanical Q factor, the squeezing ratio is directly accessible from a spectral measurement. It is encoded in the intensities of the two spectral peaks arising from the slow dynamics of the system in the rotating frame. For stronger driving, an onset of self-sustained oscillation is observed which leads to the generation of a nanomechanical frequency comb. The effect is a consequence of a resonantly induced negative effective friction force induced by the drive. This is the first observation of a frequency comb arising solely from a single mode and a single, resonant drive tone.

Tuning nonlinear damping in graphene nanoresonators by parametric-direct internal resonance — •Ata Keşkekler¹, Oriel Shohani², Martin Lee¹, Herre van der Zant¹, Peter Steeneken¹, and Farbod Alijani¹ – ¹TU Delft, Delft, The Netherlands – ²Ben-Gurion University of Negev, Beersheba, Israel

Micro/Nano-mechanical systems are utilized in many technologies and often have been used for their sensing capabilities. An ideal framework for sensitive nanomechanical devices is 2-D materials, and especially graphene, due to its exceptional mechanical, electrical and thermal properties. By their atomically thin nature, these systems are fundamentally nonlinear. In addition to their geometric nonlinearities, graphene membranes have shown nonlinear energy decay mechanisms. Nonlinear damping in these devices is a fundamental limitation to their sensing capabilities yet its full understanding is an open question. Among different dissipation mechanisms, an important factor that is hypothesized to affect damping properties of graphene nanodrums is the intermodal couplings. In this work, we study the nonlinear dynamics of a nanomechanical graphene resonator near its internal resonance condition to amplify the intermodal effects and uncover the physics between nonlinear damping and mode coupling. We observe a massive increase in damping in the vicinity of internal resonance that is followed by a bifurcation causing a dramatic increase of amplitude and resonance frequency. Our study opens up a route towards utilizing modal interactions and parametric resonance to realize resonators with engineered nonlinear dissipation over wide frequency range.

DY 12.4 Mon 16:30 H20 From period-doubling bifurcations to time crystals and coherent Ising ma**chines** — •Oded Zilberberg^{1,2}, Toni L. Heugel², Jan Košata², Javier del Pino², R. Chitra², and Alexander Eichler² — ¹Department of Physics, University of Konstanz, 78464 Konstanz, Germany — ²Department of Physics, ETH Zürich, CH-8093 Zürich, Switzerland

Networks of coupled parametric resonators (parametrons) hold promise for parallel computing architectures. These are classical systems with period-doubling bifurcations, where the logic information is stored in oscillation modes of the system. Such networks similarly realize the physics of so-called discrete time crystals (DTCs). The latter are a many-body state of matter whose dynamics are slower than the forces acting on it. I will report on our theoretical and experimental work on parametron networks, their relation to DTCs and their potential application for the realization of coherent Ising machines.

#### DY 12.5 Mon 17:00 H20

Sideband and noise squeezing effects in nonlinear mechanical membrane resonators — •Mengqi Fu¹, Fan Yang¹, Yuxuan Jiang², and Elke Scheer¹

– ¹Fachbereich Physik, Universität Konstanz, 78457 Konstanz, Germany — ²Anhui University, Hefei, China

The nonlinearity of a mechanical system has been shown to squeeze the noise by redistributing it in two conjugates of the observables under certain conditions and therefore provides a way to break the sensing limit of mechanical systems. In this work, we develop a novel method to characterize the noise squeezing of a nonlinear mechanical system by the frequency response of the low-frequency modulation based on a suspended silicon nitride (Si-N) membrane (~ 500 nm thickness) structure [1]. We first demonstrate an antiresonance effect between the "quasi modes" of the nonlinear mechanical system in the sideband spectra through low-frequency two-tone probing measurements. Then a direct connection between the antiresonance frequency and the noise squeezing factor of the system can be established to characterize the noise squeezing factor in a simple and robust method.

DY 12.6 Mon 17:15 H20 Invited Talk 2D membranes in motion - •HERRE VAN DER ZANT - Kavli Institute of Nanoscience, Department of Quantum Nanoscience, Delft University of Tech-

nology, The Netherlands Atomically thin membranes are ideal building blocks for nanoelectromechanical systems (NEMS) because of their unique mechanical properties and their low mass. We make membranes by transferring atomically thin layers on top of silicon oxide substrates that are pre-patterned with circular or rectangular holes. The suspended membranes are characterized by a laser interferometer set-up that gives access to information on the dynamics in the frequency- and timedomain. The setup is equipped with a moveable x-y stage so that the membrane motion can be visualized; the nonlinear response of the motion is used to extract the mechanical parameters including the Young's modulus. Recently, it has become clear that nanomechanics can also probe thermodynamic properties such as thermal conductivity, specific heat, and thermal expansion [Dynamics of 2D material membranes, 2D Materials 8 (2021) 042001]. Specifically, phase transitions are typically accompanied by abrupt changes in the specific heat, resulting in accompanying changes in the strain of the material which are measured via mechanical resonances. In this way, we have detected the Néel temperature of antiferromagnetic FePS₃ membranes, their magnetic anisotropy and studied the nonlinear coupling between magnetic and elastic properties.

DY 14.1 Tue 9:30 H18 Non-Markovian Brownian systems: from single-particle thermodynamics to collective behavior — • SABINE KLAPP — Institut fuer Theoretische Physik, TU Berlin, Hardenbergstrasse 36, 10623 Berlin

Recently, the dynamical behavior and the thermodynamics of stochastic systems involving time-delay or, more generally, memory effects has become a focus of growing interest. Indeed, memory is essentially omnipresent in many complex fluids and biological systems, but may also arise, e.g., due to delayed feedback protocols or sensorial delay in active systems. The theoretical description of such systems is still challenging due to the non-Markovian nature of the underlying

Langevin equations, particularly in the case of discrete time delays. Here we present, first, recent research for Brownian particles subject to feedback with discrete or distributed time delay. We discuss peculiar thermodynamic features, such as delay-induced heat production, and the theoretical treatment based on the introduction of auxiliary variables with non-reciprocal coupling. Considering an ensemble of delayed Brownian particles we demonstrate the occurrence of new phases resembling active particles. Our second focus lies on systems with fractional Brownian motion (fBm). fBM is a well-established model for anomalous diffusion, where non-Markovianity arises through the noise correlation function. We discuss strategies how to treat this system thermodynamically and the role of memory for the collective behavior.

### DY 15: Delay and Feedback Dynamics

DY 15.1 Tue 9:30 H19 Emergence of collective motion in two-dimensional colloidal systems with delayed feedback — • ROBIN A. KOPP and SABINE H. L. KLAPP — ITP, TU Berlin, Berlin, Germany

In recent years, delayed feedback in colloidal systems has become an active and promising field of study [1], key topics being history dependence and the manipulation of transport properties. Here we study the dynamics of a twodimensional colloidal suspension, subject to time-delayed feedback. To this end we perform overdamped Brownian dynamics simulations, where the particles interact through a Weeks-Chandler-Andersen potential. Furthermore, each particle is subject to a Gaussian, repulsive feedback potential, that depends on the difference of the particle position at the current time, and at an earlier time. We observe and quantitatively study the emergence of collective motion characterized by a nonzero mean velocity and provide a possible explanation com-

Location: H18

bining single-particle and mean-field-like effects. Studying the corresponding one-particle system we obtain an understanding of the history dependence and the long-time behavior, in particular a nonzero stationary constant velocity state of the deterministic problem that translates to a constant average velocity magnitude in the stochastic system. By studying the mean square displacement we are able to point out how delayed feedback affects diffusion in the one-particle and the interacting system differently.

The role of the polarization dephasing time for stabilizing coupled nanolasers — •AYCKE ROOS¹, STEFAN MEINECKE¹, and KATHY LÜDGE² — ¹TU Berlin - Institut für Theoretische Physik, Hardenbergstraße 36, 10623 Berlin — ²TU Ilmenau - Institut für Physik, Fachgebiet Theoretische Physik 2, 98684 Ilmenau

As a prototypical model for on-chip laser networks, mutually coupled nanolasers attract attention in laser physics and dynamics. In the regime of small cavity lifetimes the carrier polarization essentially in- fluences the dynamics of such lasers. We investigate the emission dy- namics of two coupled lasers, modeled by Maxwell-Bloch type laser equations (class-C laser), and predict ways to optimize their stabil- ity, i.e., maximize their locking range. We find that tuning the cavity lifetime to the same order of magnitude as the dephasing time of the microscopic polarization yields optimal operation conditions, which allow for wider tuning the steady state solutions and nu- merically characterize the emission dynamics via the underlying bi- furcation structure. The dephasing time is found to be a crucial pa- rameter, which impacts the observed dynamics in the parameter space spanned by frequency detuning, coupling strength and coupling phase.

Frequency combs and localized states in time-delayed Kerr-Gires-Tournois interferometers — •THOMAS G. SEIDEL^{1,2}, JULIEN JAVALOYES², and SVETLANA V. GUREVICH^{1,2} — ¹Institute for Theoretical Physics & Center for Nonlinear Science (CeNoS), University of Münster, Schlossplatz 2, 48149 Münster, Germany — ²Dpt. de Física, Universitat de les Illes Balears & IAC-3, Campus UIB, E-07122 Palma de Mallorca, Spain

We study theoretically the formation of phase-locked temporal localized states (TLSs) and frequency combs. Our system consists in an optically injected Fabry-

Perot micro-cavity containing a Kerr medium that is coupled to an external cavity. Using a first-principles model based on delay algebraic equations (DAEs) and applying a combination of direct numerical simulations and path continuation methods, we disclose sets of multistable dark and bright TLSs coexisting on their respective bistable homogeneous backgrounds. We show that the detuning of the injection with respect to the micro-cavity resonance controls the region of existence of TLSs and its change can lead to a period-doubling route to chaos. Understanding the influence of the system parameters on physical mechanisms such as group delay dispersion and third order dispersion do not appear so obvious in the DAE model. Therefore, we transform the DAE into a real order parameter equation by using a rigorous multiple time scale analysis applied at the onset of bistability. The normal form given by a real Ginzburg-Landau equation and the full DAE model exhibit excellent quantitative agreement in both oneand two-parameter bifurcation diagrams.

#### DY 15.4 Tue 10:15 H19

Dynamics of square waves in a vertical external-cavity delayed Kerr-Gires-Tournois interferometer — •ELIAS R. KOCH¹, THOMAS G. SEIDEL^{1,2}, JULIEN JAVALOYES², and SVETLANA V. GUREVICH^{1,2} — ¹Institute for Theoretical Physics & Center for Nonlinear Science (CeNoS), University of Münster, Schlossplatz 2, 48149 Münster, Germany — ²Dpt. de Física, Universitat de les Illes Balears & IAC-3, Campus UIB, E-07122 Palma de Mallorca, Spain

We study theoretically the mechanisms of square wave (SW) formation in a monomode micro-cavity, containing a nonlinear Kerr medium coupled to a long external feedback cavity under continuous wave injection. Employing a firstprinciple delay-algebraic equation (DAE) model in the long delay limit, we provide a simple analytical approximation of the SW's plateau intensities and the bifurcation points limiting the range of existence of the SWs. Using a combination of path-continuation techniques and direct numerical simulations, we show that depending on the system parameters SWs can exhibit homoclinic snaking leading to the formation of complex-shaped multistable SW solutions. Beyond that, more complex SW dynamics can be identified, including a period doubling route to chaos. The results obtained from the full DAE model and the simple analytical approximation are in excellent agreement. Furthermore, we demonstrate that SWs can be used as a platform to host other structures and we show that robust multiple bound states consisting of localized pulses can be formed on the SW plateaus.

**Density fluctuations in bacterial binary mixtures** — •SILVIA ESPADA BURRIEL, VICTOR SOURJIK, and REMY COLIN — Max Planck Institute for Terrestrial Microbiology, Karl-von-Frisch-strasse 10, 35043 Marburg & Center for Synthetic Microbiology (SYNMIKRO), Karl-von-Frisch-strasse 14, 35043 Marburg

In wild environments, bacteria are found as mixtures of motile and sessile species, which interact physically and chemically to give rise to complex community organization. Very little is understood of the role of physical interactions in these processes: Numerical works on dry active matter and experiments on colloidal systems have shown that the activity of the active particles may affect the spatial distribution of passive particles with which they are mixed. However, the physical behavior of binary mixtures of bacteria remains largely unexplored. In our study, we present a novel phenomenon in which non-motile bacteria form large density fluctuations when mixed with motile bacteria, distinct from the aforementioned behaviors. We systematically explored the phase diagram of the mixtures in experiments combining microfluidics, fluorescence (confocal) microscopy, quantitative image analysis and parameter tuning by genetic engineering. Our experimental results show that the emergence of these large density fluctuations of the non-motile cells in presence of motile cells is controlled by hydrodynamic interactions between the motile and non-motile cells and by the sedimentation of the non-motile cells, possibly because it breaks the systems symmetry.

**Pulsating Active Matter** — •YIWEI ZHANG and ETIENNE FODOR — 0 Av. de la Faiencerie, 1511 Luxembourg

Active matter features the injection of energy at individual level keeping the system out of equilibrium, which leads to novel phenomenologies without any equilibrium equivalents. So far, most active matter models assign a velocity to each particle, whilst we herein consider a system of pulsating soft particles where the activity sustains particles' periodic deformation instead of spatial displacement. At sufficiently high density, we reveal the existence of wave propagation independent of any particle migration, and derive the corresponding phase diagram. We study the character of phase transitions, and investigate the underlying physical mechanisms, using both particle-based simulations and hydrodynamic analysis. Location: H18

DY 16.3 Tue 10:30 H18

**Long-Range Nematic Order in Two-Dimensional Active Matter** — •BENOÎT MAHAULT¹ and HUGUES CHATÉ^{2,3} — ¹MPIDS, 37077 Göttingen, Germany — ²SPEC, CEA-Saclay, 91191 Gif-sur-Yvette, France — ³CSRC, Beijing 100193, China

Studies of active matter continue to flourish, exploring more and more complex situations in an increasingly quantitative manner. Evidence has accumulated that shows active matter exhibits properties that are impossible in thermal equilibrium or even in driven systems. In spite of all this progress, important fundamental questions remain open. Such a long-standing issue is whether true long-range nematic order can emerge in two space dimensions. In this talk, we will present theoretical and numerical results obtained from minimal models of self-propelled polar particles aligning nematically. Our study shows that the orientational order emerging from such systems is quasi-long-ranged beyond the scale associated to induced velocity reversals, which is typically extremely large and often cannot even be measured. On scales where particle motion is ballistic, nematic order appears truly long-range. A hydrodynamic theory for this de facto phase is derived, and we show that its structure and symmetries differ from conventional descriptions of both polar flocks and active nematics. Our analysis of this field theory predicts  $\pi$ -symmetric propagative sound modes and the scaling form of space-time fluctuations. Finally, numerical results confirm the theory and allow us to estimate all scaling exponents.

**Collective behavior of repulsive chiral active particles with non-reciprocal couplings** — •KIM L. KREIENKAMP and SABINE H. L. KLAPP — Technische Universität Berlin, Germany

Mixtures of chiral active particles [1] as well as non-reciprocal systems [2] show intriguing collective behavior like pattern formation and traveling waves. The combination of both – non-reciprocal couplings in mixtures of chiral active particles – promises a rich variety of collective dynamics.

Here, we investigate how non-reciprocal couplings and naturally occurring repulsive interactions due to finite particle sizes affect the collective behavior in a mixture of two species of particles. We analyze the effects due to non-reciprocity and finite size individually as well as their interplay based on a field description of the system in terms of the particle concentration and director field, measuring the overall orientation of particles at a certain position.

We derive the field equations under the mean-field assumption by coarsegraining microscopic Langevin equations for individual chiral particles, which are modeled as self-propelling circle swimmers with soft repulsive forces, comprising the finite size effects. Particles of the two species rotate with different intrinsic frequencies and align with near-by particles. Focusing on non-reciprocity, we use a non-mutual alignment between the particles.

**Memory-induced chirality in self-freezing active droplets** — •ARITRA K. MUKHOPADHYAY¹, KAI FENG², JOSÉ CARLOS UREÑA MARCOS¹, RAN NIU², QIANG ZHAO², and BENNO LIEBCHEN¹ — ¹Technische Universität Darmstadt, 64289 Darmstadt, Germany. — ²Huazhong University of Science and Technology, 430074 Wuhan, China.

We experimentally realize and numerically model a new type of self-propelled droplet swimmer which exhibits chiral motion due to self-induced memory effects without requiring any explicit symmetry breaking caused by specific droplet geometries or complex environments. The droplets are composed of a binary polymer mixture that solidifies over time, simultaneously emitting certain polymers into their environment. A spontaneous asymmetry of the emitted polymer concentration along the stationary droplet surface induces Marangoni flows which cause the droplet to initially self-propel ballistically. However, the emitted polymers diffuse slowly and form long-lived trails with which the droplet can self-interact in the course of time and this leads to a dynamical transition from ballistic to chiral motion. The droplets persistently exhibit chiral motion with the same handedness until at even later times a second transition occurs when the droplets confine themselves leading to self-trapping over the timescale of our experiments and simulations. Our results exemplify a new route to realizing synthetic active particles whose dynamics can be controlled via the pronounced self-induced memory effects.

**Role of advective inertia in active nematic turbulence** – •COLIN-MARIUS KOCH and MICHAEL WILCZEK — Theoretical Physics I, University of Bayreuth, Bayreuth

Suspensions of active agents with nematic interactions can exhibit complex dynamics such as mesoscale turbulence. Continuum descriptions for such systems are inspired by the hydrodynamic theory of liquid crystals and feature an advective nonlinearity which represents inertial effects. The typically low Reynolds number of such active flows raises the question whether and under which conditions the active stresses present in these systems can excite inertial flows. To address this question, we investigate mesoscale turbulence in a two-dimensional model for active nematic liquid crystals. In particular, we compare numerical simulations with and without nonlinear advection and frictional damping of the flow field. Studying the nondimensionalized equations of motion, we find that inertia can trigger large-scale motion even for small microscopic Reynolds numbers if the active forcing is sufficiently large and the Ericksen number is sufficiently low. Performing a spectral analysis of the energy budget, we identify an inverse energy transfer caused by inertial advection, whose impact is small in comparison to active forcing and viscous dissipation but accumulates over time. We additionally show that surface friction, mimicked by a linear friction term, dissipates the transported energy and suppresses the large-scale motion. We conclude that, without an a priori knowledge of model parameters matching experiments, including inertia and friction may be necessary for consistent modeling of active nematic turbulence.

#### DY 16.7 Tue 11:45 H18

**Pumping in active microchannels** — •GONCALO ANTUNES^{1,2,3}, PAOLO MALGARETTI^{1,2,3}, SIEGFRIED DIETRICH^{2,3}, and JENS HARTING^{1,4} — ¹Helmholtz-Institut Erlangen-Nürnberg für Erneuerbare Energien (IEK-11), Forschungszentrum Jülich, Erlangen, Germany — ²Max–Planck-Institut für Intelligente Systeme, Stuttgart, Germany — ³Universität Stuttgart, Stuttgart, Germany — ⁴Friedrich-Alexander-Universität Erlangen-Nürnberg, Nürnberg, Germany

Much attention is currently being given to the problem of manipulating fluids at the microscale, with successful applications to fields such as 3D fabrication and biomedical research. Often micropumps are a fundamental component of these microfluidic systems. An intriguing technique to manipulate fluid flows in a channel is diffusioosmosis. Fluid flow is obtained upon imposing an inhomogeneous concentration of some solute, which generates flow in a boundary layer around the channel walls. This inhomogeneity is the result of a spatially inhomogenous production rate of solute inside the channel.

We show that a solute-producing, corrugated, active channel can act as a micropump even when it is fore-aft symmetric. This result is obtained by coupling the Stokes equation with an advection-diffusion equation for the solute concentration, which we solve analytically in the limit of thin, weakly-corrugated channels. Lattice Boltzmann simulations further support the existence of the symmetry-breaking. Our calculations are also valid for left-right asymmetric channels, and provide a tool to optimize the pumping rate of an active microchannel by tuning its shape or its solute production rate.

DY 16.8 Tue 12:00 H18

Active Refrigerators Powered by Inertia — •LUKAS HECHT¹, SUVENDU MANDAL¹, HARTMUT LÖWEN², and BENNO LIEBCHEN¹ — ¹Institut für Physik kondensierter Materie, Technische Universität Darmstadt, Hochschulstr. 8, D-64289 Darmstadt, Germany — ²Institut für Theoretische Physik II - Soft Matter, Heinrich-Heine-Universität Düsseldorf, Universitätsstraße 1, D-40225 Düsseldorf, Germany

We present the operational principle for a refrigerator which uses inertial effects in active Brownian particles (ABPs) to locally reduce the (kinetic) temperature by two orders of magnitude below the environmental temperature. This principle requires two ingredients: First, we need the feature of inertial ABPs to undergo motility-induced phase separation into coexisting phases with different (kinetic) temperatures and second, a mechanism which localizes the dense phase in the targeted cooling domain is required.

Here, we exploit the peculiar but so-far unknown shape of the phase diagram of inertial ABPs to initiate motility-induced phase separation in the targeted cooling domain only. Remarkably, active refrigerators operate without requiring isolating walls separating the cooling domain from its environment. This feature opens the route towards using active refrigerators to systematically absorb and trap substances such as toxins or viruses from the environment.

#### DY 16.9 Tue 12:15 H18

The influence of motility on bacterial accumulation in a microporous channel — •CHRISTOPH LOHRMANN¹, MIRU LEE², and CHRISTIAN HOLM¹ — ¹Institute for Computational Physics, University of Stuttgart, Allmandring 3, 70569 Stuttgart, Germany — ²Institute for Theoretical Physics, Georg-August-Universität Göttingen, 37073 Göttingen, Germany

Swimming microorganisms are often encountered in confined geometries where also an external flow is present, e.g. in filters or inside the human body. To investigate the interplay between microswimmer motility and external flows, we developed a model for swimming bacteria based on point coupling to an underlying lattice Boltzmann fluid. Random reorientation events reproduce the statistics of the run-and-tumble motion of the bacterium E. coli. We present the application of the model to the study of bacterial dynamics in a channel with a single cylindrical obstacle. In accordance with experimental measurements, simulations show asymmetric accumulation behind the obstacle only when the bacteria are active and an external flow is present.

Inertial dynamics of an active Brownian particle^{*} — •JONAS MAYER MARTINS and RAPHAEL WITTKOWSKI — Institut für Theoretische Physik, Center for Soft Nanoscience, Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany

Active Brownian motion commonly assumes spherical overdamped particles. However, self-propelled particles are often neither symmetric nor overdamped yet underlie random fluctuations from their surroundings. Active Brownian motion has already been generalized to include asymmetric particles. Separately, recent findings have shown the importance of inertial effects for particles of macroscopic size or in low-friction environments. We aim to consolidate the previous findings into the general description of a self-propelled asymmetric particle with inertia. We derive the Langevin equation of such a particle as well as the corresponding Fokker-Planck equation. Furthermore, a formula is presented that allows to reconstruct the hydrodynamic resistance matrix of the particle by measuring its trajectory. Numerical solutions of the Langevin equation show that, independent of the particle's shape, the noise-free trajectory at zero temperature starts with an inertial transition phase and converges to a circular helix. We discuss this universal convergence with respect to the helical motion that many microorganisms exhibit.

Stochastic motion under active driving due to inverted dry (solid) friction — •ANDREAS M. MENZEL — Otto-von-Guericke-Universität Magdeburg, Magdeburg, Germany

It has become common to describe the motion of actively driven or self-propelled objects using a driving force of constant magnitude. We assume that this driving force always acts along the current velocity direction. Moreover, we consider objects featuring a nonpolar axis, along which driving and propagation occur [1].

In that case, spontaneous symmetry breaking decides on the heading of propagation, that is, "forward" or "backward" along the nonpolar axis. Stochastic

#### Dynamics and Statistical Physics Division (DY)

As it turns out, active driving under these circumstances corresponds to inverted dry (solid) friction of the Coulomb type. Corresponding tools of theoretical analysis can thus be adopted, mapping the velocity spectrum to the one of a quantum-mechanical harmonic oscillator subject to a repulsive delta potential. In this way, the diffusion coefficient can be calculated analytically. We evaluate velocity and displacement statistics. Outward propagating displacement maxima emerge under increased active driving. The trajectories feature pronounced cusps when velocity reversals occur.

Our results should apply, for instance, to certain types of vibrated nonpolar rods and swimming bacteria that may reverse their propagation direction. [1] A. M. Menzel, submitted.

DY 17.1 Tue 10:30 H19 Caustics in turbulent aerosols — •BERNHARD MEHLIG — University of Gothenburg

Turbulent aerosols are suspensions of heavy particles in a turbulent fluid - such as water droplets in the turbulent air of a cumulus cloud, or dust grains in the turbulent gas around a growing star. The analysis of such highly non-linear and multi-scale problems poses formidable challenges. Experiments resolving the particle dynamics have only recently become possible, and direct numerical simulations of such systems are still immensely difficult.

Here I describe a different approach, to analyse the dynamics of turbulent aerosols in terms of synthetic turbulence models, using methods from nonequilibrium statistical physics and dynamical-systems theory. Although the models are highly idealised, their analysis has led to significant progress in understanding the mechanisms determining the particle dynamics. As an example I discuss the formation of mathematical catastrophes in the phase-space dynamics of turbulent aerosols, akin to caustics in geometrical optics. I describe where and how often these singularities form, and I explain their physical significance. I conclude with a discussion of successes and limitations of this statistical approach, and with a summary of open questions.

DY 18.1 Tue 11:15 H19 Stable Poisson chimeras in networks of two subpopulations — •SEUNGJAE LEE and KATHARINA KRISCHER — Technical University of Munich, Garching, Germany

In this talk, we introduce recent results on dynamical and spectral properties of chimeras in two-population network based on Kuramoto order parameter and Lyapunov stability analysis. In particular, we address two qualitatively different dynamics of incoherent oscillator populations according to the given initial conditions, and which led to the classification of Poisson and non-Poisson chimera states. We numerically calculate the Lyapunov exponents and covariant Lyapunov vectors to determine the spectral properties of the chimera states, and then expound the classification of the Lyapunov exponents. Our stability analysis also confirms that the chimera states of Kuramoto-Sakaguchi phase oscillators in two-population networks are neutrally stable in many directions. Furthermore, we demonstrate that two *perturbations* of the phase model that reflect more realistic situations render Poisson chimeras stable. These models consider a nonlocal intra-population network and Stuart-Landau planar oscillators with amplitude degrees of freedom, respectively. Both these 'perturbations' might be considered a heterogeneity of the phase model and give rise to an asymptotically attracting Poisson chimera in two-population networks.

DY 18.2 Tue 11:30 H19

#### On rational reactions - and other ones - of overloaded magnetic gears -•INGO REHBERG and STEFAN HARTUNG — Universität Bayreuth

Experiments exploring the coupling of two rotating spherical magnets reveal a cogging-free coupling for two specific angles between the input and output rotation axes. The striking difference between these two phase-locked modes of operation is the reversed sense of rotation of the driven magnet. For other angles, the cogging leads to a more complex dynamical behaviour. The experimental results can be understood by a mathematical model based on pure dipole-dipole interaction, with the addition of adequate friction terms [1].

Like all magnetic couplings, the setup contains intrinsic overload protection. The dynamic answer of the gear with cogging to an overload shows a plethora of modes of the driven magnet.

Heteroclinic units acting as pacemakers: Entrained dynamics for cognitive processes — •BHUMIKA THAKUR and HILDEGARD MEYER-ORTMANNS — School of Science, Jacobs University Bremen, Campus Ring 1, 28759 Bremen, Germany Heteroclinic dynamics is a suitable framework for describing transient and reproducible dynamics such as cognitive processes in the brain. We demonstrate how heteroclinic units can act as pacemakers to entrain larger sets of units from a resting state to hierarchical heteroclinic motion that is able to describe fast oscillations modulated by slow oscillations, features which are observed in brain dynamics. The entrainment range depends on the type of coupling, the spatial location of the pacemaker and the individual bifurcation parameters of the pacemaker and the driven units. Noise as well as a small back-coupling to the pacemaker facilitate synchronization. Units can be synchronously entrained to different temporal patterns, depending on the selected path in the hierarchical heteroclinic network. These locally generated temporal sequences of information items can be transferred over a spatial grid by entrainment to the pacemaker dynamics. Such spatiotemporal patterns are believed to code information in brain dynamics. Depending on the number and location of pacemakers on two-dimensional grids, synchronization can be maintained in the presence of a large number of resting state units and mediated via target waves when the pacemakers are concentrated to a small area of such grids. In view of brain dynamics, our results indicate a possibly ample repertoire for coding information in temporal patterns.

#### DY 18.4 Tue 12:00 H19

Suppression of quasiperiodicity in circle maps with quenched disorder -•David Müller-Bender¹, Johann Luca Kastner¹, and Günter Radons^{1,2} ¹Institute of Physics, Chemnitz University of Technology, 09107 Chemnitz, Germany — ²Institute of Mechatronics, 09126 Chemnitz, Germany

We show that introducing quenched disorder into a circle map leads to the suppression of quasiperiodic behavior in the limit of large system sizes. Specifically, for most parameters the fraction of disorder realizations showing quasiperiodicity decreases with the system size and eventually vanishes in the limit of infinite size, where almost all realizations show mode-locking. Consequently, in this limit, and in strong contrast to standard circle maps, almost the whole parameter space corresponding to invertible dynamics consists of Arnold tongues.

Details can be found in the preprint D. Müller-Bender, J. L. Kastner, and G. Radons, Suppression of quasiperiodicity in circle maps with quenched disorder, arXiv:2204.09392 [nlin.cd] (2022).

Reservoir Computing and Nonlinear Dynamics - •ULRICH PARLITZ - Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany -Institute for the Dynamics of Complex Systems, Georg-August-Universität Göttingen, Göttingen, Germany

We discuss the interrelation between reservoir computing (RC) and nonlinear dynamics (NLD). On the one hand, the performance of RC can be characterized and improved by concepts from NLD such as generalized synchronization and delay embedding. On the other hand, RC can be used to predict and control dynamical systems, including hybrid architectures that employ physically informed machine learning. Various aspects of this mutual relationship between RC and NLD are illustrated using low-dimensional and spatially extended chaotic dynamical systems.

DY 18.6 Tue 12:30 H19 Chameleon attractors in deterministic and stochastic Lorenz-63 systems - •Reik V. Donner^{1,2}, Tommaso Alberti³, and Davide Faranda⁴ - $^1\mathrm{Hochschule}$  Magdeburg-Stendal, Magdeburg, Germany —  $^2\mathrm{Potsdam}$  Institute for Climate Impact Research, Potsdam, Germany – ³National Institute for Astrophysics, Rome, Italy — ⁴LSCE, Université Paris-Saclay, Gif-sur-Yvette, France

Location: H19

#### Dynamics and Statistical Physics Division (DY)

The dynamical chaacteristics of a trajectory on a chaotic or stochastic attractor undergo marked changes when successively eliminating the low-frequency variability components and focusing on the fast fluctuations only, motivating the new concept of Chameleon attractors. Here, we study the time scale dependent instantaneous and average fractal characteristics of partial sums of dynamical modes identified by means of empirical mode decomposition for the Lorenz63 system and two stochastic versions thereof with additive and multiplicative noise as obtained by exploiting recurrences in phase space using extreme value theory. While the average fractal dimensions converge to the expected values as more and more low-frequency modes are included, we find an excess dimension larger than 3 for higher frequency modes below the Lyapunov time scale resulting from the stochastic components.

#### DY 19.1 Tue 11:30 H20

Disorder-free localization transition in a two-dimensional lattice gauge theory — •NILOTPAL CHAKRABORTY¹, MARKUS HEYL^{1,2}, PETR KARPOV¹, and RODERICH MOESSNER¹ — ¹Max Planck Institute for physics of complex systems, Dresden — ²University of Augsburg, Augsburg

While the nature of the quantum localization transition (QLT) is still debated for conventional many-body localization, here we provide the first comprehensive characterization of the QLT in two dimensions (2D) for a disorder-free case. Disorder-free localization can appear in homogeneous 2D LGTs such as the U(1) quantum link model (QLM) due to an underlying classical percolation transition fragmenting the system into disconnected real-space clusters. Building on the percolation model, we characterize the QLT in the U(1) QLM through a detailed study of the ergodicity properties of finite-size real- space clusters via level-spacing statistics and localization in configuration space. We argue for the presence of two regimes - one in which large finite-size clusters effectively behave non-ergodically, a result naturally accounted for as an interference phenomenon in configuration space and the other in which all large clusters behave ergodically. As one central result, in the latter regime we claim that the QLT is equivalent to the classical percolation transition and is hence continuous. Utilizing this equivalence we determine the universality class and critical behaviour of the QLT from a finite-size scaling analysis of the percolation problem.

DY 19.2 Tue 11:45 H20 Quantifying local memory in disordered systems across the ETH-MBL transition — •SEBASTIAN WENDEROTH and MICHAEL THOSS — Physikalisches Institut, Albert-Ludwigs-Universität Freiburg, Freiburg

Thermalization decribes the process of a system reaching thermal equilibrium with its environment. The asymptotic state solely depends on a few macroscopic parameters of the environment. Hence, the information about the initial state is lost during the process. Many-body localized systems fail to thermalize due to the absence of transport, and thus, some information about the initial state is retained in local observables at all times.

Based on the time-evolution of a subsystem, we present a concept which can be used to quantify the influence of the initial state on local observables. Using this approach, we investigate local memory in the XXZ Heisenberg spin chain with random local disorder, a paradigmatic model exhibiting a transition from thermalizing to localized dynamics. We discuss the loss of local information and identify different delocalization mechanisms.

DY 19.3 Tue 12:00 H20

**Dynamically Induced Exceptional Phases in Quenched Interacting Semimetals** — •CARL LEHMANN¹, JAN CARL BUDICH¹, and MICHAEL SCHÜLER² — ¹TU Dresden, Dresden, Germany — ²Paul Scherrer Institute, Villigen, Switzerland We report on the dynamical formation of exceptional degeneracies in basic correlation functions of nonintegrable one- and two-dimensional systems quenched to the vicinity of a critical point. Remarkably, fine-tuned semimetallic points in the phase diagram of the considered systems are thereby promoted to topologically robust non-Hermitian (NH) nodal phases emerging in the coherent time evolution of a dynamically equilibrating system. Using nonequilibrium Greens function methods within the conserving second Born approximation, we predict observable signatures of these NH nodal phases both in equilibrated spectral functions and in the nonequilibrium dynamics of single-particle density matrix functions.

### DY 19.4 Tue 12:15 H20

**Nontrivial damping of quantum many-body dynamics** — •TJARK HEITMANN¹, JONAS RICHTER², JOCHEN GEMMER¹, and ROBIN STEINIGEWEG¹ — ¹Department of Physics, University of Osnabrück, Germany — ²Department of Physics and Astronomy, University College London, UK

Understanding how the dynamics of a given quantum system with many degrees of freedom is altered by the presence of a generic perturbation is a notoriously difficult question. Recent works predict that, in the overwhelming majority of cases, the unperturbed dynamics is just damped by a simple function, e.g., ex-

ponentially. While these predictions rely on random-matrix arguments and typicality, they can only be verified for a specific physical situation by comparing to the actual solution or measurement. Crucially, it also remains unclear how frequent and under which conditions counterexamples to the typical behavior occur. Here, we discuss this question from the perspective of projection-operator techniques, where exponential damping of a density matrix occurs in the interaction picture but not necessarily in the Schrödinger picture. We show that a nontrivial damping in the Schrödinger picture can emerge if the dynamics in the unperturbed system possesses rich features, for instance due to the presence of strong interactions. This suggestion has consequences for the time dependence of correlation functions. We substantiate our theoretical arguments by largescale numerical simulations of charge transport in the extended Fermi-Hubbard model with nearest-neighbor interactions as perturbations to the integrable reference system.

DY 19.5 Tue 12:30 H20 Effect of electron-electron interaction on the spectral statistics in circular sector graphene billiards — •XIANZHANG CHEN^{1,2} and LIANG HUANG¹ — ¹Lanzhou Center for Theoretical Physics, and Key Laboratory for Magnetism and Magnetic Materials of MOE, Lanzhou University, Lanzhou, Gansu 730000, China — ²Université de Strasbourg, CNRS, Institut de Physique et Chimie des Matériaux de Strasbourg, UMR 7504, F-67000 Strasbourg, France

The spectral statistics is a fundamental issue in quantum chaos and has been used widely as a measure to probe the complexity of the underlying quantum systems. In this work, we adopt the one-orbital mean-field Hubbard model to investigate the effect of many-body interactions on the spectral statistics of circular sector graphene billiards. It is found that the spectral statistics are insensitive to the Hubbard interaction U for most of the energy ranges, except for energies around the Dirac point. We choose two representative systems, whose spectral statistics follow Poisson and Gaussian orthogonal ensemble (GOE) when U = 0, respectively. As U increases, for both cases, the spectral statistics moves toward GOE. However, after passing a critical value  $U_c$ , the spectral statistics turns back toward Poisson as U is increased further, due to the emerging gap and henceforth distinct behaviors of the quasiparticles. In addition, the energies above and below the Dirac point may exhibit different spectral statistics. These results uncover the intriguing connection between Hubbard interaction and the spectral statistics in graphene sector billiards. A physical picture is provided to understand these effects.

DY 19.6 Tue 12:45 H20 Anisotropy-mediated localization — •IVAN KHAYMOVICH — Nordic Institute for Theoretical Physics, Stockholm, Sweden

Recently, the standard picture of Anderson localization transition in ddimensional long-range (e.g. dipolar) systems has been argued due to several reported counterintuitive examples of (at least power-law) localization beyond the convergence of the perturbation theory. In addition, wave-function spatial decay rates obey a "mysterious" duality [1] mapping different powers 'a' of power-law bending symmetrically around the critical point a=d.

In my talk, I address this intriguing question, present a general approach applicable to all such models, and uncover the role of correlations and the origin of the above duality [2]. The phenomenon of the correlation-induced localization [2] is just the very peak of the iceberg in this field. Therefore I will focus on the effects of anisotropy [3] in dipolar system and show the reentrant localization governed by the anisotropy parameter given by the tilt of an electric field. Note that the range of systems is also not limited by the dipolar systems, but includes also the Weyl semimetals, ultracold atoms, Rydberg excitations in the optical traps and many others.

Writing in Water - •THOMAS PALBERG and NADIR MÖLLER - Institut für Physik, Johannes Gutenberg Universität Mainz

Writing is an ancient cultural technique, typically performed by leaving some trace in or on a solid surface. We here explore the possibilities of leaving the trace in a liquid medium close to a surface and obtain lines or letters with high contrast and durability. Ion exchange (IEX) resin beads are used as mobile proton or hydroxyl ion sources. Moving them across the substrate in low-salt water, leaves a pH trace. Added autonomously swimming particles are able to follow this trace, mimicking hunter and prey dynamics or mate tracing, but without leaving a visible testimony. Written lines are realized by adding larger amounts of micron-sized passive particles, which settle to the like-charged substrate. Being phoretically drawn to or repelled from the pH traces, they form a well-visible trail behind the source. Trails of cationic IEX are white on black, those of anionic IEX are black on white. Their diffusive fading is slowed by continued phoretic flows and trails are stable up to hours. Sources moving autonomously just scribble. Sources propelled straight by gravity leave high-contrast lines. Deliberate tilting sequences for the substrate, then, facilitate writing.

Composition Dependent Instabilities in Mixtures With Many Components — •FILIPE THEWES, MATTHIAS KRÜGER, and PETER SOLLICH — Institut für Theoretische Physik, Georg-August-Universität Göttingen, Göttingen, Germany Understanding the phase behavior of mixtures with many components is a key step towards a physics-based description of intracellular compartmentalization. We study the instabilities of a model where the interactions as quantified by the second virial coefficients are taken as random Gaussian variables. Using tools from free probability theory we obtain the spinodal curve and the nature of instabilities for an arbitrary distribution of components, thus lifting the drastic simplification of uniform composition that has been made in earlier work. We illustrate our results with examples and show that, by controlling the density of only a few components, one can systematically change the nature of instabilities and achieve demixing for realistic scenarios, which appeared to be ruled out by previous studies. Inspired by these results, we introduce an additive model taking into account also deterministic interactions. We show how this systematic interaction leads to a competition between different forms of instabilities that can be tuned by controlling the model parameters. Since most experimental protocols for complex mixtures rely on tuning either the composition or systematic interactions, we expect our results to significantly extend the range of mixtures that can be treated within the mean-field model.

Phase behaviour of mixtures of hard spheres and hard rods - • POSHIKA GANDHI¹, JOERI OPDAM², ANJA KUHNHOLD¹, TANJA SCHILLING¹, and REMCO TUINIER² – ¹Institute of Physics, Albert-Ludwigs-University Freiburg, Germany – ²Institute for Complex Molecular Systems, Eindhoven University of Technology, The Netherlands

Phase behaviours of complex mixtures are challenging to predict. A binary mixture of hard spherocylinders (HSC) and hard spheres (HS) is one such system. As rod-like particles have large excluded volume, a free volume theory (FVT) can be used to gain insights into demixing phenomenon and phase stability.

Vliegenthart et al[1] modified an existing FVT for binary mixtures of HS to accommodate HSC. This FVT works well for the needle limit, i.e., weak excluded volume interactions between HSC. It, however, predicts the phase boundaries at too low HSC concentrations. Opdam et al[2] showed that by incorporating excluded volume interactions between the depletants even in the reservoir improves the FVT significantly.

We used the new FVT to predict phase boundaries of colloidal mixtures and compared them to MC simulations. The results show that accounting for all the excluded volumes of all the components may be pivotal in understanding phase behaviour of colloidal mixtures [3].

Markov State Modelling of Self Assembling Colloidal Systems - • SALMAN FARIZ NAVAS and SABINE H.L. KLAPP — ITP, Technische Universität Berlin, Germanv

Many colloidal particle systems display self-assembly phenomena yielding, e.g., clusters or gel-like materials. The current project focuses on the use of phase space discretization techniques towards developing a coarse-grained description of self-assembly processes in colloidal systems.

Specifically, we develop a corresponding Markov State Model from particleresolved Brownian Dynamics simulations, wherein the Markov states are the various local structural configurations present in the system and the Markovian process describing the stochastic transition of particles from one structure to the other.

The specific self-assembly problem studied here involves the aggregation of colloidal particles with field-induced multipolar interactions [1]. We use bond orientational order parameters and the coordination number as parameters to define the discrete states. The number of particles in the largest cluster in the system (n) is used as a parameter to quantify the progress of the overall aggregation. Transition probability matrices (TPM) between the different states are then computed for each value of n. Information regarding relaxation times and pathways relevant to the aggregation process are extracted by analyzing changes in the TPM elements.

**Repulsion of topological defects in quasi-2D liquid crystal films** — •KIRSTEN HARTH^{1,2} and RALF STANNARIUS³ — ¹Fachbereich Technik, TH Brandenburg, Brandenburg an der Havel, Deutschland – ²MARS und MRTM, Otto von Guericke Universität Magdeburg, Deutschland – ³Institut für Physik und MARS, Otto von Guericke Universität Magdeburg, Deutschland

The dynamics of topological defects is of interest, e.g., in phase transitions, cosmology or structural organization of colloids and active matter. Liquid crystals are a straightforward system allowing optical characterization of defect motion. As anisotropic fluids, they are characterized by orientational order, introducing long-range elastic forces, in addition to liquid-like fluidity with viscosity coefficients related to, e.g., the local shear flow directions respective to the local orientational field. This causes intriguing effects and must not be neglected.

The comparison of recent exeriments [1,2] in free-standing smectic C films to theoretical and numerical predictions [2,3] leaves a number of questions unanswered. A proper consideration of flow coupling and / or of an anistropy of the elastic constants in a simulation with realistic boundary conditions may solve the issues. We explain why elastic anisotropy is particularly important here. Experimental and numerical data are compared to elucidate the effect of elastic constants and flow on the repeulsion dynamics.

Incipient motion for 3d geometries — •DOMINIK GEYER, PAOLO MALGAR-ETTI, OTHMANE AOUANE, and JENS HARTING — Helmholtz Institute Erlangen-Nürnberg for Renewable Energy (IEK-11), Cauerstr. 1, 91058 Erlangen, Germany

The incipient motion describes the threshold conditions between erosion and sedimentation. This natural process is relevant for a broad field of natural and industrial processes, for example, cell detachment, cleaning of surfaces, and transportation in pipelines. Our interest is in the incipient motion of a single particle on non-trivial geometries. The crucial parameter for describing incipient motion is the so-called Shields number which is the ratio between viscous forces and buoyancy. Interestingly, the incipient motion has been reported at values of the Shields number much smaller than unity ( $\theta \simeq 10^{-2}$ ) hence questioning whether the proposed Shields number is indeed capturing the relevant physical phenomena. In order to critically discuss this aspect, we perform lattice Boltzmann simulations of a solid particle on a substrate consisting of solid spheres taking into account the local fluid velocity and the particle size. Our numerical data will allow us to calculate the effective viscous force acting on the particle and hence to propose possible corrections to the Shields number which can better account for the experimental and numerical data.

DY 23.7 Wed 11:15 H18

**Phase behaviour in a mono-layer colloidal membrane** — •LÉA BEAULES, ANJA KUHNHOLD, and TANJA SCHILLING — Institute of Physics, Albert-Ludwigs-University Freiburg, Germany

Kosterlitz-Thouless-Halperin-Nelson and Young (KTHNY) theory predicted that the melting of a purely 2D hard disk system would be defect-mediated and occur via two continuous transitions: from the solid to the intermediate hexatic phase and, from the hexatic to the fluid phase. Since then phase behaviour of this system as well as closely related systems have been extensively investigated and debated, showing that the hexatic-liquid transition is of first order for purely hard system [1]. Additionally, upon increasing interaction range or adding dispersity in the system the transition can become continuous or the hexatic phase can vanish [2].

However a large number of real systems can be more accurately approximated as a quasi-2D system that exhibits out of plane interactions, e.g. biological membranes; therefore understanding their role in the phase behaviour is important. Thus to extend our understanding of these systems, we use Monte-Carlo simulations to study an infinite mono-layer membrane of hard rod-like particles. We investigate how the orientational degree of freedom of the rods, and the range of their out of plane interactions affect the phase behaviour of the system.

DY 23.8 Wed 11:30 H18

**Particle-resolved topological defects of smectic colloidal liquid crystals in 2d confinement** — •RENÉ WITTMANN¹, PAUL A. MONDERKAMP¹, LOUIS B. G. CORTES^{2,3}, DIRK G. A. L. AARTS³, FRANK SMALLENBURG⁴, and HARTMUT LÖWEN¹ — ¹Institut für Theoretische Physik II: Weiche Materie, Heinrich-Heine Universität Düsseldorf, Germany — ²School of Applied and Engineering Physics, Cornell University, USA — ³Department of Chemistry, Physical and Theoretical Chemistry Laboratory, University of Oxford, UK — ⁴Laboratoire de Physique des Solides, CNRS, Université Paris-Saclay, France

We present a general classification scheme [1] of the intrinsic structure of smectic colloidal liquid crystals in two spatial dimensions, dictated by the interplay between the intrinsic layering and the externally imposed boundary structure. Thereby, we demonstrate that topological defects emerge in the form of spatially extended grain-boundaries, which are characterized by coexisting nematic and tetratic orientational order. We examine these intriguing topological properties on the particle scale by means of Monte-Carlo simulations, fundamentalmeasure-based density functional theory and real-space microscopy of colloidal rods. The structural details agree on a quantitative level. In particular, we analyze the typical shape of grain-boundary networks in a large range of polygonal confinements [1] and the stability of different competing topological states in nontrivial domains with additional interior boundaries [2].

**Structure of nematic hard rod tactoids** — •ANJA KUHNHOLD¹ and PAUL VAN DER SCHOOT² — ¹University of Freiburg, Freiburg, Germany — ²Eindhoven University of Technology, Eindhoven, The Netherlands

Droplets of ordered phases of anisotropic particles take on specific shapes and internal structures. Compared to droplets of spherical particles, tactoids are elongated with cusp-like tips. Several parameters dictate the overall shape and structure: density of the system, elastic constants of the particles, anchoring strength, interfacial tension, and volume of the tactoid. [1]

We compare Monte Carlo simulation results of hard rod tactoids in a bath of spherical ghost particles to predictions from a scaling theory. We focus on small tactoids where the macroscopic scaling description might break down. We find that smaller tactoids have a more uniform director field than larger tactoids. Also, the segment density increases towards the tactoid tips in agreement with the theory. In addition, we find further density modulations when the average density increases.

Besides, we test the effect of an aligning field on the shape and structure of the tactoids and find that the director field becomes more uniform and the aspect ratio increases, but not to a vast extent. [2]

**Optimising Energetics in Field Theories: Pareto Front and Phase Transitions** — •ATUL TANAJI MOHITE and ETIENNE FODOR — University of Luxembourg, Department of Physics and Materials Science, L-1511, Luxembourg

Field theories have been extremely successful in characterizing the universal properties of various phase transitions, and in delineating a few canonical models which capture the essential Physics in a large class of systems. Interestingly, a generic framework for optimizing the energetic cost associated with the finite-time driving of such systems is still largely missing. Here, building on recent advances in stochastic thermodynamics and optimal transport theory, we show how to analytically derive the optimal driving protocols that minimise average stochastic work, which we apply to cases with either conserved or non-conserved scalar order parameter in the weak noise regime. Moreover, we formulate a numerical multi-optimization problem to simultaneously optimize the mean and fluctuations of stochastic work, leading to revealing a first-order phase transition in the corresponding Pareto front, which features the coexistence of multiple optimal protocols. Overall, our results elucidate how to drive field theories at a minimal energy cost, with the potential to be deployed to a broad class of systems.

**Replica-Symmetry Breaking for Ulam's problem** — •PHIL KRABBE¹, HENDRIK SCHAWE², and ALEXANDER K. HARTMANN¹ — ¹Institute of Physics, University of Oldenburg, Germany — ²LPTM, CY Cergy Paris Université, France

For a given sequence  $X = x_1, x_2, ..., x_n$  of numbers, an increasing subsequence (IS) is a subset of l elements i(1) < i(2) < ... < i(l) such that  $x_{i(1)} < x_{i(2)} < ... < x_{i(l)}$ . The longest increasing subsequences (LIS) problem, i.e. to maximise l, was considered numerically first by S. Ulam and is a well studied topic. Here we consider the length l as an energy and study the canonical ensemble of ISs controlled by temperature parameter T, which includes the LIS for  $T \rightarrow 0$ . We extended our algorithm from [1] such that we can draw ISs in perfect equilibrium in polynomial time. This allows us to study large sequences with up to n = 8192 numbers.

We studied the IS numerically [2] for sequences X being permutations of integers. As measurable quantities, we analysed the mean energy, the specific heat Cand and the overlap q between the drawn ISs. Our exact-sampling results indicate that the IS exhibits in the thermodynamic limit a complex energy landscape in the spirit of Replica Symmetry Breaking, characterised by a broad distribution P(q) of overlaps and a hierarchical organization of the configuration space.

**Optimality of nonconservative driving for finite-time processes with discrete states** — •BENEDIKT REMLEIN and UDO SEIFERT — II. Institut für Theoretische Physik, Universität Stuttgart, 70550 Stuttgart, Germany

An optimal finite-time process drives a given initial distribution to a given final one in a given time at the lowest cost as quantified by total entropy production. We prove that for a system with discrete states this optimal process involves nonconservative driving, i.e., a genuine driving affinity, in contrast to the case of a system with continuous states. In a multicyclic network, the optimal driving affinity is bounded by the number of states within each cycle. If the driving affects forward and backwards rates nonsymmetrically, the bound additionally depends on a structural parameter characterizing this asymmetry [1]. [1] B. Remlein and U. Seifert, Phys. Rev. E 103, L050105 (2021)

Phase shift in periodically driven non-equilibrium systems: Its identification and a bound — •JULIUS DEGÜNTHER, TIMUR KOYUK, and UDO SEIFERT — II. Institut für Theoretische Physik, Universität Stuttgart, 70550 Stuttgart, Germany Time-dependently driven stochastic systems form a vast and manifold class of non-equilibrium systems used to model important applications on small length scales such as bit erasure protocols or microscopic heat engines. One property that unites all these quite different systems is some form of lag between the driving of the system and its response. For periodic steady states, we quantify this lag by introducing a generalized phase difference. We prove two tight bounds for this generalized phase difference, which provide upper limits to the lag such systems can yield. The first and most general bound depends only on the relative speed of the driving. The second more detailed bound takes additional information about the rates into account. We show that both bounds can be saturated by an appropriate choice of parameters.

#### DY 24.5 Wed 10:45 H19

Thermodynamic inference in partially accessible Markov networks: A unifying perspective from transition-based waiting time distributions — •JANN VAN DER MEER, BENJAMIN ERTEL, and UDO SEIFERT — II. Institut für Theoretische Physik, Universität Stuttgart, 70550 Stuttgart, Germany

The inference of thermodynamic quantities from the description of an only partially accessible physical system is a central challenge in stochastic thermodynamics. A common approach is coarse-graining, which maps the dynamics of such a system to a reduced effective one. While coarse-graining states of the system into compound ones is a well studied concept, recent evidence hints at a complementary description by considering observable transitions and waiting times. We consider waiting time distributions between two consecutive transitions of a partially observable Markov network and their ratios to quantify irreversibility and entropy production. We formulate criteria whether this entropy estimator provides a lower bound or recovers the full physical entropy production. Additionally, we derive estimators for the topology of the network, i.e., the presence of a hidden cycle, its number of states and its driving affinity. From a different perspective, our results can be condensed into a fluctuation theorem for an equivalent semi-Markov process. This mathematical perspective provides a unifying framework to compare our and known estimators. The correct version of time-reversal is crucial to clarify the relationship of formal versus physical irreversibility. Numerical calculations illustrate our exact results and estimate the quality of our bounds.

DY 24.6 Wed 11:00 H19

**Geometric Brownian Information Engine** — •DEBASISH MONDAL, RAFNA RAFEEK, and SYED YUNUS ALI — Department of Chemistry, Indian Institute of Technology Tirupati, Andhra Pradesh, India

We design a geometric Brownian information engine by considering overdamped Brownian particles inside a 2-D monolobal confinement with irregular width. Under such detention, particles experience an effective entropic potential which has a logarithmic form. We employ a feedback control protocol as an outcome of error-free position measurement. We reposition the centre of the confinement to the feedback site  $(x_f)$  instantaneously when the position of the trapped particle crosses the measurement distance  $(x_m)$  for the first time. Then, the particle is allowed to thermal relaxation. We find the exact analytical value of the upper bound of extractable work as  $(\frac{5}{3} - 2ln2)k_BT$ . We introduce a constant force G downwards to the transverse coordinate. G tunes the entropic contribution in the effective potential and hence the standard deviation ( $\sigma$ ) of the probability distribution. The upper bound of the achievable work shows a cross-over from  $(\frac{5}{3} - 2ln2)k_BT$  to  $\frac{1}{2}k_BT$  when the system changes from an entropy dominated regime to energy dominated one. Compared to an energetic analogue, the loss of information during the relaxation process is higher in the entropy-dominated region, which accredits the less value in achievable work. We recognize that the extracted work is maximum when  $x_f = 2x_m$  with  $x_m \sim 0.6\sigma$ , irrespective of the extent of the entropic limitation. The average displacement increases with growing entropic control and is maximum when  $x_m \sim 0.81\sigma$ .

**Percolation properties of the Ising spin glass in two dimensions** — •LAMBERT MÜNSTER and MARTIN WEIGEL — Institut für Physik, TU Chemnitz, 09107 Chemnitz, Germany

Cluster representations provide a framework to study critical phenomena from the geometrical perspective of percolation. Due to frustration the common Fortuin-Kasteleyn cluster representation of ferromagnets is not well suited to describe the spin-glass transition [1,2]. The order parameter of this transition is the overlap which is naturally defined with respect to two replicas. In the present work we hence study a two-replica cluster representation [3] of the twodimensional Ising spin glass by performing Monte Carlo simulations at low temperatures. Our data is consistent with the existence of a zero-temperature percolation transition in agreement with the zero-temperature spin-glass transition in two dimensions. The overlap is proportional to the difference in density of the two largest clusters.

**Replica-symmetry breaking for directed polymers in correlated random media** — •ALEXANDER K. HARTMANN — Inst. of Physics, University of Oldenburg The phase-space behavior of complex system can often be described by *replica-symmetry breaking* (RSB), as introduced by Giorgio Parisi for mean-field Ising spin glasses [1] and highlighted by the Nobel price 2021. Numerically, spin glasses and related problems are notoriously hard to study, such that models exhibiting RSB have been treated so far only for small sizes. Here, directed polymers on 1+1 dimensional lattices at temperature T are considered [2]. New ensembles with correlations of the disorder as well as fractal patterning are introduced [3]. This model allows for direct sampling in perfect thermal equilibrium for large system sizes of  $N = L^2 = 32768 \times 32768 \approx 10^9$  sites. Fluctuations of the free energy and transverse extension are obtained and compared with the standard uncorrelated ensemble. The phase-space structure is studied via the distribution of overlaps, hierarchical clustering methods and analysis of ultrametricity. One ensemble shows a simple behavior like a ferromagnet. The other two ensembles exhibit indications for multiple RSB. In total, the present model ensembles of-fer convenient numerical access to comprehensively studying complex RSB-like behavior.

DY 26.3 Wed 10:30 H20

Interplay of disorder and flat band geometry for generalized Lieb models in 3D with correlated order — •JIE LIU¹, CARLO DANIELI², JIANXIN ZHONG¹, and RUDOLF A. RÖMER^{1,3,4} — ¹School of Physics and Optoelectronics, Xiangtan University, Xiangtan 411105, China — ²MPI-PaKS, Nöthnitzer Strasse, Dresden, Germany — ³Department of Physics, University of Warwick, Coventry, CV4 7AL, United Kingdom — ⁴CY Advanced Studies and LPTM (UMR8089 of CNRS), CY Cergy-Paris Université, F-95302 Cergy-Pontoise, France

Uniform Anderson disorder in generalized 3D Lieb models gives rise to the existence of bounded mobility edges and destroys the macroscopic degeneracy of the compactly-localized states. We now introduce correlated order such that this degeneracy remains and the compactly-localized states are preserved. We obtain the energy-disorder phase diagrams via transfer matrix methods, computing the localization lengths and via sparse-matrix direct diagonalization, using rvalue energy-level statistics. For suitably large disorders, we can finite-size scale both quantities and identify mobility edges with critical properties close to the

Location: H39

standard Anderson transition in 3D. Intriguingly, the survival of the compactlylocalized states lead to seemingly diverging mobility edges. For small disorder, however, a change from extended to localized behavior can be found upon decreasing disorder — leading to an unconventional "inverse Anderson" behavior.

DY 26.4 Wed 10:45 H20

Anomalous collective dynamics of auto-chemotactic populations — JASPER VAN DER KOLK¹, •FLORIAN RASSHOFER¹, RICHARD SWIDERSKI¹, ASTIK HALDAR², ABHIK BASU², and ERWIN FREY^{1,3} — ¹Arnold Sommerfeld Center for Theoretical Physics and Center for NanoScience, LMU München, Theresienstraße 37, Munich, Germany — ²Theory Division, Saha Institute of Nuclear Physics, HBNI, 1/AF Bidhannagar, Calcutta 700 064, West Bengal, India — ³Max Planck School Matter to Life, Hofgartenstraße 8, Munich, Germany

While the role of local interactions in non-equilibrium phase transitions is well studied, a fundamental understanding of the effects of long-range interactions is lacking. In particular, we ask the question how long-ranged interactions can alter the universal behaviour close to an absorbing state. As a model system, we study the critical dynamics of reproducing agents subject to auto-chemotactic interactions and limited resources.

A renormalization group analysis reveals distinct scaling regimes for fast (attractive or repulsive) interactions; for slow signal transduction the dynamics is dominated by a diffusive fixed point. Further, we present a novel nonlinear mechanism that stabilizes the continuous transition against the emergence of a characteristic length scale due to a chemotactic collapse.

DY 26.5 Wed 11:00 H20

**Population Annealing Monte Carlo Using the Rejection-Free n-Fold Way Update Applied to a Frustrated Ising Model on a Honeycomb Lattice** – •DENIS GESSERT^{1,2}, MARTIN WEIGEL^{1,3}, and WOLFHARD JANKE² – ¹Centre for Fluid and Complex Systems, Coventry University, Coventry, CV1 5FB, United Kingdom – ²Institut für Theoretische Physik, Leipzig University, Postfach 100920, 04009 Leipzig, Germany – ³Institut für Physik, Technische Universität Chemnitz, 09107 Chemnitz, Germany

Population annealing (PA) is a Monte Carlo method well suited for problems with a rough free energy landscape such as glassy systems. PA is similar to repeated simulated annealing, with the addition of a resampling step at each temperature. While a large population may to some extent compensate for imperfect equilibration, it is clear that PA must fail if almost no spins are flipped during equilibration.

This is the case in systems with a phase transition at a very low temperature where a high Metropolis rejection rate makes sampling phase space near infeasible. To overcome this slow-down we propose a combination of the PA framework with the rejection-free "n-fold way" update and achieve an exponential speed-up at low temperatures as compared to Metropolis.

To test our method we study the Ising model with competing ferromagnetic  $(J_1 > 0)$  nearest and antiferromagnetic  $(J_2 < 0)$  next-to-nearest neighbor interactions on a honeycomb lattice. As  $T_c$  becomes arbitrarily small when approaching the special point  $J_2 = -J_1/4$  with  $T_c = 0$  we consider this a good choice to test the efficacy of our method.

DY 26.6 Wed 11:15 H20

Critical behavior of the three-state random-field Potts model in three dimensions — MANOJ KUMAR¹, VARSHA BANERJEE², SANJAY PURI³, and •MARTIN WEIGEL¹ — ¹Institut für Physik, Technische Universität Chemnitz, 09107 Chemnitz, Germany — ²Department of Physics, Indian Institute of Technology, Hauz Khas, New Delhi – 110016, India — ³School of Physical Sciences, Jawaharlal Nehru University, New Delhi – 110067, India.

Enormous advances have been made in the past 20 years in our understanding of the random-field Ising model, and there is now consensus on many aspects of its behavior at least in thermal equilibrium. In contrast, little is known about its generalization to the random-field Potts model which has a number of important experimental realizations. Here we start filling this gap with an investigation of the three-state random-field Potts model in three dimensions. Building on the success of ground-state calculations for the Ising system, we use a recently developed approximate scheme based on *graph-cut methods* to study the properties of the zero-temperature random fixed point of the system that determines the zero and non-zero temperature transition behavior. We find compelling evidence for a continuous phase transition. Implementing an extensive finite-size scaling (FSS) analysis, we determine the critical exponents and compare them to those of the random-field Ising model.

Symmetries and zero modes in sample path large deviations — •TIMO SCHORLEPP¹, TOBIAS GRAFKE², and RAINER GRAUER¹ — ¹Institute for Theoretical Physics I, Ruhr-University Bochum, Bochum, Germany — ²Mathematics Institute, University of Warwick, Coventry, United Kingdom

Sharp large deviation estimates for stochastic differential equations with small noise, based on minimizing the Freidlin-Wentzell action functional under appropriate boundary conditions, can be obtained by integrating certain matrix Riccati differential equations along the large deviation minimizers or instantons, either forward or backward in time. Previous works in this direction often rely on the existence of isolated minimizers with positive definite second variation. By adopting techniques from field theory and explicitly evaluating the large deviation prefactors as functional determinant ratios using Forman's theorem, we extend the approach to general systems where degenerate submanifolds of minimizers exist. The key technique for this is a boundary-type regularization of the second variation operator. This extension is particularly relevant if the system possesses continuous symmetries that are broken by the instantons. We find that removing the vanishing eigenvalues associated with the zero modes is possible within the Riccati formulation and amounts to modifying the initial or final conditions and evaluation of the Riccati matrices. We apply our results in multiple examples including a dynamical phase transition for the average surface height in short-time large deviations of the one-dimensional Kardar-Parisi-Zhang equation with flat initial profile.

**Diffusivity dependence of the transition path ensemble** — LUKAS KIKUCHI, RONOJOY ADHIKARI, and •JULIAN KAPPLER — DAMTP, Cambridge University, Cambridge, UK

Transition pathways of stochastic dynamical systems are typically approximated by instantons. Here we show, using a dynamical system containing two competing pathways, that at low-to-intermediate temperatures, instantons can fail to capture the most likely transition pathway. We construct an approximation which includes fluctuations around the instanton and, by comparing with the results of an accurate and efficient path-space Monte Carlo sampling method, find this approximation to hold for a wide range of temperatures. Our work delimits the applicability of large deviation theory and provides methods to probe these limits numerically.

DY 28.3 Wed 11:45 H19 Sampling Rare Event Energy Landscapes via a Birth-Death Process —

•BENJAMIN PAMPEL¹, SIMON HOLBACH², LISA HARTUNG², and OMAR VALSSON^{1,3} — ¹Max-Planck-Institute für Polymerforschung, Ackermannweg 10, 55128 Mainz — ²Institut für Mathematik, Johannes Gutenberg-Universität Mainz, Staudingerweg 9, 55099 Mainz — ³Department of Chemistry, University of North Texas, Denton, TX, USA

We investigate a novel sampling algorithm that augments Langevin dynamics with birth-death moves. This is a modification of a previously proposed algorithm [arXiv:1905.09863] that provides an approximation of a stochastic birthdeath process for a particle-based implementation. The method connects multiple parallel Langevin dynamics simulations of the same system with a birth-death scheme to facilitate global sampling according to the equilibrium distribution. We investigate the algorithm theoretically, implement it into a custom molecular simulation code, and test it via numerical simulations. We also examine the behavior of the algorithm under change of parameters. In this process, we observe the desired sampling for all tested systems. We find that the performance of the method is independent of the intrinsic time scales and barriers of the system, which is favorable for systems with processes on long time scales.

**MD simulations of partially frozen water in silica nanopores** — •SEBASTIAN KLOTH and MICHAEL VOGEL — TU Darmstadt, Institut für Physik kondensierter Materie, Hochschulstr. 6, 64289, Darmstadt, Germany

The properties of confined water are of enormous importance in nature and technology. In particular, the effects of partial freezing on structure and dynamics is highly relevant for, e.g. geology, cryopreservation and our understanding of the glass transition of water [1]. A powerful tool to study structural and dynamical properties of confined liquids are MD simulations [2]. We use this method to gain a better understanding of the effect of partial crystallization on the properties of confined water. A series of silica confinements with and without an artificially frozen crystalline core were prepared and the remaining liquid water layer was analyzed. Dynamics and structures of liquid layers with various thicknesses and their temperature dependencies are determined and compared to those with interfacial layers in the absence of a frozen crystalline core. We show that partial crystallization has substantial effects on the properties of confined water. Additionally the simulation results are used to calculate spectral densities of water dynamics for comparison with results of experimental studies. In particular, we explore which model for the functional form of the spectral density should be used in NMR spin-lattice relaxation studies on the dynamics of completely liquid or partially frozen water in nanopores.

DY 28.5 Wed 12:15 H19

Driven aging dynamics on sparse networks — •Benedikt Johannes  $Grüger^1$ , Diego Tapias¹, and Peter Sollich^{1,2} — ¹Institute for Theoretical Physics, Georg-August-Universität Göttingen, 37077 Göttingen, Germany -²Department of Mathematics, King's College London, London WC2R 2LS, UK We investigate the interaction of two paradigmatic ways of being out of equilibrium, aging and driving, in simple models of glassy dynamics. We specifically consider the Bouchaud model, where a system jumps between the numerous minima of a rough energy landscape in configuration space. As the temperature decreases, the system undergoes a dynamical phase transition, at which the relaxation time diverges. With an additional field, we then drive the system by biasing its dynamics towards higher/lower jumping activity. We investigate the spectrum of the (biased) master operator in that framework, using a population dynamics algorithm based on cavity theory that allows us to deduce statements about the thermodynamic limit. Combining this with extensive diagonalization we identify novel regimes in the bias-temperature phase diagram that are distinguished by the occurrence of different kinds of eigenvector localization and are linked to the existence of a spectral gap. We also present methodological advances in the form of novel strategies for operating the population dynamics algorithm.

Moiré-pattern evolution couples rotational and translational friction at crystalline interfaces — •XIN CAO¹, ANDREA SILVA^{2,3}, EMANUELE PANIZON⁴, ANDREA VANOSSI^{2,3}, NICOLA MANINI⁵, ERIO TOSATTI^{2,3,4}, and CLEMENS BECHINGER¹ — ¹Fachbereich Physik, Universität Konstanz, 78464 Konstanz, Germany — ²CNR-IOM, Consiglio Nazionale delle Ricerche - Istituto Officina dei Materiali, c/o SISSA, Via Bonomea 265, 34136, Trieste, Italy — ³International School for Advanced Studies (SISSA), Via Bonomea 265, 34136 Trieste, Italy — ⁴The Abdus Salam International Centre for Theoretical Physics (ICTP), Strada Costiera 11, 34151 Trieste, Italy — ⁵Dipartimento di Fisica, Università degli Studi di Milano, Via Celoria 16, 20133 Milano, Italy

We experimentally and theoretically study the rotational dynamics and depinning of two-dimensional colloidal crystalline clusters on periodically corrugated surfaces under well-controlled torques. We demonstrate that the traversing of locally commensurate areas of the moiré pattern through the edges of clusters, which is hindered by potential barriers during cluster rotation, eventually controls its rotational depinning. The experimentally measured depinning thresholds as a function of cluster size strikingly collapse onto a universal theoretical curve which predicts a superlow-static-torque state for large clusters. We further reveal a cluster-size-independent rotation-translation depinning transition when lattice-matched clusters are driven jointly by a force and a torque. Our work provides guidelines to the design of nanomechanical devices that involve rotations on atomic surfaces.

Accurate dynamics from memory in chemical reactions with small copy numbers — •MOSHIR HARSH and PETER SOLLICH — Institut für Theoretische Physik, Georg-August-Universität Göttingen

Chemical reactions in the regime of small copy numbers of species such as *gene* regulation or *protein* interaction networks show large fluctuations, making mean field solutions as given by mass action kinetics unreliable. Accurate calculations of the one and two-time quantities of these stochastic processes remain a challenging problem; numerical solutions to the master equation or stochastic simulations can be deployed, but these are computationally intensive and do not allow likelihood inference from dynamical trajectories.

Here, we present a method that captures the fluctuations beyond mean field using self-consistently determined *memory*: by integrating information from the past we can systematically improve our approximation for the dynamics of chemical reactions. This memory is not added ad-hoc, but can be shown to arise naturally by considering the effective action of the Doi-Peliti field theory of chemical reactions. The effective action is treated perturbatively but we can selfconsistently resum a very large class of diagrams resulting in a stable expansion. We demonstrate this method and its accuracy on single and multi-species binary reactions across a range of parameter values. We show how this approach also opens a route to making inferences from experimentally measured dynamics.

Invited TalkDY 29.1Wed 12:00H18Derivation of a continuum description of sheared jammed soft suspensionsfrom particle dynamics- ERIC BERTIN, NICOLAS CUNY, and ROMAIN MARI- Univ. Grenoble Alpes, CNRS, LIPhy, 38000 Grenoble, France

Jammed soft suspensions exhibit a rich phenomenology under deformation, including the existence of a yield stress and non-monotonous stress relaxations. Starting from the microscopic particle dynamics, we derive using a set of approximations a continuum description in terms of the macroscopic stress tensor (or more precisely, its traceless part) for given applied time-dependent deformations. The coefficients appearing in this equation are expressed in terms of the packing fraction and of particle-level parameters. This constitutive equation rooted in the microscopic dynamics qualitatively reproduces a number of salient features of the rheology of jammed soft suspensions, including the presence of yield stresses for both the shear component of the stress and the normal stress difference. Time-dependent protocols like the relaxation after a preshear are also considered, showing that a stronger preshear eventually leads to a more relaxed stress. This new methodology opens avenues for future developments, and involves physically more transparent approximations than the Mode Coupling approach.

**Clusters and fractals in non-reciprocally interacting colloids** — •SEBASTIAN FEHLINGER and BENNO LIEBCHEN — Institut für Physik kondensierter Materie, TU Darmstadt, Hochschulstraße 8, D-64289 Darmstadt, Germany

Non-reciprocal interactions are widespread in nature. For the specific case of a binary mixture of passive particles, the breaking of the action reaction principle can lead to formation of active colloidal molecules which are capable of self-propulsion. For small systems, such active molecules have already been realized in experiments based on phoretically interacting binary colloidal mixtures [1,2].

The focus of the present work is to understand the many body behaviour of active molecules. Using particle based simulations and continuum theory, we find that non-reciprocal attractions in a binary mixture of non-motile particles can destabilize the uniform disordered phase and lead to clusters which grow in time. Surprisingly, for a wide parameter range, the clusters only grow up to a certain size such that coarsening is arrested. We attribute this to an effective screening effect which hinges on the characteristic spatiotemporal organization of the two species within the clusters. In addition, remarkably, in a different parameter regime, we find porous macroclusters featuring significant holes and a fractal dimension which differs from the one expected for conventional diffusion limited aggregation.

Analysis of transient dynamics of bioconvection in swimming algae — •Alexander Jarosik, Florian von Rüling, and Alexey Eremin — Otto-von-Guericke Universität, Magdeburg, Germany

Swimming unicellular algae Chlamydomonas reinhardtii exposed to light form intricate hydrodynamic instability patterns called bioconvection. High-density plumes of cells are formed in the top layer, descend to the container's bottom, and rise again to the top. This instability arises from coupling between the gyroand phototactic behaviour of the cells, their physical properties and the flow. In this work, we analyse the microswimmer's dynamics as a function of the cell density, confinement of the environment and light. The transient behaviour of the plume formation is analysed using the Continuous Wavelet Transformation (CWT). We demonstrate that the plume formation can be controlled by local illumination.

**Optimal turbulent transport in microswimmer suspensions** — •HENNING REINKEN¹, SABINE H. L. KLAPP¹, and MICHAEL WILCZEK² — ¹Technische Universität Berlin — ²Universität Bayreuth

Microwsimmer suspensions, a paradigmatic example of an active fluid, selforganize into complex spatio-temporal flow patterns, including regular vortex lattices and mesoscale turbulence. This work investigates the transport properties of these suspensions by tracking the diffusive motion of passive tracers in the turbulent flow. We apply a continuum model for the effective microswimmer velocity field [1,2], where the dynamics is governed by the competition between relaxation to a regular vortex lattice and destabilization by nonlinear advection. Varying the strength of nonlinear advection, we observe two qualitatively different regimes of flow transport that we distinguish with the help of the dimensionless Kubo number K, which compares different time scales. Right above the transition to turbulence, the flow field evolves very slowly ( $K \gg 1$ ) and the spatial vortex structures lead to dominant trapping effects. In contrast, for large advection strength, much faster dynamics ( $K \ll 1$ ) leads to transport properties completely determined by the temporal correlations of the flow. In between  $(K \approx 1)$ , we observe a regime of optimal transport, where the diffusion coefficient reaches a maximum.

Interfacial activity dynamics of confined active droplets — •PRASHANTH RAMESH^{1,2}, BABAK VAJDI HOKMABAD¹, ARNOLD J.T.M. MATHIJSSEN³, DMITRI O. PUSHKIN⁴, and CORINNA C. MAASS^{1,2} — ¹Max Planck Institute for Dynamics and Self-Organization — ²University of Twente — ³University of Pennsylvania — ⁴University of York

Active emulsions exhibit a complex hydrodynamic mode spectrum driven by chemical advection-diffusion instabilities. We study such an active emulsion consisting of oil droplets that dynamically solubilize in a supramicellar aqueous surfactant solution. It has been predicted that the interaction with self-generated chemical fields leads to multistable higher-mode flow fields and chemorepulsive phenomena. To investigate such chemodynamic effects, we study cylindrical droplets pinned between the top and bottom surfaces of a microfluidic reservoir, such that they only produce pumping flows, while we simultaneously quantify the chemical concentration field and the hydrodynamic velocity field. With increasing droplet radius we observe: vortical structures generated by the droplet migrating around the interface, bistability between a dipolar and quadrupolar flow mode, and, eventually, a transition to multipolar modes. We further measured flow fields by particle image velocimetry and compared them to a hydrodynamic model based on a Brinkman squirmer. A simultaneous quantification of the flow fields and oil-filled micelle distribution suggests that a local buildup of chemical products leads to a saturation of the surface, which affects the propulsion mechanism and eventually suppresses all activity.

**Hydrodynamics and fluctuations in bacterial models** — •SUBHADIP СНАКRABORTI — Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany — Max-Planck-Zentrum für Physik und Medizin, Erlangen, Germany

Motivated by a biological example of the persistent motion of bacteria, we propose two one-dimensional models of active lattice gases with hardcore interactions. Using macroscopic fluctuation theory (MFT), we analytically derive hydrodynamics for those models and calculate two density-dependent transport coefficients - the bulk-diffusion coefficient and the conductivity, and verify the Einstein relation (ER) by comparing the ratio of those transport coefficients with subsystem number fluctuation. The first model consisting of particles with competing mechanisms of short and long-range hopping obeys the Einstein relation, and exhibits, in the limit of infinite range hopping, upon tuning density (or activity), a 'superfluid' transition from a finitely conducting state to an infinitely conducting one. Interestingly, the bulk-diffusion coefficient remains constant throughout. The diverging conductivity induces 'giant' number fluctuations in the system. In the second model, consisting of hardcore run and tumble particles with persistent motion in one direction decided by an associated spin variable until the direction of spin is reversed, we perform a similar calculation and find that the Einstein relation is violated. This analytic framework could be useful for a better understanding of the collective behavior of many biological systems such as bacterial colonies and other multicellular aggregates, in the context of dynamics and transport properties.

DY 31.6 Wed 16:30 H18 Shearing an Active Glass — •RITUPARNO MANDAL and PETER SOLLICH — Institut für Theoretische Physik, Göttingen, Germany

Recent experiments and simulations have revealed glassy features of cytoplasm, tissues and dense assemblies of self propelled colloids. This prompts the fundamental question of whether non-equilibrium (active) amorphous materials are essentially equivalent to their passive counterparts, or whether they can present qualitatively different behaviour. To tackle this challenge we investigate the yielding and mechanical behaviour of a model active glass former, a Kob-Andersen glass in two dimensions where each particle is driven by a constant propulsion force whose direction varies diffusively over time. Using extensive Molecular Dynamics simulations, we focus in particular on the effects of the intermittent dynamics in the regime of highly persistent activity and reveal a novel type of shear induced orientational ordering in the system.

Active motion with varying self propulsion — LORENZO CAPRINI¹, ALEXANDER R. SPRENGER¹, UMBERTO M. B. MARCONI², HARTMUT LÖWEN¹, and •RENÉ WITTMANN¹ — ¹Institut für Theoretische Physik II: Weiche Materie, Heinrich-Heine Universität Düsseldorf, Germany — ²School of Sciences and Technology, University of Camerino, Italy

Active Brownian Particles (ABPs), commonly perceived as the standard model for (dry) active motion, are characterized by a constant self-propulsion velocity along the direction of a unit vector which performs rotational diffusion. In nature, however, the swim velocity is usually not a constant in time and space. Here, we present a generic form of the equations of motion of active particles, which account for two aspects of varying self propulsion. First, we introduce a general stochastic process with fluctuating modulus of the self-propulsion vector, which defines a parental active model (PAM). We argue that the two well-known models of ABPs and Active Ornstein-Uhlenbeck Particles (AOUPs) emerge as limiting cases of the PAM [1], i.e., they are rather sisters than cousins. Second, we demonstrate that a position-dependent swim-velocity field can be consistently introduced for any self-propulsion mechanism [2]. Finally, we discuss the effects of varying self propulsion in external confinement [1,3] and predict the stationary probability distributions in terms of effective interactions [3].

Perturbing the athermal jamming transition by activity - •MICHAEL SCHMIEDEBERG — Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany

By minimizing the interaction energy in a soft sphere system without crossing energy barriers the discontinuous athermal jamming transion can be observed at a packing fraction of about 0.64 in three dimensions [1]. We consider the jamming of active particles where the activity corresponds to a perturbation to the athermal jamming process. We find that due to the activity the transition becomes continuous and the transition packing fraction might occur at a different density [2]. The critical exponents agree to those of the universality class of directed percolation. As a consequence, athermal jamming of passive particles seems to be a (singular) limit of the jamming transition in an active system. Note that other perturbation like thermal fluctuations lead to a similar behavior [3]. Therefore, athermal active particles can be seen as a prototype system that leads to new insights how jamming with perturbations (as also studied in [2-5]) can be related to glassy dynamics.

Ejection of marine microplastics by raindrops: A computational and experimental study — •Moritz Lehmann¹, Lisa Marie Oehlschlägel², Fabian Häusl¹, Andreas Held², and Stephan Gekle¹ – ¹Biofluid Simulation and Modeling - Theorethische Physik VI, Universität Bayreuth —  2 Umweltchemie und Luftreinhaltung, Technische Universität Berlin

Raindrops impacting water surfaces such as lakes or oceans produce myriads of tiny droplets which are ejected into the atmosphere at very high speeds. Here we combine computer simulations and experimental measurements to investigate whether these droplets can serve as transport vehicles for the transition of microplastic particles with diameters of a few tens of micrometers from ocean water to the atmosphere. Using the Volume-of-Fluid lattice Boltzmann method, extended by the immersed-boundary method, we performed more than 1600 raindrop impact simulations and provide a detailed statistical analysis on the ejected droplets. Using typical sizes and velocities of real-world raindrops, we

DY 31.9 Wed 17:15 H18 Non-equilibrium phase separation in mixtures of catalytically active particles: size dispersity and screening effects  $- \cdot$  VINCENT OUAZAN-REBOUL¹, JAIME AGUDO-CANALEJO¹, and RAMIN GOLESTANIAN^{1,2} – ¹Max Planck Institute for Dynamics and Self-Organization, Am Fassberg 17, D-37077, Göttingen, Germany — ²Rudolf Peierls Centre for Theoretical Physics, University of Oxford, OX1 3PU, Oxford, UK

Biomolecular condensates in cells are often rich in catalytically active enzymes. This is particularly true in the case of the large enzymatic complexes known as metabolons, which contain different enzymes that participate in the same catalytic pathway. One possible explanation for this self-organization is the combination of the catalytic activity of the enzymes and a chemotactic response to gradients of their substrate, which leads to a substrate-mediated effective interaction between enzymes. These interactions constitute a purely non-equilibrium effect and show exotic features such as non-reciprocity. Here, we analytically study a model describing the phase separation of a mixture of such catalytically active particles. We show that a Michaelis-Menten-like dependence of the particles' activities manifests itself as a screening of the interactions, and that a mixture of two differently sized active species can exhibit phase separation with transient oscillations. We also derive a rich stability phase diagram for a mixture of two species with both concentration-dependent activity and size dispersity.

eral size (L) and their height (H). Rather recently, however, investigations have also focused on RB convection in laterally extended systems, as it was found that the time-averaged mean velocity resembles the laminar pattern under weak

Location: H19

driving. In my talk I will first discuss some recent developments in the research of large scale patterns in RB convection. Then I will present our own results from volumetric spatially velocity measurements in a rectangular RB cell with a square horizontal cross-section and an aspect ratio  $\Gamma = L/H = 16$ . Via Lagrangian particle tracking, we have measured the velocity and acceleration of up to 300,000 fluorescent microspheres simultaneously and have calculated the entire three-dimensional velocity field with a resolution of about the Kolmogorov length. From these data, we can determine the large scale patterns, as well as their morphology and follow their slow temporal evolution.

Location: H20 the Loschmidt echo. They have close connection with Fisher zeros of the par-

tition function extended to imaginary temperatures (real time). Because the Loschmidt echo is hard to measure it is not easy to observe DQPT experimentally. In this talk I will explain how one can detect DQPT both as a function of time and as a function of quench amplitude in finite size string observables. These findings are in very good agreement with an experiment by J. Zhang et. al. Nature 551, 601 (2017) performed in a trapped ion simulator.

simulate straight impacts with various raindrop diameters as well as oblique impacts. We find that a 4 mm diameter raindrop impact on average ejects more than 167 droplets. We show that these droplets indeed contain microplastic concentrations similar to the ocean water within a few millimeters below the surface. To further assess the plausibility of our simulation results, we conduct a series of laboratory experiments, where we find that microplastic particles are indeed contained in the spray. Based on our results and known data, we estimate the global relevance of this transport mechanism.

Transition between 2D and 3D rotating incompressible convection in direct numerical simulations — •Kevin Lüdemann and Andreas Tilgner — Institute of Astrophysics and Geophysics, Göttingen, Germany

Direct numerical simulations of an incompressible fluid with a Prandtl number of 0.7 are used to investigate differences between exact 2D and 3D convection.

The fluid is rotating about a direction perpendicular to the direction of gravity (centrifugal gravity) and zonal flow is suppressed by horizontal walls in a container with an aspect ratio of 0.5. The convection is controlled by a Rayleigh number ranging from  $10^4$  to  $10^9$  and rotation is characterised by the Ekman number ranging from  $10^{-1}$  down to  $10^{-5}$ . Due to the Taylor-Proudman theorem, the convective flow will be restrained to the plane perpendicular to the direction of rotation at high rotation rates. This behaviour will break down once convective driving and therefore kinetic energy is large enough. Thermal transport and kinetic energy density show different scalings for the 2D and 3D flow. The stability theory of a vortex with elliptical streamlines is tailored to the geometry in order to explain the transition. Ultimately, a dependence of the Reynolds number on the Rossby number is found Re  $\propto Ro^{-2}$  for small Rossby numbers. Both are based on the RMS velocity of the vortex.

The onset of non-Gaussian velocity gradient statistics in low-Reynolds number flows — •MAURIZIO CARBONE¹ and MICHAEL WILCZEK^{1,2} — ¹Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, 37077 Göttingen, Germany — ²Theoretical Physics I, University of Bayreuth, Universitätsstr. 30, 95447 Bayreuth, Germany

The Reynolds number prescribes the range of active scales involved in a turbulent flow. Stirring a fluid through a Gaussian forcing at vanishingly small Reynolds produces a multi-point Gaussian field, while flows at higher Reynolds exhibit non-Gaussianity, cascades, anomalous scaling and preferential alignments. Recent works (Yakhot and Donzis, Phys. Rev. Lett. 2017) showed that low-Reynolds flows exhibit features of high-Reynolds turbulence.

We address the onset of turbulent features in low-Reynolds flows by combining a perturbation theory of the full Navier-Stokes equations (Wyld, Ann. Phys. 1961) with the Lagrangian modelling of velocity gradients along fluid particle trajectories (Meneveau, Annu. Rev. Fluid Mech. 2011). We construct a stochastic model for the velocity gradient in which all the model coefficients follow directly from the Navier-Stokes equations. The associated Fokker-Planck equation for the single-time velocity gradient probability density admits analytic solutions which show the onset of non-Gaussianity: skewness, intermittency and preferential alignments arise in the gradients statistics as the Reynolds number increases. The results are in excellent agreement with direct numerical simulations of low-Reynolds flows.

#### DY 34.4 Wed 16:30 H19

**Temporal large-scale intermittency and its impact on flow statistics** – •LUKAS BENTKAMP^{1,2} and MICHAEL WILCZEK^{1,2} – ¹Theoretical Physics I, University of Bayreuth, Universitätsstr. 30, 95447 Bayreuth – ²Max Planck Institute for Dynamics and Self-Organization, Am Faßberg 17, 37077 Göttingen

Turbulent flows in three dimensions are characterized by the transport of energy from large to small scales, the so-called energy cascade. Since the small scales are the result of the nonlinear dynamics across the scales of the energy cascade, they are often thought of as universal and independent of the large scales. However, as famously remarked by Landau in 1959, sufficiently slow variations of the large scales should nonetheless be expected to impact small-scale statistics. Such variations, often termed large-scale intermittency, are almost inevitable in experiments and even in simulations, while differing from flow to flow.

Here we evaluate the impact of temporal large-scale fluctuations on velocity,

velocity gradient, and acceleration statistics by introducing controlled variations of the energy injection rate into direct numerical simulations of turbulence. We find that slow variations can have a strong impact on flow statistics, amplifying the tails of the measured distributions. We also show that the stronger tails can be accounted for by superposing an ensemble of stationary flows such that the temporal variations of an appropriate flow measure such as the energy dissipation rate are matched. Overall, our work demonstrates that in order to ensure comparability of statistical results in turbulence, large-scale intermittency needs to be taken into account.

#### DY 34.5 Wed 16:45 H19

**Towards an effective description of turbulent superstructures in simple shear flows** — •FABIÁN ÁLVAREZ-GARRIDO and MICHAEL WILCZEK — Theoretical Physics I, University of Bayreuth, Bayreuth

Turbulent flows driven by large-scale forces such as convection, shear, or rotation may display large-scale coherent flows, namely turbulent superstructures, coexisting with fully developed turbulence on the small scales. A complete description of these flows involves innumerable degrees of freedom, yet turbulent superstructures seem to evolve according to a comparably lower-dimensional set of equations. In addition, despite the ubiquity of turbulent superstructures, their interplay with the smaller scales is not yet fully understood. We study a simple shear-driven flow, the three-dimensional Kolmogorov flow. The large scales in this flow feature the formation of large-scale vortex pairs. Moreover, the system exhibits permanent dynamics between states having a different number of vortex pairs. Employing amplitude equations, we characterize the dynamics of the large scales close to the onset of the vortex pairs. We show that the dynamics close to the onset correspond to the one of a two-dimensional flow. Furthermore, we show that far from the onset, the derived model captures the structure of the large-scale vortices. Based on data from direct numerical simulations, we introduce new stochastic terms to these amplitude equations to model the contribution of the small scales to the dynamics of the large ones. These modified amplitude equations can qualitatively reproduce the dynamics of these large-scale vortex pairs and shed light on the role of small-scale turbulence in the formation of turbulent superstructures.

**3D** simulation of convection patterns in dry salt lakes — •LUCAS GOEHRING¹, MATTHEW THREADGOLD², CÉDRIC BEAUME², and STEVE TOBIAS² — ¹Nottingham Trent University, Nottingham, UK — ²University of Leeds, Leeds, UK

Salt deserts are some of the most extreme and beautiful landscapes in the worldflat silver-white crystalline plains covered with bizarre and seemingly unnatural shapes. The most prominent feature of these fantastic landscapes is a characteristic tiling of polygons, formed by ridges in the salt-encrusted surface, and always a few meters across. Recently, a dynamical model has been proposed to explain their formation as the surface expression of buoyancy-driven convection happening in the wet salty soil beneath the desert surface. Here, we present a 3D numerical model of the salt lake problem, where a fluid-saturated porous medium is subject to a constant surface evaporation, mimicking the conditions of a desert with an underground aquifer near the surface. We look in turn at the initial instabilities expected in this system, and how they will evolve in time into a dynamical steady state. In this we focus on identifying the patterns that develop in the model, and exploring how the surface flux of salinity depends on the driving parameters.

THz-induced high-order harmonic generation and nonlinear transport in graphene — •WENWEN MAO¹, ANGEL RUBIO^{1,2}, and SHUNSUKE A. SATO^{3,1} — ¹Max Planck Institute for the Structure and Dynamics of Matter, Luruper Chaussee 149, 22761 Hamburg, Germany — ²Center for Computational Quantum Physics (CCQ), Flatiron Institute, 162 Fifth Avenue, New York, NY 10010, USA — ³Center for Computational Sciences, University of Tsukuba, Tsukuba 305-8577, Japan

Employing the quantum master equation with phenomenological relaxation, we theoretically study the nonequilibrium dynamics of THz-induced high-order harmonic generation in graphene. We first performed fully dynamical simulation to investiget the high-order harmonic generation in graphene induced by THz laser fields. We found that the emitted harmonics is enhanced with the increase in the chemical potential, and this observation is consistent with the recent experiments. Then we introduce a quasi-static picture to develop the microscopic understanding of the THz-induced currents and the population distribution of conduction band in graphene from the viewpoint of a nonequilibrium picture of electron dynamics. The nonlinear electric conductivity of graphene is

also investigated under static electric fields for various field strength and chemical potential shifts. The impact of electron temperature change is also investigated to compare with the thermodynamic model in the previous work.

Explicit expressions for stationary states of the Lindblad equation for a finite state space — •BERND MICHAEL FERNENGEL — TU Darmstadt, Germany

The Gorini-Kossakowski-Sudarshan-Lindblad Equation describes the time evolution of the probabilities of and the coherences between the quantum mechanical states. It is often used to model open quantum systems. We give explicit expressions of stationary solutions of the Lindblad equation in the case of a finite state space, using the concept of state transition networks of Markov chains. Our treatment is based on the so-called quantum-jump unravelling, which is an ensembles of stochastic quantum trajectories, compatible with the Lindblad equation. A single such trajectory shows a continuous time evolution, which is interrupted by stochastic jumps. We discuss differences to the classical case and conditions, under which the Lindblad equation is asymptotically stable (also called 'relaxing'). **Eigenstate entanglement in coupled kicked spin chains with chaotic dynamics** — •TABEA HERRMANN, MAXIMILIAN F. I. KIELER, and ARND BÄCKER — TU Dresden, Institut für Theoretische Physik, Dresden, Germany

We study the behaviour of the eigenstate entanglement in two coupled quantum chaotic kicked spin chains in dependence on the coupling strength. It is demonstrated that a random matrix transition ensemble explains the transition from the uncoupled case to strong coupling. Remarkably, the numerical results can be described by an extended perturbation theory which was introduced for the case of two coupled chaotic one-body-systems.

#### DY 35.4 Wed 16:15 H20

Quantum chaos in microwave cavities with mixed dynamics — •LENNART ANDERSON and ANDREAS WIECK — Angewandte Festkörperphysik, Ruhr-Universität Bochum

Based on the analogy of the Schrödinger equation with Dirichlet boundary conditions and the Helmholtz equation for a flat resonator, it is possible to study the dynamical and statistical properties of quantum billiards experimentally in the quasi-classical limit. Billiards, i.e. dynamical systems in which a particle moves ballistically and gets reflected by hard walls, provide a very simple model system, since the entire dynamics only depends on the geometry of the boundary. We investigate Hamiltonian systems with divided phase space, i.e. systems enabling a continuous transition from completely regular to completely chaotic dynamics, like the mushroom billiard, introduced by L. Bunimovich, in the quantum regime. Generalizations of the mushroom billiard and further geometries, i.e. those ranging from convex to non-convex domains, are considered. We further discuss the experimental setup and the impact of parameters like the conductivity of the resonator.

**NQCDynamics.jl: Nonadiabatic quantum classical dynamics in the Julia language** – •JAMES GARDNER¹, OSCAR A. DOUGLAS-GALLARDO¹, WOJCIECH G. STARK¹, JULIA WESTERMAYR¹, SVENJA M. JANKE^{1,2}, SCOTT HABERSHON¹, and REINHARD J. MAURER¹ – ¹Department of Chemistry, University of Warwick, United Kingdom – ²Institute of Advanced Study, University of Warwick, United Kingdom

Accurate and efficient methods to simulate nonadiabatic and quantum nuclear effects in high-dimensional and dissipative systems are crucial for the prediction of chemical dynamics in the condensed phase. To facilitate effective development, code sharing, and uptake of newly developed dynamics methods, it is important that software implementations can be easily accessed and built upon. In this talk, I will present the NQCDynamics.jl package, which provides a Julia language framework for established and emerging methods for performing semiclassical and mixed quantum-classical dynamics in the condensed phase. The code provides several interfaces to existing atomistic simulation frameworks, electronic structure codes, and machine learning representations. In addition to the existing methods, the package enables the development and deployment of new dynamics methods for condensed phase quantum dynamics, which I will show using examples based on model Hamiltonians and full-dimensional abinitio systems.

#### DY 35.6 Wed 17:00 H20

Metastability and quantum coherence-assisted sensing in interacting parallel quantum dots — •STEPHANIE MATERN¹, KATARZYNA MACIESZCZAK², SIMON WOZNY¹, and MARTIN LEIJNSE¹ — ¹NanoLund and Solid State Physics, Lund University, Box 118, 22100 Lund, Sweden — ²TCM Group, Cavendish Laboratory, University of Cambridge, J. J. Thomson Ave., Cambridge CB3 0HE, United Kingdom

We study the transient dynamics of two interacting parallel quantum dots weakly coupled to macroscopic leads to gain access to the non-equilibrium transport properties. The stationary state current of this quantum system is known to be sensitive to perturbations much smaller than any other energy scale in the system, specifically compared to the system-lead coupling and the temperature. We show that this is due to a bistable point which leads to a regime in the dynamics where the system exhibits metastability and the dynamics is described as classical dynamics between two metastable phases. The competition of those two metastable phases explain the sensitive behaviour of the stationary current towards small perturbations. We show that this behaviour bears the potential of utilizing the parallel dot as charge sensor which makes use of the quantum coherence effects to achieve a high sensitivity that is not limited by temperature. We analyse the sensitivity in terms of the current signal to noise ratio and find that the parallel dots outperform an analogous single dot setup for a wide range of parameters.

**Classical and Quantum Dynamics in Resonance Channels** — •JAN ROBERT SCHMIDT, ARND BÄCKER, and ROLAND KETZMERICK — TU Dresden, Institut für Theoretische Physik, Dresden, Germany

In higher-dimensional Hamiltonian systems resonance channels play a prominent role for chaotic transport. It is typically slow due to Arnold diffusion, leading quantum mechanically to dynamical localization. Resonance channels widen as they approach the chaotic sea. We show that this geometry induces classically a drift. Quantum mechanically this leads to a transition from localization to delocalization if the drift is strong enough. This is quantified using a transition parameter depending on classical quantities only. Numerically this is confirmed for a 4D symplectic map.

DY 35.8 Wed 17:30 H20 Coupling in Optical Microcavity-Arrays — •Tom Rodemund and Martina Hentschel — Department of Physics, Technische Universität Chemnitz, Chemnitz, Germany

Optical microcavities capture light by total internal reflection in so-called whispering-gallery modes. Deformed disk-shaped microcavities, for example of Limaçon shape, allow one to keep high Q-factors while manipulating the far-field emission via the resonator geometry, thereby allowing for a wide range of applications from microlasers to sensors.

Coupling of several microdisk resonators enhances the possibilities to tame light considerably [1]. Depending on the number and distance of the coupled cavities, the far-field characteristics vary tremendously and can even be reversed [1]. Here, we investigate the underlying mechanisms. To this end we use phasespace methods and analyze the resonance wave functions in real space as well as the corresponding Husimi functions to characterize the coupling behavior. We employ ideas from ray-wave correspondence to deepen our insight by establishing a relation to the nonlinear light ray dynamics and its fingerprint in the Poincaré surface of section.

DY 35.9 Wed 17:45 H20

Time-dependent Redfield and Lindblad equations with effective timedependent temperature — •NIKODEM SZPAK, LUKAS LITZBA, ERIC KLEINHER-BERS, and JÜRGEN KÖNIG — Theoretische Physik, Universität Duisburg-Essen, Lotharstr. 1, 47048 Duisburg

For a quantum system coupled to environment we apply the first Markov approximation and write the Redfield equation at the first order in the systemenvironment coupling. Then, we evaluate the remaining time-dependent integral and approximate it uniformly for all times, temperatures and energies by one simple analytical function which corresponds to the Fermi-Dirac distribution with time-dependent effective temperature T(t). Thus, we obtain a new Redfield equation with time-dependent effective temperature. A consecutive approximation brings it to the Lindblad equation with time-dependent Lindblad operators whose time-dependence enters solely via T(t). The variation of the effective temperature T(t) reflects the sudden switch-on of the system-environment interaction at the beginning and becomes high at early times to eventually fall to the true environment temperature T. We discuss possible physical effects and their measurability in some simple examples.

DY 38.1 Thu 10:00 H18 Underscreening in the Restricted Primitive Model - • ANDREAS HÄRTEL -Institute of Physics, University of Freiburg, Germany

Electric double layers occur where charges are screened by other charges, for instance, when charged surfaces of electrodes, colloids, or cells are exposed to electrolytes (mobile ions in a solvent). Increasing the concentration of mobile ions leads to more efficient screening, if concentrations are sufficiently low. At high concentrations, however, the screening by finite-sized ions becomes less efficient than those of point-like ions due to packing, an effect called underscreening. Some experiments report underscreening as a strong effect that follows some universal scaling [1], but the observation could not been explained by theoretical models yet. Conversely, independent theoretical studies actually ruled out the most important model for electrolytes of finite-sized ions as a candidate able to explain underscreening, namely the restricted primitive model [2]. In this talk I will discuss in which sense underscreening can and cannot be found in the restricted primitive model and in which sense the effect follows some universal scaling. I will support the discussion by recent theoretical results obtained from simulations and liquid state theories.

DY 38.2 Thu 10:15 H18

Reciprocal and nonreciprocal eigenmodes of viscoelastic fluids - •JULIANA Caspers¹, Clemens Bechinger², Nikolas Ditz², Matthias Fuchs², Fe-LIX GINOT², KARTHIKA KRISHNA KUMAR², LUIS FRIEDER REINALTER², and MATTHIAS KRÜGER¹ — ¹Institute for Theoretical Physics, Georg-August Universität Göttingen, 37073 Göttingen, Germany — ²Fachbereich Physik, Universität Konstanz, 78457 Konstanz, Germany

Complex fluids such as wormlike micellar solutions are in general non-Markovian. In equilibrium, their behavior is often well approximated by a simple Maxwell model with one characteristic timescale [1]. Recoil experiments, after a colloidal probe has been sheared through the solvent, however, displayed a double-exponential relaxation [2]. We found excellent agreement of our measurements with a linear two-bath particle model. Depending on whether the optical trap which confines the probe is turned on or off, we find two sets of eigenmodes in our model, corresponding to either nonreciprocal (trap on) or reciprocal (trap off) forces. Using different recoil protocols as well as equilibrium mean square displacement measurements we confirmed the existence of these two different sets of timescales with experiments. Finally, for linear systems, we find a Volterra relation between two memory kernels, characterizing reciprocal and nonreciprocal forcing.

Elastic Turbulence in von Kármán geometry — •REINIER VAN BUEL and HOL-GER STARK — Institut für Theoretische Physik, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin, Germany

Elastic turbulence, occurring in viscoelastic fluid flow at vanishing Reynolds numbers, is an interesting flow state [1-4] and has been experimentally studied in the von Kármán geometry [1]. Elastic turbulence is especially appealing for the mixing of fluids on the micron scale, which is extremely challenging in Newtonian fluids where transport relies on diffusion. Here, we present a fully three-dimensional numerical investigation of the von Kármán flow using the Oldroy-B model [4]. We observe a non-axisymmetric mode with four-fold symmetry that drives the flow instability towards elastic turbulence and compare it to results obtained from a linear stability analysis. By analyzing the velocity fluctuations and defining an order parameter, we identify a bistable flow state above a sub-critical transition, which switches between a weakly chaotic flow state and elastic turbulence and exhibits hysteretic behavior. Furthermore, we reveal a sharp increase in the flow resistance at the transition to elastic turbulence, which we attribute to the elastic contribution of the work performed at the open side surface of the flow. Finally, an analysis of the spatial and temporal velocity power spectra confirms the turbulent nature of the flow.

Coarsening dynamics of quasi 2D emulsions in free-standing smectic films •CHRISTOPH KLOPP, TORSTEN TRITTEL, and RALF STANNARIUS — Institute for Physics, Otto von Guericke University Magdeburg, Germany

Hydrodynamic phenomena in thin films play a crucial role in biological systems, in nature and modern technology. Various experimental and theoretical studies explored, e.g., the motion of objects in quasi two-dimensional films [1], the merging of inclusions [2-4] and the structural change of emulsions during longterm observations. Here, we demonstrate and describe the coarsening dynamics of emulsions formed by smectic islands (flat circular regions) on liquid crystal bubbles in microgravity at the International Space Station (ISS). The smectic islands form polydisperse, disordered arrangements representing quasi 2D emulsions. We analyze the time evolution of these ensembles that proceed through direct island coalescence or the exchange of material through the background film (Ostwald ripening). Coarsening is ubiquitous in liquid emulsions and foams, and important for their stability. We compare our results with such systems and analyze the dominant process for the 2D coarsening dynamics.

Phase transitions in the generalised chiral Lebwohl-Lasher model — • PHILIPP ELSÄSSER and ANJA KUHNHOLD - Institute of Physics, Albert-Ludwigs-University Freiburg, Germany

The behaviour of liquid crystals can be described by using the Lebwohl-Lasher (LL) model, where unit vectors that resemble nematic directors are positioned on a simple cubic lattice. Due to the interaction potential, which favours parallel orientations, this model is well suited to analyse isotropic-nematic (IN) phase transitions.

There exist several extensions to this model with which its applicability can get further enhanced. We use two combined extensions to obtain the generalised chiral Lebwohl-Lasher model: We apply a generalisation to tune the sharpness of the potential, as in the work of Fish and Vink [1] and add a chiral term which is based on the work of Memmer et al. [2]. In this system we study the phase transition properties with the help of Monte Carlo simulations. To identify characteristic properties of the transitions, we apply finite-size scaling. This allows us to determine chirality-sharpness parameter pairs with which we can manipulate the nature of the transition between ordered and disordered states [3].

Location: H20

First, I will show how monodisperse emulsions form when droplets grow in a mesh that can break and re-arrange. We demonstrate that stiffness gradients cause elastic ripening, which biases droplets toward softer regions. These processes quantitatively explain experiments where oil droplets form in PDMS gels. The same physics applies to droplets interacting with the cytoskeleton in cells. In the second part, I will show how driven reactions control droplet size and position so that multiple droplets can coexist. Taken together, our models identify key physical processes that allow cells to control the phase separation of biomolecules.

DY 39.1 Thu 10:00 H19 Dynamics of tagged particles in a biased  $A + A \rightarrow \emptyset$  system in one dimension : result for asynchronous and parallel updates — •RESHMI ROY¹, PARONGAMA SEN¹, and PURUSATTAM RAY² - ¹University of Calcutta, Kolkata, India -²IMSC, Chennai, India

We have studied dynamical features of tagged particles in one dimensional  $A + A \rightarrow \emptyset$  system, where the particles A have a bias  $\epsilon$  such that they move towards their nearest neighbour with the probability  $0.5 + \epsilon$  and move in the opposite direction with probability  $0.5 - \epsilon$  and annihilate on contact. We found that for  $\epsilon > 0$  when asynchronous dynamics is used to update the system, probability distribution  $\Pi(x, t)$  of the particles shows a double peak structure with a dip at x = 0 and it assumes a double delta form at very late time regime. For any  $\epsilon > 0$ , there is a crossover at time  $t^*$ , below which the particle motions are highly correlated, and beyond  $t^*$ , the particles move as independent biased walkers. When we use parallel updating rule,  $\Pi(x, t)$  shows a non-Gaussian single peaked structure and the fraction of surviving particle  $\rho(t)$  shows a ln t/t variation. For the deterministic point  $\epsilon = 0.5$ , we found that an isolated pair of particles, termed as dimers, can survive indefinitely in the system which is exclusive for parallel dynamics. When  $\epsilon$  is made negative,  $\Pi(x, t)$  becomes Gaussian as found in  $\epsilon = 0$ . A comparative analysis for the relevant quantities using asynchronous and parallel dynamics shows that there are significant differences for  $\epsilon > 0$  while the results are qualitatively similar for  $\epsilon < 0$ .

Wrinkling in Curved Films — • MEGHA EMERSE and LUCAS GOEHRING — Nottingham Trent University, Nottingham, United Kingdom

Thin films or sheets exposed to external forces can become unstable to drastic shape changes, often forming regular or periodic patterns like wrinkles, folds, creases, etc. This can be distinctly observed when one tries to wrap a world map onto a globe since it is unachievable without creating any wrinkles. Wrinkling is a self-initiated process, spontaneously generating periodic structures out of a uniformly smooth surface and represents a pathway for simply creating regular surface topography. Here, we study thin elastic membranes that form complex wrinkle patterns when put on substrates where there is a mismatch in their inherent shape. Using 3D-printed moulds, we prepare elastic membranes with different curvatures, including cases of positive and negative Gaussian curvature, and shapes with two distinct principal curvatures. Through these, we experimentally investigate the dependence of the amplitude and wavelength of the wrinkles that spontaneously form when these curved membranes are constrained by a flat fluid substrate. We also study how these properties change along the membrane, for example with distance from the film edges.

Exploring Bifurcations in Bose-Einstein Condensates via Phase Field Crystal Models — •Alina B. Steinberg¹, Fabian Maucher², Svetlana V. GUREVICH^{1,3}, and UWE THIELE^{1,3} - ¹Institut für Theoretische Physik, Westfälische Wilhelms-Universität Münster, Wilhelm-Klemm-Strasse 9, 48149 Münster, Germany — ²Departament de Física, Universitat de les Illes Balears \& IAC-3, Campus UIB, E-07122 Palma de Mallorca, Spain — ³Center of Nonlinear Science (CeNoS), Westfälische Wilhelms-Universität Münster, Corrensstrasse 2, 48149 Münster, Germany

To facilitate the analysis of pattern formation and phase transitions in Bose-Einstein condensates as well as to unravel analogies we present an explicit approximate mapping from the nonlocal Gross-Pitaevskii equation with cubic nonlinearity to a model of phase field crystal type. This approximation is valid close to the superfluid-supersolid phase transition and permits us to explore the phase transition through the corresponding bifurcation diagrams obtained via numerical path continuation. Additionally the effects of phenomenological

A viable approximate approach is to start from a conservative coarse-grained force-field and to extend the standard Newtonian equation of motion used in molecular simulation with a linear generalized Langevin thermostat. We demonstrate how such a thermostat can be parametrized to correctly represent dynamic properties, both in a purely bottom-up approach[2,3] or by applying iterative optimization.[3] We consider the Asakura-Oosawa model as a test case.[3]

Phase Field Crystal model for particles with *n*-fold rotational symmetry in two dimensions — • ROBERT F. B. WEIGEL and MICHAEL SCHMIEDEBERG Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany

We introduce a Phase Field Crystal (PFC) model for particles with n-fold rotational symmetry in two dimensions [1]. The n-fold symmetry of the particles corresponds to the one that can be realized for colloids with symmetrically arranged patches, with the patches being either attractive or repulsive.

Our approach is based on a free energy functional that depends on the reduced one-particle density, the strength of the orientation, and the direction of the orientation, where all these order parameters depend on the position. The functional is constructed such that for particles with axial symmetry (*i. e.* n = 2) the PFC model for liquid crystals [2] is recovered. We explain how both, repulsive as well as attractive patches, are described in our model.

We discuss the stability of the functional and explore phases that occur for  $1 \le n \le 6$ . In addition to isotropic, nematic, stripe, and triangular order, we also observe cluster crystals with square, rhombic, honeycomb, and even quasicrystalline symmetry.

DY 39.5 Thu 11:15 H19 Control-optimisation for spatiotemporal chaos in 2D excitable media through a genetic algorithm — •Marcel Aron^{1,2,3}, Thomas Lilienkamp^{2,4}, Stefan Luther^{1,2,3,5}, and Ulrich Parlitz^{2,3,5} — ¹Institute of Pharmacology and Toxicology, University Medical Center Göttingen, Göttingen, Germany -²Max Planck Institute for Dynamics and Self-Organization, Göttingen, Germany - ³Institute for the Dynamics of Complex Systems, Georg-August-Universität Göttingen, Göttingen, Germany — ⁴Computational Physics in den Life Sciences, Technische Hochschule Nürnberg, Nürnberg, Germany $-\,{}^5\mathrm{German}$  Center for Cardiovascular Research (DZHK), Partner Site Göttingen, Göttingen, Germany The emergence of spatiotemporal chaos (i.e. fibrillation) in the cardiac muscle (an excitable medium) leads to loss of pumping function and sudden cardiac death. Clinically, such episodes are treated with high-energy electric shocks to control (terminate) the chaotic dynamics and restore a regular heart rhythm. However, high shock energies result in increased risk of tissue damage or worsening the overall prognosis. This motivates the search for alternatives, including periodic sequences of low-energy electric pulses of constant field strength, which has seen success in pre-clinical trials on pig hearts.

Here we show that non-uniform pulse energies and time intervals can be used to further optimise the control of spatiotemporal chaos in 2D simulations of homogeneous cardiac tissue. We use a simplified shock-application model and define control-performance metrics to employ a genetic algorithm in the search for more efficient control approaches.

The French flag problem revisited: Creating robust and tunable axial patterns without global signaling — •STEPHAN KREMSER¹, GABRIEL VERCELLI^{1,2}, and ULRICH GERLAND¹ — ¹Physics Department, Technical University of Munich — ²MIT Microbiology Program, Massachusetts Institute of Technology

Wolpert's French flag problem conceptualizes the task of forming axial patterns with broad regions in multicellular systems. Wolpert described two different solutions to his problem, the balancing model and thresholding of a morphogen gradient, both of which require global, long-range signaling between cells. Since global signaling becomes challenging in large systems, we computationally explore alternative solutions, which use only local cell-cell signaling and are simple enough to potentially be implemented in natural or synthetic systems. We employ cellular automata rules to describe local signal processing logics, and search for rules capable of robust and tunable axial patterning with evolutionary algorithms. This yields large sets of successful rules, which however display only few types of different behaviors. We introduce a rule alignment and consensus procedure to identify patterning modules that are responsible for the observed behaviors. With these modules as building blocks, we then construct local schemes for axial patterning, which function also in the presence of noise and growth, and for patterns with a larger number of different regions. The regulatory logic underlying these modules could therefore serve as the basis for the design of synthetic patterning systems, and as a conceptual framework for the interpretation of biological mechanisms.

**Coupling-Mediated Protein Waves in Mass-Conserved Pattern Forming Systems** — •BENJAMIN WINKLER¹, SERGIO ALONSO MUÑOZ², and MARKUS BÄR^{1,3} — ¹Physikalisch-Technische Bundesanstalt — ²Universitat Politècnica de Catalunya — ³TU Berlin

The formation of protein patterns inside biological cells is of crucial importance for their spatial organization, growth and division. In many cases these dynamics can be described by coupled, mass-conserving reaction-diffusion equations [Brauns et al., PRX, 2020]. Motivated by the question how the generation of cell polarity is influenced by membrane heterogeneity, we study the behavior of the coupled dynamics of two well-known, mass-conserved systems. System A is therein given by a simplified model [Mori et al., Biophys.J., 2008] for the emer-

#### Thursday

gence of cell polarity with a single pair of activated-inactivated proteins M and B. The inactive, fast-diffusing species (B) in the bulk of the cell becomes activated (M) when bound to the cell membrane. When endowed with a positive feedback on the membrane-mediated activation, the system exhibits inherent polarizability. System B is described by the Cahn-Hilliard equation, two membrane species demixing into a pattern of comparatively small, static droplets. We then consider a difference in interaction affinity for M with respect to the two phases of the cell membrane and an additional contribution in the chemical potential of the membrane, depending on the presence of M. In the so coupled system, the emergence of traveling waves can be observed above a finite threshold of coupling strength.

Robustness of *in vivo* Min patterns underlines complex protein interaction motives — •HENRIK WEYER, LAESCHKIR WÜRTHNER, and ERWIN FREY — Arnold Sommerfeld Center for Theoretical Physics and Center for NanoScience, Department of Physics, Ludwig-Maximilians-Universität München, Theresienstraße 37, D-80333 München, Germany

The Min protein system organizes the symmetric cell division of E. coli bacteria: Two proteins, MinD and MinE, undergo pole-to-pole oscillations via a reaction-diffusion mechanism, and guide the cell-division machinery towards midcell. In elongated, filamentous cells the pole-to-pole oscillations transition into a standing-wave pattern forming several stripes along the cell. We show that modeling of the latent MinE state, which allows for Min pattern formation over a large range of MinE densities, suppresses standing-wave patterns. This effect is explained to demonstrate a generic mechanism that latent states form a homogeneous reservoir in reaction-diffusion systems. We reason that the MinE–MinD interaction cannot be described as a single hydrolysis step, and that MinE plays a more complex role in the Min protein network, a finding supported by recent experimental evidence.

**Depinning and structural transitions of confined colloidal dispersions under oscillatory shear** — •MARCEL HÜLSBERG and SABINE H.L. KLAPP — ITP, Technische Universität Berlin, Germany

Strongly confined colloidal dispersions under shear exhibit a variety of dynamical phenomena, including a depinning transition, which is accompanied by lateral structural changes [1].

Here, we investigate the depinning behaviour of these systems under pure oscillatory shearing with shear rate  $\dot{\gamma}(t) = \dot{\gamma}_0 \cos(\omega t)$ , as it is a common scenario in rheological experiments [2].

The colloids' depinning behaviour is assessed from a microscopic level based on particle trajectories, which are obtained from overdamped Brownian Dynamics simulations. The numerical approach is complemented by an analytic one based on an effective single-particle model in the limits of weak and strong driving.

Investigating a broad spectrum of shear rate amplitudes  $\dot{y}_0$  and frequencies  $\omega$ , we observe complete pinning as well as temporary depinning behaviour. We discover that temporary depinning occurs for shear rate amplitudes above a frequency-dependent critical amplitude  $\dot{y}_0^{\rm crit}(\omega)$ , for which we attain an approximate functional expression.

Above  $\dot{\gamma}_0^{\text{crit}}(\omega)$ , we further observe a variety of dynamical structures, whose stability exhibits an intriguing ( $\dot{\gamma}_0, \omega$ ) dependency. This might enable new perspectives for potential control schemes.

**Ballistic Hot Brownian Motion** — •XIAOYA SU¹, FRANK CICHOS¹, and KLAUS KROY² — ¹Peter Debye Institute for Soft Matter Physics, University Leipzig, Leipzig, Germany — ²Institute of Theoretical Physics, University Leipzig, Leipzig, Germany

Brownian motion is the erratic motion of particles in a fluid due to the bombardment of the particle with solvent molecules providing thermal energy and viscous friction. It is fundamental for the dynamics of soft matter and defines the prototype of a fluctuation dissipation relation. While at long timescales the motion is purely stochastic, it is at shorter times influenced by hydrodynamic effects and even ballistic at ultrashort timescales. Yet, the ballistic motion, same as the stochastic motion, is still determined by the temperature of the system. Here we explore the transition to the ballistic regime for a hot Brownian particle, i.e. a microparticle which is heated by a laser in an optical trap. In this case the particle temperature is different from the solvent temperature and so far, only theoretical predictions exist for the relevant temperature determining the particle velocity.

We report the first measurements of the thermal non-equilibrium process in a

Location: H20

specially designed optical trap which is able to resolve particle displacements of about 20 pm with a time-resolution of 10ns. We show how the mean squared displacement of the particle from the nanosecond to the second timescale changes as a function of the surface temperature of the particle and discuss the model of a frequency dependent effective temperature of hot Brownian motion.

Stochastic action for tubes: Connecting path probabilities to measurement – •JULIAN KAPPLER¹, JANNES GLADROW^{2,3}, ULRICH F. KEYSER³, and RONOJOY ADHIKARI¹ – ¹DAMTP, Cambridge University, Cambridge, UK – ²Microsoft Research, Cambridge, UK – ³Cavendish Laboratory, University of Cambridge, Cambridge, UK

The trajectories of diffusion processes are continuous but nondifferentiable, and each occurs with vanishing probability. This introduces a gap between theory, where path probabilities are used in many contexts, and experiment, where only events with nonzero probability are measurable. We bridge this gap by considering the probability of diffusive trajectories to remain within a tube of small but finite radius around a smooth path. This probability can be measured in experiment, via the rate at which trajectories exit the tube for the first time, thereby establishing a link between path probabilities and physical observables. In my contribution I will show how this link can be used to both measure ratios of path probabilities [1], and to extend the theoretical stochastic action from individual paths to tubes [2]. I will furthermore relate our results to the usual path-integral formalism.

DY 40.4 Thu 10:45 H20 Size matters for Bayesian chemotaxis —  $\bullet$ JULIAN RODE¹, MAJA NOVAK^{1,2}, and BENJAMIN M. FRIEDRICH^{1,3} — ¹cfaed, TU Dresden, Germany — ²Department of Physics, University of Zagreb, Croatia — ³PoL, TU Dresden, Germany Navigation by chemical cues e.g. chemotaxic is employed by single biological

Navigation by chemical cues, e.g., chemotaxis, is employed by single biological cells and animals. The size and speed of search agents dictate noise levels and thus optimal strategies to find a target.

Here, we address information theory of gradient sensing for an ideal agent and ask for optimal strategies as a baseline for real agents. We extend the seminal work on infotaxis [1], by applying its idea of maxi- mizing information gain to agents of finite size. These agents can now measure gradients both by temporal comparison due to their active motion [1], and by spatial comparison across their diameter, prompt- ing an optimal weighting of both information sources [2].

In the absence of noise, trajectories show stereotypic behavior; the entropy of directional uncertainty collapses onto a master curve pa- rameterized by a signal-to-noise ratio. Unlike [1], we account for rota- tional diffusion, which is prevalent for microscopic agents: Its compe- tition with information gain due to spatial comparison sets an effec- tive measurement time (given by the inverse geometric mean of a rate constant of information gain and the rotational diffusion coefficient), which is different from the typical bound argued by Howard Berg for bacterial chemotaxis (inverse rotational diffusion coefficient) [3].

DY 40.5 Thu 11:15 H20 Superstatistics of protein diffusion dynamics in bacteria — •YUICHI ITTO — Aichi Institute of Technology, Aichi, Japan — ICP, Universität Stuttgart, Stuttgart, Germany

In recent years, non-Gaussian normal/anomalous diffusion have experimentally been observed in a wide class of living cells. Superstatistics is a "statistics of statistics" with two largely separated time scales for treating nonequilibrium complex systems. Here, a superstatistical diffusion theory [1] is presented for obtaining a q-Gaussian displacement distribution decaying as a power law found for heterogeneous diffusion phenomenon of DNA-binding proteins in bacteria [2]. This theory takes into account the joint fluctuations of both the diffusion exponent and the (inverse) temperature, which are hierarchically combined with a fractional Brownian motion describing a local stochastic process of the proteins. Correlation between the fluctuations is also discussed and its weakness is shown to be essential. The results obtained are in a good agreement with the experimental data.

Generalised master equation for diffusion and reaction problems in heterogeneous media — DANIELA FRÖMBERG¹ and •FELIX HÖFLING^{1,2} — ¹Department of Mathematics and Computer Science, Freie Universität Berlin — ²Zuse Institute Berlin

The kinetics of chemical reactions in a heterogeneous or crowded medium significantly deviates from that in a well-mixed, aqueous environment. One example is the partitioning of cell membranes and intracellular spaces, e.g., into cytoplasm and nucleus. For reaction-diffusion problems in such compartmentalised spaces, we extend a recently proposed generalised master equation (GME) for non-Markovian jump processes [1]. The GME governs the time evolution of the occupation probability of the spatial domains, its main ingredient are first-passage time densities encoding the transport behaviour in each domain. The domains can differ with respect to their diffusivity, geometry, and dimensionality, but can also refer to transport modes alternating between diffusive, driven, or anomalous motion. We discuss further the inclusion of barriers and the Markovian limit of the GME.

For a cherry-pit geometry with a reactive inner domain, we obtain the firstreaction time density and infer the effective reaction rate constant. This rate constant is timescale dependent and exhibits an enhancement at intermediate times by orders of magnitude and an algebraically slow convergence to the long-time limit. Our stochastic approach does not depend on the existence of a stationary distribution and thus overcomes a limitation of the classical Smoluchowski theory.

Molecular dynamics simulations of supercooled water in silica pores — •MARKUS HANEKE, ROBIN HORSTMANN, and MICHAEL VOGEL — TU Darmstadt, Institut für Physik kondensierter Materie, Hochschulstr. 6, 64289, Darmstadt, Germany

Being highly relevant in biology as well as in technology and other areas, water is subject to extensive research. Especially its anomalies pose questions. Commonly, it is argued that the anomalies of water originate in the supercooled state, which is therefore regularly subject to exploration. To suppress freezing in experimental studies, confinements can be employed, where silica pores proved to be very useful.

Molecular dynamic simulations are a valuable tool to take a closer look. They allow analyses with high spatial and temporal resolution while making it easy to extract dynamic and static information. [1]

Here, we perform simulations to analyse the diffusion of water in silica pores. We want to find the influence of the pore on dynamics, as well as of the capping if the water outside of the pore freezes.

Results of our analysis are, that the diffusion inside of the pore is anomalous and slowed down. The systems show to be subdiffusive. Capping not only restricts diffusion but also slows down local relaxation and yields a nearly triangular probability density of propagation distance, contradicting free 1D-diffusion. [1] R. Horstmann, L. Hecht, S. Kloth, and M. Vogel. "Structural and Dynamical Properties of Liquids in Confinements: A Review of Molecular Dynamics Simulation Studies". In: Langmuir 2022 38 (21), 6506-6522

**Localization persisting under aperiodic driving** — •HONGZHENG ZHAO^{1,2}, FLORIAN MINTERT², JOHANNES KNOLLE^{2,3,4}, and RODERICH MOESSNER¹ — ¹Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — ²Imperial College London, London, United Kingdom — ³Technical University of Munich, Munich, Germany — ⁴Munich Center for Quantum Science and Technology, Munich, Germany

Localization may survive in periodically driven (Floquet) quantum systems, but is generally unstable for aperiodic drives. In this work, we identify a hidden conservation law originating from a chiral symmetry in a disordered spin-1/2 XX chain. This protects indefinitely long-lived localization for general–even aperiodic–drives. Therefore, rather counter-intuitively, adding further potential disorder which spoils the conservation law delocalizes the system, via a controllable parametrically long-lived prethermal regime. This provides a first example of persistent single-particle 'localization without eigenstates'. Reference: arXiv:2111.13558 **Prethermalization in confined spin chains** — •STEFAN BIRNKAMMER, ALVISE BASTIANELLO, and MICHAEL KNAP — Technical University Munich, Germany Unconventional nonequilibrium phases with restricted correlation spreading and slow entanglement growth have been proposed to emerge in systems with confined excitations, calling their thermalization dynamics into question. Here, we investigate the many-body dynamics of a confined Ising spin chain, in which domain walls in the ordered phase form bound states reminiscent of mesons. We show that the thermalization dynamics after a quantum quench exhibits multiple stages with well separated time scales. The system first relaxes towards a prethermal state, described by a Gibbs ensemble with conserved meson number. The prethermal state arises from rare events in which mesons are created in close vicinity, leading to an avalanche of scattering events. Only at much later times a true thermal equilibrium is achieved in which the meson number conservation is violated by a mechanism akin to the Schwinger effect.

Enhanced state transfer by complex instability in coupled tops — •MAXIMILIAN FRIEDRICH IRENÄUS KIELER and ARND BÄCKER — TU Dresden, Institut für Theoretische Physik, Dresden, Germany

By considering coupled tops we provide a mechanism for a fast transfer between two specific states representing bits. This crucially relies on that fact that the semiclassical limit corresponds to a higher-dimensional system which allows for more types of stability of fixed points than the two-dimensional case. Tuning the parameters, the coupled tops have fixed points with complex instability. Quantum mechanically this allows for a rapid transfer between coherent states located at these points, which is much faster than the coexisting dynamical tunneling.

#### DY 43.4 Thu 15:00 P2

**Quantum signatures of partial barriers in 4D symplectic maps** — •JONAS STÖBER, ARND BÄCKER, and ROLAND KETZMERICK — TU Dresden, Institut für Theoretische Physik, Dresden, Germany

Partial transport barriers in the chaotic sea of Hamiltonian systems restrict classical transport, as they only allow for a small flux between phase-space regions. Quantum mechanically for 2D symplectic maps one has a universal quantum localizing transition: quantum transport is suppressed if the Planck cell of size h is much greater than the flux  $\Phi$ , while mimicking classical transport if h is much smaller. The scaling parameter is  $\Phi/h$ .

In a higher-dimensional 4D map one would naively expect that the relevant scaling parameter is  $\Phi/h^2$ . However, we show that due to dynamical localization along resonance channels the localization length modifies the scaling parameter. This is demonstrated for coupled kicked rotors for a partial barrier that generalizes a cantorus to higher dimensions.

Metallicity in the Dissipative Hubbard-Holstein Model: Markovian and Non-Markovian Tensor-Network Methods for Open Quantum Many-Body Systems — •MATTIA MORODER¹, MARTIN GRUNDNER¹, FRANÇOIS DAMANET², ULRICH SCHOLLWÖCK¹, SAM MARDAZAD¹, THOMAS KÖHLER³, SEBASTIAN PAECKEL¹, and STUART FLANNIGAN⁴ — ¹Department of Physics, Ludwig-Maximilians-Universität München, München, Germany — ²Institut de Physique Nucléaire, Atomique et de Spectroscopie, CESAM, University of Liège, B-4000 Liège, Belgium — ³Department of Physics and Astronomy, Uppsala University, Uppsala, Sweden — ⁴Department of Physics & SUPA, University of Strathclyde, Glasgow G4 0NG, United Kingdom

We investigate the impact of dissipation on polarons and bipolarons in the paradigmatic Hubbard-Holstein model. We do so by combining the non-Markovian hierarchy of pure states (HOPS) method and the Markovian Quantum Jump (QJ) method with the newly-developed projected-purification (PP) method for matrix-product states (MPS).

By studying the system's dynamics after global quenches from different ground states, we show that dissipation reduces the polaron's mobility and the electron pairing.

We also find that PP gives a significant speedup (proportional to the phononic local Hilbert space dimension) and allows to systematically converge all observables to very high accuracy in an automated fashion.

Source-driven optical microcavities — •Lukas Seemann and Martina Hentschel — TU Chemnitz

Optical microcavities – open billiards for light – are known to possess far field emission patterns that sensitively depend on their geometric shape: the geometry determines the light's nonlinear dynamics and, via the associated unstable manifold and invariant measure, the emission characteristics. However, this behavior might change, and new features can be added, when the microcavity is driven by a local internal light source [1]. Here, we investigate the properties of optical microcavities with sources both with ray and with wave methods. To this end we extend the ray picture by the phase information and collect the wavelength-dependent phase information along the ray trajectories. We use phase-space methods to analyze the source-induced time-dependent dynamics and compare the Poincaré surface of section for rays with phase to the Husimi function dynamics of wave solutions, thereby exploring chances and limitations of ray-wave correspondence.

How to distinguish between indistinguishable particles — •MICHAEL TE VRUGT — Institut für Theoretische Physik, Center for Soft Nanoscience, Philosophisches Seminar, 48149 Münster, Germany

Does exchanging two indistinguishable particles lead to a new physical state? While the answer appears to be clear in quantum mechanics (no), the situation in *classical* statistical mechanics is up to considerable debate. In this work [1], we show that order-preserving dynamics, a recently developed formalism that allows for an accurate treatment of single-file diffusion within dynamical density functional theory, provides a strong argument for haecceitism (the view that such an exchange does make a difference) since it requires treating observationally indistinguishable particle configurations as being different. This result turns out to have interesting consequences for the concept of thermodynamic equilibrium.

DY 44.2 Thu 15:00 P2 Operationally Accessible Uncertainty Relations for Thermodynamically Consistent Semi-Markov Processes — •BENJAMIN ERTEL, JANN VAN DER MEER, and UDO SEIFERT — II. Institut für Theoretische Physik, Universität Stuttgart, 70550 Stuttgart, Germany

Semi-Markov processes generalize Markov processes by adding temporal memory effects as expressed by a semi-Markov kernel. We recall the path weight for a semi-Markov trajectory and the fact that thermodynamic consistency in equilibrium imposes a crucial condition called direction-time independence for which we present an alternative derivation. We prove a thermodynamic uncertainty relation that formally resembles the one for a discrete-time Markov process. The result relates the entropy production of the semi-Markov process to mean and variance of steady-state currents. We prove a further thermodynamic uncertainty relation valid for semi-Markov descriptions of coarse-grained Markov processes that emerge by grouping states together. A violation of this inequality can be used as an inference tool to conclude that a given semi-Markov process cannot result from coarse-graining an underlying Markov one. We illustrate these results with representative examples [1].

Lane formation of gravitationally driven model colloids in two-dimensional linear channels — •MARC ISELE, KAY HOFMANN, and PETER NIELABA — Physics Department, University of Konstanz, Konstanz, Germany

We conducted Brownian dynamics simulations to investigate the segregation phenomena of driven model colloids in two-dimensional linear channels. Two kinds of spherical particles of different sizes were driven in the same direction by a gravitational force. The difference in driving force acting on these particles creates a segregation similar to the lane formation of oppositely driven colloids. We had a closer look at parameter values facilitating lane formation and the resulting lanes were examined more closely. This approach creates a system which is easier to reproduce in experiments than the conventional oppositely driven setups by tilting a linear channel with two particle kinds of different size.

Geometric Brownian Information Engine : Essentials of optimal work and performance. — •RAFNA RAFEEK, SYED YUNUS ALI, and DEBASISH MONDAL — Department of Chemistry and Center for Molecular and Optical Sciences & Technologies, Indian Institute of Technology Tirupati, Yerpedu 517619, Andhra Pradesh, India

We investigate a Geometric Brownian Information Engine (GBIE) in the presence of an error-free feedback controller that transforms the information gathered on the state of particles entrapped in mono-lobal geometric detention into extractable work. We determine the benchmarks for utilizing the available information in an output work and the optimum operating requisites for best performance. Apart from a reference measurement distance xm and feedback site xf, upshots of the information engine also depend on the transverse constant bias force(G). G tunes the entropic contribution in the effective potential and the standard deviation ( $\sigma$ ) of the equilibrium marginal probability distribution.

We find that the upper bound of the achievable work shows a crossover from  $(5/3-2\ln 2)$ kBT to 1/2kBT when the system changes from entropy to an energydominated one. The higher loss of information during the relaxation process, accredits the lower value of work in entropic instances of GBIE. We recognize that the work extraction reaches a global maximum when xf=2xm with xm=0.6 $\sigma$ , irrespective of the extent of the entropic limitation. Also we explore the effect of entropic control on the unidirectional passage of the particle and efficacy of the GBIE.

#### DY 44.5 Thu 15:00 P2

Shear flow induced instability of a trapped colloidal particle in a complex medium — •LEA FERNANDEZ and SABINE H.L. KLAPP — Institute for Theoretical Physics, TU Berlin

The motion of a colloidal particle in a complex medium, bound by an optical trap and subjected to a shear flow can be modelled by the Lanvegin equations for an over-damped harmonic oscillator in *n* dimensions. Here we treat  $n_{obs}$  observed, physical variables, with  $n = n_{obs} + n_{int}$ , and  $n_{int}$  internal, auxiliary variables modelling a complex medium. Analytical and numerical results are presented for  $n_{obs} = 2$  and  $n_{int} = 1$ , where the coupling between the observed variables is given by a plane Couette flow. We analyse the dynamics of averages, probability densities, and trajectories using Brownian dynamics and the Smoluchowski equation. Of special interest is the effect of the coupling with the auxiliary variable. The focus is on coupling parameters where the steady shear flow causes a transition from a stationary state to an in-stationary state, corresponding to a delocalisation of the particle, when the shear rate exceeded a critical value.

Quantifying the potential energy landscape within nanoconfinements by MD simulations — •SIMON HEFNER, ROBIN HORSTMANN, and MICHAEL VOGEL — TU Darmstadt, Institut für Physik kondensierter Materie, Hochschulstr. 6, 64289, Darmstadt, Germany

Nanoconfinements find applications in various fields from catalysis to electronics, [1] although the properties of confined systems are still not fully understood. For instance, the effects of different kinds of confinements on the dynamical and structural properties of confined liquids are still elusive. To obtain a better understanding of those effects MD simulations are well suited [2]. Here, we performed simulations for TIP4P/2005 water. Neutral pores of water were prepared. From the time-averaged static density profile in the pore the potential energy landscape was reconstructed and the energy barrier against water motion at the wall and in bulk were calculated and compared. We calculated the temperature and radial dependence of the energy barrier. The translational dynamics of water can be derived form the obtained energy landscape using the Arrhenius law. We further applied these methods to other kinds of pore systems and liquids and compared the results.

**Fluctuations of work and heat in a driven entropic potential** — •SYED YUNUS ALI, PRASHANTA BAURI, and DEBASISH MONDAL — Department of Chemistry and Center for Molecular and Optical Sciences & amp; Technologies, Indian Institute of Technology Tirupati, Yerpedu 517619, Andhra Pradesh, India

We consider the motion of an over-damped Brownian particle in twodimensional bilobal confinement driven by a periodic field in the presence of a transverse bias force. The confinement results in an entropic bistable potential in a reduced dimension. We calculate the work done and absorbed heat over a period and their mean and relative variance fluctuations in entropy and energydominated regimes. The average work done and absorbed heat over a period show turnover behavior as a function of noise strength and frequency input. Therefore, these observables can be considered potential quantifiers of the entropic stochastic resonance phenomena. We find that the heat fluctuations over a single period are always greater than the work fluctuations. We also discuss the applicability of steady-state fluctuation theorems in this system.

**Exploiting Brownian motion and correlations for computing** – •ALESSANDRO PIGNEDOLI¹ and KARIN EVERSCHOR-SITTE² – ¹Twist Group, Faculty of Physics, University of Duisburg-Essen – ²Twist Group, Faculty of Physics, University of Duisburg-Essen

Brownian motion is a natural phenomenon that can be exploited for computing [1]. Particle swarm optimization [2] based on the ideas of swarm intelligence is an example of this sort of computation. While the random motion of particles allows the exploration of the entire phase space of the system, interactions and driving forces break ergodicity. This allows for an efficient solution to an optimization problem, which can be identified by looking at the system's correlations and statistical observables. To accomplish Brownian computation, we employ a Langevin model to describe magnetic skyrmions [3], which are topologically stable magnetic whirls that have been shown to behave like interacting Brownian particles [4].

"Walking droplets" constitute a model system to investigate active transport dynamics driven by complex memory kernels. The droplet stores positional information in a wavefield at an oil interface that in return serves as a propulsive mechanism. The complexity of the wavefield and the amount of positional information are remotely controlled through a single scalar value, the memory of the system, which corresponds to the persistence time of the waves. In this study, we investigate the high-memory limit of both the droplet and the wavefield dynamics. We show that an overload of memory brings the droplet to a diffusive dynamics which cannot be distinguished from a active markovian dynamics. The wavefield however contains all the correlations of the dynamics and exhibits an energy-minimization principle and equipartition of energy in the eigenmodes of the wavefield.

**Coarse-graining of systems with discrete Markovian dynamics** — STEFAN KLUMPP and •MIGUEL RODRÍGUEZ MARTÍN — Institute for the Dynamics of Complex Systems, University of Göttingen, Göttingen.

There exists a wide range of physical systems that can be described by discrete Markovian dynamics. In many cases it is desirable to reduce the number of states in order to lower the computational cost or obtain an effective description that captures the most relevant effects at a given scale. A steady stateconserving method of coarse graining based on merging adjacent states and obtaining new transition rates from the optimization of the Kullback-Leibler divergence is generalized by minimizing the Rényi divergence instead. The resulting transition rates depend on the quotients between the steady state probabilities of the merged states in the original system, so a method is developed to compute these transition rates without the need of finding the steady state probabilities. Making use of the similarities between the master equation and Schrödinger's equation, a formulation for classical discrete Markov processes analogous to quantum mechanics is developed, both in the frame of Schrödinger's formulation and second quantization. These are used to study coarse graining under the constraint that the steady state must be conserved.

**Molecular dynamics simulations of binary mixtures in nanostructured pores** — NIELS MÜLLER, MICHAEL VOGEL, and •MARKUS HANEKE — TU Darmstadt, Institut für Physik kondensierter Materie, Hochschulstr. 6, Darmstadt, Germany Water and its mixtures are fairly common in nature and technology.

Here, we seek to understand the influence of solid surfaces with nanostructured porous confinements on binary aqueous mixtures. For this purpose, we exploit that MDS allow us to determine structural and dynamical properties in a spatially resolved manner. The inner surfaces and the aqueous mixtures of the simulated systems are made of differently polarized molecules. The composition and temperature are varied, approaching the regime of spinodal decomposition.

We find that the nanostructured surfaces impose a corresponding nanoscopic phase separation onto the confined mixtures. Explicitly, the concentration of the mixture components varies along the pore axis in phase with the surface patterning, where the effect is stronger near the pore walls. Moreover, the particle mobility differs between the components and depends on the position within the porous confinement. In particular, the imposed concentration fluctuations cause diffusion barriers.

Microcanonical analysis of model polymers interacting via many-body dispersion — •BENEDIKT AMES, MARIO GALANTE, MATTEO GORI, and ALEXAN-DRE TKATCHENKO — Department of Physics and Materials Science, Université du Luxembourg

Non-covalent interactions play a crucial role in the energetics and structure formation of many systems of interest for physics, chemistry and biology.

Among computational methods which include van der Waals (vdW) interactions, the many-body dispersion framework (MBD) attains an excellent accuracy by accounting for all orders of the coupling. Its application has shown the importance of going beyond the pairwise (PW) approximation, for example to obtain the correct energy ordering of molecular crystals and for the adhesion of 2D structures. Nevertheless, the phenomena of MBD-driven dynamics remain largely unexplored.

Here, as a means to probe these dynamics, we study the phase transitions of a simplified model polymer via microcanonical inflection point analysis [1], a recent generalization of the notion of phase transitions from the thermodynamic limit to finite-size systems. By contrasting simulations using MBD and PW methods, we explore whether the different characteristics of each vdW model manifest themselves in distinct properties of the polymer's clustering transition.

Arcsine laws in non-equilibrium regime — •AVIJIT KUNDU^{1,2}, RAUNAK DEY², BISWAJIT DAS², and AYAN BANERJEE² — ¹University of Bayreuth, Universitystrasse 30, 95447, Bayreuth, Germany — ²Indian Institute of Science Education and Research Kolkata, Mohanpur, Kalyani, 741246, India

Most of the processes in the mesoscopic world especially inside living cell are far from thermal equilibrium. The time evolution of such processes is important to study to characterize the processes. Remarkably, Paul Lévy defined arcsine laws for three variables related to the stochastic Wiener process. Here we have studied stochastically driven colloidal particle in a viscous fluid and observed the entropic current, work done on the system or dissipated by it, follow the Lévy arcsine laws in the large time limit. The significant lead of this work is to show the convergence of cumulative distribution to the arcsine law is faster for the case of near equilibrium system where the entropy production rate is smaller. We also have tested the convergence rates of cumulative distributions for different non-equilibrium systems by driving the optically trapped colloidal probe with external noise parameters and changing the flow field by introducing a microbubble in its vicinity.

Phase transition in clustering algorithms — • JULIAN ZITTERICH and ALEXAN-DER K. HARTMANN — Institute of Physics, University of Oldenburg, Germany A well known problem in data analysis and machine learning is the clustering problem. It consists of grouping a set of data vectors into subsets, such that similar vectors end up in the same subset. How to define similarity and how to find these subgroups depend much on the investigated problem, thus many algorithms and metrics exists. Also it may that an algorithm is not able to successfully detect structure in the given data. Thus, we study here ensembles of artificially generated data controlled by parameters such that for some parameter values the clustering is easy or at least possible while for other values it is hard or impossible. Thus, from a statistical physics viewpoint we are interested in phase transitions of the clustering problem between such phases. Previously, the existence of such phase transitions was observed for a single ensemble in high-dimensional space by using the AMP algorithm [1]. Here, we investigate numerically [2] four different state-of-the-art cluster algorithms and analyse their behaviour for increasingly complex ensembles. Low complexity ensembles are realized by direct sampling of data vectors, while high complexity ensembles are implemented by short simulations of simple models of interacting particles.

**Chemfiles: reading and writing atomistic modeling files** — •GUILLAUME FRAUX — Institute of Materials, EPFL, Lausanne, Switzerland

Running atomistic simulations produces enormous amounts of data, which has to be post-processed in order to extract scientifically relevant information. Unfortunately, this task is made much harder by the vast menagerie of existing file formats, all containing similar data in a different formatting.

Chemfiles is a software library providing a unified interface to these formats, allowing researchers to spend their time analyzing their data instead of writing file parsers over and over. Chemfiles is implemented in C++, and provides programming interfaces to most of the scientific languages: Python, Fortran, C, Rust and Julia. 21 different formats are currently supported, including both text and binary (i.e. XTC, TNG, DCD, ...) formats. All text formats can be read and written with multiple compression standards (gzip, xz, bzip2). Chemfiles also offers a comprehensive atom selection language, including the unique feature of simultaneous selection of multiple atoms (e.g. pairs: name(#1) == H and name(#2) == 0 and distance(#1, #2) < 3.0).

Overall, chemfiles one of the fastest libraries for reading files used in atomistic simulation, being between 20% and 10 times faster than other commonly used libraries; while offering a simpler and easy to use programming interface; freeing up time for scientists working with these file formats.

Phase transitions for two-stage stochastic minimum spanning tree optimisation problem — •ROBERT STRASSEN and ALEXANDER K. HARTMANN — Institute of Physics, University of Oldenburg

Phase transitions in classical optimization problems have been studied extensively in statistical physics [1]. Here, we consider two-stage stochastic optimization problems, where the optimization is performed in two different stages, such that in the first stage not all information is available. In particular, we consider the two-stage stochastic minimum spanning tree (MST) problem for undirected graphs with given initial edge costs. In the second stage, one of a set of random scenarios is realized, involving different edge costs. In each stage, edges can be selected such that a spanning tree is finally formed, aiming at a minimum expected total costs. Unlike the conventional MST problem, the two-stage version is generally worts-case "hard" to solve, even though there are problem instances that are "easy". We investigate numerically [2] the problem by the calculation of bounds and applying several approximation algorithms, including one of Dhamdere et al. [3] on various random ensembles of graphs. Our aim is to find out whether there are phase transitions between typical easy and hard problem phases.

Critical Casimir effect in the square-lattice Ising model with quenched surface disorder — •LUCA CERVELLERA and ALFRED HUCHT — Theoretische Physik, Universität Duisburg-Essen and CENIDE, 47048 Duisburg, Germany For the square-lattice Ising model, the critical Casimir amplitude and force can be calculated exactly for many geometries and boundary conditions. From a recent exact solution for the cylinder with length *L*, circumference *M*, and with arbitrary random boundary conditions at one boundary, we determine the full density of thermodynamic states  $\omega(\delta F, m_B)$ , with residual free energy  $\delta F$  and boundary magnetization  $m_B$  at criticality. From this quantity we can derive the disorder averaged Casimir potential for different aspect ratios and disorder ensembles.

#### DY 44.18 Thu 15:00 P2

Anomalous collective dynamics of auto-chemotactic populations — JASPER VAN DER KOLK¹, FLORIAN RASSHOFER¹, •RICHARD SWIDERSKI¹, ASTIK HALDAR², ABHIK BASU², and ERWIN FREY^{1,3} — ¹Arnold Sommerfeld Center for Theoretical Physics and Center for NanoScience, Department of Physics, Ludwig-Maximilians-Universität München, Munich, Germany — ²Theory Division, Saha Institute of Nuclear Physics, HBNI, 1/AF Bidhannagar, Calcutta 700 064, West Bengal, India — ³Max Planck School Matter to Life, Hofgartenstraße 8, 80539 Munich, Germany

While the role of local interactions in nonequilibrium phase transitions is well studied, a fun- damental understanding of the effects of long-range interactions is lacking. We study the critical dynamics of reproducing agents subject to auto-chemotactic interactions and limited resources. A renormalization group anal-

221

ysis reveals distinct scaling regimes for fast (attractive or repulsive) interactions; for slow signal transduction the dynamics is dominated by a diffusive fixed point. Further, we present a novel nonlinear mechanism that stabilizes the continuous transition against the emergence of a characteristic length scale due to a chemotactic collapse.

#### DY 44.19 Thu 15:00 P2

Multifractality at the integer quantum Hall transition — •MARTIN PUSCHMANN¹, DANIEL HERNANGÓMEZ-PÉREZ², BRUNO LANG³, SOUMYA BERA⁴, and FERDINAND EVERS¹ — ¹Institute of Theoretical Physics, University of Regensburg, D-93053 Regensburg, Germany — ²Department of Molecular Chemistry and Material Science, Weizmann Institute of Science, Rehovot 7610001, Israel — ³IMACM and Institute of Applied Computer Science, Bergische Universität Wuppertal, D-42119 Wuppertal, Germany — ⁴Department of Physics, Indian Institute of Technology Bombay, Mumbai 400076, India

The quantum Hall transitions are still one of the bigger mysteries of condensed matter theory. In the past twenty years several conjectures have been made as to what the field theory of the critical fixed point of the integer (class A) quantum Hall transition could be. The multifractal spectrum provides a characteristic fingerprint of the phase transition. Here, recent analytical work predicts a parabolic dependency of the anomalous dimension  $\Delta_q = q(1-q)/4$ , where the exponents  $\tau_q = 2(q-1) + \Delta_q$  describe the system-size scaling of wavefunction moments  $|\Psi|^{2q}$  [1]. In great analogy to our previous analysis on the spin (class C) quan-

tum Hall transition [2], we investigate the multifractal spectrum of the class A transition and similarly demonstrate the presence of quartic terms in  $\Delta_q$ . Our findings are thus clearly inconsistent with the strict parabolicity predicted for "traditional" conformal field theories. [1] M. R. Zirnbauer, Nucl. Phys. B 941, 458 (2019) [2] M. Puschmann et al., Phys. Rev. B 103, 235167 (2021)

#### DY 44.20 Thu 15:00 P2

**Detection of defects in soft quasicrystals with neural networks** — •ALI DOENER and MICHAEL SCHMIEDEBERG — Theoretische Physik I, Erlangen, DE The aim of this work is to construct and employ a neural network for the detection of topological defects in dodecagonal quasicystalline patterns. Even though quasircrystals are aperiodic, they exhibit a longe-range order. Furthermore, in principle any discrete rotational symmetry can occur.

In this work, dodecagonal quasicrystalline patterns in two-dimensions with a built-in dislocation are generated and employed as input images of the neural network. The network then should figure out not only the position but also the type of the Burgers vector of the defect.

Our trained neural network is able to recognize the type of the Burgers vector very good. The position of the dislocation is recognized up to a mean deviation from the real position that is much smaller that the small length scale in the quasicrystals. In future, we want to train the network with patterns that contain multiple dislocations as well as phasonic excitations.

Influence of protective measures on rare-event behavior of the dynamics of the SIR model. — •TIMO MARKS, YANNICK FELD, and ALEXANDER K. HART-MANN — Institute of Physics, University of Oldenburg

Since the outbreak of the SARS-CoV-2 pandemic in early 2020, there has been a surge of interest in modeling disease spreading. The basis of many more complex models is the SIR model [1], in which the population is divided into a group of *Susceptible, Infected* and *Recovered* individuals.

Here, the SIR model is applied to a small-world ensemble that can model social interactions of a real population [2]. Using large-deviation methods and in particular the Wang-Landau algorithm, the distributions of quantities of interest can be calculated over basically the full support [3]. To include protective measures, once a predefined threshold of simultaneously infected nodes is reached, the transmission parameter is decreased. We compare the impact of these measures with unrestrained disease spreading on the level of the full probability distributions, which were obtained down to probabilities such as  $10^{-50}$ . We thereby observe significant changes in the shape of the distributions.

Pattern Formation in non-ideal systems: From Turing patterns to active droplets — •LUCAS MENOU and DAVID ZWICKER — Max Planck Institute für dynamik und selbstorganisation, Göttingen, Germany

Turing's seminal reaction-diffusion model explains how patterns form in nonequilibrium systems. Typical Turing models assume ideal diffusion, which implies dilute or ideal systems. In contrast, active droplets use chemical reactions to control phase separation emerging in strongly interacting systems. We unite both theories by combining the classical Cahn-Hilliard model, which describes non-ideal solutions, with the typical non-linear reactions responsible for Turing patterns. We find that interactions can promote or suppress the emergence of periodic patterns. Interestingly, patterns can form even when all species have equal diffusivity, which is impossible in traditional Turing models. Taken together, our theory shows a rich behavior that interpolates between the traditional Turing patterns and active droplets.

**Chaotic Diffusion in Delay Systems: Giant Enhancement by Time Lag Modulation** — •TONY ALBERS, DAVID MÜLLER-BENDER, LUKAS HILLE, and GÜNTER RADONS — Institute of Physics, Chemnitz University of Technology, Chemnitz, Germany

We consider a typical class of systems with delayed nonlinearity, which we show to exhibit chaotic diffusion. It is demonstrated that a periodic modulation of the time-lag can lead to an enhancement of the diffusion constant by several orders of magnitude. This effect is the largest if the circle map defined by the modulation shows mode locking and more specifically, fulfills the conditions for laminar chaos. Thus we establish for the first time a connection between Arnold tongue structures in parameter space and diffusive properties of a delay system. Counterintuitively, the enhancement of diffusion is accompanied by a strong reduction of the effective dimensionality of the system.

Bistable vortices formed by active particles with retarded interactions — XI-ANGZUN WANG¹, •PIN-CHUAN CHEN², KLAUS KROY², VIKTOR HOLUBEC³, and FRANK CICHOS¹ — ¹Peter Debye Institute for Soft Matter Physics, Leipzig University, Leipzig, Germany — ²Institute for Theoretical Physics, Leipzig University, Leipzig, Germany — ³Department of Macromolecular Physics, Faculty of Mathematics and Physics, Charles University, Prague, Czech Republic

In recent experiments done in the Molecular Nanophotonics Group in the Peter Debye Institute, thermophoretic microswimmers are observed to self-assemble into bi-stable rotational modes due to retarded attractive interactions.

For the particular case where a single swimmer is attracted to an immobilized target, we show how we can analytically understand such non-linear stochastic time-delayed system. This could be achieved by Taylor expanding the equation for small time delay. The system can then be described by an overdamped Langevin equation with a potential determined by time delay, and the transition in between the two stable modes is well predicted by Kramers' escape rate. However, expanding the delayed term in Taylor series is actually not as trivial as it seems to be, as instability would occur if we keep derivatives up to arbitrarily high orders.

For the case where multiple swimmers are present, the swimmers form a cluster with co-rotating and counter-rotating shells. We further discuss the competition between the time-delay and hydrodynamic effects, which result in this phenomenon.

DY 45.5 Thu 15:00 P2

Synchronizing Cells Based on Local Interactions —  $\bullet$ Stephan Kremser, Mareike Bojer, and Ulrich Gerland — Physics Department, Technical University of Munich

Tissue-wide temporal synchronization of cellular processes is a desirable property for many systems in synthetic and developmental biology. Here, we look at a setting were cells have only limited information about the behavior of neighboring cells, receiving new information only after these neighbors change their internal state. Under these assumptions, we ask if global synchronization can be reached based on local (e.g. direct contact) interactions. We develop a conceptual model of the synchronization process and explore it computationally for different dimensions and interaction network topologies of the tissue. We show that temporal corrections to cellular processes based on magnitude ('proportional feedback control') or sign ('on-off feedback control') of local time differences are enough to conserve local synchronization and bound global asynchrony by a

222

constant independent of time for a long period of time. This allows us to establish a link to the physics of growing surfaces and to investigate the interplay of patterning and synchronization dynamics.

Network complexity versus network synchronicity: A case study of the Kuramoto model on complex networks — Archan Mukhopadhyay and •Jens Christian Claussen — University of Birmingham, UK

During the last two decades, complexity measures for graphs and networks have gained significant attention (see [1] for a comparison), especially in the aim to distinguish "complex" topologies from regular lattices as well as random structures. However, what is the influence of topology on dynamics? Here we specifically analyze synchronization in a network of Kuramoto oscillators where the topology (between a high-complexity graph and a random graph) is parameterized by a complexity measure, as Offdiagonal Complexity [2] or one of the other graph complexity measures. This approach may provide a new light on both the influence of complexity on synchronization, as well as the complexity measures and which aspects of dynamical complexity these may predict.

**Quantum synchronization in a network of dissipatively coupled oscillators** — •JUAN NICOLAS MORENO, CHRISTOPHER W. WÄCHTLER, and ALEXANDER EIS-FELD — Max Planck Institute for the Physics of Complex Systems, Dresden, Germany

Synchronization in classical systems has a long history and by now is a very well understood phenomenon. However, the question whether the classical notions of synchronization can be extended to the quantum regime has only recently been addressed in investigations of classically inspired models like quantum Van der Pol oscillators as well as models without classical analog. Inspired by the theoretical prediction that two-level atoms are able to synchronize even without interacting directly [1], we investigate a network of dissipatively coupled quantum harmonic oscillators. Within a mean-field approximation we find that the network is able to synchronize. For the fully quantum system described in terms of a Lindblad master equation we analyze various measures that have been proposed in the literature. Additionally, we investigate the Liouvillian spectrum in order to draw connections between the spectrum and the synchronization measures.

Neural Network-Based Approaches for Multiscale Modelling of Topological Defects — •Kyra Klos¹, Karin Everschor-Sitte², and Friederike SCHMID¹ — ¹Johannes Gutenberg University, Mainz, Germany — ²University of Duisburg-Essen, Duisburg, Germany

Topological defects and their dynamics are a heavily researched topic in a wide range of physics fields [1].

Due to the multiscale character of those defect structures, numerically simulating a large number of them in full microscopic detail gets highly computationally expensive, as the large size of associated deformation fields around each core leads to a complex interaction pattern.

To give a possible insight into the connection between the macroscopic (particle) description of a model with topological defects and the underlying microscopic structure, we propose the use of neural networks. With a spin-dynamic simulated microscopic model as training data, we use a conditional generative adversarial network system [2] with Wasserstein-loss [3] to generate reasonable spin-configurations from given defect configuration inputs. To guarantee the generation of realistic spin configuration, we also include additional physical constraints into our generator.

**Characterizing quasicrysalline patterns with neural networks** — •JONAS BUBA and MICHAEL SCHMIEDEBERG — Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany

There exist multiple ways to generate two dimensional quasicrystal patterns such as superpositions of plane waves [1-3] or projection methods [4], each using different parametrisations. A deep convolutional Autoencoder is utilized to determine whether an artifical neural network is capable of finding sufficient parametrisations for these patterns.

Furthermore another neural network was used to classify them by symmetry. Finally, deep dream methods [5] are employed to analyze which features the artificial intelligence bases its symmetry classification on. Currently we are trying to find out how the deep dream approach can be applied to modify existing patterns by enhancing features corresponding to specific symmetries.

Influence of delay-times on photonics reservoir computing performance — •LINA JAURIGUE and KATHY LÜDGE — Institut f. Physik, Technische Universität Ilmenau, Weimarer Str. 25, 98684 Ilmenau, Germany

Reservoir computing is a machine learning approach that utilises the non-linear responses of dynamical systems to perform computational tasks. Due to the relative simplicity of this approach the implementation in hardware is practicable, particularly the delay-based reservoir computing paradigm. Delay-based reservoirs use a single non-linear node subject to self-feedback. The high-dimensional dynamics that arise due to the feedback are utilised by driving the reservoir with time-multiplexed inputs. There have been a number of successful implementations of delay-based reservoirs in electronic, opto-electronic and photonic systems, among others. However, a challenge that remains is the efficient optimisation of a reservoir for performance on a variety of tasks. To this end we explore the influence of the delay-time on the performance of time-series prediction tasks and compare the computational performance of different methods of including task specific delay-timescales in a photonic reservoir setup.

(DLR), Insitut für Optische Sensorsysteme, Rutherfordstr. 2, 12489 Berlin, Germany

Reservoir computing is a versatile, fast-trainable approach for machine learning that utilities the capabilities of dynamical systems. The common approach is to use a nonlinear element and a delay line to construct a virtual network. These virtual networks have limited topology. By utilizing cesium cells as coherent optical memory cells to create a hybrid architecture [1] the limitations of topology can be overcome and a more dynamically versatile virtual network can be created. The optical memory used in the corresponding experiment performs well in memory bandwidth but experiences high noise levels. [2] The dynamics and noise resistance of this approach is examined to find an optimal approach for different time series prediction tasks.

Analysis of liquid distribution in microchannel systems using the electrohydraulic analogy — •MARIUS PÄTZOLD¹, FELIX SENF¹, CARL E. KRILL III², and Othmar Marti¹ — ¹Institut für experimentelle Physik, Universität Ulm — ²Institut für funktionelle Nanosystem, Universität Ulm

The research program investigates the calculation of leakages in hydraulic systems by modelling the latter using electric resistor networks as an alternative to simulations employing computational fluid dynamics.

Based on a rigid geometry that describes a network of channels having rectangular cross sections of constant height, the hydraulic properties of the network are examined. The system is then modelled using an electric resistor network that incorporates these hydraulic properties. For a given pressure drop between the inlet and outlets, the model can be solved and leakages can be calculated using a modified nodal analysis.

The results show that modelling the geometry in this manner can be an efficient alternative to simulations using computational fluid dynamics within the requirements set by the electric-hydraulic analogy. Modelling hydraulic networks that are not within these requirements, like those with very short channels or highly complex channel networks, leads to the propagation of errors through the network, resulting in significant differences between the modelling and simulation approach.

Topological fine structure of smectic grain boundaries and tetratic disclination lines within three dimensional smectic liquid crystals^{*} — PAUL A. MONDERKAMP¹, RENÉ WITTMANN¹, •MICHAEL TE VRUGT², AXEL VOIGT³, RAPHAEL WITTKOWSKI², and HARTMUT LÖWEN¹ — ¹Institut für Theoretische Physik II: Weiche Materie, Heinrich-Heine-Universität Düsseldorf, Universitätsstraße 1, 40225 Düsseldorf, Germany — ²Institut für Theoretische Physik, Center for Soft Nanoscience, Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany — ³Institut für Wissenschaftliches Rechnen, Technische Universität Dresden, 01062 Dresden, Germany

Based on recent insights into the orientational topology of smectic grain boundaries in two dimensions, we analyse boundaries in three-dimensional confined smectics from the perspective of tetratic symmetry. Monte-Carlo simulations show the emergence of orientational grain boundaries. Using a 3d tetratic order parameter constructed from the Nelson-Steinhardt invariants, we show that the orientational topological fine structure of the planar smectic grain boundaries can be interpreted as a pair of tetratic disclination lines that are located on the edges of the nematic domain boundary [1]. Thereby, we shed light on the fine structure of the orientational topology of grain boundaries in three-dimensional confined smectics.

**From a microscopic inertial active matter model to the Schrödinger equation*** — •MICHAEL TE VRUGT^{1,2}, TOBIAS FROHOFF-HÜLSMANN¹, EYAL HEIFETZ³, UWE THIELE¹, and RAPHAEL WITTKOWSK1^{1,2} — ¹Institut für Theoretische Physik, Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany — ²Center for Soft Nanoscience, Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany — ³Porter School of the Environment and Earth Sciences, Tel Aviv University, 69978 Tel Aviv, Israel

Field theories for the one-body density of an active fluid, such as the paradigmatic active model B+, are simple yet very powerful tools for describing phenomena such as motility-induced phase separation. No comparable theory has been derived yet for the underdamped case. In our work [1], we introduce active model I+, an extension of active model B+ to particles with inertia. The governing equations of active model I+ are systematically derived from the microscopic Langevin equations. We show that, for underdamped active particles, thermodynamic and mechanical definitions of the velocity field no longer coincide and that the density-dependent swimming speed plays the role of an effective viscosity. Moreover, active model I+ contains the Schrödinger equation in Madelung form as a limiting case, allowing to find analoga of the quantum-mechanical tunnel effect and of fuzzy dark matter in the active fluid. We investigate the active tunnel effect analytically and via numerical continuation. [1] M. te Vrugt et al., arXiv:2204.03018

Inertial Active Particles in Unbiased ac Fields Sediment at the Top Wall — •JOSÉ CARLOS UREÑA MARCOS and BENNO LIEBCHEN — Institut für Physik Kondensierter Materie, Technische Universität Darmstadt, Darmstadt, Germany

A detailed understanding of the controllability of the swimming direction of active particles through external fields is crucial for many of their proposed future applications, from nanomedicine to bioapplications.

While such steering is often achieved with dc fields with a net gradient, we show in this work that the use of rapidly oscillating ac fields allows the steering of inertial active particles even in the absence of a net gradient. To demonstrate this, we develop an analytical framework which shows that fast ac fields can stabilise fixed points in the dynamics of active particles which would otherwise be unstable.

To exemplify the applicability of this scheme, we explore inertial active particles in a gravitational field and observe that, in the presence of a rapidly oscillating ac field, a substantial fraction of them persistently travel in the upward direction and sediment at the top wall of the simulation box.

Rheological properties of Stcokmayer supracolloidal magnetic polymers under shear flow — •VLADIMIR ZVEREV¹, EKATERINA NOVAK¹, and IVAN NOVIKAU² — ¹UNIVIE, Vienna, Austria — ²Ekaterinburg, Russia

Supracolloidal magnetic polymers (SPMs) are polymer-like structures in which magnetic nanoparticles Construction SPMs has recently been made possible. Their advantage is that they keep their structure independently from the temperature. SPMs can be potentially used as an alternative to nanoparticles in magnetic fluids to obtain a desired and easily controlled magnetic or rheological response.

We assume SMPs formed by monodisperse magnetic colloids, modeled as identical spherical beads. We consider SMPs of four different topologies: chain-, Y-, X- and ring-like ones. Using Langevin dynamics simulations, we pay our attention to solutions of filaments, the magnetic nanoparticles in which are not only interacting via dipole-dipole potential but also via short-range attractive forces (Van der Waals force). Such filaments tend to aggregate in dense spherical droplet-like clusters. The resulting composite soft colloid is placed in the microchannel, where its behavior in the shear flow under influence of an external field is investigated, varying a wide range of system parameters. It was found that clusters can demonstrate oscillating in time magnetic response and complex mutual infulence of the flow and the magnetic field.

The work was supported by RSF 19-72-10033.

**Experimental study of statistical structures and forces in granular matter** — AMELIE MAYLÄNDER¹, CLARA C. WANJURA², LUKAS REITER¹, RAPHAEL BLUMENFELD^{3,2}, and •OTHMAR MARTI¹ — ¹Institute of Experimental Physics, Ulm University, D-89069 Ulm — ²Cavendish Laboratory, University of Cambridge, CB3 0HE, UK — ³Gonville & Caius College, University of Cambridge, Trinity Street, Cambridge CB2 1TA, United Kingdom

We investigated the structure-forces coevolution in rotational shear of a planar assembly of photo-elastic polyurethane-discs of four different sizes under constant confining stress. Disc positions and contacts were determined using unpolarized red light. A dark-field polariscope, using circularly polarized blue light, detected mechanical deformations and the force network. The experiment ran through: a de-correlation step, initial state preparation, steady-state dynamics.

Repeated measurements of the structure and cell order distribution of the geometric contact network were carried out, validating theoretical predictions of detailed balance[1] and maximum entropy[2]. Simultaneously detected force chain

Location: P2

networks had more cells of higher orders than the geometric network, providing less than maximum entropy. This is attributed to the sensitivity of force detection to low-force contacts. Characteristic differences also existed in the shapes of small cells.

Ising-like critical behavior of vortex lattices in an active fluid — •Henning Reinken¹, Sebastian Heidenreich², Markus Bär², and Sabine H. L. Klapp¹ — ¹Technische Universität Berlin — ²Physikalisch-Technische Bundesanstalt Berlin

Turbulent vortex structures emerging in bacterial active fluids can be organized into regular vortex lattices by weak geometrical constraints such as obstacles [1,2]. Here we show, using a continuum-theoretical approach [3], that the formation and destruction of these patterns exhibit features of a continuous second-order equilibrium phase transition, including long-range correlations, divergent susceptibility, and critical slowing down. The emerging vorticity field can be mapped onto a two-dimensional (2D) Ising model with antiferromagnetic nearest-neighbor interactions by coarse-graining. The resulting effective temperature is found to be proportional to the strength of the nonlinear advection in the continuum model [4].

**Cohesive rotation of particles with misaligned perception-dependent motility** — •RODRIGO SAAVEDRA, GERHARD GOMPPER, and MARISOL RIPOLL — Institute of Biological Information and Institute for Advanced Simulation, Forschungszentrum Jülich, Germany

Systems of agents with discontinuous motility that activate according to visual perception rules have been found to aggregate into cohesive groups. Here we study the formation of rotating cohesive clusters by considering the particles' vision cone to have a fixed misalignment with respect to the self-propulsion direction. Together with the motility rule, we find this mechanism to facilitate both cohesion and rotation of the cluster. The presence of steric interactions translates into a compact cluster which might eventually be driven by particles in its outer layer. We systematically explore the effect of misalignment and perception on the cluster morphology by means of particle-based numerical simulations. We find good agreement of the results with a proposed coarse-grained model.

**Diffusion in a sulfonated co-polynaphthoyleneimide proton exchange membrane studied by NMR** — •CELINE WOLTER, ALEXEI PRIVALOV, and MICHAEL VOGEL — TU Darmstadt, Institut für Physik kondensierter Materie, Darmstadt, Germany

Nowadays, most fuel cells are based on proton-exchange membranes such as Nafion, which contain fluorine and therefore have some disadvantages for disposal. One alternative are flourine-free hydrocarbon-based polymers. Their respective characteristics for use in fuel cells are similar to Nafion membranes, but they are easier and cheaper to produce and recycle. An important parameter for these systems is the proton diffusion coefficient, since it is related to charge transfer across the membrane and removal of the resulting water. We investigated self-diffusion in a sulfonated co-polynaphthoylenimide proton exchange membrane using ¹H static field gradient (SFG) nuclear magnetic resonance (NMR). The polymer under study has a ratio of hydrophilic to hydrophobic groups of 60:40, and the saturation humidity of the samples varies from 31% to 100%. For this polymer, the magnetization transfer effects between protons in the membrane framework and water protons must be taken into account. To do this, we applied a model that accounts for such exchange phenomena and were able to determine the diffusion coefficients within a few percent uncertainty in the temperature range from 190 K to 365 K. We found a significant decrease in diffusion at low water concentrations and an increase in activation energy below 250 K, indicating a change in the diffusion mechanism.

#### DY 46.10 Thu 15:00 P2

**Non-mechanical Electrowetting Pump On a Chip** — •SEBASTIAN BOHM^{1,2}, HAI BINH PHI², LARS DITTRICH², and ERICH RUNGE¹ — ¹Technische Universität Ilmenau, Theoretische Physik 1, Weimarer Str. 25, 98693 Ilmenau — ²5microns GmbH, Ehrenbergstr. 11, 98693 Ilmenau

Numerical simulations suggests that by using the EWOD (electrowetting-ondielectric) effect a micropump can be manufactured, that works completely without any moving components [1,2]. The volume stroke is generated by the periodic movement of liquid-vapor interfaces in a large number ( $\approx 10^6$ ) of microcavities ( $\Delta V \approx 1$  pl per cavity). Passive Tesla-Diodes are used to rectify the resulting volume stroke to completely forgo any moving parts. Even though our simulation suggests a high efficiency comparable to that of conventional designs in particular for small pumps, the actual realization poses multiple challenges. In this work, first experimental results of the characterization of the micropump are presented. The manufacturing process is described, which is based on an smart combination of processes commonly used in microsystems technology. This enables a cost-effective manufacturing that can be carried out entirely on wafer level. In addition, the direct integration of the pump into wafer-based microfluidic or lab-on-a-chip applications is facilitated. Possible use cases are presented and discussed.

**Collective Behaviour of Active Assemblies Induced by Internal Feedback** — •LISA ROHDE and FRANK CICHOS — Molecular Nanophotonics Group, Peter Debye Institute for Soft Matter Physics, Leipzig University, Linnéstr. 5, 04103 Leipzig, Germany

Collective phenomena and self-organising processes in nature such as structure formation of cells or flocking of birds are generated by physical interactions between autonomous objects ruled by feedback, information processing or sensing. Recently there has been an increasing interest in studying the collective behaviour of artificial active particles that provide the basic functionality of selfpropulsion on the microscale. Here, we introduce physical interactions between artificial microswimmers in a crowded environment by implementing feedback rules to mimic the self-organisation of their living counterparts. We use differently shaped Janus particles capped with a thin gold layer. They are driven by self-thermophoresis, which we control by heating the gold layer with a laser. Depending on the shape of the Janus particle we observe different clustering behaviour as a result of a positive feedback mechanism by which Janus particles are attracted due to a temperature increase of a growing cluster. Our system reacts on hydrodynamic flow fields that are internally induced by other components by showing for example, a polarised motion of particles when being subjected to the feedback loop. We investigate and quantify the role of shape dependent hydrodynamic flow fields on the feedback mechanism by dedicated experiments on the clustering of active assemblies.

**Bacterial swimmers' motility under external and light-induced flows** — •VALERIIA MURAVEVA^{1,2}, ROBERT GROSSMANN¹, MAREK BEKIR², SVETLANA SANTER², and CARSTEN BETA¹ — ¹Biological Physics, University of Potsdam, Potsdam, Germany — ²Smart Soft Matter, University of Potsdam, Potsdam, Germany

We report on changes in the swimming strategy of rod-shaped bacteria under flow conditions.

To swim bacteria utilise lash-like organelles on the cell body, flagella. The model organism for this study is the soil bacterium Pseudomonas putida, which has a rod-shaped body and multiple flagella located at one pole of the cell, so they can act in concert to drive the bacterium in a single direction. The strategy of switching between different swimming modes in bulk was well described. Here, we study the cells' locomotion strategy under flow to better understand the processes of infection spreading and biofilm formation in a natural environment.

To create shear stress conditions hydrodynamic flows are used. For varying the geometry of flow patterns on the micron-scale we also use light-induced flow technics (in particular thermo-osmosis on a gold surface) to create flow locally and to advect or trap swimming bacteria.

To analyse the well-known "run-and-turn" strategy, we concentrate on characteristic features of the swimming pattern: changes in the run-time and turn angle distributions. We also study mutant cell lines under flow (cells with partial or total deficiency in motor function) to elucidate the role of the different components of the motility apparatus in this process.

DY 46.13 Thu 15:00 P2

**Phase behaviour of mixtures of attractive rods and spheres** — ANJA KUHN-HOLD and •ELEONORA FOSCHINO — nstitute of Physics, Albert-Ludwigs-University Freiburg, Germany

The aim of this project is to study a mixture of anisotropic rod-shaped particles and spherical particles in a bulk by means of Monte Carlo simulations. The goal is to find regions in the parameter space that show stable de-mixed phases in threedimensional systems and stable mixed phases in two-dimensional systems. This would be preliminary to the study of thickness-dependent de-mixing during film growth, which was observed and studied in experiments with blends of organic molecular semiconductors (JR. Banerjee et Al., "Evidence for Kinecally Limited Thickness Dependent Phase Separaon in Organic Thin Film Blends", 2013).

The simulation is based on an implementation of the Metropolis algorithm in a box with periodic boundary conditions. Rod-shaped particles are modelled as hard spherocylinders and spherical particles as hard spheres, and the spheres/rods composition is kept constant, as well as the volume of the simulation box. All particles interact through hard-body repulsion and an additional pair potential, to mimic van der Waals interactions between molecules in the mixture. The parameter space includes the rod-shaped particles' dimensions (the spherocylinders' diameter with respect to the spheres' diameter and the aspect ratio), as well as the strengths and ranges of the attractive interaction.

**Electrophoretic mobility of liquid droplets** — •ALEXANDER REINAUER and CHRISTIAN HOLM — Institute for Computational Physics, Stuttgart, Germany Electrophoresis of liquid droplets displays many complex phenomena with applications for phase separation and transport in biological systems. It is significantly more complex than particle electrophoresis due to the mobility of the surface charges as well as the non-rigid nature of the fluid-fluid interface. To investigate the different contributions we conduct a lattice Boltzmann (LB) simulation study of freely suspended liquid droplets under application of an external electric field. We use the Color-Gradient multicomponent LB extension which is coupled to a lattice electrokinetics model for dissolved charged chemical species. Our ongoing study intends to quantify the influence of the viscosity ratio, the salt concentration as well as the charge of the droplet on the measured electrophoretic mobility.

Capacitive Density Functional Theory – C++ support for classical Density Functional Theory implementations — •MORITZ BÜLTMANN, PHILIPP PELAGEJCEV, and ANDREAS HÄRTEL — Institute of Physics, University of Freiburg, Germany

CapDFT is a C++ library and provides functional implementations and methods to implement classical Density Functional Theory (DFT) calculations. It is currently developed in our Statistical Physics of Soft Matter and Complex Systems group at the University of Freiburg and we would be happy to discuss ideas and concepts at our poster.

DY 46.16 Thu 15:00 P2

The Scallop Theorem and Swimming at the Mesoscale — •MAXIME HUBERT¹, OLEG TROSMAN¹, YLONA COLLARD², ALEXANDER SUKHOV³, JENS HARTING³, NICOLAS VANDEWALLE², and ANA-SUNČANA SMITH^{1,4} — ¹PULS group, FAU Erlangen-Nürnberg, Erlangen, Germany — ²GRASP, University of Liège, Liège, Belgium — ³Helmholtz Institute Erlangen-Nürnberg for Renewable Energy (IEK-11), Forschungszentrum Jülich, Nürnberg, Germany — ⁴Group for Computational Life Sciences, Ruder Bošković Institute, Zagreb, Croatia

By comparing theoretical modeling, simulations and experiments, we show that there exists a swimming regime at low-Reynolds number solely driven by the inertia of the swimmer itself. This is demonstrated by considering a dumbbell with an asymmetry in coasting time in its two spheres. Despite deforming in a reciprocal fashion, the dumbbell swims by generating a non-reciprocal Stokesian flow, which arises from the asymmetry in coasting times. This asymmetry acts as a second degree of freedom, which allows for recasting the scallop theorem at the mesoscopic scale at the lowest level of theory.

## DY 46.17 Thu 15:00 P2

**Fisher-Widom line for systems with competing repulsive and attractive interaction** — •MATTHIAS GIMPERLEIN and MICHAEL SCHMIEDEBERG — FAU Erlangen-Nuremberg, Germany

We study colloid-polymer mixtures interacting via a Double-Square-Well potential (DSW-potential) consisting of hard core repulsion, short range attraction and longer range repulsive interaction. The Fisher-Widom line (FW-line) can be used as an indicator for the interplay between repulsion and attraction in the system. It seperates regimes of monotonically (attraction dominates) or oscillatory (repulsion dominates) decaying pair correlation function in the phase diagram.

Solving the Ornstein-Zernike equation we find that the regime of monotonically decaying pair correlation function decreases. On the high density side of the phase diagram repulsion dominates (hard core interaction), but the introduction of the longer range repulsive step leads to a dominance of repulsion also on the low density side of the phase diagram. Only for intermediate densities and temperatures close to the critical temperature attraction dominates the system.

Further research includes a detailed check and analysis of the theoretical results by Brownian Dynamics simualtions. The intersection of the binodal and the FW-line could be interesting for the structure of systems below the binodal line and eventually for gel network formation.

#### DY 46.18 Thu 15:00 P2

Self-propelled Ellipsoidal Swimmers — •GORDEI ANCHUTKIN¹, VIKTOR HOLUBEC², ARTEM RYABOV³, and GORDEI ANCHUTKIN¹ — ¹Molecular Nanophotonics Group, Peter Debye Institute for Soft Matter Physics, Leipzig University, 04103 Leipzig, Germany — ²Institute for Theoretical Physics, Leipzig University, 04103 Leipzig, Germany — ³Department of Macromolecular Physics, Faculty of Mathematics and Physics, Charles University, CZ-180 00 Praha, Czech Republic The active motion of microswimmers has attracted broad interest for the last decades. A variety of active particles with different shapes and designs have been demonstrating various applications from biosensing to synergistic drug delivery most of them, though, with spherical particles involving a single orientational relaxation time. To generalize the complexity of active microswimmers* behavior, we investigate the fundamentals of active motion for microswimmers with multiple timescales of rotational diffusion. We investigate Janus ellipsoids thermophoretically propelled along the short axis of the ellipsoid. We report three different motion regimes of Janus ellipsoids: the active ballistic motion, run and tumble, and the diffusive regime. Using mean squared displacement analysis, we describe each regime and the corresponding time scales and show the coupling between translational and orientational motions. Our experimental results are compared to a theoretical model of an active ellipsoid motion. The different modes of active motion on different timescales deliver interesting perspectives to explore the interaction with obstacles and other particles at different densities.

#### DY 46.19 Thu 15:00 P2

Hyperspace-simulations of quasicrystalline structures on periodic substrates — •JOHANNES SCHÖTTNER and MICHAEL SCHMIEDEBERG — FAU, Erlangen, Deutschland

We perform Monte Carlo simulations a toy model where particles move on a hyperlattice. Therefore, jumps in hyperspace corresponding to phasonic flips are considered while phononic noise is not taken into account. Note that the interaction energy is determined after the particles have been projected onto the physical space. This approach can be used to learn about the stability and other physical properties of quasicrystals. Our work here is motivated by experiments [1] where quasi-crystalline structures grows self-organized on a crystalline surface. Therefore, we consider an external periodic potential that acts in our toy model. Our goal is to investigate how phasonic modes are influenced by the external periodic potential. A major advantage of our approach is that by construction we know all hyperspace positions of all particles. Furthermore, phasonic excitations due to the external potential can be determined without ambiguity. [1] Förster et al., Nature, 502:215*218, 10 (2013)

DY 46.20 Thu 15:00 P2

**Theory of scanning gate Microscopy in graphene** – •XIANZHANG CHEN^{1,2}, GUILLAUME WEICK², DIETMAR WEINMANN², and RODOLFO JALABERT² – ¹Lanzhou Center for Theoretical Physics, and Key Laboratory for Magnetism and Magnetic Materials of MOE, Lanzhou University, Lanzhou, Gansu 730000, China – ²Université de Strasbourg, CNRS, Institut de Physique et Chimie des Matériaux de Strasbourg, UMR 7504, F-67000 Strasbourg, France

The conductance of graphene nanoribbons and quantum point contacts under scanning gate microscopy tip has been systematically studied. The first- and second-order conductance corrections caused by the tip potential disturbance in armchair graphene are expressed in terms of the scattering states of the unperturbed structure using a scattering approach for a noninvasive probe. The second-order term prevails in the conductance plateaus for armchair graphene strips, but the first-order corrections dominate everywhere at the conductance steps for graphene shaped in quantum point contact. For the stronger tip, where the perturbation approach breaks down, we discovered that conductance corrections exhibit resonance effects at specific values of the tip potential width and strength, which can be regarded as carriers trapped below the tip. Additionally, the numerical results for zigzag graphene also follow the weak probe theory.

#### DY 46.21 Thu 15:00 P2

Characterization and control of traffic-jam transition for self-propelled particles with *q*-fold discrete symmetry: The restricted Active Potts Model — •SWARNAJIT CHATTERJEE¹, MINTU KARMAKAR², MATTHIEU MANGEAT¹, HEIKO RIEGER¹, and RAJA PAUL² — ¹Saarland University, Saarbrücken, Germany — ²Indian Association for the Cultivation of Science, Kolkata, India

We undertake comprehensive numerical simulations of the *q*-state active Potts model (APM) [EPL 130, 66001 (2020); Phys. Rev. E 102, 042601 (2020)] applying distinct volume exclusions to the self-propulsion of the active particles in the quest to explore the characteristics of the emerging phases, kinetic arrest, and jamming transitions. We broadly explore two scenarios where (a) the population of a lattice site is prearranged (hard-core restriction) and (b) particle movements are governed by a local repulsive field (soft-core restriction) and show that such effects lead to a surprisingly rich variety of self-organized spatial patterns. While bands and lanes of moving particles commonly occur without or under weak volume exclusion, strong volume exclusion along with low temperature, high activity, and large particle density facilitates traffic jams. Through a number of phase diagrams, we identify the phase boundaries separating the jammed and free-flowing phases and study the transition between these phases which provide us with both qualitative and quantitative predictions of how jamming might be delayed or dissolved. We further validate our numerical findings with a hydrodynamic model description.

DY 46.22 Thu 15:00 P2

Polar flocks with discretized directions: the active clock model approaching the Vicsek model — •MATTHIEU MANGEAT, SWARNAJIT CHATTERJEE, and HEIKO RIEGER — Universität des Saarlandes, Saarbrücken, Germany

We study the off-lattice two-dimensional q-state active clock model (ACM) as a natural discretization of the Vicsek model (VM) [Phys. Rev. Lett. **75**, 1226 (1995)] describing flocking. The ACM consists of particles able to move in the plane in a discrete set of q equidistant angular directions, as in the active Potts model (APM) [EPL **130**, 66001 (2020); Phys. Rev. E **102**, 042601 (2020)], with a local alignment interaction inspired by the ferromagnetic equilibrium clock model. A collective motion emerges at high densities and low noise. We compute phase diagrams of the ACM and explore the flocking dynamics in the region, in which the high-density (polar liquid) phase coexists with the low-density (gas) phase. We find that for a small number of directions, the flocking transition of the ACM has the same phenomenology as the APM, including macrophase separation and reorientation transition from transversal to longitudinal band motion as a function of the particle self-propulsion velocity. For a larger number of directions, the flocking transition in the ACM becomes equivalent to the one of the VM and displays microphase separation and only transverse bands, i.e. no reorientation transition. Concomitantly also the transition of the  $q \rightarrow \infty$  limit of the ACM, the active XY model (AXYM), is in the same universality class as the VM. We also construct a coarse-grained hydrodynamic description for the ACM and AXYM akin to the VM.

All members of the Dynamics and Statistical Physics Division are invited to participate.

# DY 48: Invited Talk Kathy Lüdge (joint session DY/SOE)

Time: Friday 9:30-10:00

**Invited Talk** DY 48.1 Fri 9:30 H19 **Photonic Reservoir Computing: Analytic insights and possibilities for opti mization** — LINA JAURIGUE¹, FELIX KÖSTER², and •KATHY LÜDGE¹ — ¹Institute of Physics, Technische Univ. Ilmenau, Weimarer Str. 25, 98684 Ilmenau — ²Institute of Theoretical Physics, Technische Univ. Berlin, Hardenbergstr. 36, 10623 Berlin

Reservoir computing has gained a lot of attention because its relatively simple setup that can be easily implemented in hardware, specifically with optical devices. Using one nonlinear node, i.e., a laser with an optical feedback loop and time-multiplexed input, already allows to solve complex time-series prediction tasks after a proper training via linear regression. Nevertheless, the performance depends on properly adjusted timescales and not every physical system is suitable for a given task [1].

We present ways to improve the computing performance of delay-based photonic reservoir computing systems using delay-time tuning, and we discuss to what extent delay-coupled laser-networks with more than one optical element can be beneficial to improve the overall performance. Furthermore, we discuss analytic insights into the information processing capacity of a reservoir computing system and its correlation to the linear system response of the reservoir as well as to the series expansion of a chosen task.

Large-Deviation Properties of Non-equilibrium RNA Work Processes — •PETER WERNER and ALEXANDER K. HARTMANN — Institute of Physics, University of Oldenburg, Germany

The Higgs *RNA model* [1] is one of the few cases of a model with quenched disorder and complex free energy landscape, where *exact* partition function calculation and sampling can be done in polynomial time. Building on previous work [2], non-equilibrium properties of this model are investigated further. Here, we are interested in the case where, by applying an external force, RNAs are stretched or refolded, like it is also done in experiments with real RNA. Such processes are realized by first sampling an RNA secondary structure in equilibrium and subsequently performing a non-equilibrium MC Simulation during which the external force parameter is varied. The performed physical work *W* and secondary structures are measured during the processes.

By utilizing a *large-deviation algorithm* that is based on biasing random numbers [3], we are able to measure the work distributions P(W) over a wide range of the support down to probabilities such as  $10^{-40}$ . We show how work distributions and the corresponding *large-deviation rate function* behave under an appropriate length variations of various nucleotide sequences, specifically, whether the *large-deviation* principle holds.

Choosing the right event (in non-reversible event-chain Monte Carlo) — •PHILIPP HÖLLMER¹, NICOLAS NOIRAULT², BOTAO LI², A. C. MAGGS³, and WERNER KRAUTH² — ¹University of Bonn, Germany — ²École normale supérieure de Paris, France — ³ESPCI Paris, France

The general framework of event-chain Monte Carlo (ECMC) constructs nonreversible Markov chains for continuous statistical-physics models ranging from hard-disk systems to long-range interacting molecular systems. Over recent years, several algorithms from the family of ECMC have been proposed, which, in the event-driven formulation of ECMC, only differ in their treatment of events (e.g., of disk collisions in a hard-disk system). Still, we show that different variants can have widely different performances. As a first example, we consider locally stable sparse hard-disk packings. Using a scaling theory confirmed by simulation results, we obtain two classes for the escape from slightly relaxed hard-disk

lation results, we obtain two classes for the escape from slightly relaxed hard-disk packings parameterized by a relaxation parameter. In one class, the escape time varies algebraically with the relaxation parameter. In the other class, the escape time only scales as the logarithm of the relaxation parameter. As a second example, we consider integrated autocorrelation times in dense systems of flexible extended hard-disk dipoles. Here, the ECMC variants show order-of-magnitude spreads. We expect the performance differences to carry over to long-range interacting molecular systems, where the choice of the optimal ECMC variant is thus highly important.

#### DY 49.3 Fri 10:00 H20

The GOE ensemble for quasiperiodic tilings without unfolding: *r*-value statistics — •RUDOLF A. RÖMER¹ and UWE GRIMM² — ¹University of Warwick, Coventry, UK — ²Open University, Milton Keynes, UK

We study the level-spacing statistics for non-interacting Hamiltonians defined on the two-dimensional quasiperiodic Ammann–Beenker (AB) tiling. When applying the numerical procedure of "unfolding", these spectral properties in each irreducible sector are known to be well-described by the universal Gaussian orthogonal random matrix ensemble. However, the validity and numerical stability of the unfolding procedure has occasionally been questioned due to the fractal self-similarity in the density of states for such quasiperiodic systems. Here, using the so-called *r*-value statistics for random matrices, P(r), for which no unfolding is needed, we show that the Gaussian orthogonal ensemble again emerges as the most convincing level statistics for each irreducible sector [1]. The results are extended to random-AB tilings where random flips of vertex connections lead to the irreducibility.

Classical density functional theory and the primitive model: beyond the standard mean-field approximation — •MORITZ BÜLTMANN and ANDREAS HÄRTEL — Albert-Ludwigs-Universität Freiburg, Physikalisches Institut

To understand the physics of electrolyte solutions one often uses the *primitive model*, where ions are represented by charged hard spheres in a dielectric back-

Location: H19

Location: H20

Location: H19

ground. The powerful theory of density functionals, which is widely known from quantum mechanics, can also be applied to such systems in the context of statistical physics. There, the first order of a functional perturbation yields the *mean-field electrostatic functional*, which also contributes at particle separations that are forbidden due to the hard-core interations.

In this talk I summarize our findings from the article [J. Phys.: Condens. Matter **34** 235101], where we modified the mean-field functional such that the occuring pair potential is constant for distances smaller than hard-core contact. The resulting formalism involves weighted densities similar to the ones used in most hard-sphere functionals. Comparing different functionals and result from MD simulations, we analyze density profiles, direct and total correlation functions, and thermodynamic sum rules. Thereby, we found that the modifications improved the predictions compared to the standard mean-field functional significantly. Finally, I report on recent findings of the modified mean-field functional e.g. concerning the decay behavior of total correlation functions.

Recoil experiments determine the eigenmodes of viscoelastic fluids — KARTHIKA KRISHNA KUMAR¹, FÉLIX GINOT¹, •JULIANA CASPERS², LUIS REINALTER¹, MATTHIAS KRÜGER², and CLEMENS BECHINGER¹ — ¹Fachbereich Physik, Universität Konstanz, Germany — ²Institute for Theoretical Physics, Georg-August Universität Göttingen, Germany

Probing viscoelastic media using colloidal particles reveals their complex relaxation processes at the microscopic level. Unlike Newtonian fluids, viscoelastic fluids can store and dissipate energy on much longer timescales because of their microstructure, therefore, these materials play a significant role in many technical applications. In this work, we perturb a viscoelastic fluid by driving a colloidal particle through the fluid using an optical tweezer. On deforming the viscoelastic matrix, the fluid tries to relax back by pushing the particle to recoil when the trap is turned off. The trajectory of such a recoiling particle exhibits a bi-exponential behavior indicating two distinct relaxation processes of the fluid. Detailed investigation shows that a microscopic model, with two fictitious bath particles connected to the probe particle via harmonic springs, explains the observed behavior. The analytical solution to the model also reveals two more timescales corresponding to the relaxation of the bath particles when the probe is fixed. The need for two bath particles to explain the results can be justified by considering the fluid as a glassy system, however, further experiments are required to confirm this.

FIPS: A generic framework for many-particle simulations focusing on efficiency and reliability^{*} — •JULIAN JEGGLE and RAPHAEL WITTKOWSKI — Institut für Theoretische Physik, Center for Soft Nanoscience, Westfälische Wilhelms-Universität Münster, 48149 Münster, Germany

Numerical calculation of particle trajectories in many-particle systems is an important class of molecular dynamics (MD) simulations that has been implemented in well-known MD packages such as GROMACS, HOOMD-blue, and LAMMPS. Recently, efforts have been made to develop more flexible data models for this task with the help of modern programming techniques. In this talk, we present further advancements into this direction in the form of FIPS, the *flexibly integrating particle simulator*. This tool enables the simulation of manyparticle systems and their dynamics described by a domain specific language heavily inspired by GPU shaders. Unlike traditional MD packages, we utilize just-in-time compilation and shared-state concurrency to achieve a high degree of efficiency. To increase resilience towards programming errors, our implementation is tightly coupled to Rust, a novel systems programming language with a focus on reliability, in particular for concurrent applications.

The reversible heat production during the electric double layer buildup: Analysis with an extension of the primitive model by hydration shells — •PHILIPP PELAGEJCEV, FABIAN GLATZEL, and ANDREAS HÄRTEL — Albert-Ludwigs-Universität Freiburg

The reversible heat production during the electric double layer (EDL) buildup was measured experimentally [Janssen et al., Phys. Rev. Lett. 119, 166002 (2017)] and in theoretical work [Glatzel et al., J. Chem. Phys. 154, 064901 (2021)], it was found that steric interactions of ions with the flat electrodes, which result in the so-called Stern layer, are sufficient to explain the experimental results. In the latter only symmetric ion sizes in a restricted primitive model were examined.

In this work, I present the impact of ion asymmetry on the reversible heat production for each electrode separately. Additionally, an extension of the primitive model where hydration shells of ions can evade in the vicinity of the electrodes is discussed. With this extended model one can describe situations where one electrode is heated and the other electrode is cooled simultaneously during charging, while both electrodes together behave similarly to the already mentioned experimental results.

Thus, in experiments the heat production should be measured for each electrode separately. By this, the importance of certain ingredients for a primitive model based electrolyte could be evaluated experimentally, finally leading to a deeper understanding of EDLs. **Uncovering broken detailed balance hidden by unknown degrees** — •GABRIEL KNOTZ, TILL MORITZ MÜNKER, TIMO BETZ, and MATTHIAS KRÜGER — Fakultät für Physik, Georg-August-Universität, Göttingen, Germany

The complex nature of non equilibrium systems remains a challenging task in statistical physics, but especially for living matter. A major experimental problem is, that often some relevant degrees cannot be observed (are hidden) which complicates theoretical analysis. We study a non-equilibrium model with two degrees of freedom. If both degrees are observed, the breaking of detailed balance can easily be quantified. However, by treating one of the degrees as hidden, the trajectory of the other is time reversal symmetric. To still detect the breakage of detailed balance we can use a new quantity, the mean backward relaxation (MBR), that measures the relaxation of displacements caused by the fluctuating forces. By deriving rigorous statements for equilibrium in general and calculating the MBR for the non-equilibrium system, we show that the MBR reveals that the system breaks detailed balance even though one degree is hidden. Further we are able to relate the deviation of the MBR compared to an equilibrium system to an effective energy. This analysis adds a new approach to systems that deal with unknown, but relevant non-equilibrium degrees of freedom.[1]

Generalized hydrodynamics description of the classical Toda lattice and highlow pressure domain wall initial conditions — •CHRISTIAN MENDL and HER-BERT SPOHN — Technische Universität München (TUM)

We review and discuss generalized hydrodynamics applied to the classical Toda lattice, a paradigmatic example for an interacting integrable system. One first identifies the Lax matrix of the system, which is closely related to the microscopic conservation laws. For the Toda lattice, the free energy can be expressed in terms of the eigenvalue spectrum of the Lax matrix. One finally arrives at semi-analytic formulas for dynamical correlation functions in equilibrium, which show good agreement with molecular dynamic simulations.

In the second part, we focus on domain wall initial conditions, for which the left and right half lattice are in thermal equilibrium but with distinct parameters. The particular case of interest is a jump from low to high pressure at uniform temperature and zero mean velocity, whereby the scaling function for the average stretch is forced to change sign. The hydrodynamic equations seem to be singular at zero stretch, but nevertheless the self-similar solution exhibits smooth behavior.

**The square-lattice Ising model on the rectangle** — •**F**RED HUCHT — Universität Duisburg-Essen, Lotharstraße 1, 47048 Duisburg

For the square-lattice Ising model, the universal critical Casimir potential and force scaling functions can be calculated exactly for many geometries and boundary conditions. We present a recent exact solution of the square lattice Ising model on the  $L \times M$  rectangle, with open boundary conditions in both directions [1], in terms of the determinant of a  $M/2 \times M/2$  Hankel matrix **H**. The M - 1 independent matrix elements of **H** are Fourier coefficients of a certain symbol function, which is given by the ratio of two characteristic polynomials. These polynomials are associated to the different directly related through the symmetry of the considered Ising model under exchange of the two directions. This representation is a major simplification of earlier results [2,3].

**Anomalous cooling and overcooling of active colloids** — •FABIAN JAN SCHWARZENDAHL and HARTMUT LÖWEN — Institut für Theoretische Physik II: Weiche Materie, Heinrich-Heine-Universität Düsseldorf, 40225 Düsseldorf, Germany

The phenomenon that a system at a hot temperature cools faster than at a warm temperature, referred to as the Mpemba effect, has been recently realized for trapped colloids. Here, we investigate the cooling and heating process of a selfpropelling active colloid using numerical simulations and theoretical calculations with a model that can directly be tested in experiments. Upon cooling activity induces a Mpemba effect and the active particle escapes an effective temperature description. At the end of the cooling process the notion of temperature is recovered and the system can exhibit even smaller temperatures than its final temperature, a surprising phenomenon which we refer to as activity-induced overcooling.

Active Ornstein-Uhlenbeck model for self-propelled particles with inertia — •GIA HUY PHILIPP NGUYEN, RENÉ WITTMANN, and HARTMUT LÖWEN — Institut für Theoretische Physik II: Weiche Materie, Heinrich-Heine-Universität Düsseldorf, Germany

Self-propelled particles, which convert energy into mechanical motion, exhibit inertia if they have a macroscopic size or move inside a gaseous medium, in contrast to micron-sized overdamped particles immersed in a viscous fluid. We have studied an extension of the active Ornstein-Uhlenbeck model, in which the self-propulsion is described by colored noise, to access these inertial effects affecting their translational motion [1]. In this talk, analytical solutions of the mean displacement, mean-squared displacement and velocity autocorrelation function will be discussed for a free active particle and in more general settings including an active dimer, a time-dependent mass and various external forces.

#### DY 50.3 Fri 10:30 H18

A quantitative scattering theory of active particles — •THOMAS IHLE¹, RÜDI-GER KÜRSTEN¹, and BENJAMIN LINDNER² — ¹Institute for Physics, University of Greifswald, Greifswald — ²Institute for Physics, Humboldt University of Berlin, Berlin

We consider a particular model of self-propelled particles with Kuramoto-type alignment interactions. Starting from the N-particle Fokker-Planck equation we observe that the usual factorization Ansatz of the probability density, often called Molecular Chaos approximation, predicts a relaxation behavior which qualitatively disagrees with agent-based simulations. Therefore, we develop a scattering theory which resolves the time-evolution of the two-particle correlation function, i.e. goes beyond the mean-field approximation. The theory does not require input from agent-based simulations; it is self-consistent and leads to analytical expressions. We show that this theory predicts the relaxation behavior of the system and the transport coefficients with high precision in certain parameter ranges.

#### DY 50.4 Fri 10:45 H18

Hierarchical self-organization in communicating polar active matter — •ALEXANDER ZIEPKE¹, IVAN MARYSHEV¹, IGOR S. ARANSON², and ERWIN FREY¹ — ¹Ludwig-Maximilians-Universität München, München, Germany — ²Pennsylvania State University, University Park PA, USA

Self-organization in active matter plays an important role for various biological and artificial systems. In numerous cases, inter-agent communication is a key mechanism for the formation and localization of critical structures, such as the fruiting body in Dictyostelium discoideum or aggregation clusters in quorumsensing bacteria. Despite its importance, the specific role of communication and its interplay with self-propulsion remains largely unexplored.

We propose a model for communicating active matter that endows selfpropelled polar agents with information processing and signal relaying capabilities. We show that information processing greatly enriches the ability of these systems to form complex structures, allowing them to self-organize through a range of different collective dynamical states at multiple hierarchical levels. This provides insights into the role of self-sustained signal processing for selforganization in biological systems and opens pathways for applications using chemically driven colloids or microrobots.

#### DY 50.5 Fri 11:00 H18

Motivated by the challenge of targeted delivery of micron-sized objects, we investigate a novel type of bio-hybrid active matter, composed of motile cells acting as autonomously moving agents that transport passive cargoes. The transport process is a collective phenomenon: a bead can be lost by one cell and may picked up by another one, or multiple cells transport one bead together, thereby giving rise to an intermittent, stochastic stop-and-go dynamics. Combining experiment and active matter theory, we investigate the emerging transport properties of this system. We first deduce the waiting time distributions of active and passive transport episodes from experiments with the amoeba Dictyostelium discoideum: whereas the duration of actual transport phases - determined by the time that cells and cargoes are in contact - are exponentially distributed, the waiting time distribution for passive periods exhibits power-law characteristics which results from the search of cells looking for immobile colloids. We predict displacement distributions and the mean-squared displacement of colloids based on the statistics of waiting times and particularly point out a crossover from normal to subdiffusive scaling. These results provide the basis for the future design of cellular micro-carriers and for extending our findings to more advanced transport tasks in complex, disordered environments, such as tissues.

**Odd viscosity and active turbulence of hydrodynamic microrotors** — •JOSCHA MECKE¹, YONGXIANG GAO², DIRK G.A.L. AARTS³, ALBERTO MEDINA¹, GER-HARD GOMPPER¹, and MARISOL RIPOLL¹ — ¹Institute of Biological Information Processing, Forschungszentrum Jülich, Germany — ²Institute for Advanced Study, Shenzhen University, China — ³Department of Chemistry, University of Oxford, UK

Suspensions of rod-like silica colloids with a ferromagnetic head are considered in a rotating magnetic field applied parallel to a substrate. The magnetic moment is oriented perpendicular to the rod axis which implies a non-equilibrium vertical orientation to the substrate and synchronous spinning in the rotating field. We combine experiments and simulations to study the collective properties of these rotors. The hydrodynamic flows generated by the colloid rotations induce a cascade of translational motions in the neighbouring colloids. Thus, the rotors can be regarded as active matter with transport coefficients varying with local configuration and thus rotor density. The competition between hydrodynamic and steric interactions renders the translational dynamics non-monotonous in rotor density. The ensemble dynamics shows the emergence of eddies of various sizes reminiscent of turbulence. Furthermore, the rotor fluid is a realisation of a chiral active fluid with odd viscosity, that manifests itself in stress forces orthogonal to the direction of shear. In vortex flow, the stress acts like an effective pressure leading to density-vorticity correlations. Our experimental and numerical results are found to be in agreement.

Two-temperature activity drives liquid-crystal and crystalline order in soft repulsive spherocylinders — •JAYEETA CHATTOPADHYAY, SINDHANA PANNIR-SIVAJOTHI, KAARTHIK VARMA, SRIRAM RAMASWAMY, CHANDAN DASGUPTA, and PRABAL K. MAITI — Centre for Condensed Matter Theory, Department of Physics, Indian Institute of Science, Bangalore 560012, India

We study the scalar activity induced phase separation and liquid crystal ordering in a system of Soft Repulsive Spherocylinders (SRS) of various aspect ratios (L/D). Activity was introduced by increasing the temperature of half of the SRS (labeled 'hot') while maintaining the temperature of the other half constant at a lower value (labeled 'cold'). The difference between the two temperatures scaled by the lower temperature provides a measure of the activity. We find that activity drives the cold particles through a phase transition to a more ordered state and the hot particles to a state of less order compared to the initial equilibrium state. For L/D = 5, the cold components of a homogeneous isotropic (I) structure acquire nematic (N) and, at higher activity, crystalline (K) order. Similarly, the cold zone of a nematic initial state undergoes smectic (Sm) and crystal ordering while the hot component turns isotropic. Interestingly, we observe liquid crystal ordering for the spherocylinders having aspect ratio below Onsager's limit. The hot particles occupy a larger volume and exert an extra kinetic pressure, confining, compressing and provoking an ordering transition of the cold-particle domains.

Spontaneous trail formation in populations of communicating active walkers — ZAHRA MOKHTARI¹, ROBERT I. A. PATTERSON², and •FELIX HÖFLING^{1,3} — ¹Dept. Mathematics and Computer Science, Freie Universität Berlin — ²WIAS Berlin — ³Zuse Institute Berlin

How do ants form long stable trails? Despite abundant evidence that trail formation in colonies of insects or bacteria originates in their sensing of and responding to the deposits of chemicals that they produce, there is no consensus on the minimum required ingredients for this phenomenon. To address this

#### Location: H18

issue, here, we develop an agent-based model in terms of active random walkers communicating via pheromones, which can generate trails of agents from an initially homogeneous distribution [1]. Based on extensive off-lattice computer simulations we obtain qualitatively the non-equilibrium state diagram of the model, spanned by the strength of the agent-chemical interaction and the number density of the population. In particular, we demonstrate the spontaneous formation of persistent, macroscopic trails, and highlight some behaviour that is consistent with a dynamic phase transition. We also propose a dynamic model for few macroscopic observables, including the sub-population size of trail-following agents, which captures the early phase of trail formation. At high densities and for strong alignment, we observe that rotating clusters ("ant mills") are more stable than trails and can swallow them up.

Extending the active Phase Field Crystal model to describe motility-induced condensation and crystallization — •MAX PHILIPP HOLL¹ and UWE THIELE^{1,2} — ¹Institut für Theoretische Physik, Universität Münster — ²Center for Nonlinear Science, Universität Münster

The passive conserved Swift-Hohenberg equation (or phase-field-crystal [PFC] model) corresponds to a gradient dynamics for a single order parameter field related to density [1]. It provides a microscopic continuum description of the thermodynamic transition between liquid and crystalline states. A recent extension allows one to investigate both, vapour-liquid and liquid-solid transitions [3]. We first discuss the bifurcation and phase structure of this passive, i.e., thermodynamic model. Our subsequently introduced extension of the standard active PFC model [2] is able to describe passive and active (motility-induced) vapour-liquid and liquid-solid transitions. This is shown through a bifurcation and phase analysis based on path continuation supplemented by time simulations.

**Engines driven by active fields** — •PATRICK PIETZONKA¹ and MICHAEL E. CATES² — ¹Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — ²Department of Applied Mathematics and Theoretical Physics, University of Cambridge, United Kingdom

On macroscopic scales, where trajectories of individual particles cannot be observed, active matter may appear like matter in thermal equilibrium. We discuss how the non-equilibrium character of active matter can nonetheless be revealed by using it as a working medium of engines delivering mechanical work in an isothermal environment. We focus on scalar active field theories such as the active model B as minimal continuum models for active matter undergoing a phase separation. The shape and chemical potential of droplets can be controlled through external potentials and activity patterns. We show how an asymmetric periodic activity pattern can drive a flow of active matter against an external force, thus acting as an autonomous engine. Moreover, we calculate and optimise the work that can be extracted by a cyclic engine that manipulates the activity and the potential landscape.

Reinforcement learning of optimal active particle navigation — •MAHDI NASIRI and BENNO LIEBCHEN — Institut für Physik kondensierter Materie, Technische Universität Darmstadt, Hochschulstraße 8, D-64289 Darmstadt, Germany

In sufficiently complex environments, there is no simple way to determine the fastest route of an active particle that can freely steer towards a given target. In fact, while classical path planning algorithms (e.g. A*, Dijkstra) tend to fail to reach the global optimum, analytical approaches are incapable of handling generic complex environments. To overcome this gap in the literature, in the present work, we develop a policy gradient-based deep reinforcement learning method that employs a hybrid continuum-based representation of the environment and allows, for the first time, to determine the asymptotically optimal path in complex environments. Our results provide a key step forward towards a universal path planner for future intelligent active particles and nanorobots with potential applications in microsurgery as well as in drug and gene delivery.

**Machine Learning the 2D percolation transition** – •DJÉNABOU BAYO^{1,2}, ANDREAS HONECKER², and RUDOLF A. RÖMER¹ – ¹Departement of Physics, University of Warwick, Coventry, CV47AL, United Kingdom – ²Laboratoire de Physique Théorique et Modélisation (LPTM) (CNRS UMR8089), CY Cergy Paris Université, 95302 Cergy-Pontoise, France

The percolation model is one of the simplest models in statistical physics displaying a phase transition. A classical lattice is occupied randomly with a given probability at each site (or bond). A phase transition from a non-percolating to a percolating state appears around the so-called percolation threshold. Machine Learning (ML) and Deep Learning (DL) techniques are still relatively new methods when applied to physics. Recent work shows that ML/DL techniques seemingly detect the percolation transition from images of percolation clusters. We employ such supervised learning techniques, i.e., classification and regression for 2D site percolation. We find that the identification of spanning clusters provided by such methods does not fully correlate with their existence. Rather, the identification seems to rely on proxy measures such as the site occupation density. Furthermore, constructing challenging cluster distributions show scope for much misclassification when using even highly trained DL networks. Unsupervised ML strategies, such as variational autoencoders, might be able to reconstruct percolation clusters with acceptable spatial resolution, but in many cases struggle to reproduce the geometry of spanning clusters faithfully. Our work uses Python and the ML/DL libraries of PyTorch.

Effects of measures on phase transitions in two cooperative susceptibleinfectious-recovered dynamics — ADIB KHAZAEE¹ and •FAKHTEH GHANBARNEJAD^{1,2} — ¹Sharif University of Technology, Tehran, Iran — ²Chair for Network Dynamics, Institute for Theoretical Physics and Center for Advancing Electronics Dresden (cfaed), Technical University of Dresden, 01062 Dresden, Germany

In recent studies, it has been shown that a cooperative interaction in a coinfection spread can lead to a discontinuous transition at a decreased threshold. Here, we investigate effects of immunization with a rate proportional to the extent of the infection on phase transitions of a cooperative co-infection. We use the mean-field approximation to illustrate how measures that remove a portion of the susceptible compartment, like vaccination, with high enough rates can change discontinuous transitions in two coupled susceptible-infectiousrecovered dynamics into continuous ones while increasing the threshold of transitions. First, we introduce vaccination with a fixed rate into a symmetric spread of two diseases and investigate the numerical results. Second, we set the rate of measures proportional to the size of the infectious compartment and scrutinize the dynamics. We solve the equations numerically and analytically and probe the transitions for a wide range of parameters. We also determine transition points from the analytical solutions. Third, we adopt a heterogeneous mean-field approach to include heterogeneity and asymmetry in the dynamics and see if the results corresponding to homogeneous symmetric case stand. **Memory formation in adaptive networks** — •KOMAL BHATTACHARYYA¹, DAVID ZWICKER¹, and KAREN ALIM^{1,2} — ¹Max Planck Institute for Dynamics and Self-Organization, 37077 Göttingen, Germany — ²Physik-Department, Technische Universität München, Garching, Germany

Continuous adaptation of networks like our vasculature ensures optimal network performance when challenged with changing loads. Here, we show that adaptation dynamics allow a network to memorize the position of an applied load within its network morphology. We identify that the irreversible dynamics of vanishing network links encode memory. Our analytical theory successfully predicts the role of all system parameters during memory formation, including parameter values which which prvent memory formation. We thus provide an analytically tractable theory of memory formation in disordered systems.

DY 52.5 Fri 12:30 H19

Inference of fractional nonlinear models from temperature time series and application to predictions — •JOHANNES A. KASSEL and HOLGER KANTZ — MPI for the Physics of Complex Systems, Dresden, Germany

We introduce a method to reconstruct macroscopic models of one-dimensional nonlinear stochastic processes with long-range correlations from sparsely sampled time series by combining fractional calculus and discrete-time Langevin equations. We reconstruct a model for daily mean temperature data recorded at Potsdam (Germany) and use it to predict the first frost date. Including the Arctic Oscillation Index as an external driver into our model, we predict extreme temperatures for several European weather stations, illustrating the potential of long-memory models for predictions in the subseasonal-to-seasonal range.

# HL 1: Tutorial: 2D Quantum Materials and Heterostructures: From Fabrication to Applications (joint session HL/TUT)

Due to the atomic thickness of 2D materials, stacking of different monolayers has opened the door for artificial van der Waals heterostructures. By exploiting the strongly different nature of the individual layers (semiconducting, metallic, magnetic, superconducting, etc.) and rotating them from layer to layer, heterostructures with unique physical properties and functionalities can be envisioned for novel electronic or optical devices. The tutorial will cover the fabrication of these heterostructures and their potential use in applications ranging from electronic to optical devices, operating at the quantum level.

Time: Sunday 16:00-18:20

#### Tutorial

HL 1.1 Sun 16:00 H2 Discovering, Creating, and Exploring Novel Atomically-Thin Materials and Heterostructures — • JOSHUA ROBINSON — The Pennsylvania State University, University Park, PA, USA

The last decade has seen an exponential growth in the science and technology of two-dimensional materials. Beyond graphene, there is a huge variety of layered materials that range in properties from insulating to superconducting. Furthermore, heterogeneous stacking of 2D materials also allows for additional dimensionality for band structure engineering. In this talk, I will discuss recent breakthroughs in two-dimensional atomic layer synthesis and properties, including novel 2D heterostructures and realization of unique 2D allotropes of 3D materials (e.g. 2D metals and oxides). Our recent works demonstrate that the properties and doping of 2D materials, especially synthetic 2D materials, are extremely sensitive to the substrate choice. I will discuss substrate impact on 2D layer growth and properties, doping of 2D materials, selective area synthesis of 2D materials, and creating 2D allotropes from traditionally 3D materials for photonic and quantum applications. Our work and the work of our collaborators has lead to a better understanding of how substrate not only impacts 2D crystal quality, but also doping efficiency in 2D materials, and stabilization of 3D materials at their quantum limit.

#### Tutorial

HL 1.2 Sun 16:35 H2

Non-identical moire twins in bilayer graphene - •REBECA RIBEIRO-Palau¹, Everton Arrighi¹, Viet-Hung Nguyen², Mario Di Luca¹, Gaia Maffione¹, Kenji Watanabe³, Takashi Taniguchi³, Dominique Mailly¹, and JEAN-CHRISTOPHE CHARLIER² - ¹Universite Paris-Saclay, CNRS, Centre de Nanosciences et de Nanotechnologies (C2N), 91120 Palaiseau, France -²Institute of Condensed Matter and Nanosciences, Universite catholique de Louvain (UCLouvain), 1348 Louvain-la-Neuve, Belgium — ³National Institute for Materials Science, 1-1 Namiki, Tsukuba, Japan

I will present recent results which demonstrate that the moire superlattice formed by a bilayer graphene aligned with BN, is present every 60 deg, but the symmetry is broken between the 0 deg and 60 deg alignments, creating nonidentical "moire twins" with different electronic properties. In particular, electron transport measurements display a fully developed valley Hall effect at 0 deg while on the contrary, it is completely absent at 60 deg. We explain this effect by performing numerical simulations, which highlight the central role of the atomic-scale structural relaxation of the second graphene layer. This in-plane atomic relaxation, different for the two alignments, impacts on the electronic band structure of our system. Our results demonstrate that in situ control of the rotational order provides a unique insight on the interplay between mechanical and electronic properties, and increases the posibilities for band-structure engineering on van der Waals heterostructures.

Tutorial HL 1.3 Sun 17:10 H2 Single-photon emitters in 2D materials — •STEFFEN MICHAELIS DE VASCON-CELLOS - University of Münster, Institute of Physics and Center for Nanotechnology, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany

Single-photon sources are key components for quantum technologies, such as communications, cryptography, computation, and metrology. Recently, the family of solid-state quantum light emitters was joined by single-photon sources in atomically thin materials [1]. Compared to 3D bulk materials, the 2D host crystals with their high structural flexibility allow for a high photon extraction efficiency, new methods for the deterministic creation, and convenient integration with photonic circuits.

In this tutorial, I will introduce the basic properties of single-photon emitters in different 2D van der Waals material systems and discuss present experimental methods for their creation, control, and coupling to photonic nanostructures.

#### Tutorial

HL 1.4 Sun 17:45 H2  $Introduction \ to \ 2D \ superconducting \ spintronics - \bullet {\tt Elke \ Scheer} - {\tt Depart}$ ment of Physics, University of Konstanz, Konstanz

The proximity effect between a conventional (s-wave) 3D superconductor (S) and a ferromagnet (F) can lead to the formation of Cooper pairs with parallelspin (spin-triplet) alignment instead of the conventional antiparallel-spin (spinsinglet) state. The demonstration of spin-triplet generation in S/F systems [1,2] has inaugurated the field of superconducting spintronics aiming at developing energy-efficient spintronic devices [3]. Both superconductivity and ferromagnetism depend on the dimensionality of the system, but have been shown to exist in 2D or quasi-2D systems [4,5]. The possibility to exfoliate layered van der Waals (vdW) materials down to the few-layer limit [6] in combination with the existence of S and of F vdW materials makes this material basis in particular promising to explore triplet S in 2DS/2DF heterostructures. In this tutorial talk I will briefly recall the physics of SF spintronics in 3D, before I will describe the particular properties and challenges in the investigation of 2D-SF hybrid systems and give an overview over the so far best-studied material combinations and target devices.

# HL 2: Spin Phenomena in Semiconductors

#### Location: H31

Time: Monday 9:30-11:00

#### Invited Talk

HL 2.1 Mon 9:30 H31

**Observation of quantum Zeno effects for localized spins** – •ALEX GREILICH¹, NIKITA V. LEPPENEN², VITALIE NEDELEA¹, EIKO EVERS¹, DMITRY S. SMIRNOV², and MANFRED BAYER¹ — ¹Experimentelle Physik 2, Technische Universität Dortmund, 44221 Dortmund, Germany — ²St. Petersburg, Russia

One of the main dephasing mechanisms for the localized carrier spins in semiconductors is the coupling to the fluctuating nuclear spin environment. Here we present an experimental observation on the effects of the quantum back action under pulsed optical measurements and demonstrate that the nuclei-induced spin relaxation can be influenced. We show that the fast measurements freeze the spin dynamics and increase the effective spin relaxation time, the so-called quantum Zeno effect. Furthermore, we demonstrate that if the measurement rate is comparable with the spin precession frequency in the effective magnetic field, the spin relaxation rate increases and becomes faster than in the absence of the measurements, an effect known as the quantum anti-Zeno effect.

#### HL 2.2 Mon 10:00 H31

Interplay of spin-orbit coupling and spin diffusion on spin helices lifetime in GaAs quantum wells — •SERGIU ANGHEL¹, KARL SCHILLER¹, GO YUSA^{2,3}, TAKAAKI MANO⁴, TAKESHI NODA⁴, and MARKUS BETZ¹ — ¹Experimentelle Physik 2, Technische Universität Dortmund, Otto-Hahn-Straße 4a, D-44227 Dortmund — ²Department of Physics, Tohoku University, Sendai 980-8578, Japan — ³Center for Spintronics Research Network, Tohoku University, Sendai 980-8578, Japan — ⁴National Institute for Materials Science, Tsukuba, Ibaraki 305-0047, Japan

This work reveals the dependence of the persistent spin helix (PSH) lifetime on spin diffusion coefficient and the electron density, by employing time-resolved magneto-optical Kerr effect microscopy to study the spin polarization evolution in low-dimensional GaAs QWs. It is shown that for the achieving the longest PSH lifetime, the variation of scattering rate with the electron density is of higher importance than the fulfilling of the persistent spin helix condition when the Rashba  $\alpha$  and Dresselhaus  $\beta$  parameters are balanced (suppression of D'yakanov-Perel spin dephasing mechanism). More specifically, the PSH relaxation rate is determined mostly by the spin diffusion coefficient that depends on electron density nonmonotonously. The longest experimentally observed PSH lifetime occurs at an electron density, corresponding to the transition from Boltzmann to Fermi-Dirac statistics - several times higher than that when the persistent spin helix is expected. These facts highlight the role the electron density may play when considering applications for spintronic devices.

#### HL 2.3 Mon 10:15 H31

Selective optical charging and spin preparation of a single quantum dot molecule — •C. THALACKER¹, F. BOPP¹, A. AHMADI¹, N. REVENGA¹, F. VÖGL¹, C. CULLIP¹, K. BOOS¹, F. SBRESNY¹, N. BART², A. WIECK², A. LUDWIG², D. REUTER³, J. SCHALL⁴, S. REITZENSTEIN⁴, H. RIEDL¹, K. MÜLLER¹, and J. J. FINLEY¹ — ¹Walter Schottky Institut and Physik Department, TU München, Garching, Germany — ²Ruhr-Universität Bochum, Bochum, Germany — ³Universität Paderborn, Paderborn, Germany — ⁴Technische Universität Berlin, Berlin, Germany

Coherence, ease of control and scalability lie at the heart of hardware for distributed quantum technologies. Spin-photon interfaces based on III-V semiconductor quantum dots (QDs) combine properties such as strong light-matterinteractions, robust spin-photon selection rules and ease of integration into opto-electronic devices. Two vertically stacked QDs, a so-called QD-molecule (QDM) are expected to exhibit enhanced coherence times ( $T_2^*$ ) due to the formation of singlet-triplet (S-T) qubits. We embed a single QDM into an ultralow capacitance p-i-n diode that allows for ultrafast electrical tuning (>500 MHz). Photon extraction efficiencies are improved to >20% by deterministically placing a circular Bragg grating around the QDM. Using our device we demonstrate all optical control of the charge state, as well as optical spin pumping. Our results form the basis of an optically active S-T spin-qubit with enhanced coherence.

HL 2.4 Mon 10:30 H31

**Resonant spin amplification in Faraday geometry** — •NEDELEA VITALIE¹, PHILIPP SCHERING², DMITRY SMIRNOV³, EIKO EVERS², EVGENY ZHUKOV^{1,3}, DMITRI YAKOVLEV^{1,3}, MANFRED BAYER^{1,3}, UHRIG GÖTZ², and ALEX GREILICH¹ — ¹Experimental Physics 2, TU Dortmund University, Dortmund, Germany — ²Condensed Matter Theory, TU Dortmund University, Dortmund, Germany — ³St. Petersburg, Russia

The possibility to use the spin degree of freedom for quantum information continues to drive research on semiconductors nanostructures. The main characteristic in this field is defined by the lifetime of the information or the spin coherence time. One of the most basic parameters of the spin dynamics is the g factor, which is often anisotropic in semiconductor nanostructures. Its transverse component can be measured very precisely when a magnetic field is applied in Voigt geometry by means of the resonant spin amplification effect (RSA).

Model consideration predict [1] that the realization of the RSA effect in Faraday geometry, where a magnetic field is applied parallel to the optically induced spin polarization, can be realized for a central spin interacting with a fluctuating spin environment. To confirm theory, we chose an ensemble of singly-charged (In,Ga)As/GaAs quantum dots, where the resident electron spin interact with the surrounding nuclear spins. The observation of RSA in Faraday geometry requires intense pump pulses with a high repetition rate and can be enhanced by means of the spin-inertia effect. Potentially, it provides the most direct and reliable tool to measure the longitudinal g factor of the charge carrier.

#### HL 2.5 Mon 10:45 H31

**Cavity-enhanced single-shot readout of a quantum dot spin within 3 ns** — •Nadia Olympia Antoniadis¹, Mark Richard Hogg¹, Willy Frederik Stehl¹, Alisa Javadi¹, Natasha Tomm¹, Rüdiger Schott², Sascha René Valentin², Andreas Dirk Wieck², Arne Ludwig², and Richard John Warburton¹ — ¹Department of Physics, University of Basel — ²Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum

Rapid, high-fidelity single-shot readout of quantum states is a ubiquitous requirement in quantum information technologies. Readout of spin states in optically active emitters can be achieved by driving a spin-preserving optical transition and detecting the emitted photons. The speed and fidelity of this approach is typically limited by a combination of low photon collection rates and measurement back-action. Here, we demonstrate single-shot optical readout of a semiconductor quantum dot spin state, achieving a readout time of only a few nanoseconds. Our approach embeds a gated InAs quantum dot device into an open microcavity architecture. The Purcell enhancement generated by the microcavity selectively increases the readout transition emission rate, as well as efficiently channelling the emitted photons into a well-defined detection mode. We achieve single-shot readout of an electron spin state in 3 ns with a fidelity of (95.85±0.71)%, and observe quantum jumps using repeated single-shot measurements. Our work reduces the spin readout-time to values well below both the achievable spin T1 and T2* times in InAs quantum dots, opening up new possibilities for their use in quantum technologies.

HL 3.1 Mon 9:30 H32

Pushing the limits in real-time meeasurements of quantum dynamics — •ERIC KLEINHERBERS¹, PHILIPP STEGMANN², ANNIKA KURZMANN³, MAR-TIN GELLER¹, AXEL LORKE¹, and JÜRGEN KÖNIG¹ — ¹Faculty of Physics and CENIDE, University Duisburg-Essen, 47057 Duisburg, Germany — ²Department of Chemistry, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA — ³2nd Institute of Physics, RWTH Aachen University, 52074 Aachen, Germany

Time-resolved studies of quantum systems are the key to understand quantum dynamics at its core. The real-time measurement of individual quantum numbers as they switch between certain discrete values, well known as random telegraph signal, is expected to yield maximal physical insight. However, the signal suffers from both systematic errors, such as a limited time resolution and noise from the measurement apparatus, as well as statistical errors due to a limited amount of data. Here we demonstrate that an evaluation scheme based on factorial cumulants can reduce the influence of such errors by orders of magnitude [1]. The error resilience is supported by a general theory for the detection errors as well as experimental data of single-electron tunneling through a self-assembled quantum dot. Thus, factorial cumulants push the limits in the analysis of random telegraph data which represent a wide class of experiments in physics, chemistry, engineering and life sciences.

HL 3.2 Mon 10:00 H32

Location: H32

Creating and detecting poor man's Majorana bound states in interacting quantum dots — •ATHANASIOS TSINTZIS¹, RUBÉN SEOANE SOUTO^{1,2}, and MARTIN LEIJNSE^{1,2} — ¹Division of Solid State Physics and NanoLund, Lund University, S-221 00 Lund, Sweden — ²Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, DK-2100 Copenhagen, Denmark

We theoretically study a system of two quantum dots (QDs) coupled via a third (coupler) QD which is additionally proximitized by an s-wave superconductor. For a wide parameter range, the system can be tuned to sweet spots with a doubly-degenerate ground state, as switches between even- and odd-parity ground states are found to be ubiquitous. The necessary ingredients are a) a finite magnetic field to break the spin degeneracy and b) spin-orbit interaction to mix the spin species. The sweet spots harbor poor man's Majorana bound states (Phys. Rev. B 86, 134528, 2012) whose quality is quantified by calculating the Majorana polarizations of the degenerate ground states (Phys. Rev. B 101, 125431, 2020). The QDs' electrochemical potentials are the control knobs utilized to reach the sweet spots and local and non-local conductance calculations provide a useful map for experimentalists navigating the parameter space. The above system can be realized in a semiconductor 2D electron gas or nanowire with gate- or epitaxially defined QDs coupled to a grounded superconductor. This work provides a path towards near-future demonstration of nonabelian and non-local Majorana properties, with possible (more long-term) applications in topologically protected quantum computing.

#### HL 3.3 Mon 10:15 H32

Interference and parity blockade in transport through a Majorana box — •MAXIMILIAN NITSCH¹, RUBÉN SEOANE SOUTO^{1,2}, and MARTIN LEIJNSE^{1,2} — ¹Division of Solid State Physics and NanoLund, Lund University, S-22100 Lund, Sweden — ²Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, DK-2100 Copenhagen, Denmark

A Majorana box - two topological superconducting nanowires coupled via a trivial superconductor - is a building block in devices aiming to demonstrate nonabelian physics, as well as for topological quantum computer architectures. We theoretically investigate charge transport through a Majorana box and show that current can be blocked when two Majoranas couple to the same lead, fixing their parity. In direct analogy to Pauli spin blockade in spin qubits, this parity blockade can be used for fast and high-fidelity qubit initialization and readout, as well as for current-based measurements of decoherence times. Furthermore, we demonstrate that transport can distinguish between a clean Majorana box and a disordered box with additional unwanted Majorana or Andreev bound states.

#### HL 3.4 Mon 10:30 H32

**Wave-function mapping of excited quantum dot states** — •DANIEL HECKER¹, JENS KERSKI¹, NELSON CREUTZBURG¹, ARNE LUDWIG², ANDREAS D. WIECK², MARTIN GELLER¹, and AXEL LORKE¹ — ¹Faculty of Physics and CENIDE, University of Duisburg-Essen, Germany — ²Chair of Applied Solid State Physics, Ruhr-University Bochum, Germany

Self-assembled quantum dots (QDs) are promising candidates for quantum information technologies, quantum sensing and various electro-optical applications. They are often approximated as two-dimensional harmonic oscillators. Although this approximation of electron states in a harmonic oscillator is very successful, the influence of the electron-electron interaction on the excited fewparticle wave-functions and their dynamics into equilibrium has not been studied in detail.

We investigate an ensemble of InAs/GaAs QDs, embedded in a high-electronmobility transistor with a two-dimensional electron gas (2DEG) as conductive channel. By applying a gate voltage to the transistor, the QDs can be selectively occupied with electrons tunneling from the 2DEG, and the time-resolved transconductance of the 2DEG can be measured. A rate equation based evaluation of the transconductance allows us to determine the tunneling rates of the QD states. In combination with a magnetic field that tunes the wave functiondependent tunneling probability, this enables us to investigate the shape and dynamics of the (excited) few-electron states.

#### HL 3.5 Mon 10:45 H32

Charge tuning of GaAs quantum dots using Schottky diode structure — •NAND LAL SHARMA¹, GHATA SATISH BHAYANI¹, OLIVER G. SCHMIDT², and CASPAR HOPFMANN¹ — ¹Institute for Integrative Nanosciences, IFW Dresden, Helmholtzstrasse 20, 01069 Dresden, Germany — ²Material Systems for Nanoelectronics, Technical University Chemnitz, 09107 Chemnitz, Germany Semiconductor quantum dots (QDs) are promising candidates for high quality

photon sources and the biexciton-exciton cascade in these structures is one of the most advanced techniques for generation of entangled photon pairs. In this work droplet etched GaAs/AlGaAs QDs [1] are embedded in Schottky diode structures within nanomembranes. The membranes are transferred to Au coated substrates via selective etching. The Au coated substrate facilitates the back while the Si-doped GaAs acts as the top contact. The QD photoluminescence from different charge states is controlled by application of an external bias. The effects of quantum dot charging, quantum confined Stark effect, exciton fine structure and photon coherence are investigated as a function of bias voltage.

HL 3.7 Mon 11:45 H32

Electrostatic coupling of double layer self-assembled quantum dots — •LUKAS BERG¹, LAURIN SCHNORR¹, THOMAS HEINZEL¹, ARNE LUDWIG², and ANDREAS DIRK WIECK² — ¹Heinrich-Heine Universität, Düsseldorf, Germany — ²Ruhr-Universität, Bochum, Germany

The electron capture- and emission dynamics of two layers of self-assembled quantum dots in large distance to each other as well as to their reservoirs is studied by time resolved capacitance spectroscopy. The occupation dynamics of the individual layers can be well separated at certain bias voltages. Additionally, an interaction of the electrostatic character is observed in terms of a shift of emission lifetimes and the extracted binding energies. To model this effect, the corresponding system of rate equations is solved.

#### HL 3.8 Mon 12:00 H32

**Temperature-dependence of current peaks in InAs double quantum dots** — •OLFA DANI¹, ROBERT HUSSEIN², JOHANNES C. BAYER¹, SIGMUND KOHLER³, and ROLF J. HAUG¹ — ¹Institut für Festkörperphysik, Leibniz Universität Hannover, Hanover, Germany — ²Institut für Festkörpertheorie und -optik, Friedrich-Schiller-Universität Jena, Jena, Germany — ³Instituto de Ciencia de Materiales de Madrid, CSIC, Madrid, Spain

We investigate electron transport through asymmetrically coupled InAs double quantum dots. Measurements of the resonances of single-electron tunneling shows a quite strong temperature dependence of those coherent current peaks. Their width and background increase with temperature in the range of 1.5-21 K, which indicates an influence of the substrate phonons. The broadening of such peaks can be modeled with rather good precision and can be fully explained with quantum dissipation [1] modeled by two baths, the one coupling to the dot occupation, the other to the inter-dot current. Application of magnetic fields helps us to identify the different quantum dot states. [1] Olfa Dani, Robert Hussein, Johannes C. Bayer, Sigmund Kohler, Rolf J. Haug, Temperature-dependent broadening of coherent current peaks in InAs double quantum dots, arXiv:2204.06333 (2022)

#### HL 3.9 Mon 12:15 H32

Heterogeneous III-V nanowire quantum emitters on silicon photonic circuits — •HYOWON JEONG¹, AKHIL AJAY¹, NITIN MUKHUNDHAN¹, MARCUS DÖBLINGER², JONATHAN J. FINLEY¹, and GREGOR KOBLMÜLLER¹ — ¹Walter Schottky Institute & Physics Department, Technische Universität München, Garching, Germany — ²Department of Chemistry, Ludwig-Maximilians-Universität München, Munich, Germany

III-V quantum dots (QDs) act as naturally bright and highly efficient quantum emitters that can generate deterministic single or entangled photons pairs. QDs embedded in a nanowire (NW) serve as a scalable platform for site-selective and geometry-controlled in-situ heterogeneous integration onto photonic waveguides (WG) - a crucial milestone for the realization of a Quantum Photonic Integrated Circuit.

In the first part, we show by numerical modelling how geometrical parameters of a NW and Si-WG design influence the spontaneous emission enhancement of the QD emitter and the in-coupling efficiencies at the NW-WG interface [1]. Preliminary experiments towards the development of an integrated III-V NW-QD system are then presented. Here, we demonstrate a droplet-free site-selective epitaxy of NWs, where first data of GaAsSb/InGaAs axial heterostructures and their distinct luminescence features will be shown. Furthermore, we discuss control of Indium incorporation into the InGaAs axial segment, in order to tune the emission wavelength before optimizing the axial size, progressing towards an axial QD.

#### HL 3.10 Mon 12:30 H32

**Optoelectronic properties of GaAs(Sb)-AlGaAs core-shell NW diodes on silicon** — •TOBIAS SCHREITMÜLLER, PATRICK JONG, DANIEL RUHSTORFER, AKHIL AJAY, ANDREAS THURN, JONATHAN FINLEY, and GREGOR KOBLMÜLLER — Walter Schottky Institute, Technical University of Munich, 85748 Garching, Germany

The ability to integrate III-V semiconductor nanowires (NW) on the silicon (Si) platform opens many perspectives for advanced nanoelectronic and optoelectronic device applications on-chip. However, for energy-efficient device performance, the design of axial or radial heterostructures, the control of accurate doping properties and the formation of low-resistance ohmic contacts are crucial. In this contribution, we present ongoing developments of radial n-i-p coremultishell NW heterostructures monolithically integrated on the n-Si (111) platform. The NW structure is designed to host n-type doped GaAs(Sb) cores, while the shell is composed of either GaAs homojunctions or (In,Al)GaAs(Sb)-based heterojunctions that define intrinsic and p-type doped regions. We show that

n-type conduction is feasible in the Si-doped core by pioneering a novel catalystfree, vapor-solid growth process of Si-doped GaAs NWs using molecular beam epitaxy (MBE). The n-doped NW cores were then implemented into radial n-i-p NW homo-junction devices to establish electrical contact formation and perform first electroluminescence (EL) experiments. The EL measurements illustrate successful diode characteristics, with luminescence features that are typical for the underlying material properties.

Spin lasing in bimodal quantum dot micropillar cavities — •NIELS HEEERMEIRE¹, TOBIAS HEUSER¹, JAN GROSSE¹, NATALIE JUNG², MARKUS LINDEMANN², NILS GERHARD², MARTIN HOFMANN², and STEPHAN REITZENSTEIN¹ — ¹Institut für Festkörperphysik, Technische Universiät Berlin, D-10623 Berlin, Germany — ²Lehrstuhl für Photonik und Terahertztechnologie, Fakulktät für Elektrotechik und Informationstechnik, Ruhr-Universität Bochum, D-44780 Bochum

Spin-controlled lasers have been shown to provide ultra-fast polarization dynamics in excess of 200 GHz. In contrast to conventional semiconductor lasers their temporal properties are not limited by the intensity dynamics, but are governed primarily by the birefringent mode splitting that determines the polarization oscillation frequency. Another class of modern semiconductor lasers are high-beta emitters which benefit from enhanced light-matter interaction due to strong mode confinement in low-mode-volume microcavities. In such structures, the emission properties can be tailored by the resonator geometry to realize for instance bimodal emission behavior in slightly elliptical micropillar cavities. We utilize this feature to demonstrate and explore spin-lasing effects in bimodal high-beta quantum dot micropillar lasers. The studied microlasers show spin laser effects with polarization oscillation frequencies up to 15 GHz controlled by the ellipticity of the resonator. Our results reveal appealing prospects for very compact and energy-efficient spin lasers and can pave the way for future purely electrically injected spin lasers enabled by short injection path lengths. Laser and Photonics Reviews 2022, 16, 2100585.

#### HL 4.2 Mon 9:45 H33

**Temperature-dependent lasing operation of hybrid semiconductor nanowire** - **metal grating plasmonic nanolasers** — •FRANCESCO VITALE¹, DANIEL REPP², THOMAS SIEFKE², UWE ZEITNER², THOMAS PERTSCH², and CARSTEN RONNING¹ — ¹Institut für Festkörperphysik, Friedrich-Schiller-Universität Jena, Max-Wien-Platz 1, D-07743 Jena — ²Institut für Angewandte Physik, Friedrich-Schiller-Universität Jena, Albert-Einstein-Straße 15, D-07745 Jena

Nanowire(NW)-based semiconductor-insulator-metal (SIM) plasmonic structures represent a benchmark platform for the next generation of hybrid nanolasers, capable of sustaining sub-wavelength hybrid lasing modes, which, in turn, lead to an overcoming of diffraction-limited mode footprints and an acceleration of the lasing dynamics, when compared to their photonic counterparts. In this work, we report on the realization and optical investigation of hybridized SIM platforms, in which single ZnO NWs are deterministically overlaid onto metal gratings (MGs), FIB-milled into a 70 nm Al layer with a nanometric Al₂O₃ spacer on top. By performing ns-excitation steady-state micro-PL, we study the spectral and temporal properties of such hybrid platforms, as a function of the cavity geometry (i.e. NW size, grating period and NW-trench orientation) and temperature. We report about room-temperature lasing in some of these hybrid NW-MG structures and lowering of the lasing threshold compared to the planar SIM plasmonic nanolasers.

#### HL 4.3 Mon 10:00 H33

Field-resolved high-order sub-cycle nonlinearities in a terahertz quantum cascade laser — •JOSEF RIEPL¹, JÜRGEN RAAB¹, PAVEL ABAJYAN², HANOND NONG², JOSHUA FREEMAN³, LIANHE H. LI³, EDMUND H. LINFIELD³, A. GILES DAVIES³, ANDREAS WACKER⁴, TIM ALBES⁵, CHRISTIAN JIRAUSCHEK⁵, CHRISTOPH LANGE⁶, SUKHEEP S. DHILLON², and RUPERT HUBER¹ — ¹University of Regensburg, Germany — ²Université de Paris, France — ³University of Leeds, UK — ⁴Lund University, Sweden — ⁵Technical University of Munich, Germany — ⁶TU Dortmund University, Germany

lence band of GaSb is higher in energy than the conduction band in InAs, in bulk. In addition, the materials are nearly lattice matched, leading to structures with almost no strain. In two dimensions, the InAs/GaSb quantum well is a topological insulator, exhibiting a hybridization gap in the topologically non-trivial regime where quantum spin Hall edge states are present. We have calculated the non-trivial band structures and wave functions of InAs/GaSb core-shell-shell nanowires, using  $\mathbf{k} \cdot \mathbf{p}$  theory. For hollow core-shell-shell InAs/GaSb nanowires, we also calculate the wave functions for a finite system with wire ends, using a BHZ model with parameters taken from the resulting  $\mathbf{k} \cdot \mathbf{p}$  calculations. We establish that there are localized end-states, with energies inside the bulk gap. However, in contrast to the topological edge states in two dimensions, these end states are fourfold degenerate, and split into two Kramers pairs under potential disorder along the nanowire growth direction. Nevertheless, the end states are robust against potential disorder applied in the angular direction, as long as the bulk band gap is not closed.

#### Location: H33

Employing ultrafast electron dynamics in quantum cascade lasers (QCLs) holds enormous potential for intense, compact mode-locked terahertz (THz) sources, squeezed THz light, frequency mixers, and comb-based metrology systems. Yet the important sub-cycle dynamics have been notoriously difficult to access in operational THz QCLs. Here, we perform the first ultrafast two-dimensional high-field spectroscopy of a free running THz QCL. The detected strong incoherent and coherent nonlinearities up to eight-wave mixing do not only reveal extremely short gain recovery times, but also reflect the nonlinear polarization dynamics of the QCL laser transition for the first time. A density-matrix approach reproducing all nonlinearities and their ultrafast evolution, allows us to map the coherently induced trajectory of the Bloch vector. The observed nonlinearities benefit from resonant enhancement in a regime of negative absorption and bear potential for various future applications, ranging from efficient intracavity frequency conversion and mode proliferation to passive mode locking.

#### HL 4.4 Mon 10:15 H33

**Tuning nanowire lasers via hybridization with two-dimensional materials** — •EDWIN EOBALDT¹, FRANCESCO VITALE¹, MAXIMILIAN ZAPF¹, MAR-GARITA LAPTEVA¹, CHRISTOF NEUMANN², ANDREY TURCHANIN^{2,3}, GIANCARLO SOAVI^{1,3}, and CARSTEN RONNING^{1,3} — ¹Institute of Solid State Physics, Friedrich Schiller University Jena, 07743 Jena, Germany — ²Institute of Physical Chemistry, Friedrich Schiller University Jena, 07743 Jena, Germany — ³Abbe Center of Photonics, Friedrich Schiller University Jena, 07745 Jena, Germany

Semiconductor nanowires have attracted great scientific attention due to their remarkable waveguiding properties and their intrinsic capability to lase under sufficiently high excitation, thus, paving the way towards nanoscaled coherent light sources and the realization of all-optical circuits. After the spectral and temporal characteristic of single nanowire lasers have been extensively studied during the past decade, today's research focuses on their effective integration into functional and nanoscaled environments. In this regard, the hybridization of semiconductor nanowire lasers with two-dimensional materials could offer new capabilities for a dynamical emission tuning enabled by charge transfer processes at the heterointerface. As a proof of concept, hybrids systems containing ZnO nanowires on top of MoS₂ monolayers were investigated by micro-photoluminescence measurements. By further adopting a deterministic transfer approach, it was possible to study hybridization-related changes of the lasing emission on one and the same nanowire.

#### HL 4.5 Mon 10:30 H33

**Generalization of the Siegert relation** — •MONTY LEON DRECHSLER^{1,2}, FREDERIK LOHOF^{1,2}, and CHRISTOPHER GIES^{1,2} — ¹Institute for Theoretical Physics, University of Bremen, Bremen, Germany — ²Bremen Center for Computational Materials Science, University of Bremen, Bremen, Germany

The Siegert relation connects the first- and second-order coherence properties of light. While it is valid for thermal light, this relation is routinely extended also to the partially coherent regime of high- $\beta$  nanolasers, where it aids in the identification of the lasing threshold [1]. We test the validity of this extension by introducing a generalized Siegert relation. Based on the cluster expansion method we derive a full two-time quantum optical theory and combine it with our new approach, allowing us to revise the Siegert relation in different device regimes. We find that correlations lead to deviations from the Siegert relation and in particular highlight the influence correlations related to sub- and super-radiance [2].

Development of a 850 nm VCSEL array for real world QKD via the BB84 and decoy state protocol — •MORITZ BIRKHOLD, MICHAEL ZIMMER, SERGEJ VOLLMER, MICHAEL JETTER, and PETER MICHLER — Institut für Halbleiteroptik und Funktionelle Grenzflächen, Universität Stuttgart, Allmandring 3, 70569 Stuttgart

Quantum key distribution offers fundamental advantages over classical key distribution. If done correctly a perfectly private key (e.g. a one time pad) can be exchanged between two parties and any eavesdroping attack will be detected. This could be an intresting feature for e.g. worldwide financial applications but the technological hurdles to overcome are numerous.

Here we show the advances towards a complete eight VCSEL array with an integrated polarization grating in the light emission window, to create quantum states and transmit the quantum key. The basic structure is grown by metalorganic vapor-phase epitaxy (MOVPE). Then this structure is processed to allow data transmission in the GHz regime. Varoius methodes including a co-planar contact geometry are used to achieve this. A vektor network analyzer is than used to measure the scattering parameter as well as the transmission bandwith. Finally a eye diagramm is recorded to determine the data rate. The polarization grating is defined by an electron beam lithography and etched with an ICP machine to allow light output in four different polarizations. The pulses of the eight different VCSEL are evaluated for indistinguishability.

Investigations on high- $\beta$  silver-coated InP-based metallic nanolasers and their spectral line shape behavior — •MONTY LEON DRECHSLER¹, J. BUCHGEISTER¹, A. KOULAS-SIMOS², K. LAIHO², G. SINATKAS², T. ZHANG³, J. XU³, F. LOHOF¹, F. JAHNKE¹, C. GIES¹, W. W. CHOW⁴, C.-Z. NING³, and S. REITZENSTEIN² — ¹University of Bremen, Bremen, Germany — ²Technical University of Berlin, Berlin, Germany — ³Tsinghua University, 1303 Beijing 100084, China — ⁴Sandia National Laboratories, Albuquerque, New Mexico, USA

We investigate a silver-coated InP-based metallic nanolasers with a diameter of several 100 nm and  $\beta$ -factor close to unity, pushing the device in the regime of quantum optics. We use a quantum optical semiconductor laser model utilizing an equation of motion approach together with the cluster expansion technique to analyze the device. Photon correlations quantified by  $g^{(1)}(\tau)$  and  $g^{(2)}(\tau)$  are an essential tool for this research. Information about the energy spectrum and the detection characteristics of photons is encoded in them. In this study, an unconventional behavior of the spectral line shape was found. We observe that the line shape takes a Gaussian profile above the laser threshold. The exciting question arises whether the Gaussian line shape can be used as an indicator of laser activity. In previous works, a similar behavior has been reported, but no explanation was given. We provide an explanation for this behavior of the line shape in the framework of an open-cavity multimode model.

#### HL 4.8 Mon 11:45 H33

Extraction of silver losses at cryogenic temperatures through optical characterization of Ag-coated plasmonic nanolasers — •ARIS KOULAS-SIMOS¹, GEORGIOS SINATKAS^{1,2}, TAIPING ZHANG³, JIA-LU XU³, WILLIAM E. HAYENGA⁴, QIANG KAN⁵, RUIKANG K. ZHANG⁵, MERCEDEH KHAJAVIKHAN^{4,6}, CUN-ZHENG NING^{3,7}, and STEPHAN REITZENSTEIN¹ — ¹Institut für Festkörperphysik, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin, Germany — ²Institute of Integrated Photonics, RWTH Aachen University, Campus Blvd. 73, Aachen 20 52074, Germany — ³Department of Electronic Engineering, Tsinghua University, Beijing, 100084, China — ⁴CREOL, The College of Optics and Photonics, University of Central Florida, Orlando, FL, USA — ⁵Institute of Semiconductors, Chinese Academy of Sciences, Beijing, 100083, China — ⁶Ming Hsieh Department of Electrical and Computer Engineering, University of Southern California, Los Angeles, CA, USA — ⁷School of Electrical, Computer and Energy Engineering, Arizona State University, Tempe, 85287, Arizona, USA

We present a rigorous method for the extraction of silver losses at temperatures T from 10 K to 180 K at NIR wavelengths through T-dependent  $\mu$ PL studies on silver-coated InP-based nanolasers in conjunction with cavity simulations. The numerical algorithm maps the changes of the Q-factor, estimated at transparency, into the imaginary part of silver permittivity. The results are in good agreement with theoretical predictions estimating a drop of one order from room

to cryogenic temperatures. This data is long missing from the literature and sets a pathway for the optimization of plasmonic nanolasers.

HL 4.9 Mon 12:00 H33

Quantum-optical study of an InGaAsP metallic cavity nanolaser: A systematic approach to the identification of lasing – •J. BUCHGEISTER¹, M. L. DRECHSLER¹, F. LOHOF¹, C. GIES¹, A. KOULAS-SIMOS², K. LAIHO², G. SINATKAS², T. ZHANG⁴, J. XU⁴, Q. KAN⁶, R. K. ZHANG⁶, C.-Z. NING^{4,5}, S. REITZENSTEIN², W. W. CHOW³, and F. JAHNKE¹ – ¹Universität Bremen, Germany – ²Technische Universität Berlin, Germany – ³Sandia National Laboratories, USA – ⁴Tsinghua University, China – ⁵Arizona State University, USA – ⁶Institute of Semiconductors, China

Semiconductor nanolasers as small-scale sources of coherent light have become increasingly important for applications in the data industry for their size, powerefficiency, and modulation speed. Determining the presence of lasing, however, is challenging due to the near-thresholdless behaviour of ultra-efficient devices, which requires going beyond I/O characteristics. The research presented here focuses on a quantum-optical study of a silver-coated InGaAsP nanolaser by means of a full quantum-mechanical semiconductor laser theory. We calculate the timeresolved single- and two-photon correlation function, allowing us to identify the onset of coherent emission with confidence. Our theoretical model can match the experimentally obtained data using a single set of realistic parameters and hence presents a comprehensive strategy for the identification of lasing while being extensible to those gain materials requiring a more pronounced focus on quantum-material aspects, like TMDCs.

#### HL 4.10 Mon 12:15 H33

Random Lasing with Dye-doped Fluorescent Aerogels — •MATTHIAS KESTLER, THEOBALD LOHMÜLLER, and JOCHEN FELDMANN — Chair for Photonics and Optoelectronics, Nano-Institute Munich and Department of Physics, Ludwig-Maximilians-Universität (LMU), Königinstr. 10, 80539 Munich, Germany

Aerogels are a translucent, amorphous network of colloidal particles, which scatter light at visible wavelengths. Doping an aerogel matrix with fluorescent dyes or nano-particles enables their wider use for optical applications, including random lasing. Here, we report on the synthesis of fluorescent silica aerogels by supercritical drying of dye-doped silica gels. By our refined process, we obtain large, porous samples, where scattering events lead to closed photon paths that act as optical oscillators in the micrometer range. We analyze the corresponding photo-luminescence, amplified stimulated emission and random lasing spectra that are obtained for different dye-loaded aerogel samples. Random lasing is confirmed by different characteristic features like a lasing threshold, bandwidth narrowing and strongly fluctuating Anderson localized modes. Furthermore, we find that the extraordinary thermal stability of aerogels enables the use of high laser pumping energies without visible sample degradation.

#### HL 4.11 Mon 12:30 H33

Towards a novel vertical external-cavity surface-emitting laser based on a grating waveguide structure — •PETER GIERSS¹, ANA ĆUTUK¹, MAXIM LEYZNER², UWE BRAUCH², MARWAN ABDOU AHMED², MICHAEL JETTER¹, THOMAS GRAF², and PETER MICHLER¹ — ¹Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology (IQST) and SCoPE, University of Stuttgart, Allmandring 3, 70569 Stuttgart — ²Institut für Strahlwerkzeuge, University of Stuttgart, Pfaffenwaldring 43, 70569 Stuttgart

Vertical external-cavity surface-emitting lasers (VECSELs) provide favorable properties compared to other laser systems. The external cavity allows for incorporation of additional optical elements like birefringent filters or absorbers for passive mode-locking which makes it very attractive for various applications. While the possibility of band-gap engineering and a broad gain spectrum are also advantageous, the heat dissipation from the active region due to the thick distributed Bragg reflector (DBR) is a drawback.

A novel approach is a VECSEL based on a grating waveguide structure (GWS) paired with a low-refractive-index heat-spreader below the active region. The absence of a DBR improves the heat removal while the guided-mode resonances from the GWS should provide good coupling of the pump and laser field as well as the high reflectivity necessary for the laser operation. We present the progress towards the realization of an AlGaInP-based GWS-VECSEL for laser emission in the red spectral range.

The Electronic Structure of  $Cs_2AgBiBr_6$  at Room Temperature – •JULIAN GEBHARDT^{1,2} and CHRISTIAN ELSÄSSER^{1,2,3} – ¹Fraunhofer Institute for Mechanics of Materials IWM, 79108 Freiburg — ²Cluster of Excellence livMatS at FIT - Freiburg Center for Interactive Materials and Bioinspired Technologies, Albert-Ludwigs-University Freiburg, 79104 Freiburg — ³Freiburg Materials Research Center (FMF), Albert-Ludwigs-University Freiburg, 79104 Freiburg Cs₂AgBiBr₆ is a stable halide double perovskite with a band gap of about 2.2 eV. Therefore, it is intensively studied as possible lead free alternative to hybrid perovskite solar cell absorber materials such as methylammonium-lead iodide. However, power conversion efficiencies of solar cells with this material have not yet exceeded 3%. A detailed understanding of the electronic structure of this material is difficult, due to the variance of reported data and experimental as well as theoretical difficulties that occur in going beyond a qualitative understanding of such an indirect semi-conductor at device operation temperature. Here we combine self-energy corrected electronic-structure theory including spin-orbit coupling and structural dynamics at room temperature to model and understand this compound in a quantitative manner, and we compare our theoretical findings with experimental ones. Based on an achieved good agreement, we propose that the observed low power conversion efficiencies can be attributed to the density of states in the conduction band region. From the relation between dimensionality and electron conductivity, we suggest a general design principle for absorber material search.

#### HL 5.2 Mon 9:45 H34

Photon-echo spectroscopy of a CH₃NH₃PbI₃ perovskite single crystal — •STEFAN GRISARD¹, ARTUR V. TRIFONOV^{1,2}, ALEKSANDR N. KOSAREV^{1,3}, ILYA A. AKIMOV^{1,3}, DMITRII R. YAKOVLEV^{1,3}, JULIAN HÖCKER⁴, VLADIMIR DYAKONOV⁴, and MANFRED BAYER^{1,3} — ¹Experimentelle Physik 2, Technische Universität Dortmund — ²Spin Optics Laboratory, St. Petersburg State University, Russia — ³St. Petersburg, Russia — ⁴Experimental Physics 6, Julius-Maximilian University of Würzburg

Lead halide perovskites such as CH₃NH₃PbI₃ (MAPbI₃) show outstanding characteristics important for photovoltaic and optoelectronic applications. However, the peculiarities of light-matter interactions in these materials are far from being fully explored. Here, we applied time-resolved photon echo spectroscopy to a high quality MAPbI₃ single crystal highlighting the importance of inhomogeneous broadening of excitonic transitions even at cryogenic temperatures. Furthermore, we developed an experimental photon-echo polarimetry method that unambiguously identifies contributions from exciton and biexciton to the coherent optical response. Most importantly, our method allows to accurately extract the biexciton binding energy of 2.4meV, even though the period of the observed quantum beats exceeds the coherence times of exciton and biexciton.

#### HL 5.3 Mon 10:00 H34

Structural properties of (hot-)pressed MAPbI₃ films revealed by detailed temperature-dependent optical analyses — •CHRISTINA WITT¹, KONSTANTIN SCHÖTZ¹, NICO LEUPOLD², SIMON BIBERGER¹, PHILIPP RAMMING¹, RALF MOOS², and FABIAN PANZER¹ — ¹Soft Matter Optoelectronics, University of Bayreuth, Bayreuth 95440, Germany — ²Department of Functional Materials, University of Bayreuth, Bayreuth 95440, Germany

Halide perovskites attracted much attention in recent years, due to the remarkable increase in corresponding solar cell efficiencies. More recently, hot-pressing has emerged as attractive method for manufacturing and post-treatment of perovskite films [1, 2]. However, a detailed understanding regarding the role of temperature during hot-pressing on resulting film properties is still missing. Thus, we use temperature-dependent PL and absorption measurements of MAPbI₃ thin films pressed with different temperatures and in detail analyze their optical properties. This allows us to draw conclusions about structural and optoelectronic properties, revealing that an increased temperature improves film morphology, structural and optoelectronic film properties.

#### HL 5.4 Mon 10:15 H34

Application of atomic layer deposition and x-ray photoelectron spectroscopy in perovskite solar cells — •Małgorzata Kot¹, Chittaranjan Das², Lukas Kegelmann³, Hans Koebler³, Mikhailo Vorokhta⁴, Carlos Escudero⁵, Steve Albrecht³, Antonio Abate³, and Jan Ingo Flege¹ — ¹BTU Cottbus-Senfteberg, Cottbus, Germany — ²KIT, Eggenstein-Leopoldshafen, Germany -  3  HZB, Berlin, Germany -  4  Charles University, Prague, Czech Republic -  5  ALBA Synchrotron, Cerdanyola del Vallès, Spain

In this work we have utilized near-ambient pressure and ultra-high vacuum Xray photoelectron spectroscopy as well as atomic layer deposition to investigate perovskite solar cells (PSCs). We have demonstrated that ultrathin room temperature atomic layer-deposited aluminium oxide on the perovskite surface very effectively suppresses iodine migration[1] and improves the long term stability and efficiency of PSCs [2,3]. Furthermore, exposure to light proves more detrimental to the perovskite film than exposure to water vapor.[2] Absorbed photons create Frenkel defects in the perovskite crystal and their number strongly depends on the used illumination. The higher the photon flux, the higher the concentration of Frenkel defects, and thus the stronger the degradation of power conversion efficiency and the stronger the hysteresis in the J-V characteristics. #### HL 5.5 Mon 10:30 H34

Chemical Engineering of Ferroelastic Twin Domains in MAPbI3 Thin Films — •YENAL YALCINKAYA¹, ILKA HERMES¹, TOBIAS SEEWALD², KATRIN AMANN-WINKEL¹, LOTHAR VEITH¹, LUKAS SCHMIDT-MENDE², and STEFAN A.L. WEBER¹ — ¹Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany — ²Department of Physics, University of Konstanz, Universitätsstr. 10, 78464, Germany

In this study, we introduce a new chemical method for controlling the strain in methylammonium lead iodide (MAPbI3) perovskite crystals by varying the ratio of Pb(Ac)2 and PbCl2 in the precursor solution. We used a combination of piezoresponse force microscopy (PFM) and X-ray diffraction (XRD) to observe the effect on crystal strain. We observed larger ferroelastic twin domains upon increasing the PbCl2 content, indicating increased crystal strain via PFM images. We confirmed the increased crystal strain via the XRD patterns with strong crystal twinning features. We suggest that this behaviour is caused by different evaporation rates of methylammonium acetate and methylammonium chloride which led to a strain gradient during the crystallization as revealed by time-of-flight secondary ion mass spectroscopy (ToF-SIMS) and grazing incidence x-ray diffraction (GIXRD) measurements. We observed films with larger twin domain structures show an increased carrier via time-resolved photoluminescence (TRPL). The results demonstrate the potential of chemical strain engineering as an easy method for controlling strain-related e*ects in lead halide perovskites.

#### HL 5.6 Mon 10:45 H34

Inspecting the local structure of cubic phase halide perovskites from firstprinciples — •XIANGZHOU ZHU, SEBASTIÁN CAICEDO-DÁVILA, CHRISTIAN GEHRMANN, and DAVID A. EGGER — Department of Physics, Technical University of Munich, Garching, Germany

Halide perovskites (HaPs) have been identified as one of the most promising optoelectronic materials in recent years. Different from the conventional inorganic semiconductors, HaPs exhibit profound deviations from their average atomic structure at finite temperature, which have important consequences for their optoelectronic properties. However, a detailed understanding of these local structural fluctuations, the underlying physical mechanisms as well as their consequences is far from complete. Here, we perform molecular dynamics (MD) calculations based on density functional theory (DFT) to investigate the local structure and anharmonic dynamics of CsPbBr3 in the cubic phase at T=425 K and 525K. We find that motions of neighboring Cs-Br atoms interlock within a nominal cubic unit cell. This manifests in the most likely Cs-Br distance being significantly shorter than what is inferred from an ideal cubic structure. Furthermore, we use the statistical information on the dynamic atomic distributions to quantify the effective potential associated with certain atomic motions at two temperatures. We find that Br motions occur in a dynamically disordered potential energy landscape and relate the Cs motion as well the Cs-Br coupling to PbBr₆ octahedral rotations.

HL 5.7 Mon 11:30 H34

Distinct Resonances in Absorption Spectra of Lead Halide-based Quantum Dots — •ANJA BARFÜSSER, QUINTEN A. AKKERMAN, SEBASTIAN RIEGER, AM-RITA DEY, AHMET TOSUN, TUSHAR DEBNATH, and JOCHEN FELDMANN — Chair for Photonics and Optoelectronics, Nano-Institute Munich and Department of Physics, Ludwig-Maximilians-Universität (LMU), Königinstr. 10, 80539 Munich, Germany

In recent years, perovskite nanocrystals have attracted much attention for their unique optical properties. Here, we discuss sphere-like lead halide-based quantum dots with diameters in the range of 4.5-12 nm featuring a multitude of distinct resonances in their absorption spectra. We have investigated the nature of these resonances by comparing experimental data with model calculations based on weak and strong confinement. In transient absorption experiments, bleaching and induced absorption signals are observed, which we discuss in terms of confined excitons and biexcitonic contributions.

#### HL 5.8 Mon 11:45 H34

Revealing the doping density in perovskite solar cells and its impact on device performance — •FRANCISCO PEÑA-CAMARGO and MARTIN STOLTERFOHT — Physik weicher Materie, Institut für Physik und Astronomie, Universität Potsdam, Karl-Liebknecht-Str. 24-25, 14776 Potsdam, Germany

Inorganic semiconductors can be electronically doped with high precision. Conversely, there is still conjecture regarding the assessment of the electronic doping density in metal-halide perovskites, not to mention of a control thereof. This study presents a multifaceted approach to determine the electronic doping density for a range of different lead-halide perovskite systems. Optical and electrical characterisation techniques comprising intensity-dependent and transient photoluminescence, AC Hall effect, transfer-length-methods, and charge extraction measurements were instrumental in quantifying an upper limit for the doping density. The obtained values are subsequently compared to the electrode charge per cell volume at short-circuit conditions ( $CU_{bi}/eV$ ), which amounts to roughly 10¹⁶ cm⁻³. This figure of merit represents the critical limit below which dopinginduced charges do not influence the device performance. The experimental results demonstrate consistently that the doping density is below this critical threshold (<  $10^{12}$  cm⁻³ which means  $\ll CU_{bi}/eV$ ) for all common lead-based metal-halide perovskites. Nevertheless, although the density of doping-induced charges is too low to redistribute the built-in voltage in the perovskite active layer, mobile ions are present in sufficient quantities to create space-charge-regions in the active layer.

HL 5.9 Mon 12:00 H34 Ground-state structures, electronic structure, transport properties and optical properties of anion-ordered anti-Ruddlesden-Popper phase oxide perovskites — •Dan Han, Shizhe Wang, Thomas Bein, and Hubert Ebert -Department Chemie, Ludwig-Maximilians-Universität München, Germany Anti-Ruddlesden-Popper (ARP) phase oxide perovskites Ca4OA2 (A = P, As, Sb, Bi) have recently attracted great interest in the field of ferroelectrics and thermoelectrics, while their optoelectronic application is dominantly limited by their indirect band gaps. In this work, we consider A-site anion ordering in Ca4OA2 (A = P, As, Sb, Bi), and find that it induces an indirect-to-direct band gap transition. Using first-principles calculations, we study the ground-state structures, electronic structure, transport properties and optical properties of anion-ordered ARP phase oxide perovskites Ca4OAA'. Based on an analysis of the lattice dynamics, the ground-state structures of Ca4OAsSb, Ca4OAsBi, Ca4OPSb and Ca4OPBi are identified. In contrast to the Ruddlesden-Popper (RP) phase oxide and halide counterparts, Ca4OAA' show larger band dispersion along the out-ofplane direction, smaller band gaps and highly enhanced out-of-plane mobilities, which is ascribed to the short interlayer distances and enhanced covalency of the pnictides. Although the out-of-plane mobilities of these n = 1 ARP phase perovskites highly increase, comparatively strong polar optical phonon (POP)

scattering limits the further enhancement of their mobilities. This work shows that these anion-ordered Ca4OAA' exhibit the potential for optoelectronic applications.

#### HL 5.10 Mon 12:15 H34

Including light management concepts in performance prediction modelling of perovskite-silicon tandem solar cells by implementing transfer matrix method — AMINREZA MOHANDES^{1,2}, PEYMANEH RAFIEIPOUR^{1,2}, MOHAMMAD MOADDELI¹, and •MANSOUR KANANI¹ — ¹Department of Materials Science and Engineering, School of Engineering, Shiraz University, Shiraz, Iran — ²Department of Physics, Shiraz University, Shiraz, Iran

The 2-T monolithic perovskite-silicon tandem design holds a record efficiency of 29.80%, recently. To perform more accurate, complete and experimentally reliable modelling of tandem solar cell, we adopt the transfer matrix method (TMM) which incorporates the interfacial reflections, light scattering and parasitic absorption losses in the calculation of the light transmitted from the top perovskite solar cell. The results reveal that the light scattering and interfacial reflection losses cannot be ignored and the previously used Beer-Lambert exponential relation is insufficient for studying tandem configuration. Including TMM method in the performance optimization of the tandem solar cells lets to consider light management concepts more extensively. Therefore, identifying and reducing optical losses in each layer/interface and designing appropriate anti-reflection coatings in a multilayer tandem simulation can be achieved. In this study, standalone and tandem devices have been analyzed and the effect of absorber layer thickness variation, J-V curves, external quantum efficiency (EQE), filtered spectra, current matching, and tandem performance parameters on the cell efficiency is considered.

HL 5.11 Mon 12:30 H34 Highly Efficient Perovskite-on-Silicon Tandem Solar Cells on Planar and Tex-

**tured Silicon** – •CHRISTIAN M. WOLFF¹, XIN YU CHIN², KEREM ARTUK¹, DENIZ TÜRKAY¹, DANIEL JACOBS¹, QUENTIN JEANGROS², and CHRISTOPHE BALLIF^{1,2} – ¹École polytechnique fédérale de Lausanne, STI IEM PVLAB, Rue de la Maladière 71b, 2000 Neuchâtel – ²Centre Suisse d'Electronique et de Microtechnique, Rue Jaquet-Droz 1, 2002 Neuchâtel

Multi-junction devices offer the possibility to harness the sun's light beyond the limitations of single-junction solar cells. Among the different combinations perovskite-on-silicon (Pk/Si) tandems hold the great promise of high efficiencies >30%, while maintaining low cost. I will report on our latest progress in the development of Pk/Si tandems comparing our efforts on single-side and double-side textured Pk/Si tandems, reaching a  $V_{OC}$  up to 1.95V, summed short-circuit currents above  $41\text{mA/cm}^2$ , and certified efficiencies >29%, on an active area of  $1\text{cm}^2$ . We achieved these results by dedicated electrical and optical optimizations of all layers within the stack. Specifically, we reduced recombination and transport losses in the Pk absorbers through process and additive engineering for both solution-processed one-step and hybrid two-step deposited Pks, and improved the transparency of the front stack electrodes and contacts through simulation-guided optimizations of the front grid and layer thicknesses. Furthermore, we investigated the stability of single-junction Pk and tandem devices under reverse-bias and standardized accelerated aging conditions.

g-factors in van der Waals heterostructures: revealing signatures of interlayer coupling — •PAULO E. FARIA JUNIOR — University of Regensburg, Regensburg, Germany

The interplay of the spin and the orbital angular momenta of electrons in semiconductors governs the observed Zeeman splitting, often described by the effective g-factors. In the realm of 2D materials, transition metal dichalcogenides (TMDCs) are ideal candidates to explore the manifestation of coupled spin and orbital degrees of freedom under external magnetic fields. In this talk, I will cover the basic physics behind the Zeeman splitting and effective g-factors, emphasizing the recent first-principles developments in monolayer TMDCs that nicely reproduce the available experimental data. These new theoretical insights demystify the valley-Zeeman physics in TMDCs and finally establish a connection to the vast existing knowledge in the area of III-V materials. Beyond monolayers, I will discuss TMDC-based van der Waals heterostructures, particularly MoSe2/WSe2 and WS2/graphene systems, in which the spin-valley physics and g-factors encode valuable information about the interlayer coupling. HL 6.2 Mon 10:00 H36

Optical Properties of Encapsulated Transition-Metal Dichalcogenide Monolayers, Bilayers, and Heterostructures — •MANAN SHAH¹, PHILIP KLEMENT¹, SANGAM CHATTERJEE¹, KYUNGNAM KANG², EUI-HYEOK YANG², and ARASH RAHIMI-IMAN¹ — ¹I. Physikalisches Institut und Zentrum für Materialwissenschaften, Justus-Liebig Universität Gießen, D-35392, Germany — ²Department of Mechanical Engineering, Stevens Institute of Technology, Hoboken, NJ, 07030, USA

Van-der-Waals heterostructures (vdW-HSs) based on 2D-layered materials have received unrivaled attention among nanomaterials due to their promising optoelectronic properties induced by moiré potential landscapes; secondly, their strong light-matter interactions; and third, the promise of bandgap engineering capabilities. The optical properties of transition-metal dichalcogenides (TMDs) depend considerably on the substrate, stacking configuration, interface quality, and encapsulation. As more and more layered materials have come into the focus, the demand for a comprehensive understanding of their optical, optoelectronic, and vibronic properties is increasing drastically.

We focus on the discussion of photoluminescence and the Raman response of tungsten-based TMD monolayers and stacks thereof [1, 2], as well as encapsulated configurations. We further aim at unraveling structural alterations and emission properties by monitoring the temporal behavior in their responses. [1] Semiconductors 2019, 53, 2140. [2] Sci. Rep. 2022, 12, 6939.

HL 6.3 Mon 10:15 H36

**Electrically Tunable Photoluminescence in Monolayer MoS₂ and graphene/MoS₂ Heterostructures** — •TARLAN HAMZAYEV and GIANCARLO SOAVI — Institute of Solid-State Physics, Friedrich Schiller University Jena, Germany

The optical response of monolayer (ML) transition metal dichalcogenides (TMDs) is dominated by the co-existence, even at room temperature, of excitons, bi-excitons, and trions.

The photoluminescence (PL) emission of these quasi-particles can be modulated via external knobs, such as doping, pressure and strain. In particular, the PL emission from the neutral exciton is greatly modulated during the crossover from the undoped to the highly doped regime [1]. In the latter case, PL emission is mainly suppressed due to the presence of trions, which have a fast non-radiative decay.

In this work, we study the gate dependence of the PL emission in encapsulated ML  $MoS_2$  and ML graphene/ $MoS_2$  heterostructures (HS). We show that in the HS region the PL emission mainly comes from neutral excitons even at large values of external gate voltage, thus confirming that graphene is an efficient filter for PL emission [2]. This work clarifies the interplay between charge transfer and PL filtering in graphene/TMD layered HS.

HL 6.5 Mon 11:00 H36

Non-resonant and resonant low-frequency Raman scattering in twisted TMDC bilayers at millikelvin temperatures — •HENDRIK LAMBERS¹, NI-HIT SAIGAL¹, TORSTEN STIEHM¹, FLORIAN SIGGER², LUKAS SIGL², MIRCO TROUE², JOHANNES FIGUEIREDO², ALEXANDER HOLLEITNER², and URSULA WURSTBAUER¹ — ¹Institute of Physics, University of Münster, Münster, Germany — ²Walter Schottky Institute and Physics Department, TU Munich, Garching, Germany

Twisted TMDC bilayers are subject of many current studies because they can host many body physics and correlated phases such as superconductors and Mott insulators.[1] The moiré potential evolving with a twist angle or lattice constant mismatch could also be exploited to simulate Mott-Hubbard physics. The interlayer coupling within the bilayer correlates with the interlayer breathing mode and the shear mode, which can be characterized by low frequency Raman spectroscopy.[2] We study TMDC heterobilayers of WSe2 and MoSe2 by resonant and non-resonant Raman spectroscopy at millikelvin temperatures. The shear mode is resonant with the exciton transitions in both monolayers and its lineshape and transition energy are modified due to coupling to the exciton continuum. In addition, several sharp and highly resonant modes are observed in the high frequency Raman spectrum. We acknowledge financial support via DFG WU 637/7-1 and SPP2244. [1] L. Sigl et al., Phys. Rev. Research 2, 042044(R) (2020) [2] J. Holler et al., Appl. Phys. Lett. 117, 013104 (2020)

#### HL 6.6 Mon 11:15 H36

**Investigating Twist Angle Dependence of Exciton Resonances in WSe**₂/MOSe₂ **Heterostructures** — •CHIRAG PALEKAR, TOBIAS MANTHEI, BÁRBARA ROSA, and STEPHAN REITZENSTEIN — Institute of Solid State Physics, Technische Universität Berlin, D-10623 Berlin, Germany

Artificially produced TMDC heterostructures (HS) realized by stacking two different TMDC monolayers (ML) are a new class of promising semiconducting heterostructures. Due to their type-II band alignment, TMDC HSs tend to host the spatially indirect interlayer excitons (IX) where electrons and holes are located in conduction and valence bands, respectively, of the different layers. Here we study the twist angle dependence of IX resonances employing microphotoluminescence excitation (PLE) measurements on twisted WSe₂/MoSe₂ heterobilayer. PLE measurements reveal anti-correlation between linewidth and emission energy of IX. Resonant excitation at intralayer exciton energies of constituent ML yields high emission intensity of the IX with linewidth narrowing above 10 meV. We measure a drastic reduction in PL emission from IX for twist angles in the range of  $10^\circ$  -  $50^\circ$  due to large interlayer separation. Moreover, we show a noticeable IX exciton resonance separation which increases as function of twist angle i.e. from  $0^\circ$  (67 meV) to  $24^\circ$  (96 meV) along with observable red shift in IX emission energy. This fundamental study of excitons resonances deepens the current understanding of physics of twisted TMDC heterostructures and paves the way for future experiments and theoretical work.

HL 6.7 Mon 11:30 H36

Counterintuitive electric-field dependence of weak antilocalization in a bilayer graphene/WSe₂ heterostructure — JULIA AMANN¹, TOBIAS VÖLKL¹, TOBIAS ROCKINGER¹, DENIS KOCHAN², KENJI WATANABE³, TAKASHI TANIGUCHI³, JAROSLAV FABIAN², DIETER WEISS¹, and •JONATHAN EROMS¹ — ¹Institute of Experimental and Applied Physics, University of Regensburg, Regensburg, Germany — ²Institute of Theoretical Physics, University of Regensburg, Regensburg, Germany — ³National Institute for Materials Science, Tsukuba, Japan

Heterostructures of bilayer graphene (BLG) and transition metal dichalcogenides (TMDC) were recently proposed as a means of generating a gate-tunable, proximity-induced spin-orbit coupling (SOC) in graphene. Total SOC splitting of the band structure increases monotonically with the out-of-plane electric field, as confirmed by recent charge transport experiments. To elucidate the spin relaxation caused by SOC, weak antilocalization (WAL) experiments are frequently employed. Contrary to the naïve expectation of a monotonic increase of the WAL effect strength with electric field *D*, we observe a maximum of WAL visibility around D = 0. This counterintuitive behaviour originates in the intricate dependence of WAL in graphene on two different spin lifetimes  $\tau_{sym}$  and  $\tau_{asy}$ , which are due to spin relaxation caused by the valley-Zeeman and Rashba terms, respectively. Our calculations, based on modeling spin precession by an 8×8 Hamiltonian of BLG with one-sided TMDC show the same non-monotonic dependence on *D* as the experimental data.

HL 6.8 Mon 12:00 H36

Millikelvin Spectroscopy on Degenerate Exciton Ensembles in van der Waals Bilayers — •Nihit Saigal¹, Torsten Stiehm¹, Hendrik Lambers¹, Florian Sigger², Lukas Sigl², Mirco Troue², Johannes Figueiredo², Alexander Holleitner², and Ursula Wurstbauer¹ — ¹Institute of Physics, University of Münster, Münster, Germany — ²Walter Schottky Institute and Physics Department, TU Munich, Garching, Germany

Homo- and hetero-bilayers of transition metal dichalcogenides host a rich variety of interlayer exciton (IX) species where the electrons and holes reside in different monolayers. [1] This leads to enhanced lifetimes of IXs and also imparts them with a permanent dipole moment. [1,2] Such IXs provide an ideal platform for exploring many body physics such as dipole-dipole interactions and Bose-Einstein condensation. [2] We have investigated IXs in a heterobilayer of MoSe2 and WSe2 encapsulated in hBN, using temperature, laser power and time dependent photoluminescence (PL) spectroscopy down to millikelvin temperatures. At lowest temperatures and exciton densities, we observe a single low energy peak in the IX PL spectrum which has been attributed to be a signature of degenerate exciton gas. [2] We observe an unexpected nearly excitation power-independent IX energies at lowest temperatures (10 mK to ~10K) that converts into the well-known dipolar blue-shift at elevated temperatures. We acknowledge financial support by DFG via WU 637/4-2 and No. HO 3324/9-2 and SPP2244.

HL 6.9 Mon 12:15 H36

Infrared photocurrent in transition-metal dichalcogenide heterostructures — JEONG WOO HAN¹, PEIZE HAN², YIJING LIU², PAOLA BARBARA², THOMAS E. MURPHY³, and •MARTIN MITTENDORFF¹ — ¹Universität Duisburg-Essen, Fakultät für Physik, 47057 Duisburg, Germany — ²Georgetown University, Department of Physics, Washington, 20057 DC, USA — ³University of Maryland, Institute for Research in Electronics and Applied Physics, College Park, 20740 MD, USA

Heterostructures of transition metal dichalcogenites (TMDCs) have characteristic optical properties like the interlayer excitons due to the band offset between two adjacent TMDC layers. Such heterostructures are promising candidates for photodetectors with higher efficiencies compared to a single TMDC layer, furthermore, the interlayer excitation enables photocurrents at photon energies below the direct bandgap of each of the layers. Here we present measurements on a MoS₂/WS₂ heterostructure at photon energies of around 800 meV, which is significantly below the interlayer exciton. The cross-shaped structure of our samples allows measurements of the heterostructure as well as each individual layer. While at high photon energies photocurrents are observed in each of the layers, the low photon energy only leads to a photocurrent when the heterostructure is illuminated. We interpret this effect to be caused by intraband absorption and subsequent interlayer tunneling.

HL 7.1 Mon 15:00 H31

A new Time-Domain Approach for Linear Responses and Electrical Conductivity — •MICHEL PANHANS^{1,2} and FRANK ORTMANN^{1,2} — ¹Department of Chemistry, TU München — ²Center for Advancing Electronics Dresden, TU Dresden

Linear-response theory is a powerful theoretical framework to investigate, e.g., electrical and magnetic transport and to compare theory with experiments. Many intriguing quantum-transport phenomena such as quantum Hall effects, spin Hall effects, and quantum spin Hall effects have been derived within this framework. Beyond the general theory, strong efforts have been spent in the last decade to develop efficient and accurate computational methods to calculate charge transport in condensed matter. [1] In our recent work, we present a new time-domain approach to calculate arbitrary linear responses, which is based on a decomposition of the general Kubo formula into time-symmetric and time-antisymmetric parts. [2] The new algorithm is at least 1000 times faster compared to former time evolution schemes. [3] As a showcase, we have investigated the quantum anomalous Hall effect of the disordered Haldane model, where the quantum dynamics of the topological state have been analyzed. The proposed theory and the computational method provide a promising route to access transport phemomena in complpex and topological systems.

Anomalous photo-Nernst currents in HfTe₅ — •Waldemar Schmunk, MAANWINDER SINGH, ALEXANDER HOLLEITNER, and CHRISTOPH KASTL -Walter Schottky Institut

Recently, strong evidence of a quasi-quantized 3D quantum Hall effect in nonmagnetic semimetals HfTe₅ and ZrTe₅ has been reported by various groups. Plateau-like features in the Hall conductivity of HfTe₅ and ZrTe₅ point towards unconventional Hall physics in these 3D semimetals. Additionally, in highdensity HfTe5 crystals, an anomalous, but non-hysteretic, Hall conductivity has been reported as well, which points to a non-zero Berry curvature. Here, we present photocurrent measurements of thin HfTe₅ films in an external magnetic field. We find a localized edge photo response with opposite polarity at opposite edges. We interpret these edge photocurrents in terms of an anomalous Nernst current arising from the local excitation, the symmetry breaking at the edges, and the anomalous Hall conductivity. Such local photocurrents open the possibility to image anomalous Hall responses and possible related edge state physics in layered quantum materials.

### HL 7.3 Mon 15:30 H31

Aharonov-Bohm oscillations and phase-coherence analysis in selectivly grown topological-insulator rings — •Gerrit Behner, Dennis Heffels, Jonas Kölzer, Kristoff Moors, Abdur Rehman Jalil, Erik Zimmer-MANN, GREGOR MUSSLER, DETLEV GRÜTZMACHER, HANS LÜTH, and THOMAS SCHÄPERS — Peter Grünberg Institut (PGI-9), Forschungszentrum Jülich, 52425 Jülich, Germany

The study of quantum-interference effects in 3D topological insulators is crucial for understanding their transport properties. We present low-temperature magneto-transport measurements on selectively-grown Sb₂Te₃ ring structures. Pronounced Aharonov-Bohm oscillations in the conductance are observed with a major contribution of surface-state transport. The surface contributions are determined from magnetotransport under the application of an in-plane magnetic Thus, they are promising for optoelectronic applications and a prime example to investigate excitonic effects.

Complementary, plasmonic supercrystals, that are arrays of metal nanoparticles, support collective plasmon modes. They facilitate an impressive amplification of the electric near-field which allows to tailor electric fields on the nanoscale.

In the presented work, we theoretically consider exciton-plasmon coupling in a hybrid structure of a TMDC layer interacting with a single metal nano-particle or a two-dimensional supercrystal. For this purpose, we develop a Maxwell-Bloch theory where the excitons are described within the Heisenberg equation of motion framework and the metal nano-particles are treated as coupled dipoles in Mie theory.

Our studies reveal new "plexcitonic" eigenstates of the hybrid system. Furthermore, we are able to compute the scattered light in the near- and far-field explicitly and identify signatures of strong exciton-plasmon coupling featuring a Rabi splitting of tens of meV.

Location: H31

field. Furthermore we determine the phase-coherence length by analysing universal conductance fluctuations. Finally, we perform quantum transport simulations based on tight-binding calculations using KWANT. The simulations allow us to reproduce the predominant features of the experimental data and further deepen the understanding of the underlying physical effects.

HL 7.4 Mon 15:45 H31 Tunneling spectroscopy simulations of topological insulator (TI) nanorib**bons** — •Dennis Heffels¹, Declan Burke², Malcolm R. Connolly², Peter Schüffelgen¹, Kristof Moors¹, and Detlev Grützmacher¹ — ¹PGI-9, FZ Jülich — ²IC London

TI nanoribbons with proximity-induced superconductivity have been proposed as a possible platform for the realization of Majorana bound states (MBS). Attempts to detect these MBS have received much attention in solid-state physics in recent years. A major goal is to exploit their unusual non-Abelian statistics for topologically protected quantum computing. A very common method for the detection of MBS is tunneling spectroscopy. Implementing this experimental scheme with TI nanoribbons is very challenging, due to stringent requirements on the interfaces of the required heterostructure. Similar experiments on semiconductor nanowires have shown that careful interpretation of the measured data is of prime importance. Here, we present simulations that are tailored to support such tunneling spectroscopy experiments on TI nanoribbons that are proximitized via the top surface with a superconductor. We show that a 3D simulation of the TI-based tunnel junction device is essential to properly describe the proximity effect and disorder, which plays a crucial role. Interestingly, the absence or presence of a zero-bias conductance peak does not always reveal whether the system is in the trivial or the topological regime. We obtain a phase diagram of subgap features in the tunneling conductance as a function of magnetic field and Fermi level.

#### HL 7.5 Mon 16:00 H31

Transport in high mobility HgTe heterostructures — •MICHAEL KICK, LENA Fürst, Johannes Kleinlein, Saquib Shamim, Hartmut Buhmann, and Lau-RENS W. MOHLENKAMP — Experimentelle Physik III, Physikalisches Institut, Universität Würzburg, Am Hubland, 97074

The Fractional Quantum Hall Effect (FQHE) has not yet been observed in the material system of HgTe. Due to recent progress in MBE growth, routinely charge carrier mobilities of HgTe heterostructures of over  $\mu > 1 \cdot 10^6 \text{ cm}^2/\text{Vs}$ are obtained which is in the same order of magnitude as in the first reported experimental observation of the FQHE in GaAs/GaAlAs heterostructures. This opens up new prospects for transport investigations into the long time still open question of fractional states in this material system.

In 2-dimensional HgTe quantum wells, transport measurements show well pronounced quantum Hall plateaus for all filling factors, but no indication of any fractional state. High magnetic field measurements show a prolonged v = 1plateau and a transition to an insulating state. Intriguingly, the v = 1 plateau exhibits a transition to an insulating state for filling factor v = 1/2.

Another possibility to observe the FQHE in HgTe is provided by the 2D surface states of a 3D topological insulator. High mobility layers,  $\mu > 2 \cdot 10^6$  cm²/Vs, of tensil strained HgTe are subject of extensive magneto-transport investigations. First results reveal so far unresolved features predicted by recent band structure calculations, while the search for FQHE states is still on.

### HL 7.6 Mon 16:45 H31

Structure-imposed electronic topology in cove-edged graphene nanorib**bons** — •Florian Arnold¹, Tsai-Jung Liu¹, Agnieszka Kuc², and Thomas HEINE^{1,2,3} – ¹Technische Universität Dresden, Dresden, Germany – ²HZDR, Leipzig, Germany — ³Yonsei University, Seoul, Republic of Korea

Cove-edged zigzag graphene nanoribbons (ZGNR-C) take their name from a regular pattern of coves which is formed by removing one terminal CH group per length unit on each zigzag edge. Based on three structural parameters that unambiguously characterize the atomistic structure of ZGNR-C, we present a scheme that classifies their electronic state, i.e., if they are metallic, topological insulators or trivial semiconductors, for all possible widths N, unit lengths a and cove position offsets at both edges b, thus showing the direct structure-electronic structure relation. We further present an empirical formula to estimate the band gap of the semiconducting ribbons from N, a, and b. Finally, we show possible ribbon terminations, which should give guidance for future synthetic efforts to realize new topological ZGNR-C with large band gap and to realize topologically protected edge states in these systems.

#### HL 7.7 Mon 17:00 H31

Temperature and magnetic field-dependent noise measurements in GaAs/AlGaAs quantum rings — •BIRKAN DÜZEL¹, OLIVIO CHIATTI¹, SVEN S. BUCHHOLZ¹, ANDREAS D. WIECK², DIRK REUTER³, and SASKIA F. FISCHER¹ ¹Novel Materials Group, Humboldt-Universität zu Berlin, 10099 Berlin, Germany — ²Angewandte Festkörperphysik, Ruhr-Universität Bochum, 44780 Bochum, Germany — ³Optoelektronische Materialien und Bauelemente, Universität Paderborn, 33098 Paderborn, Germany

Nanostructured materials offer a way to investigate phase-coherent transport of electrons and the resulting interference effects in systems. Measurements of the white noise have been used to determine system properties such as the elctron temperature  $T_e$ . Recently noise measurements in quantum ring structures have revealed white noise exceeding the expected thermal noise [1].

This work investigates the dependence of the excess noise in quantum rings on the bath temperature and applied magnetic field. Noise measurements in Al_xGa_xAs/GaAs-based etched quantum rings are performed in equilibrium with bath temperatures ranging from 15 mK to 4.2 K and magnetic fields ranging from -50 mT to 50 mT. Additionally, magnetotransport measurements are performed at 1 K with magnetic fields ranging from 0 T to 12 T.

HL 7.8 Mon 17:15 H31

Coplanar waveguides for electronic measurements at terahertz frequencies - •Sergey Lavrentyev¹, Johannes Größmeyer¹, Gerhard Huber², and Alexander Holleitner¹ - ¹Walter Schottky Institut and Physics Department, TU Munich —  $^2 \rm Walther-Meißner-Institut$  and Physics Department, TU Munich

We explore the usability of gold coplanar waveguides on a sapphire substrate as contacts for electronic transport measurements on 2D and topological materials in the terahertz regime. Our simulations reveal different modes with low attenuation. For the coplanar waveguide, we find the lowest attenuation in even modes compared to the predominance of odd modes in coplanar strip geometries. Moreover, our results show a frequency dependent behavior of the complex refractive index of the modes at sub-millimeter wavelengths. We find that gold coplanar waveguides are well suited for electronic measurements at terahertz frequencies.

HL 7.9 Mon 17:30 H31

Influence of fixed scatterers of various sizes and densities on the giant negative magnetoresistance in two dimensional electron gases. - •JANUS LAMMERT¹, BEATE HORN-COSFELD¹, JAKOB SCHLUCK¹, MIHAI CERCHEZ¹, Thomas Heinzel¹, KLaus Pierz², Hans Werner Schumacher², and Dominique Mailly³ - ¹Institut für Experimentelle Physik der kondensierten Materie, Heinrich-Heine-Universität, Universitätsstraße 1, 40225 Düsseldorf, Germany — ²Physikalisch-Technische Bundesanstalt, Bundesallee 100, 38116 Braunschweig, Germany — ³CNRS, Univ. Paris-Sud, Université Paris-Saclay, C2N Marcoussis, 91460 Marcoussis, France

The giant negative magnetoresistance (GNMR) in a 2DEG is studied through the effects produced by artificial scatterers (Lorentz arrays [1]) with varying scatterer density. The influence of the different types and ratios of scattering mechanisms shed light on both the temperature independent and the temperature dependent parts of the GNMR [2]. The effect of scattering on the shape and amplitude of the GNMR will be discussed. [1] H. A. Lorentz, Proc. R. Acad. Sci. Amsterdam 7, 438, 1905, [2] B. Horn-Cosfeld et al. Phys. Rev. #### HL 7.10 Mon 17:45 H31

First-principles calculations of temperature-dependent transport in semiconductors - DAN HAN, ANDREAS HELD, •MASAKO OGURA, and HUBERT EBERT — Ludwig-Maximilians-University Munich, Munich, Germany

The carrier mobility is one of the central properties of semiconductors. So far, most first-principles calculations of carrier mobilities for bulk semiconductors are based on the Boltzmann transport equation. In this contribution, we present an alternative scheme to evaluate temperature dependent carrier mobilities.

As a starting point, we calculate the electronic structures using the Korringa-Kohn-Rostoker (KKR) Green's function method in combination with the coherent potential approximation (CPA) alloy theory allowing for chemical as well as temperature induced disorder in the material. Dealing with undoped elemental or compound systems, we account this way for lattice vibrations, i.e. atom displacements depending on temperature, which affect the electronic structure and also cause a finite electric resistivity. The corresponding electric conductivity is calculated by means of the Kubo-Greenwood formula implemented on the basis of the KKR-CPA. The carrier mobility is evaluated from the resulting temperature-dependent conductivity and carrier concentration. Results for the intrinsic transport properties of undoped elemental and compound semiconductors will be presented.

Single and indistinguishable photons are basic building blocks for many quantum technology applications. Here (PRL, 125, 233605 (2020)), we investigate the degree of indistinguishability of cascaded photons emitted from a three-level quantum ladder system; in our case the biexciton-exciton cascade of semiconductor quantum dots. Despite unprecedented single-photon purity, we theoretically show that the indistinguishability for both emitted photons is inherently limited by the ratio of the lifetimes of the excited and intermediate states. We confirm this finding both experimentally and with quantum optical simulations by comparing the quantum interference visibility of cascaded and noncascaded exciton emission of the same quantum dot. Based on our model, we propose photonic structures or stimulated emission (PRL, 128, 093603, (2022)) from the excited to the intermediate state to increase the lifetime ratio and overcome the limited indistinguishability.

#### HL 8.2 Mon 15:30 H32

Carrier dynamics in quantum-dot tunnel- injection structures: microscopic theory and experiment — •MICHAEL LORKE¹, IGOR KHANONKIN², STEPHAN MICHAEL¹, JOHANN PETER REITHMAIER³, GADI EISENSTEIN², and FRANK JAHNKE¹ — ¹Institute for Theoretical Physics, University of Bremen, Otto-Hahn-Allee 1, Bremen, 28359, Germany – ²Electrical Engineering Department and Russel Berrie Nanotechnology Institute, Technion, Haifa, 32000, Israel - ³Technische Physik, Institute of Nanostructure Technologies and Analytics, Center of Interdisciplinary Nanostructure Science and Technology (CINSaT), University of Kassel, Kassel, 34132, Germany

Among the challenges for the next generation of semiconductor lasers is the enhancement of their modulation speed to satisfy the need for higher data transfer rates. For this purpose, tunnel injection lasers are an appealing concept, as they promise improved modulation rates and better temperature stability. Moreover, they eliminate a major detrimental effect of quantum dot lasers, which is the gain nonlinearity caused by hot carriers. It is shown in this work how the aforementioned improvements depend on the design of tunnel-injection devices. We perform a theory-experiment comparison on scattering times in tunnel injection devices to highlight the importance of alignment between the injector well and the quantum dot ensemble. It is shown how differences in the coupling to the injector quantum well caused by the alignment lead to scattering times into the quantum dot ensemble that vary by an order of magnitude.

HL 8.3 Mon 15:45 H32

Statistical limits for entanglement swapping with independent semiconductor quantum dots — •JINGZHONG YANG¹, MICHAEL ZOPF¹, PENGJI LI¹, NAND LAL SHARMA², WEIJIE NIE², FREDERIK BENTHIN¹, TOM FANDRICH¹, EDDY PATRIC RUGERAMIGABO¹, CASPAR HOPFMANN², ROBERT KEIL², OLIVER. G. SCHMIDT^{2,3,4}, and FEI DING^{1,5} — ¹Institut für Festkörperphysik, Leibniz Universität Hannover, Appelstraße 2, 30167 Hannover, Germany — ²Institute for Integrative Nanosciences, Leibniz IFW Dresden, Helmholtzstraße 20, 01069 Dresden, Germany — ³Material Systems for Nanoelectronics, Technische Universität Chemnitz, 09107 Chemnitz, Germany — ⁴Nanophysics, Faculty of Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, 01062 Dresden, Germany — ⁵Laboratorium für Nano- und Quantenengineering, Leibniz Universität Hannover, Schneiderberg 39, 30167 Hannover, Germany

Semiconductor quantum dots are promising constituents for future quantum communication. Here we explore the limits for sources of polarization-entangled photons from biexciton-exciton cascade of the quantum dots. We stress the necessity of tuning the exciton fine structure, and explain why the time evolution of photonic entanglement in quantum dots is not applicable for large quantum networks. We identify the critical device parameters and present a numerical model for benchmarking the device scalability in order to bring the realization of distributed semiconductor-based quantum networks one step closer to reality.

HL 8.4 Mon 16:00 H32

**Maximally entangled and GHz-clocked on-demand photon pair source** — •CASPAR HOPFMANN¹, WEIJIE NIE¹, NAND LAL SHARMA¹, CARMEN WEIGELT¹, FEI DING², and OLIVER G. SCHMIDT^{1,3,4} — ¹Institute for Integrative Nanosciences, Leibniz IFW Dresden, Helmholtzstr. 20, 01069 Dresden, Germany — ²Institut für Festkörperphysik, Leibniz Universität Hannover, Appelstr. 2, 30167 Hannover, Germany — ³Material Systems for Nanoelectronics, Technische Universität Chemnitz, 09107 Chemnitz, Germany — ⁴Nanophysics, Faculty of Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, 01062 Dresden, Germany

We present a 1 GHz-clocked, maximally entangled and on-demand photon pair source based on droplet etched GaAs quantum dots using two-photon excitation. By employing these GaP microlens-enhanced devices in conjunction with their substantial brightness, raw entanglement fidelities of up to 0.95 and post-selected photon indistinguishabilities of up to 0.93, the suitability for quantum repeater based long range quantum entanglement distribution schemes is shown. Comprehensive investigations of a complete set of polarization selective two-photon correlations facilitate an innovative method to determine the extraction and excitation efficiencies directly - opposed to commonly employed indirect techniques. Additionally, time-resolved analysis of Hong-Ou-Mandel interference traces reveal an alternative approach to the investigation of pure photon dephasing.

#### HL 8.5 Mon 16:15 H32

Photoneutralization of charges in GaAs quantum dot based entangled photon emitters — JINGZHONG YANG¹, TOM FANDRICH¹, •FREDERIK BENTHIN¹, ROBERT KEIL², NAND LAL SHARMA², WEIJIE NIE², CASPAR HOPFMANN², OLIVER G. SCHMIDT^{2,3,4}, MICHAEL ZOPF¹, and FEI DING^{1,5} — ¹Institut für Festkörperphysik, Leibniz Universität Hannover, Germany — ²Institute for Integrative Nanosciences, Leibniz IFW Dresden, Germany — ³Material Systems for Nanoelectronics, Technische Universität Chemnitz, Germany — ⁴Nanophysics, Faculty of Physics and Würzburg-Dresden Cluster of Excellence ct.qmat, TU Dresden, Germany — ⁵Laboratorium für Nano- und Quantenengineering, Leibniz Universität Hannover, Germany

Semiconductor-based quantum dot emitters are an attractive source for generating pairwise photonic entanglement and a promising constituent of photonic quantum technologies. However, quantum dots typically suffer from luminescence blinking, lowering the efficiency of the source and hampering their scalable application in quantum networks. We investigate the spectral and quantum optical response of the quantum dot emission by introducing an additional wavelength tunable gate laser. Under two-photon resonant excitation of the neutral biexciton in a GaAs/AlGaAs quantum dot, the blinking of the neutral exciton emission was observed. Our finding demonstrates that the emission blinking can be actively suppressed by controlling the balance of free electrons and holes in the vicinity of the quantum dot thereby significantly increasing the quantum efficiency by 30%.

#### HL 8.6 Mon 17:00 H32

**Franson interference on a resonantly driven biexciton cascade** – •MARCEL HOHN¹, KISA BARKEMEYER², MATTHIAS KUNZ¹, ARSENTY KAGANSKIY¹, SAMIR BOUNOUAR¹, ALEXANDER CARMELE², SVEN RODT¹, and STEPHAN REITZENSTEIN¹ – ¹Institut für Festkörper Physik, Technische Universität Berlin, 10623 Berlin, Germany – ²Institut für Theoretische Physik, Technische Universität Berlin, 10623 Berlin, Germany

The deterministic generation of entangled photon pairs is of special interest for applications in quantum communication and computation. As many experi-

ments focus on entanglement in the polarization base, energy-time entangled photons used for Franson interference offer the advantage of high robustness in long-distance fiber transmission. We report on Franson measurements performed in cw mode on the resonantly driven biexciton cascade of a deterministically fabricated quantum dot device. The two-photon visibility of such a three-level system crucially dependents on the decay rates of the ideally long upperand short living intermediate state [1]. A relation hard to achieve for the biexciton cascade, where the lifetime of the biexciton state is usually short compared to the exciton state. Nevertheless, our measurements yield a high two-photon visibility up to  $(73 \pm 2)\%$ , surpassing the CHSH inequality of 70.7% [2]. This result demonstrates the high potential of generating energy time entangled photons in a resonantly driven biexciton cascade.

HL 8.7 Mon 17:15 H32 Red Detuned Excitation of a Quantum Dot – •YUSUF KARLI¹, FLORIAN Kappe¹, Thomas Bracht², Julian Münzberg¹, Tim Seidelmann³, Voll-RATH MARTIN AXT³, SAIMON COVRE DA SILVA⁴, ARMANDO RASTELLI⁴, VIKAS REMESH¹, DORIS REITER⁵, and GREGOR WEIHS¹ — ¹Institute für Experimentalphysik, Universität Innsbruck, Innsbruck, Austria -²Institut für Festkörperthe-orie, Universität Münster, Münster, Germany -³Theoretische Physik III, Universität Bayreuth, Bayreuth, Germany —  4 Institute of Semiconductor and Solid State Physics, Johannes Kepler University Linz, Linz, Austria – ⁵Condensed Matter Theory, Department of Physics, TU Dortmund, Dortmund, Germany Semiconductor quantum dots have emerged as promising sources of highly indistinguishable single photons. To operate as an on-demand photon source, a quantum dot must be prepared in its exciton state, for which, several protocols exist. A recent remarkable theoretical discovery, also presented at this conference, showed that the exciton state in a quantum dot can be efficiently populated by two red-detuned pulses in a swing-up mechanism. We demonstrate the experimental implementation of this mechanism relying on amplitude-shaping of a broadband laser pulse in a 4f shaper including a spatial light modulator. The decisive advantage of our scheme is that both pulses are red-detuned and therefore, no higher-lying states of the quantum dot will be directly addressed. Our results contribute towards an effortless method for generating high-purity single photons, yet most importantly, removing the need for stringent polarization filtering.

#### HL 8.8 Mon 17:30 H32

**Dephasing mechanisms revealed by two-photon coincidence measurements** — •JULIAN WIERCINSKI, MORITZ CYGOREK, and ERIK M. GAUGER — SUPA, Institute of Photonics and Quantum Sciences, Heriot-Watt University, Edinburgh, UK

Cooperative effects of entangled quantum emitters play a key role in quantum technologies like, e.g., quantum computing and are known to influence their light emission as well as absorption - a key ingredient for highly efficient quantum batteries and light harvesting complexes. Only recently, cooperative emission of two quantum dots has been observed experimentally.

Inspired by these results we use numerically complete methods to theoretically investigate the impact of different dephasing mechanisms on the cooperative emission of two quantum dots. We show that different dephasing mechanisms lead to severe qualitative differences in the two-photon coincidence signals. These can be explained by the influence of dephasing on the dynamics of the inter-emitter entanglement. Therefore, we argue, two-photon coincidence measurements make dephasing visible in the experiment acting as a probe for underlying dephasing mechanisms.

#### HL 8.9 Mon 17:45 H32

**Bandwidth Limit in Optically Detected Single Electron Tunneling Events** — •JENS KERSKI¹, HENDRIK MANNEL¹, PIA LOCHNER¹, ERIC KLEINHERBERS¹, ANNIKA KURZMANN², ARNE LUDWIG³, ANDREAS D. WIECK³, JÜRGEN KÖNIG¹, AXEL LORKE¹, and MARTIN GELLER¹ — ¹Faculty of Physics and CENIDE, University of Duisburg-Essen, Germany — ²2nd Institute of Physics, RWTH Aachen University, Germany — ³Chair of Applied Solid State Physics, Ruhr-University Bochum, Germany

Measurements of single quantum processes have recently attracted increasing attention. One example is the counting of single electron tunnel events in quantum dots. These individual quantum jumps are usually measured electrostatically. However, new optical detection methods have been developed that promise higher time resolution, although their potential has not yet been fully investigated. Here, we study the resonance fluorescence of the excitonic transition from a self-assembled quantum dot embedded in a tailored diode structure.

We detect the optical signal with single photon resolution and use a postprocessing procedure to identify the optimal bandwidth for the analysis of our data. We demonstrate that we can evaluate our data with up to 175 kHz bandwidth and show how the chosen bandwidth affects the determined tunneling rates and the evaluation by full counting statistics. Using a simple model, we discuss how the Poisson distribution of the photons limits the time resolution

even in ideal measurements and propose how a time resolution of more than 1 MHz could be achieved.

HL 8.10 Mon 18:00 H32 The Origin of Antibunching in Resonance Fluorescence - •LUKAS HANSCHKE^{1,2}, LUCAS SCHWEICKERT³, JUAN CAMILO LÓPEZ CARREÑO⁴, EVA SCHÖLL^{1,3}, KATHARINA D. Laussy^{4,8}, Val Zwiller³, Kai Müller², and Klaus D. Jöns¹ – ¹PhoQS, CeOPP, and Department of Physics, Paderborn University, Germany – ²WSI, MCQST and TU Munich, Germany – ³KTH Stockholm, Sweden — ⁴University of Wolverhampton, UK — ⁵JKU Linz, Austria — ⁶Sapienza University Rome, Italy — ⁷Universidad Autónoma de Madrid, Spain ⁸Moscow, Russia

We present measurements that prove that the simultaneous observation of subnatural linewidth and antibunching of resonance fluorescence is not possible. High-resolution spectroscopy reveals the sharp spectral feature of the weak driving regime with a vanishing component of incoherently scattered light. Filtering the emission in the order of the Fourier limited linewidth leads to the loss of antibunching in the correlation measurement. Our theoretical model identifies two-photon interference between the coherent and incoherently scattered light as the origin of antibunching. This prefigures schemes to achieve a source of single photons with sub-natural linewidth [PRL 123, 170402 (2020)].

# HL 9: Focus Session: Exceptional Points and Non-Hermitian Physics in Semiconductor Systems

The strong recent interest into nonconservative/non-Hermitian systems and their exotic degeneracies - so-called exceptional points - is driven by the occurrence of rather unconventional and fascinating physics and by potential applications such as ultrasensitive sensing, orbital angular momentum lasers, and topological energy transfer for mode and polarization conversion. This Focus Session aims at discussing the latest experimental and theoretical results in the rapidly developing field with special focus on semiconductor systems, where engineering the interplay of coupling, dissipation and amplification mechanisms offers novel opportunities. Moreover, we give an overview to young scientists of the exciting possibilities of interdisciplinary research in this field.

Invited Talk

HL 9.1 Mon 15:00 H33 Exceptional points in optics: From bulk materials to one-dimensional confined systems — • CHRIS STURM — Felix Bloch Institute for Solid State Physics, Universität Leipzig, Leipzig, Germany

The research of exceptional points (EP) was initiated by W. Voigt in 1902 when he discovered that for certain directions in orthorhombic crystals only one circular polarized eigenstate exists, as soon as absorption sets in [1]. These directions corresponds to EPs in the momentum space. The presence of such EP is not limited to orthorhombic crystals only and appears in many optical systems. Here we present an overview of the appearance and the properties of these EPs in bulk crystal and optically one-dimensional confined systems. We show that the properties of the EPs in bulk crystals are determined by the dielectric function and the symmetry of the crystal, which allows to distinguish between optically biaxial materials having triclinic, monoclinic or orthorhombic crystal symmetry. In the presence of an optical confinement, like in thin films or microresonators, EPs can even appear in systems consisting of optically uniaxial materials, which was recently observed experimentally (e.g. Ref. [2]). Furthermore, in contrast to bulk crystals, the properties of the EPs are determined not only by the dielectric function of the materials but depends also on the design of the system, e.g., film thickness and confinement properties.

Complex Skin Modes in Non-Hermitian Coupled Laser Arrays •MERCEDEH KHAJAVIKHAN and YUZHOU LIU — 1002 Childs Way, Los Angeles, CA 90089

In the realm of non-Hermitian physics, the possibility of complex and asymmetric exchange interactions between a network of oscillators has been theoretically shown to lead to novel behaviors like delocalization, skin effect, and bulkboundary correspondence. While the ramifications of these theoretical works in optics have been recently pursued in synthetic dimensions, the Hatano-Nelson model has yet to be realized in real space. In this work, by using active optical oscillators featuring non-Hermiticity and nonlinearity, we introduce an anisotropic exchange between the resonant elements in a lattice, an aspect that enables us to observe the non-Hermitian skin effect, phase locking, and near-field beam steering in a Hatano-Nelson laser array. This work can open up new regimes of phase-locking in lasers while shedding light on the fundamental physics of non-Hermitian systems.

#### **Invited Talk** HL 9.3 Mon 16:15 H33 Non-Hermitian effects in exciton polaritons — •ELIEZER ESTRECHO — ARC Centre of Excellence in Future Low-Energy Electronics Technologies and Department of Quantum Science and Technology, Research School of Physics, The

Australian National University, Canberra, ACT 2601, Australia I will present our experimental results highlighting non-Hermitian effects in exciton-polariton systems-quasiparticles arising from the strong coupling of

excitons in semiconductors and photons in a cavity. This hybrid system is naturally non-Hermitian due to inherent loss and gain. The former arises from photon leakage through the cavity mirrors and the short lifetime of excitons, while the latter arises from an external pump used to maintain the density, for example, in the creation of Bose-Einstein condensates.

Using exciton-polariton condensates, we demonstrate exceptional points in the deformation parameter space of a quantum billiard. In particular, we are able to trace the energy levels close to the exceptional point, observe the topological Berry phase, and demonstrate the chirality of the state.

We also observe exceptional points in momentum space. By studying the energy and pseudospin structure, we directly measured a novel non-Hermitian topological invariant and differentiated it from its Hermitian counterparts. Furthermore, we also observe an anomalous dispersion resulting from the dissipative coupling of excitons and photons. The resulting inverted dispersion leads to a negative-mass propagation where the particles move in the opposite direction to their momentum.

Nonlinear dynamics and exceptional points in exciton-polariton condensates - •STEFAN SCHUMACHER — Physics Department & CeOPP, Paderborn University, Germany

Non-Hermitian physics and exceptional points have attracted significant attention in the past two decades. Enormous progress has been made for example in non-Hermitian optics. Non-Hermitian degeneracies and exceptional points have also been demonstrated for exciton polaritons in semiconductor microcavities [1]. For non-resonant excitation, polaritons can spontaneously exhibit macroscopic coherence, known as polariton condensation. The nonequilibrium nature of polariton condensates makes them perfect for studies of non-Hermitian physics. The gain can be tailored by varying the spatial optical pump profile, for example allowing realization of PT-symmetric lattices [2]. The polariton-polariton interaction gives rise to inherently nonlinear phenomena such as vortex formation [3]. Recently, we reported the observation of an exceptional point in a double-well potential [4]. There, the polariton condensate can be localized in one well and switched off by an additional optical excitation in the other well that surprisingly induces additional loss [4]. The nonlinearity and related energy blueshift also allows to approach the exceptional point. This work paves the way to explore non-Hermitian physics in a system with strong nonlinearity and in tailored potential energy landscapes. [1] T. Gao et al., Nature 526, 554-558 (2015). [2] X. Exceptional points in anisotropic ZnO thin films - •SEBASTIAN HENN, EVGENY KRÜGER, CHRIS STURM, and MARIUS GRUNDMANN - 1 Universität Leipzig, Faculty of Physics and Earth Sciences, Felix Bloch Institute for Solid State Physics, Linnéstr. 5, 04103 Leipzig, Germany

In this talk we present findings regarding the existence of exceptional points in anisotropic thin films. Analogous to degeneracies of optic axes in absorptive biaxial materials, so-called singular optic axes [1], anisotropic transparent structures contain exceptional points in momentum space, where two orientationand polarization-dependent modes are equal in resonance energy and lifetime. The latter is determined by dissipative photon loss at the interfaces, which renders the system non-Hermitian. This phenomenon has been observed in dielectric optical microcavities [2] and principally exists also in anisotropic thin films, where resonances correspond to well-known Fabry-Pérot modes. We show re-

Degradation of the electrooptical properties of UVB LEDs observed by temperature dependent electroluminescence spectroscopy —  $\bullet$ JAKOB HÖPFNER¹, PRITI GUPTA¹, MARTIN GUTTMANN¹, JAN RUSCHEL², JOHANNES GLAAB², TIM KOLBE², ARNE KNAUER², TIM WERNICKE¹, MARKUS WEYERS², and MICHAEL KNEISSL^{1,2} — ¹Technische Universität Berlin, Institute of Solid State Physics, Berlin, Germany — ²Ferdinand-Braun-Institut, Berlin, Germany

The operation of UVB-LEDs induces changes in their electrooptical characteristics, especially a gradual reduction in the emission power. As the lifetime of a device is a key property for its application, it is important to understand the microscopic processes governing their degradation behavior. We report an investigation on UVB-LEDs emitting at 310 nm before and after aging for 1000 h at 100 mA ( $67 \text{ Acm}^{-2}$ ) and a heatsink temperature of 70 °C using temperature(T)dependent electroluminescence spectroscopy from 20 K - 340 K. Before aging, the external quantum efficiency (EQE) at 10 mA gradually increases with decreasing temperature from 0.8 % at 340 K to 1.8 % at 150 K and stays at that level for lower temperatures, indicating that EQE(T) is dominated by the radiative recombination efficiency. After 1,000 h of operation, the EQE has reduced to 0.45 % at 340 K and it shows a maximum of 1.4 % at 80 K. Also below 80 K, the EQE again decreases. These findings suggest a stress-induced reduction of both the radiative recombination efficiency and the carrier injection efficiency.

#### HL 10.2 Mon 15:15 H34

Short pulse operation of (Al,In)GaN laser diodes to increased linewidth and decreased coherence for laser displays — •JANNINA J. TEPASS¹, LUKAS UHLIG¹, DOMINIC KUNZMANN¹, GEORG BRÜDERL², and ULRICH T. SCHWARZ¹ — ¹Institute of Physics, Chemnitz University of Technology, 09126 Chemnitz, Germany — ²ams OSRAM Group, 93055 Regensburg, Germany

Red, green, and blue (RGB) laser diodes are used as the light source in laser displays in particular laser glasses for augmented, virtual, and mixed reality (AR/VR/MR). A narrow linewidth and corresponding high coherence will lead to speckles and non-uniform scattering at the gratings used for the projection into the eye box. Therefore, it is necessary to enhance the spectral linewidth of each laser diode to about 10 nm.

Mode competition causes a dynamic broadening of the laser spectrum already to about 1 nm. Here, we explore short pulse modulation to further increase the linewidth. A wavelength chirp at the beginning of each pulse is generating additional broadening at a pulse length of the order of a few nanoseconds. This chirp is the consequence of overshooting the carrier density above the threshold carrier density, resulting in a blue-shifted gain spectrum.

We investigate these broadening effects in blue and green (Al,In)GaN and red (Al,Ga)InP laser diodes with the help of a streak camera experiment. We took measurements for varying pulse length to analyse the spectral changes of those laser diodes and the behaviour with different pulse length.

#### HL 10.3 Mon 15:30 H34

Investigation of lateral charge carrier diffusion via micro-photoluminescence in InGaN MQWs and SQWs — •CONNY BECHT¹, ULRICH T. SCHWARZ¹, MICHAEL BINDER², BASTIAN GALLER², JÜRGEN OFF², MAXIMILIAN TAUER², AL-VARO GOMEZ IGLESIAS², HENG WANG², and MARTIN STRASSBURG² — ¹Institute of Physics, Chemnitz University of Technology, 09126, Chemnitz, Germany — ²ams-OSRAM International GmbH, Leibnizstr. 4, 93053 Regensburg, Germany

InGaN multi-quantum well (MQW) structures are used to obtain highly efficient blue light emitting diodes (LED). After the injection of carriers into the active layer of blue LEDs, a part of the carriers diffuses laterally before recombining (non-)radiatively. The diffusion behaviour in InGaN MQWs is up to now poorly understood.

In this study InGaN MQWs and single QWs (SQW) are investigated by microphotoluminescence at room temperature. To study the diffusion behaviour, the excitation spot is decoupled from the detection area, which we call a pinhole scan. With the size of the excitation spot known, conclusions about the diffusion length of the charge carriers after optical pumping can be drawn. For deeper analysis of the diffusion behaviour the excitation density is varied and an external bias can be applied in addition. sults of rigorous calculations for m-ZnO thin films, based on scattering matrices whose complex poles correspond to the resonance energies. This allows to find exceptional points in two-dimensional momentum space and we confirm important characteristics, such as a square-root topology and circularity.

# HL 10: Nitrides

The results show a long-range diffusion up to several 10  $\mu$ m's. The energy shows a increasing blue shift with higher excitation power at the center (i.e. excitation spot).

HL 10.4 Mon 15:45 H34

Threshold and gain measurements of AlGaN-based UVC lasers — •MARKUS BLONSKI¹, GIULIA CARDINALI¹, BERND WITZIGMANN², NORMAN SUSILO¹, DANIEL HAUER VIDAL¹, MARTIN GUTTMANN¹, TIM WERNICKE¹, and MICHAEL KNEISSL¹ — ¹Technische Universität Berlin, Institute of Solid State Physics, Berlin, Germany — ²Department Elektrotechnik-Elektronik-Informationstechnik (EEI), University Erlangen-Nürnberg (FAU), Erlangen, Germany

Recently, first UVC laser diodes were demonstrated, with relatively high threshold current densities and pulsed operation. Critical param- eters affecting the threshold are the electron and hole wavefunctions overlap and the optical confinement factor. While thicker quantum wells (QWs) yield higher confinement factors, the wavefunctions over- lap in AlGaN QWs thicker than 3 nm is reduced due to the quantum- confined Stark effect (QCSE). In this work, the influence of QW thick- ness on lasing threshold and optical gain in AlGaN-based optically pumped lasers with SQWs between 3 nm and 12 nm emitting at 275 nm is studied. The lasing peak shifts to shorter wavelengths with respect to the spontaneous emission in thin wells, while the widest wells ex- hibit a red-shift. Similar lasing threshold power density was observed for all samples at around 1.4MW cm⁻². Variable stripe length method measurements showed positive net gain in all the samples with compa- rable values of differential net gain. Simulations of the material gain show that higher energy states contribute to the gain in wider wells, whereas in the 3 nm AlGaN QW the ground state provides the gain.

 $\begin{array}{l} \textbf{Drift-diffusion simulation of UVC-LEDs with varied emission wavelength} \\ \textbf{\bullet}\text{F}. BILCHENKO^1, A. MUHIN^1, M. GUTTMAN^{1,2}, T. WERNICKE^1, F. RÖMER^3, B. WITZIGMANN^3, and M. KNEISSL^{1,2} \\ \textbf{\bullet}^{-1} Technische Universität Berlin, Institute of Solid State Physics, Berlin, Germany \\ \textbf{\bullet}^{-2}$ Ferdinand-Braun-Institut, Leibniz-Institut für Höchstfrequenztechnik, Berlin, Germany \\ \textbf{\bullet}^{-3}Friedrich-Alexander-Universität Erlangen-Nürnberg, Lehrstuhl für Optoelektronik, Erlangen, Germany

The external quantum efficiency (EQE) of AlGaN-based deep ultraviolet (UVC) light emitting diodes (LEDs) decreases strongly for emission wavelengths ( $\lambda$ ) below 240 nm by two orders of magnitude from 1% (240 nm) to 0.01% (217 nm). We showed that the light extraction efficiency (LEE) on wafer level decreases only by a factor of less than 3 from 4% (240 nm) to 1.5% (217 nm), leaving current injection efficiency (CIE) and radiative recombination efficiency (RRE) as possible major causes for the EQE decrease. In order to estimate the contribution of the CIE and RRE to the EQE we analyse measured electroluminescence characteristics by simulating an LED-series with nominally identical heterostructure but varying AlGaN composition in the active region in order to achieve  $\lambda$  ranging from 217 nm to 263 nm. Our results suggest that, in this wavelength range, the change in CIE contributes greatly to the decrease in EQE. For devices emitting at 263 nm and 249 nm the CIE stays roughly constant at around ~50%, showing a significant decrease towards shorter  $\lambda$ , i.e. 48% at 240 nm and 2% at 217 nm. Based on these results, it appears that improvement of the CIE is paramount for achieving high-power UVC-devices.

#### HL 10.6 Mon 16:15 H34

**Realizing tunnel junctions in AlGaN-based UVC light emitting diodes emitting at 232 nm** – •VERENA MONTAG¹, FRANK MEHNKE¹, MARTIN GUTTMANN², LUCA SULMONI¹, CHRISTIAN KUHN¹, JOHANNES GLAAB², TIM WERNICKE¹, MARKUS WEYERS², and MICHAEL KNEISSL^{1,2} – ¹Technische Universität Berlin, Institute of Solid State Physics, Hardenbergstraße 36, 10623 Berlin, Germany – ²Ferdinand-Braun-Institut, Gustav-Kirchhoff-Straße 4, 12489 Berlin, Germany An ultraviolet C (UVC) -transparent p-AlGaN layer is needed to overcome the strong absorption of p-layers in deep UV light emitting diodes (LEDs). However, transparent p-AlGaN layers exhibit high sheet and contact resistances resulting in very large operating voltages. A promising alternative to standard p-contacts is the injection of holes into the AlGaN quantum well by tunnel heterojunctions

Location: H34

(TJs). This allows for low resistivity n-layers and n-contacts on both sides of the device. We have successfully demonstrated fully transparent AlGaN-based TJ-LEDs emitting at 232 nm grown entirely by metal-organic vapor phase epitaxy. A thin GaN interlayer was implemented to enhance carrier tunneling at the TJ interface. Typically, the operating voltages, the output powers and the external quantum efficiencies of a 0.15 mm² TJ-LED featuring a 8 nm thick GaN interlayer are 24 V, 77  $\mu$ W and 0.29%, respectively, measured on wafer at 5 mA in cw operation. This is the first reported TJ-LED in the wavelength range below 240 nm.

#### HL 10.7 Mon 16:45 H34

Influence of the AlGaN MQW growth temperature on the performance characteristics of DUV-LEDs with emission at 235 nm — •MARCEL SCHILLING, NORMAN SUSILO, GIULIA CARDINALI, ANTON MUHIN, FRANK MEHNKE, TIM WERNICKE, and MICHAEL KNEISSL — Technische Universität Berlin, Institute of Solid State Physics, Hardenbergstraße 36, 10623 Berlin, Germany

The realization of efficient deep ultraviolet light emitting diodes (DUV-LEDs) with emission wavelength near 235 nm is very challenging as the photon energy is very close to the band gap of AlN. For AlGaN layers with high Al mole fractions point defects like vacancies and impurities are easily incorporated during metal organic vapor phase epitaxy (MOVPE). Deep levels in the energy band gap associated with these point defects play a decisive role in non-radiative carrier recombination and consequently low internal quantum efficiency (IQE) of DUV-LEDs. Therefore, the understanding of the generation of point defects during the growth of high Al containing AlGaN layers is crucial for the development of efficient DUV-LEDs. In this study the influence of the AlGaN MQW growth temperature on the point defect density in 235 nm DUV-LEDs is investigated. DUV-LEDs were grown by MOVPE with MQW growth temperatures between 850 °C and 1100 °C. Temperature dependent PL measurements show that the point defect incorporation might be controlled with the MOVPE growth temperature. Electroluminescence measurements showed an increase in optical output power from 5  $\mu$ W up to 300  $\mu$ W at 20 mA for 235 nm DUV-LEDs for increasing MQW growth temperatures from 850°C up to 1020°C.

#### HL 10.8 Mon 17:00 H34

Temperature dependent electroluminescence spectroscopy on AlGaN-based 235nm far-UVC LEDs with different active region growth temperature •PAULA VIERCK, JAKOB HÖPFNER, MARTIN GUTTMANN, MARCEL SCHILLING, LUCA SULMONI, ANTON MUHIN, TIM WERNICKE, and MICHAEL KNEISSL -Technische Universität Berlin, Institute of Solid State Physics, Berlin, Germany Light emitting diodes (LEDs) emitting in the far ultraviolet-C (far-UVC) spectral range are promising for applications such as sensing and monitoring of gases, and skin safe disinfection. To improve their external quantum efficiency (EQE), it is crucial to understand the influence of growth parameters on their performance. In this paper, AlGaN-based LEDs emitting around 235 nm were investigated, while their active region growth temperature  $(T_{qrowth})$  was varied between 900 °C and 1100 °C. Temperature dependent light output power-current-voltage characteristics (LIV) and spectra were measured on-wafer for temperatures between 100 K and 340 K. An increasing EQE was observed for increasing  $T_{growth}$ up to 1060 °C with a maximum value of 0.25 % at room temperature. This increase in EQE is attributed to a reduced point defect incorporation at higher active region growth temperatures. This finding is supported by a shift of the EQE vs. temperature maximum from a sample stage temperature of 220 K for an active region growth temperature of 900 °C to 260 K for an active region growth temperature of 1060  $^{\circ}\mathrm{C}$  indicating an increased radiative recombination efficiency as a consequence of reduced point defect incorporation.

#### HL 10.9 Mon 17:15 H34

**UVC-LEDs grown on HTA-AlN templates with low dislocation densities and high Si doping for strain management** — •SARINA GRAUPETER¹, MICHAEL GAIL¹, GIULIA CARDINALI¹, MASSIMO GRIGOLETTO^{1,2}, SYLVIA HAGEDORN², TIM WERNICKE¹, MARKUS WEYERS², and MICHAEL KNEISSL^{1,2} — ¹Technische Universität Berlin, Institute of Solid State Physics, Hardenbergstraße 36, 10623 Berlin, Germany — ²Ferdinand-Braun-Institut (FBH),Gustav-Kirchhoff-Straße 4, 12489 Berlin, Germany

High temperature annealing (HTA) of AlN layers reduces the threading dislocation densitiy of such layers on sapphire substrates below  $10^{9}$  cm⁻² enabling UVC-LEDs with improved efficiencies. However, the HTA AlN-layers are under high compressive strain after cooling down, which leads to strain relaxation and defect formation during further LED heterostructure growth. Growing Si-doped AlN layers on HTA-AlN can reduce the strain. In this work we investigate the influence of such an AlN:Si-interlayer on the growth of UVC-LEDs emitting at 265nm on HTA AlN/sapphire templates, with different thicknesses and offcut angles. XRD measurements show a reduction of the compressive strain from 0.5% to 0.1% depending on layer thickness. Optical characterization with Photoluminescence and Cathodoluminescence shows, that depending on the layer thickness, defect formation in the form of Ga-rich plateus occurs. Electroluminescence measurements of full UVC-LED structures shows emission powers around 0.75mW at 20mA for the templates with 350nm layer thickness, which is comparable to LEDs grown on more expensive standard templates.

#### HL 10.10 Mon 17:30 H34

Distributed polarization doping for 265 nm UVC LEDs — •MASSIMO GRIGOLETTO^{1,2}, SARINA GRAUPETER¹, ANTON MUHIN¹, FEDIR BILCHENKO¹, EVIATHAR ZIFFER¹, NORMAN SUSILO¹, TIM WERNICKE¹, and MICHAEL KNEISSL^{1,2} — ¹Technische Universität Berlin, Institute of Solid State Physics, 10623 Berlin, Germany — ²Ferdinand-Braun-Institut, 12489 Berlin, Germany Distributed polarization doping (DPD) for optoelectronic devices with high aluminium mole fractions in AlGaN alloys is a promising concept for achieving high hole densities and simultaneously minimize the light absorption on the p-side. A continuous grading downward from an higher to a lower aluminium mole fraction in the alloy composition of the AlGaN layer, leads to a steady piezoelectric polarization change creating a negative net charge that is compensated by free holes. In this way, dopant-free without thermal activation is possible, which can exhibit orders of magnitude higher hole densities than comparable magnesium impurity doped AlGaN layers.

In this study we investigate the influence of the DPD graded layer design on the electro optical properties and material properties of 265 nm AlGaN-based LEDs by varying the thickness and aluminium gradient. The LED heterostructures with and without the different DPD-layers are grown by metal organic vapor phase epitaxy and analyzed by electroluminescence measurements, transmission spectroscopy, high resolution X-ray diffraction, atomic force microscopy, capacitance voltage spectroscopy and determination of sheet and contact resistance.

#### HL 10.11 Mon 17:45 H34

Temperature dependent photoluminescence spectroscopy of self-assembled InGaN superlattices embedded in GaN Nanowires — •RUDOLFO HÖTZEL¹, MANUEL ALONSO ORTS¹, TIM GRIEB², JÖRG SCHÖRMANN¹, STEPHAN FIGGE¹, and MARTIN EICKHOFF¹ — ¹University of Bremen, Institute of Solid State Physics, 28359 Bremen, Germany — ²I. Physikalisches Institut, Justus-Liebig-Universität, Heinrich-Buff-Ring 16, 35392 Giessen, Germany

In this work, the structure and optical properties of single InGaN/GaN Nanowires grown by plasma assisted molecular beam epitaxy have been analyzed by micro photoluminescence (PL), scanning transmisssion electron microscopy (STEM) and energy dispersive X-rayspectroscopy (EDX). These nanowires consist of an indium rich core that contains a self assembled InGaN superlattice within a GaN shell. In order to understand the origin of their optical properties, PL was combined with STEM analysis to idendify single nanowire structures. Temeperature-dependent as well as polarized PL were conducted on isolated nanowires and revealed an emission consisting of broader bands at room temperature and multiple narrow peak superpositions at low temperatures. The overall emission ranges from 1,8 eV to up to 2,9 eV. One contributing factor to their emission is the indium distribution within the superlattice, which was determined by EDX. A polarization dependence of the PL signal with respect to the growth direction was observed at 4K and room temperature and ascribed to the indium rich core (parallel contributions) and self assembled superlattice (perpendicular contributions).

#### HL 10.12 Mon 18:00 H34

Luminescence Characteristics of GaInN/GaN Multi Quantum Wells with Ga and N Polarity — •SAMAR HAGAG, MALTE SCHRADER, HEIKO BREMERS, UWE Rossow, and ANDREAS HANGLEITER — Institut f. Angewandte, TU Braunschweig, Germany

The optical properties of Ga- and N-polar GaInN/GaN Multi Quantum Wells (MQW) grown on sapphire and bulk N-polar GaN substrates, respectively, using metal-organic chemical vapor deposition were investigated using photoluminescence (PL) and time-resolved photoluminescence (TRPL) spectroscopy. The low temperature PL spectrum of N-polar GaInN/GaN MQW showed a reduced PL intensity and broad emission peak compared to their Ga-polar counterparts and shorter PL decay times of N-polar GaInN/GaN MQW were observed in low temperature TRPL measurements. Using non-resonant excitation, N-polar GaN PL spectra at low temperature have shown the presence of luminescence lines associated with structural defects of the type I1 basal-plane stacking faults. The low PL intensity and short PL decay time at low temperature of N-polar GaInN/GaN MQW indicate the existence of non-radiative recombination at low temperature likely caused by partial dislocations associated with the stacking faults. For the fabrication of pyramidal nanostructures serving as nanooptical light emitters, wet etching of N-polar GaInN/GaN MQW in KOH solution has been used. The etched N-polar samples have shown an improved luminescence and the absence of stacking fault-related luminescence lines. Optimization of the growth procedure for N-polar GaInN/GaN MQW is required in order to reduce structural defects.

#### HL 10.13 Mon 18:15 H34

Pump-probe studies with varying excitation wavelengths applied for GaInN/GaN single quantum wells — •MALTE SCHRADER, RODRIGO DE VASCONCELLOS LOURENCO, HEIKO BREMERS, UWE ROSSOW, and ANDREAS HANGLEITER — Institut für Angewandte Physik & Laboratory for Emerging Nanometrology, Technische Universität Braunschweig, Germany

The goal of this study is to characterize the ultra-fast carrier dynamics in c-plane GaInN/GaN single quantum wells (SQWs). To make transmission experiments possible the samples were grown on double-side polished sapphire by MOVPE. Furthermore we use time-resolved photoluminescence (TRPL) to measure the radiative and non-radiative carrier lifetimes of the samples from 5 K up to 300

Concept of an all-optical THz near-field microscope for flakes of 2D materials — •AHMAD-REZA ETEMADI, SEBASTIAN MATSCHY, AHANA BHATTACHARYA, and MARTIN MITTENDORFF — Department of physics, University of Duisburg-Essen, 47057 Duisburg, Germany

While THz spectroscopy is an excellent tool to investigate the free charge carriers in many semiconducting materials, the long-wavelength is an inherent feature linked to a large spot size in the millimeter range, and thus large samples are required. Small flakes of two-dimensional materials exfoliated from bulk crystals are usually much smaller than the spot size of a conventional THz spectrometer. The direct detection of the THz signal in the vicinity of the flake gains the phase and amplitude information with a higher spatial resolution. This is accessible by placing the sample directly on top of an electro-optic crystal. Sampling the THz field at the flake position gives access to the complex conductivity and thus the carrier density as well as the carrier mobility. A frequency-doubled fiber laser with a pulse duration of about 80 fs at 780 nm is exploited to generate and sample the THz field. GaSe, and ZnTe are employed as electro-optic crystals. Here we present the current state of the near-field microscope and the first measurements of the spatial resolution. The experimental results are accompanied by rigorous modeling of the THz propagation within the electro-optic crystal.

#### HL 11.3 Mon 15:30 H36

Ab initio description of valley-selective circular dichroism — •MAXIMILIAN SCHEBEK¹, YIMING PAN², CECILIA VONA¹, CLAUDIA DRAXL¹, and FABIO CARUSO² — ¹Institut für Physik and IRIS Adlershof, Humboldt-Universität zu Berlin, Germany — ²Institut für Theoretische Physik und Astrophysik, Christian-Albrechts-Universität zu Kiel, Kiel, Germany

By enabling control of valley degrees of freedom, valley-selective circular dichroism (VSCD) has become a key concept in valleytronics. In this work, we present an *ab initio* many-body theory of VSCD based on the Bethe-Salpeter equation. Our approach provides a new route to accurately predict the degree of valley polarization upon absorption of circularly polarized light. With the example of monolayer transition-metal dichalcogenides, we further show that valley excitons - bound electron-hole pairs formed at either the K or  $\overline{K}$  valley upon absorption of circularly-polarized light - are chiral quasiparticles characterized by a finite orbital angular momentum (OAM). Beside governing the interaction with circularly polarized light, the OAM results in a finite magnetization of excitons, which in turn provides a route for the interaction of excitons with external magnetic fields and other spin-orbital degrees of freedom.

#### HL 11.4 Mon 15:45 H36

Dark and bright exciton dynamics probed by time-resolved photoluminescence in hBN-encapsulated MoWSe₂ monolayers — •JULIAN SCHRÖER^{1,3}, JOANNA KUTROWSKA-GIRZYCKA², LESZEK BRYJA², JOANNA JADCZAK², and JÖRG DEBUS¹ — ¹TU Dortmund, Experimentelle Physik 2, AG Debus — ²Wroclaw University of Science and Technology, Department of Experimental Physics — ³Universität Rostock, Institut für Physik, AG Korn: Zweidimensionale Kristalle und Heterostrukturen

Semiconducting monolayers of ternary MoWSe₂ alloys combine the unique properties of the binary transition metal dichalcogenide (TMDC) materials

K. By using a transmission-mode degenerate pump-probe technique at 300 K the generated state occupation in the SQW can be observed directly. Different excitation wavelengths produced using an optical parametric amplifier provided pulses of nominal 35 fs duration.

We observe carrier lifetimes at room temperature in the low ns range by TRPL, which are strongly impacted by nonradiative processes. Pump-probe at 300 K gives a fast characteristic relaxation time in the low ps range and a slower component associated with the decay observed in TRPL. This indicates that a fast initial non-equilibrium relaxation is followed by a component representing recombination of a quasi-equilibrium carrier ensemble. A surprising observation is the relatively slow relaxation time of a few ps, which one would rather expect to be in the femtosecond range.

Location: H36

MoSe₂ and WSe₂. The alloying leads to, for example, brightening of the momentum- and spin-forbidden dark exciton states. Detailed studies on the dynamics of these brightened dark states are missing. We report on the exciton and trion formation lying in the 1-3 ps range, while the decay time approaches hundreds picoseconds. Additionally, strong dependences on the temperature and exciting laser light polarization are observed. In time-resolved and stationary photoluminescence measurements, we reveal the impact of the exciton and trion photoluminescence indicate possible contributions from chiral phonons as well as electrons and holes from different valleys of the Brillouin zone. Our work is a further step towards a deeper understanding of the dynamics of dark excitons in TMDC materials.

Signatures of a degenerate many-body state of interlayer excitons in a van der Waals heterostack — •JOHANNES FIGUEIREDO¹, LUKAS SIGL¹, FLO-RIAN SIGGER¹, JONAS KIEMLE¹, MIRCO TROUE¹, URSULA WURSTBAUER², and ALEXANDER HOLLEITNER¹ — ¹ Walter-Schottky-Institut, Technical University of Munich — ²Institute of Physics, Westfälische Wilhelms-Universität Münster In atomistic van der Waals heterostacks of transition metal dichalcogenides, the reduced dimensionality and changing dielectric environement leads to the formation of stronlgy bound excitons. Optically generated interlayer excitons exhibit an additional spatial separation of the electron-hole pair with a reduced overlap of the electrons' and holes' wave-functions, evidenced through their long lifetimes. These long-lived, photogenerated composite bosons yield several signatures of a quantum degenerate many-body system at cryogenic temperatures. The emergence of this state is in accordance with theoretical predictions of a critical condensation temperature above 10K. We present new insights into the phase-diagram of such interlayer exciton ensembles. [1] [1] L. Sigl *et al.*, Phys. Rev. Research 2, 042044(R) (2020)

exciton species in highly doped  $WS_2$  monolayers — DAVID TIEDE, •HOSSEIN OSTOVAR, HENDRIK LAMBERS, NIHIT SAIGAL, and URSULA WURSTBAUER — Institute of Physics, University of Münster, Münster, Germany

Semiconducting two-dimensional transition metal dichalcogenides such as WS₂ excel due to their exciton dominated light-matter interaction even at room temperature (RT) that is highly tunable by external stimuli such as doping, light excitation, dielectric environment, or strain [1]. In this work, an optimized field effect structure utilizing a polymer electrolyte top gate electrode is employed to study the evolution of the optical response in monolayer WS₂ at RT in dependence of doping by means of photoluminescence and spectroscopic imaging ellipsometry measurements. The huge geometrical gate capacitance enables capacitance spectroscopy of the conduction band as well as valence band edge yielding a gap energy of 2.6eV in agreement with the determination from the exciton Rydberg series. The gate allows the injection of large electron and hole densities exceeding  $10^{14} cm^{-2}$ , sufficient to enable the exciton Mott transition. The obtained doping dependent emission and absorption spectra also facilitate the identification of phonon activated, neutral and charged exciton species as well as dressed excitons in a fermi sea. We acknowledge financial support via DFG WU 637/7-1 and SPP2244. [1] U. Wurstbauer et al. J. Phys. D: Appl. Phys. 50, 173001 (2017).

#### HL 11.7 Mon 16:45 H36

Pump probe signatures of interlayer excitons in TMDC heterostructures —
 HENRY MITTENZWEY, MANUEL KATZER, ANDREAS KNORR, and MALTE SELIG
 — Institut für Theoretische Physik, Nichtlineare Optik und Quantenelektronik, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin, Germany

TMDC heterobilayers are promising candidates for novel optoelectronic applications, since they exhibit long-lived excitonic states with spatially separated electrons and holes located in different layers. The relaxation dynamics of these interlayer excitons and their interplay with intralayer excitons are still under investigation.

Here, we present a microscopic description for the phonon and tunneling induced formation and relaxation of intra- and interlayer excitons in a MoSe₂/WSe₂ stack. Based on the microscopic dynamics we calculate the pump probe signal for intra- and interlayer transition and their population dynamics including hot exciton bottleneck effects.

#### HL 11.8 Mon 17:00 H36

Angle- and polarization-resolved luminescence from suspended and hBN encapsulated  $MoSe_2$  monolayers — •BO HAN¹, SVEN STEPHAN¹, JOSHUA J.P. THOMPSON², MARTIN ESMANN¹, CARLOS ANTÓN-SOLANAS¹, HANGYONG SHAN¹, SAMUEL BREM³, CHRISTOPH LIENAU¹, KENJI WATANABE⁴, TAKASHI TANIGUCHI⁴, MARTIN SILIES¹, ERMIN MALIC^{2,3}, and CHRISTIAN SCHNEIDER¹ — ¹Carl von Ossietzky Universität, Oldenburg, Germany. — ²Philipps Universität, Marburg, Germany. — ³Chalmers University of Technology, Gothenburg, Sweden. — ⁴National Institute for Materials Science, Tsukuba, Japan.

We apply combined angle- and polarization-resolved spectroscopy to explore the interplay of excitonic physics and phenomena arising from the commonly utilized encapsulation on the optical properties of atomically thin transition metal dichalcogenides. In our study, we probe  $MoSe_2$  monolayers which are prepared in both a suspended and an encapsulated manner. We show that the hBN encapsulation significantly enhances the linear polarization of excitons PL at large emission angles. This degree of linear polarization of excitons can increase up to 17 % in the hBN encapsulated samples. As confirmed by finite-difference time-domain simulations, it can be directly connected to the optical anisotropy of the hBN layers. In comparison, the linear polarization at finite exciton momenta is significantly reduced in suspended  $MoSe_2$  monolayer, and only becomes notable at cryogenic conditions. This phenomenon strongly suggest that the effect is rooted in the k-dependent anisotropic exchange coupling inherent in 2D excitons.

Photonic and Phononic Couplings in Hybrid High-Q Nanocavities with Encapsulated MoS2 Monolayer — •CHENJIANG QIAN¹, VIVIANA VILLAFAÑE¹, PEDRO SOUBELET¹, ALEXANDER HÖTGER¹, TAKASHI TANIGUCHI², KENJI WATANABE², NATHAN WILSON¹, ANDREAS STIER¹, ALEXANDER HOLLEITNER¹, and JONATHAN FINLEY¹ — ¹Walter Schottky Institut and Physik Department, Am Coulombwall 4, 85748 Garching, Germany — ²National Institute for Materials Science, 1-1 Namiki, Tsukuba 305-0044, Japan

Monolayer TMDs are ideal active materials for solid-state cQED. However, the direct cou-pling of TMDs to 0D nanocavities whilst preserving pristine excitonic properties and large cavi-ty-TMD overlap remains a challenge. Most commonly, non-encapsulated TMDs are stacked on top of prefabricated photonic structures using pick-and-place assembly. In this case, environ-mental disorders strongly perturb the excitonic properties. Whilst disorder can be mitigated by full hBN encapsulation, this approach moves the TMD away from the cavity field, thereby, trad-ing spatial coupling for homogeneous linewidth. Here, we integrate hBN/MoS2/hBN heterostruc-tures to Si3N4 nanobeams as hybrid nanocavities. Our approach solves the trade-off problem by making the unpatterned heterostructure a functional part of the cavity field. Therefore, the pristine excitonic quality, high cavity mode Q-factor > 10000, and the strong cavity MoS2 overlap are achieved simultaneously. We study the coupling of MoS2 excitons to the cavity optical and vibrational modes using PL and Raman spectroscopy, and novel coupling phenomena are ob-served based.

Terahertz free carrier absorption to modulate the optical properties of nanometer-thick van der Waals semiconductors — •TOMMASO VENANZI^{1,2}, MALTE SELIG³, ALEXEJ PASHKIN², STEPHAN WINNERL², MANUEL KATZER³, HIMANI ARORA², ARTUR ERBE², AMALIA PATANE⁴, ZAKHAR R. KUDRYNSKYI⁴,

ZAKHAR D. KOVALYUK⁵, LEONETTA BALDASSARRE¹, ANDREAS KNORR³, MAN-FRED HELM², and HARALD SCHNEIDER² — ¹Sapienza University of Rome, 00185 Rome, Italy — ²Helmholtz-Zentrum Dresden-Rossendorf, 01328 Dresden, Germany — ³Technical University Berlin, 10623 Berlin, Germany — ⁴University of Nottingham, Nottingham NG7 2RD, UK — ⁵The National Academy of Sciences of Ukraine, 58001 Chernivtsi, Ukraine

Free carriers in doped semiconductors absorb terahertz radiation when the frequency of the electromagnetic field is lower or comparable to the plasma frequency of the system. This phenomenon can be used to manipulate the optical response of the material. We present here the results of two different experiments performed at the infrared free-electron laser FELBE on atomically-thin van der Waals semiconductors. In MoSe2 monolayers, we observe a terahertz-induced redshift of the trion resonance. Terahertz absorption induces an average high momentum to the carriers and this momentum gets transferred during the trion formation, resulting in a net redshift in the absorption. In few-layer InSe, the terahertz pulses induce a transient quenching of the photoluminescence emission. In both cases, a microscopic study of the hot carrier distribution cooling is also presented.

Theory of Exciton-Phonon Interaction for Stationary State Experiments in Atomically Thin Semiconductors — •MANUEL KATZER, ANDREAS KNORR, and MALTE SELIG — Nichtlineare Optik und Quantenelektronik, Technische Universität Berlin, Hardenbergstr. 36, 10623 Berlin, Germany

Atomically thin semiconductors exhibit tightly bound electron hole pairs which stimulated exciton research in recent years [1]. While typical experimental techniques include the cw excitation of the material, only few is known theoretically about the related exciton dynamics and the formation of non-equilibrium steady states. Based on excitonic Boltzmann scattering equations, we demonstrate that the formation of such stationary states is also accompanied with the formation of phonon replica in the photoluminescence excitation spectrum [2], in agreement with available experiments [3]. So far, many studies focused on the understanding of exciton dynamics in the limit of weak excitation. Above this limit, we find both bosonic but also fermionic contributions to the thermalization, due to the co-bosonic nature of excitons. Based on a Heisenberg equation of motion ansatz [4], we discuss the first order of non-linear exciton-phonon interaction exceeding the classical Boltzmann scattering limit, in order to analyze the excitor to thermalization at elevated excitation densities.

Ultrafast control of spins in transition metal dichalcogenides — •ABHIJEET KUMAR¹, DENIS YAGODKIN¹, DOUGLAS J. BOCK¹, NELE STETZUHN^{1,2}, SVI-ATOSLAV KOVALCHUK¹, ALEXEY MELNIKOV³, PETER ELLIOTT², SANGEETA SHARMA², CORNELIUS GAHL¹, and KIRILL I. BOLOTIN¹ — ¹Department of Physics, Freie Universität Berlin, 14195 Berlin, Germany — ²Max-Born-Institut für Nichtlineare Optik und Kurzzeitspektroskopie, Max-Born Straße 2a, 12489 Berlin, Germany — ³Institute for Physics, Martin Luther University Halle, 06120 Halle, Germany

Control and manipulation of the coupled spin/valley degrees of freedom in transition metal dichalcogenides (TMDs) are essential for their applications in spin/valleytronics. Here, we achieve ultrafast control of spins in TMDs via two distinct approaches, namely, proximity-coupling to another TMD and strain. First, we use a type-II heterostructure  $MoS_2 - MoSe_2$  to enable directional optical pumping of spin-polarized carriers. We find that the photoexcited carriers conserve their spin for both tunneling directions across the interface. We observe dramatic differences in the spin/valley depolarization rates for electrons and holes, 30 and <1  $ns^{-1}$ , respectively, which relates to the disparity in the spin-orbit splitting in conduction and valence bands of TMDs. Second, by applying biaxial strain (exceeding 2%) in monolayer  $WSe_2$ , we evidence the hybridization of the conduction bands with the in-gap localized defects that brightens the lowest-lying dark excitons. This novel hybrid state exhibits unique spin/valley signatures which are strongly manipulated on picosecond-timescale by strain and doping.

**Full Wafer Property Control of Local Droplet Etched GaAs Quantum Dots** — •HANS-GEORG BABIN, NIKOLAI BART, MARCEL SCHMIDT, NIKOLAI SPITZER, ANDREAS D. WIECK, and ARNE LUDWIG — Ruhr-Universität Bochum, Deutschland

Local droplet etched GaAs quantum dots (LDE-QDs) are a promising candidate for excellent single and entangled photon sources [1]. It is important that the carefully developed and highly complex structures are matched perfectly with the embedded QDs [2]. In this submission, we show a way to control QD properties during molecular beam epitaxy on a single wafer, which opens the opportunity to find optimally fitting QDs for the desired experiments by just changing the position on the wafer.

We induce flux gradients by stopping sample rotation and using the parallax of the effusion-cells, resulting in a gradual change of deposited material and cell flux. By this we can vary properties of the QDs like density and emission wavelength on a single wafer. In this work, the widest achieved wavelength shift of the ground state emission energy at 100 K extends over the range of 795 nm to 737 nm [3]. The induced surface roughness modulation additionally induces a stripe-patterned modulation, which was shown before only with Stranski-Krastanov QDs [4].

HL 12.3 Tue 10:15 H32

Towards MOVPE-grown c-band emitting InAs quantum dots on a Si (001) substrate based on heterogeneous integration of membrane and epitaxial regrowth — •PONRAJ VIJAYAN, ROBERT SITTIG, SIMONE LUCA PORTALUPI, MICHAEL JETTER, and PETER MICHLER — Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology (IQST) and SCOPE, Universität Stuttgart, Germany

Silicon photonics for telecommunications applications has garnered much attention in recent decades. The optical transparency and the large refractive index contrast of silicon in the telecommunication wavelengths allow the implementation of high-density photonic integrated circuit. The drawback of silicon photonics is that there is no native light source due to the indirect band-gap nature of silicon. Integration of III-V material, which offers outstanding optical emission properties, on silicon provides a potential solution. The monolithic integration i.e. the direct growth of III-V materials on silicon is the most desired approach. However, it is very challenging because of large lattice mismatch and material polarity difference between the III-V materials and silicon. An alternate monolithic approach is through heterogeneous integration of thin III-V membrane using direct bonding techniques followed by epitaxial regrowth. Our group has previously developed InAs QD/InGaAs MMB/GaAs substrate structures for long-distance optical fiber applications. Here, we report on the route to monolithically integrate the telecom C-band emitting InAs QD on a wafer bonded GaAs/Si substrate using MOVPE.

#### HL 12.4 Tue 10:30 H32

Non-vapor-liquid-solid selective area epitaxy of GaAs1-xSbx nanowires on silicon — Akhil Ajay¹, Hyowon Jeong¹, •Haiting Yu¹, Nitin Mukhundhan¹, Tobias Schreitmüller¹, Markus Döblinger², and Gregor Koblmüller¹ — ¹Walter Schottky Institute & Physics Department Technical University of Munich, Garching, Germany — ²Ludwig-Maximilians-University, Munich, Germany

Epitaxial growth of semiconductor nanowires(NWs)is generally known to proceed via a vapor-liquid-solid(VLS). However, an absence of the liquid droplet would be ideal for III-V NW integration on Si and the exploration of atomically abrupt NW heterostructures. In this work, we report a novel non-VLS growth mechanism for the selective area growth of GaAs1-xSbx NWs on Si(111)substrates using molecular beam epitaxy. Non-VLS NWs are known to have many structural defects and poor aspect ratios. Surprisingly, we observe an increased axial growth and aspect ratio in these NWs by adding low concentrations of Sb. This also contrasts the commonly believed enhancement in radial growth for VLS growth claimed to be due to the surfactant effect of Sb. We report on realizing control over aspect ratio and yield by optimizing SiO2 mask hole diameter, growth time and growth temperature. In this process we observe a hitherto unreported dynamic growth rate that increases with time.We also investigate the initial growth of such non-VLS NWs forming inside the SiO2 mask opening,describing the facets and morphology.We also explore n-doping in these NWs with Si which also helps in realizing nearly unity yield and homogeneity.

#### HL 12.5 Tue 10:45 H32

**Epitaxial growth and characterization of multilayer site-controlled InGaAs quantum dots based on the buried stressor method** — •IMAD LIMAME, CHING-WEN SHIH, ALEXEJ KOLTCHANOV, MORITZ PLATTNER, JOHANNES SHALL, SVEN RODT, and STEPHAN REITZENSTEIN — Institute for Solid State Physics, Technical University of Berlin, Germany

The buried-stressor epitaxial growth concept is a prim approach for the realization of site- and number- controlled quantum dots (QDs) with optical high quality. This advanced technique has a wide application spectrum including nanophotonics devices such as single-photon sources (SPSs), microlasers, and emitter-arrays for neuromorphic photonic computing. Here, we report on the development of multi-layer site-controlled QDs (ML-SCQDs) integrated in micropillar laser arrays with low threshold pump power. The buried-stressor technique utilizes a partially oxidized buried AlAs aperture to engineer the strain profile in the following GaAs capping layer and control the position and number of the QDs at the GaAs surface. Thanks to the unetched GaAs surface, the buried-stressor SCQDs exhibits excellent optical properties in comparison to other SCQDs growth approaches, using for instance nano-hole arrays as nucleation centers. Additionally, after integration into micropillar cavities the partially oxidized aperture results in additional confinement of the optical mode in lateral direction, leading to lower mode volume and higher Q-factor for a given micropillar geometry. The grown ML-SCQDs are investigated using atomic force microscopy, micro-photo- and cathodoluminescence spectroscopy.

HL 12.6 Tue 11:30 H32 Growth of shallow GaAs quantum dots and investigation of their optical properties — •MORITZ LANGER¹, NAND LAL SHARMA¹, GHATA SATISH BHAYANI¹, ANKITA CHOUDHARY¹, OLIVER G. SCHMIDT², and CASPAR HOPFMANN¹ — ¹Institute for Integrative Nanoscience - IFW Dresden, Dresden, Germany — ²Center for Materials, Architectures, and Integration of Nanomembranes (MAIN), TU Chemnitz, Chemnitz, Germany

In recent years local droplet etching developed into an attractive growth process for strain-free semiconductor quantum dots. Typically, conical nanoholes etched into Al0.15Ga0.85As buffer layer by the droplet etching process using molecular beam epitaxy machine [1], have a width of about 50 nm and a depth of 15 nm. By using migration enhanced epitaxy, these nanoholes filled with GaAs and capped with an Al0.15Ga0.85As layer, buried around 6 nm high quantum dot structures of high optical quality are obtained. For enhanced interaction of quantum dots with external stimuli e.g. magnetic fields of thin films -, it is desirable to produce quantum dots close to the surface. Consequentially, the nature of the sample surface and the electronic and optical properties the quantum dot acannot be considered independently. For this purpose, the influence of capping layer thickness on the optical properties of GaAs/Al0.15Ga0.85As quantum dots are investigated using photoluminescence spectroscopy.

#### HL 12.7 Tue 11:45 H32

**Local droplet etching on InAlAs/InP surfaces with InAl droplets** — •YITENG ZHANG¹, XIN CAO¹, CHENXI MA¹, YINAN WANG¹, BENEDIKT BRECHTKEN², ROLF J. HAUG², EDDY P. RUGERAMIGABO¹, MICHAEL ZOPF¹, and FEI DING¹ — ¹Institut für Festkörperphysik, Leibniz Universität Hannover, Hannover, Germany — ²Laboratorium für Nano- und Quantenengineering, Leibniz Universität Hannover, Hannover, Germany

GaAs quantum dots (QDs) grown by local droplet etching (LDE) have been studied extensively in recent years. The LDE method allows for high crystallinity, as well as precise control of the density, morphology, and size of QDs. These properties make GaAs QDs an ideal candidate as single photon and entangled photon sources at short wavelengths (<800 nm). For technologically important telecom wavelengths, however, it is still unclear whether LDE grown QDs can be realized. In this work, we study Indium-Aluminum (InAl) droplet etching on ultra-smooth In0.55Al0.45As surfaces on InP substrates, with a goal to lay the foundation for growing symmetrical and strain-free telecom QDs using the LDE method. We report that both droplets start to etch nanoholes at a substrate temperature above 415 °C, showing varying nanohole morphology and rapidly changing density (by more than one order of magnitude) at different temperatures. Al and In droplets are found to not intermix during etching, and instead etch nanoholes individually. The obtained nanoholes show a symmetric profile and very low densities, enabling infilling of lattice-matched InGaAs QDs on In-AlAs/InP surfaces in further works.

### HL 12.8 Tue 12:00 H32

Influence of miscut angle on the exciton fine structure in GaAs/AlAs(111) and InAs/GaAs(111) quantum dots — •GEOFFREY PIRARD¹ and GABRIEL BESTER^{1,2} — ¹Physical Chemistry and Physics Departments, University of Hamburg, Luruper Chaussee 149, D-22761 Hamburg, Germany — ²The Hamburg Centre for Ultrafast Imaging, University of Hamburg, Luruper Chaussee, 149, D-22761 Hamburg, Germany

Self-assembled quantum dots (QDs) grown on (111) surfaces constitute, in principle, excellent solid-state quantum emitters of polarized-entangled photon pairs making them promising candidates for quantum information processing applications. However, in practice, the growth on such substrates introduces limitations on the growth rate hindering the generation of sufficiently intense signal for such applications. One potential solution to address this problem is to grow these systems on misoriented substrates.

Using atomistic, million-atom screened pseudopotential theory together with configuration interaction, we perform numerical calculations and analyze the influence of the miscut on the exciton fine structure (FS) of GaAs/AlAs(111) and InAs/GaAs(111) QDs. We show that the presence the miscut modifies the spatial distribution of the electron and hole wave functions, which elongate along the [110] crystal axis. In turn, the polarization of the excitonic states acquires a clear preferential orientation and this effect is strongly enhanced in strained systems. Finally, the FS splitting increases with the miscut within a range depending on the material and the amplitude of the miscut.

### HL 12.9 Tue 12:15 H32

**Controlled MOF growth on functionalized carbon nanotubes** — •MARVIN J. DZINNIK¹, NECMETTIN E. AKMAZ¹, ADRIAN HANNEBAUER², PETER BEHRENS², and ROLF J. HAUG¹ — ¹Leibniz Universität Hannover, Institut für Festkörperphysik, 30167 Hannover — ²Leibniz Universität Hannover, Institut für Anorganische Chemie, 30167 Hannover

The class of metal organic frameworks (MOFs) is continuously growing. These materials consist of inorganic building blocks, held together by organic linker molecules. Schulze *et al.* [1] showed that adding functionalized multi-walled carbon nanotubes (MWCNTs) to a UiO-66 synthesis drastically decreased the nucleation time. The MOFs preferably grow on the MWCNT until they fully

encapsulate it. We demonstrate a mechanism to spacially control the UiO-66 MOF growth on individual carbon nanotubes and deplete the encapsulation. The MWCNTs are drop-casted on a silicon dioxide surface and then locally modified. The samples are then submerged in the synthesis solution. This process leads to a growth of MOF crystals on the MWCNT surface leaving the modified areas depleted. With this method we are able to define lines free of MOF on the length of a single MWCNT down to several hundred nanometres for example to electrically contact the tubes ends.

### HL 12.10 Tue 12:30 H32

Surface quantum dots with pure, coherent, and blinking-free single photon emission — •MICHAEL ZOPF¹, XIN CAO¹, JINGZHONG YANG¹, PENGJI LI¹, TOM FANDRICH¹, EDDY P. RUGERAMIGABO¹, CHENXI MA¹, ROBERT KEIL², FRED-ERIK BENTHIN¹, BENEDIKT BRECHTKEN¹, ROLF J. HAUG^{1,4}, YITENG ZHANG¹, SUSANNE WOCHE³, ZHAO AN¹, CONSTANTIN SCHMIDT¹, and FEI DING^{1,4} — ¹Institut für Festkörperphysik, Leibniz Universität Hannover, Germany — ²Fraunhofer-institut für Angewandte Festkörperphysik IAF, Freiburg, Germany — ³Institut für Bodenkunde, Leibniz Universität Hannover, Germany — ⁴Laboratorium für Nano- und Quantenengineering, Leibniz Universität Hannover,

The surface of semiconductor micro- and nanostructure-based devices has a major impact on their performance. Disorder and defects in the crystal typically lead to electronic states in the bandgap, degrading charge carrier transport and radiative recombination. In next generation semiconductor devices such as single or entangled photon sources, surface effects lead to low efficiency, photon dephasing, blinking or spectral jittering. Here we show unprecedented optical quality of GaAs quantum dots that are grown directly on an AlGaAs surface and passivated with 1-Octadecanethiol. Single photons are generated with 98.8 % purity, 78 % indistinguishability and narrow linewidths down to 7 µeV, close to the radiative limit. The emission is unaffected by the surface and shows no blinking over more than 12 orders of magnitude in time, yielding an on-fraction of 99.7 %. These results are likely to stimulate new fundamental studies and quantum applications.

### HL 13: Ultra-Fast Phenomena

Time: Tuesday 9:30-12:15

HL 13.1 Tue 9:30 H33

Ultrafast hot charge carrier transport across graphene nano-gaps — •JOHANNES GRÖBMEYER, PHILIPP ZIMMERMANN, and ALEXANDER HOLLEITNER — Walter Schottky Institute and Physics Department, Technical University of Munich, Germany

We study the hot charge carrier transport across nanoscale junctions for ultrafast electric pulse generation on the nanometer scale. To avoid laser ablation problems common to metal based photoemission devices, we investigate the possibility of graphene nanojunctions positioned on a sapphire substrate. We create the emitter-collector structure by bisecting a graphene strip utilizing a helium ion beam to create a ~30 nm wide nano-gap. Due to substrate interaction with the helium ion beam this gap is filled by a bulge of highly defected sapphire. Measuring the ultrafast and time-integrated charge carrier transport, we find evidence of an ultrafast photoemission across this gap. Our work demonstrates that graphene based nano-gaps have the potential of replacing photoconductive switches at low temperatures.

### HL 13.2 Tue 9:45 H33

Studying hot electron transport in bismuth with transient all optical pumpprobe spectrocopy — •FABIAN THIEMANN¹, GERMÁN SCIAINI², ALEXANDER KASSEN¹, and MICHAEL HORN-VON HOEGEN¹ — ¹University of Duisburg-Essen, Lotharstr. 1, 47057 Duisburg, Germany — ²University of Waterloo, 200 University Avenue West, Waterloo, ON N2L 3G1, Canada

Bismuth as a Peierls-Jones distorted semimetal is famous for its photoexcited coherent optical phonon modes and its delicate interplay with the electron dynamics. Especially the  $A_{1g}$  phonon mode at  $\approx 3$  THz and its characteristic softening upon photoexcitation is easily accessible and can be studied with all optical pump-probe spectroscopy, solely by monitoring the change in reflectivity  $\Delta R/R_0$ . The number of excited carriers in bismuth influences the atomic potential energy surface and thus the mode's softening. Therefore, in turn, we employed the redshift of the  $A_{1g}$  mode as a robust quantity to determine the spatial distribution of excited carriers and the absorbed energy density in the carrier system. A homogenous distribution due to ultrafast transport of hot carriers was observed, limited by an effective carrier penetration depth that is way beyond the optical skin depth.

Location: H33

HL 13.3 Tue 10:00 H33

Ultrafast Dynamics of Inter- and Intraband Transitions in GaP Investigated by fs-Time Resolved Ellipsometry —  $\cdot$ Rüdiger Schmidt-Grund¹, Noah STIEHM¹, ERICH RUNGE¹, MARTIN ZAHRADNÍK², SHIRLY ESPINOZA², MATEUSZ REBARZ², JAKOB ANDREASSON², and STEFAN KRISCHOK¹ — ¹TU Ilmenau, Technische Physik I and Theoretische Physik I, Weimarer Straße 32, 98693 Ilmenau, Germany — ²ELI Beamlines, Fyzikální ústav AV ČR, Za Radnicí 835, 25241 Dolní Břežany, Czech Republic

We discuss the ultrafast dynamics of the dielectric function after excitation with a high-power laser pulse of the semiconductor GaP in the spectral range around the fundamental absorption edge, measured by pump-probe fs-time resolved spectroscopic ellipsometry [1,2]. The excited hot carriers cause several effects: we observe in different regions of the Brillouin zone both, Pauli-blocking of valence-to-conduction-band transitions and arising of new intra-conduction and -valence-band transitions, enabled by carrier scattering within the Brillouin zone and in particular tunnelling to the indirect minimum. We understand our observations with the help of density functional theory from which we derived band structure, transition matrix elements and the joint density of states between bands energetically relevant in our study. Our results show long lasting nonequilibrium phenomena (> ns), probably due to carrier trapping processes.

### HL 13.4 Tue 10:15 H33

Multiparameter determination of time-resolved photoluminescence measurements — •SEBASTIAN BOHM¹, MAX GROSSMANN¹, STEFAN HEYDER¹, KLAUS SCHWARZBURG², PETER KLEINSCHMIDT¹, ERICH RUNGE¹, and THOMAS HANNAPPEL¹ — ¹Fakultät für Mathematik und Naturwissenschaften, Technische Universität Ilmenau, Ehrenbergstraße 29, 98693 Ilmenau — ²Institut Solare Brennstoffe, Helmholtz-Zentrum Berlin für Materialien und Energie, Hahn-Meitner-Platz 1, 14109 Berlin

Accurate knowledge of radiative, non-radiative, and trapping photoluminescence lifetimes is crucial for the understanding and improvement of semiconductor devices. In principle, these parameters can be obtained from timeresolved photoluminescence spectroscopy (TRPL) measured at different excitation level, see, e.g., M. W. Gerber and R. N. Kleiman, J. Appl. Phys. 122, 095705 (2017), DOI 10.1063/1.5001128. We show that a full multi-parameter estimation based on a suitable maximum likelihood estimator and state-of-theart non-linear multi-parameter optimization yields superior results compared to conventional data analysis.

HL 13.5 Tue 10:30 H33 Strategies for Automating Femtosecond Time-Resolved Ellipsometry Data Analysis — •NOAH STIEHM¹, YIXUAN ZHANG², ERICH RUNGE³, STE-FAN KRISCHOK¹, HONGBIN ZHANG², and RÜDIGER SCHMIDT-GRUND¹ — ¹Technische Universität Ilmenau, Fachgebiet Technische Physik I, Weimarer Straße 32, 98693 Ilmenau, Germany — ²Technische Universität Darmstadt, Research Group Theory of Magnetic Materials, Otto-Berndt-Straße 3, 64287 Darmstadt — ³Technische Universität Ilmenau, Fachgebiet Theoretische Physik I, Weimarer Straße 32, 98693 Ilmenau, Germany

With the recently developed experimental method of femtosecond time-resolved spectroscopic ellipsometry [1], it is possible to obtain the transient dielectric function of a sample after excitation in a pump-probe scheme. However, modeling the experimental data manually with established ellipsometry modeling workflows is cumbersome and significantly reduces the throughput of the experiment. Here we present strategies I) to formalize the experience and physical intuition usually entering modeling strategies, II) to reduce computational costs by application of dimensionality reduction techniques, especially in the additionally required ab-initio theory calculations, and III) to improve stability, to enable an automated modeling pipeline with minimal human intervention. HL 13.6 Tue 11:00 H33

**Coherent Dynamics of Charge-Transfer Excitons** — •MARKUS STEIN¹, MELANIE FEY¹, CHRISTIAN FUCHS², WOLFGANG STOLZ², KERSTIN VOLZ², and SANGAM CHATTERJEE¹ — ¹Institute of Experimental Physics I and Center for Materials Research, Justus-Liebig-University Giessen, Heinrich-Buff-Ring 16, D-35392 Giessen, Germany — ²Department of Physics and Material Sciences Center, Philipps-Universität Marburg, Renthof 5, 35032 Marburg, Germany

Charge carrier transport phenomena through internal interfaces in semiconductor heterostructures are currently in the spotlight of scientific research due to the advancing miniaturization of devices. However, how internal interfaces in semiconductor heterostructures affect the coherent dynamics, i.e., the transition from a coherent polarization to a population, is largely unexplored. To shed some light on the subject, we use a GaInAs/GaAs/GaAsSb type-II like double quantum well structure which, due to its design, exhibits a charge-transfer exciton resonance in the linear absorption. This allows us to study the coherent dynamics of chargetransfer excitons and excitons that can relax across the internal interface into a charge-transfer state by means of degenerate four-wave-mixing. Furthermore, adding an optical prepulse, the phase relaxation of charge-transfer excitons subjected to collisions with either free carriers or incoherent excitons is investigated.

HL 13.7 Tue 11:15 H33

Intense terahertz radiation via the transverse thermoelectric effect — •TIM PRIESSNITZ^{1,2}, PETAR YORDANOV¹, MIN-JAE KIM^{1,2,3}, GEORG CRISTIANI¹, GENNADY LOGVENOV¹, BERNHARD KEIMER¹, and STEFAN KAISER^{1,2,3} — ¹Max-Planck Institute for Solid State Research, 70569 Stuttgart, Germany — ²4th Physics Institute and Research Center SCoPE, University of Stuttgart, 70569 Stuttgart, Germany — ³Institute of Solid State and Materials Physics, Technical University Dresden, 01069 Dresden, Germany

Terahertz (THz) radiation became a powerful tool with widespread applications ranging from imaging and spectroscopy to nonlinear optical control of materials. However, efficient and scalable THz sources remain rare. Here, we present a novel approach to generate powerful THz radiation making use of an ultrafast current induced via the transverse thermoelectric effect (TTE). We realize this in off-cut grown thin films of the delafossite PdCoO₂ and the cuprate La_{1.84}Sr_{0.16}CuO₄ driven by femtosecond laser pulses resulting in an ultrafast transient diffusion of charge carriers. Characterizing the resulting THz radiation, we find it comparable in power and spectral bandwidth to standard emitters based on nonlinear crystals. A first basic model including the Seebeck anisotropy, electrical and thermal conductivities and the transient diffusivity allows materials based predictions. Due to its simplicity and potential for scalability in terms of multiple tunable material parameters, THz generation based

on the TTE opens a new avenue for high-field THz generation and novel cost-efficient emitters.

### HL 13.8 Tue 11:30 H33

Clocking the dynamics of correlated Bloch electrons on an attosecond time scale — •JOSEF FREUDENSTEIN¹, MARKUS BORSCH², MANUEL MEIERHOFER¹, DMYTRO AFANASIEV¹, CHRISTOPH PETER SCHMID¹, FABIAN SANDNER¹, MARLENE LIEBICH¹, ANNA GIRNGHUBER¹, MATTHIAS KNORR¹, MACKILLO KIRA², and RUPERT HUBER¹ — ¹University of Regensburg, 93051 Regensburg, Germany — ²University of Michigan, Ann Arbor, Michigan 48109, USA

Delocalized Bloch electrons and the low-energy correlations between them determine key properties of solids. To directly capture how many-body correlations affect the actual motion of Bloch electrons, sub-femtosecond temporal precision is desirable. Here, we study attosecond shifts in the dynamics of charge carriers at the Fermi level, combining sub-fs resolution with meV energy selectivity. Coherent excitons are injected in bulk and monolayer tungsten diselenide and subsequently accelerated by multi-terahertz light fields. Quasiparticle collisions lead to the emission of high-order sidebands, which contain key information about the ballistic dynamics of the charge carriers. We show how the excitonic binding energy, the strength of the driving field, the valley polarization and Pauli blocking influence these dynamics on an attosecond time scale and faithfully reproduce these results with quantum-dynamic many-body computations in a Wigner-function representation. This opens a new pathway to understanding emergent quantum dynamics and phases and sets a corner stone for future optoelectronics and quantum-information processing.

HL 13.9 Tue 11:45 H33

**Time-resolved ellipsometry on CuI thin films** — •CAROLA EMMINGER^{1,2}, EVGENY KRÜGER¹, MICHAEL BAR¹, SHIRLY ESPINOZA³, MARTIN ZAHRADNIK³, MATEUSZ REBARZ³, FELIX-FLORIAN DELATOWSKI³, JAKOB ANDREASSON³, MICHAEL SEIFERT⁴, SILVANA BOTTI⁴, CHRIS STURM¹, and MARIUS GRUNDMANN¹ — ¹Felix-Bloch Institut für Festkörperphysik, Universität Leipzig, Germany — ²Institut für Physik, Humboldt-Universität zu Berlin, Germany — ³ELI Beamlines, Czech Republic — ⁴Institut für Festkörpertheorie und Optik, Friedrich-Schiller-Universität Jena, Germany

We report the impact of the carrier dynamics on the dielectric function of CuI thin films by means of femtosecond pump-probe spectroscopic ellipsometry. As expected, we observe a strong decrease of the exciton peak due to the pump pulse, which starts to recover after 200-300 fs. Interestingly, we notice a small increase in absorption below the band gap after a delay time of about 400 fs, which might be explained by valence- to valence-band transitions resulting from the laser-induced increased carrier density. At about 10 ps, the dielectric function has almost fully recovered. We analyze the delay-time dependent dielectric function and discuss possible explanations for the changes related to the carrier density.

#### HL 13.10 Tue 12:00 H33

Gain recovery dynamics after stimulated emission in type-II semiconductor laser materials — •MARKUS STEIN¹, FELIX SCHÄFER¹, JANINE LORENZ¹, JOHANNES STEINER², JÖRG HADER³, JERRY MOLONEY³, TORSTEN MEIER², STEPHAN W. KOCH⁴, and SANGAM CHATTERJEE¹ — ¹Institute of Experimental Physics I and Center for Materials Research, Justus-Liebig-University Giessen, Heinrich-Buff-Ring 16, D-35392 Giessen, Germany — ²Department of Physics, Paderborn University, Warburger Strasse 100, D-33098 Paderborn, Germany — ³Wyant College of Optical Sciences, University of Arizona, 1630 East University Boulevard, Tucson, Arizona 85721, USA — ⁴Department of Physics and Material Sciences Center, Philipps-Universitä Marburg, Renthof 5, 35032 Marburg, Germany

Type-II active devices combine the advantages of spectrally broad, temperaturestable efficient gain with the potential for electrical injection pumping. Intrinsic charge-carrier relaxation dynamics limit the feasible repetition rates beyond constraints of cavity design and heat removal. Here, we investigate the recovery of material gain after a stimulated emission process in an InGaAs/GaAs/GaAsSb heterostructure, experimentally simulating the operation condition of a pulsed laser system. In an optical pump - optical probe setup, a first optical pulse injects hot charge carriers. Subsequently, a second pulse tuned to the broad spectral region in which gain is observed is used to stimulate emission. A detailed analysis of the dynamics after stimulated emission reveals that the physical limit for the highest possible laser repetition rate for this material system is in the range of 100 GHz.

Modern oxide materials exhibit a rich variety of physical properties that lead to potential applications such as sensors and detectors, solar energy harvesting, transparent and power electronics. Understanding their quantum properties at surfaces and interfaces may play a decisive role for functionalities in high-electron-mobility transistors, quantum electronics or topological quantum computation. These typically require homo- or heteroepitaxial layers of high crystallinity and investigation methods designed to reveal the fascinating physics at (complex) oxide interfaces. This session sets a focus on growth of oxide interfaces, the experimental and theoretical investigation of their novel physical, in particular quantum properties as well as fabrication and characterization of demonstrator devices.

Organized by Martin Albrecht, Oliver Bierwagen, and Saskia F. Fischer

### **Invited Talk**

HL 14.1 Tue 9:30 H34 Materials and Device Engineering for Gallium Oxide-based Electronics — NIDHIN KURIAN KALARICKAL¹, SUSHOVAN DHARA¹, ASHOK DHEENAN¹, and •SIDDHARTH RAJAN^{1,2} - ¹ECE Department, The Ohio State University - ²MSE Department, The Ohio State University

This presentation will discuss our recent work on epitaxy, heterostructure design, and electrostatics to achieve high-performance  $\beta$ -Ga2O3 lateral and vertical electronic devices. We will discuss some key results in materials growth and device design for lateral structures, including the first  $\beta$ -(Al,Ga)2O3/β-Ga2O3 modulation-doped structures with excellent transport properties, double-heterostructure modulation-doped structures, and scaled delta-doped transistors with cutoff frequency of 27 GHz, and self-aligned lateral field effect transistors with > 900 mA/mm current density. We will discuss the use of a new damage-free epitaxial etching technique using Ga atomic flux that enables highly precise fabrication of 3-dimensional structures, and applications of this etching to realize field termination in vertical diodes, and lateral FINFETs with enhanced performance. Extreme-permittivity dielectrics provide unique opportunities to create devices that can sustain extreme fields without premature breakdown of metal-semiconductor and dielectric-semiconductor interfaces. We will discuss promising results of electrostatic engineering using BaTiO3/Ga2O3 heterojunctions that enable high fields to be sustained within Gallium Oxide diodes and transistors.

#### Invited Talk

### HL 14.2 Tue 10:00 H34 Ferroelectric two-dimensional electron gases for oxide spin-orbitronics -•JULIEN BRÉHIN — Unité Mixte de Physique CNRS/Thales

Just as the apparent incompatibility between ferroelectricity and magnetism prompted the renaissance of multiferroics, the research on ferroelectric metals conjectured in the 1960s by Anderson and Blount was recently revitalized. Yet, their experimental demonstration remains very challenging due to the contraindication between the presence of free charge carriers and switchable electric dipoles. In this talk we will report on two-dimensional electron gases (2DEGs) formed on Ca-substituted SrTiO3 (STO). Signatures of the ferroelectric phase transition near 30 K are visible in the temperature dependence of the sheet resistance RS and in a strong, reproducible hysteresis of RS with gate voltage. In addition, spectroscopic measurements of the 2DEG region indicate the presence of switchable ionic displacements. Beyond their fundamental interest in materials physics, ferroelectric 2DEGs offer opportunities in spin-orbitronics: we will show how their spin-charge conversion properties, caused by the inverse Rashba-Edelstein effect, can be electrically tuned in amplitude and sign in a non-volatile way. These results open the way to a whole new class of ultralow-power spinorbitronic devices operating without the need for magnetization switching. Finally, we will describe how one can introduce magnetism into such systems to achieve multiferroic 2DEGs displaying magnetoelectric coupling.

### HL 14.3 Tue 10:30 H34

Electron transport of the two-dimensional electron gas in polar-discontinuity doped LaInO3/BaSnO3 heterostructure — Georg Hoffmann¹, Fazeel ZOHAIR¹, MARTINA ZUPANCIC², MARTIN ALBRECHT², and •OLIVER BIERWAGEN¹ — ¹Paul-Drude-Institut für Festkörperelektronik Leibniz-Institut im Forschungsverbund Berlin e.V., Hausvogteiplatz 5-7, D-10117 Berlin, Germany — ²Leibniz-Institut für Kristallzüchtung im Forschungsverbund Berlin e.V., Max-Born-Straße 2 D-12489 Berlin, Germany

Transparent semiconducting oxides (TSOs) are key players for new (opto-)electronic devices and two-dimensional electron gases (2DEGs) are relevant for high-frequency applications. Polar-discontinuity doping (interfacing a polar material with a nonpolar one), has been demonstrated to provide a 2DEG at the interface between the perovskites LaAlO3 and SrTiO3 with a high electron concentration but suffers from low room-temperature (RT) electron mobilities of SrTiO3. In this contribution we demonstrate polar-discontinuity doped 2DEG at the interface between the perovskites LaInO3 and BaSnO3, grown by plasma-assisted molecular beam epitaxy. While the individual, undoped oxide layers were found to be insulating, the formation of the polar-discontinuity

doped 2DEG at their interface is confirmed by capacitance-voltage (CV) and van der Pauw-Hall measurements. The extracted sheet electron concentrations >2e13cm^-2 and RT electron mobilities above >50cm^2/Vs are promising for device applications. The transport properties of the 2DEG are compared to those of La-doped BaSnO3 layers.

HL 14.4 Tue 10:45 H34

**Non-Abelian braiding of phonons in monolayer oxides** – •Bo Peng¹, Adrien Bouhon¹, BARTOMEU MONSERRAT^{1,2}, and ROBERT-JAN SLAGER¹ – ¹TCM Group, Cavendish Laboratory, University of Cambridge, J. J. Thomson Avenue, Cambridge CB3 0HE, United Kingdom — ²Department of Materials Science and Metallurgy, University of Cambridge, 27 Charles Babbage Road, Cambridge CB3 0FS, United Kingdom

Non-Abelian braiding of quasiparticles can encode quantum information immune from environmental noise with the potential to realize topological quantum computation. Here we propose that phonons, a bosonic excitation of lattice vibrations, can carry non-Abelian charges in their band structures that can be braided using external stimuli. Taking some earthly abundant materials such as silicates [1] and aluminium oxide [2] as representative examples, we demonstrate that an external electric field or electrostatic doping can give rise to phonon band inversions that induce the redistribution of non-Abelian charges, leading to non-Abelian braiding of phonons. We show that phonons can be a primary platform to study non-Abelian braiding in the reciprocal space, and we expand the toolset to study such braiding processes.

### 30 min. break

HL 14.5 Tue 11:30 H34 Shift of the absoption onset in corundum-like  $\alpha$ -(Ti_xGa_{1-x})₂O₃ - •ELIAS Kluth¹, Michael Fay², Christopher Parmenter³, Joseph Roberts⁴, Fa- $\label{eq:bis} BIEN MASSABUAU^5, RÜDIGER GOLDHAHN^1, and MARTIN FENEBERG^1 — ^1 Institut für Physik, Otto-von-Guericke-Universität Magdeburg, Germany — ^2 Advanced$ Materials Research Group, Faculty of Engineering, University of Nottingham, NG7 2RD, UK - ³Nottingham Nanotechnology and Nanoscience Centre, University of Nottingham, University Park, Nottingham NG7 2RD, UK -⁴School of Engineering, The University of Liverpool, Liverpool L69 3GH, UK - ⁵Department of Physics, SUPA, University of Strathclyde, Glasgow G4 0NG, UK

Corundum-like  $\alpha$ -Ga₂O₃ is a metastable phase of the polymorphic ultra-wide band gap semiconductor Ga2O3. While previous resarch has mostly focused on the stable  $\beta$ -phase the  $\alpha$ -phase is less discussed, but interesting as well as it allows bandgap-engineering by alloying e.g. with  $\alpha$ -Al₂O₃ (sapphire) or In₂O₃.

Since the transition metal oxide  $Ti_2O_3$  as well, has a corundum-like phase ( $\alpha$ phase), with a small latice mismatch of about 3.5% to  $\alpha$ -Ga₂O₃, we investigate here (0001)  $\alpha$ -Ga₂O₃ thin films alloyed with Ti, grown by ALD (atomic layer deposition).

We use spectroscopic ellipsometry in ultraviolet range to obtain the complex dielectric function (DF) of  $\alpha$ -(Ti_xGa_{1-x})₂O₃ up to x = 0.61. We find a clear red shift of the absorption onset with increasing Ti content, as well as an increase of the amplitude of the DF.

HL 14.6 Tue 11:45 H34 Optical signatures of polarons trapped at ferroelectric domain walls in bismuth ferrite — •SABINE KÖRBEL — Institute of Physics of the Czech Academy of Sciences, Prague, Czech Republic — Friedrich Schiller University Jena, Germany Ferroelectric domain walls are atomically narrow planes that can behave very differently from the surrounding bulk ferroelectric material. For example, the domain walls in many ferroelectrics can collect and conduct charge carriers despite the insulating nature of the host material. Domain walls can be created, moved, and removed again in a controlled way, thus they can be used to alter the electronic properties of the ferroelectric as desired. Charge carriers that accumulate at domain walls may induce metallic or semiconducting behavior depending on whether they are delocalized or form self-trapped small polarons. The latter may be detected, for example, as deep levels within the band gap in absorption or photoluminescence spectra. Here we predict optical signatures of charge carriers trapped as small polarons at ferroelectric domain walls in BiFeO₃, using first principles calculations.

### HL 14.7 Tue 12:00 H34

Anharmonicity of lattice vibrations in  $\alpha$ -Ga₂O₃ investigated by temperature dependent Raman spectroscopy — •Jona Grümbel¹, Rüdiger Goldhahn¹, Dae-Woo Jeon², and Martin Feneberg¹ — ¹Otto-von-Guericke Universität, Magdeburg, Germany — ²Korea Institute of Ceramic Engineering and Technology, Jinju, Republic of Korea

We investigate the Raman excitations of a corundum-like a-Ga₂O₃ thin film under temperature variation from 80K up to 790K. This yields detailed information about anharmonic processes in the crystal. For the two dominant phonon modes for each of the two Raman-active phonon mode symmetries ( $A_{1g}$  and  $E_g$ ) model calculations are performed in order to quantify the contributions of different decay mechanisms. It is shown, that our experimental data can be well described by the applied theoretical models. The determined coefficients of cubic and quartic decay for both, phonon energy and linewidth, are compared with those from hexagonal GaN and AlN as well as with those from  $\alpha$ -Al₂O₃. We observe, that for the two selected phonon modes of  $\alpha$ -Ga₂O₃ the quartic decay processes are negligible for the phonon frequencies, but not for the phonon linewidths behavior under temperature variation. A quantitative description within the model parameters is presented.

Invited Talk HL 14.8 Tue 12:15 H34 Strain-driven dissociation of water on (incipient) ferroelectrics — JOSHUA L. BATES and •CHIARA GATTINONI - Department of Chemical and Energy Engineering, London South Bank University, London, UK

Functional materials have great promise in catalysis, and especially within dynamic catalytic cycles, where the "functional" properties are used to cyclically modify the local environment of a surface to enhance turnover frequency. In particular, strain-driven mechanisms exploiting the properties of piezo- and ferroelectric materials, are of great interest.

In this work we focus on (incipient) ferroelectric nanomaterials BiFeO₃, BaTiO₃, KTaO₃ and SrTiO₃, perovskites presenting a wide range of bulk properties and behaviours. We uncover how interplay between these properties (such as the spontaneous polarization) and nanoscale effects (such as the depolarizing field and the surface structure), affect the strain-driven water-splitting abilities of these nanoscale functional materials. Finally, we identify the most desirable properties for a highly efficient ferroelectric material for dynamic catalysis.

### HL 15: 2D Materials 3 (joint session HL/CPP/DS)

### Invited Talk

HL 15.1 Tue 9:30 H36 Ultrafast all-optical modulation and frequency conversion in 2D materials - •Sebastian Klimmer¹, Artem Sinelnik^{1,2}, Isabelle Staude^{1,2}, and Gian-Carlo Soavi¹ - ¹Institute of Solid State Physics, Friedrich Schiller University Jena, Jena, Germany — ²Institute of Applied Physics, Friedrich Schiller University Jena, Jena, Germany

Large efforts have been devoted in the last years to realizing nonlinear integrated devices for frequency conversion, sensing, signal modulation and quantum optics. Two-dimensional (2D) materials, such as graphene and transition metal dichalcogenides (TMDs), provide distinct advantages in this respect thanks to their ease of integration on photonic platforms[1] and their atomically thin nature, which relaxes phase matching constraints and thus offers a practically unlimited bandwidth for nonlinear optical effects [2]. In this seminar I will present our recent results in the field of nonlinear optics with 2D materials, including ultra-broadband four-wave mixing in the telecom range, ultrafast alloptical modulation of second- and third-harmonic generation in TMDs[3] and graphene and ultrafast polarization-resolved second-harmonic spectroscopy to probe the valley degree of freedom in TMDs.

HL 15.2 Tue 10:00 H36

strain tuning of exciton and trion dynamics in monolayer WSe2 at cryogenic temperatures — •ZHAO AN¹, PEDRO SOUBELET², ANDREAS V. STIER², MICHAEL  $ZOPF^1$ , YAROSLAV ZHUMAGULLOV³, JAROSLAV FABIAN³, PAULO E. FARIA JONIOR³, JONATHAN J. FINLEY², and FEI DING^{1,4} — ¹Institut für Festkörperphysik, Leibniz Universität Hannover, Appelstraße 2, 30167 Hannover, Germany – ²Walter Schottky Institut and Physik Department, Technische Universität München, 85748 Garching, Germany — ³Institute for Theoretical Physics, University of Regensburg, 93040 Regensburg, Germany — ⁴Laboratorium fur Nano- und Quantenengineering, Leibniz Universität Hannover, Schneiderberg 39, 30167 Hannover, Germany

Transition metal dichalcogenides (TMD) receive increasing attention these years. In TMD monolayers, the light-matter interaction is driven by strong excitonic effects. Additional to neutral excitons, singlet/ triplet trions are observed, in which the additional charge is either in the same or opposite valley with respect to excitons. We apply dynamic strain at cryogenic temperatures to investigate the exciton dynamics of monolayer WSe2. Biaxial strain is electrically controlled via a piezoelectric actuator and transferred to the hBN/WSe2/hBN. We find that next to changes in the emission energy and intensity, the singlettriplet trion fine structure is affected. Polarization-resolved PL spectroscopy reveals that biaxial strain alters the polarizations of trions, which is attributed to changes in the pumping of resident electrons and the intervalley scattering of excitons and electrons.

Location: H36

HL 15.3 Tue 10:15 H36 **Optical nonlinearities in the excited carrier density of 2d TMDs** — •DANIEL ERBEN¹, ALEXANDER STEINHOFF¹, MICHAEL LORKE^{1,2}, and FRANK JAHNKE¹ —  1 Institute for Theoretical Physics, University of Bremen —  2 Bremen Center for Computational Materi- als Science, University of Bremen

The prospects of using 2d transition metal dichalcogenides (TMDs) in future optoelectronic device application requires insight in the excitation dynamics of photoexcited charge carriers and the resulting optical nonlinearities. Utilizing ab-initio electronic-state calculations combined with many-body treatment of optical excitation, we calculate the excited carrier dynamics and the nonlinear absorption in  $MoS_2$ ,  $MoSe_2$ ,  $WS_2$ , and  $WSe_2$  under various excitation conditions.

We find, that the increase of the carrier density with excitation strength deviates from a linear behaviour. Based on this, the validity range of a linear approximation for the excited carrier density as function of the pump fluence is determined. The use of a linear absorption coefficient of the unexcited system can significantly underestimate the achievable carrier density for strong pump fields. Furthermore, we study the excitation-induced many-body effects of excited charge carriers like band-gap renormalization, dephasing, screening, and scattering processes, that are mediated by the strong Coulomb interaction. Additional contributions to optical nonlinearities originate from phase space filling.

HL 15.4 Tue 10:45 H36

Second order coherence of a condensate of exciton-polaritons in an atomically thin crystal — •JENS-CHRISTIAN DRAWER¹, HANGYONG SHAN¹, SVEN Höfling², Carlos Anton-Solanas³, Martin Esmann¹, and Christian  ${\tt Schneider}^1-{}^1{\tt Universit} {\tt it} {\tt Oldenburg, Germany}-{}^2{\tt Universit} {\tt it} {\tt W} {\tt urzburg,}$ Germany — ³Universidad Autónoma de Madrid, Spain

We study the second order coherence of a condensate of exciton-polaritons emerging in a microcavity loaded with an atomically thin MoSe₂ crystal. Under cryogenic temperatures, angle-resolved PL and reflectivity measurements reveal the formation of two polariton resonances, as the hallmark of the strong coupling regime. The characteristic condensation threshold manifests via the nonlinear input-output-characteristics of the emission. In order to gain deeper information about the photon statistics emitted from the cavity, we perform the Hanbury Brown- and Twiss experiment as a function of the polariton occupation in the effective ground state. While the emission features a bunching effect below threshold, hinting at a thermal contribution of the polariton emission, above threshold the second order correlation transits towards  $g^{(2)}(\tau = 0) = 1$ , which is indicative for the formation of a coherent state in the quantum optical sense.

### HL 15.5 Tue 11:00 H36

Theoretical description of moiré excitons in twisted MoSe₂ homobilayers - •Ruven Hübner¹, Malte Kremser², Viviana Villafañe², Marko M. Petrić³, Matthias Florian⁴, Alexander Steinhoff¹, Mackillo Kira⁴, NATHAN P. WILSON², ANDREAS V. STIER², KAI MULLER³, and JONATHAN J.

 $FINLEY^2 - {}^1$ Institut für Theoretische Physik, Universität Bremen, Bremen, Germany — ²Walter Schottky Institut and Physik Department, Technische Universität München, Garching, Germany — ³Walter Schottky Institut and Department of Electrical and Computer Engineering, Technische Universität München, Garching, Germany —  4 University of Michigan, Dept. of Electrical Engineering and Computer Science, Ann Arbor, MI, USA

By introducing a twist between multiple monolayers of transition metal dichalcogenides we can observe superstructures with a new periodicity - namely the moiré lattice. Its size depends on the twist angle and therefore offers the possibility to modify properties like exciton energies as a function of the twist angle. We demonstrate, how DFT calculations of an untwisted MoSe₂ bilayer allow us to locally model the band variation inside the moiré unit cell at all dominant high symmetry points of the Brillouin zone. The resulting model provides access to arbitrary moiré potentials experienced by different exciton species and allows us to calculate their twist angle dependent spectra. For all twist angles we assign the lowest energy to interlayer excitons formed between the  $\Gamma$ - and K-valley. The twist angle dependent shift of 5 meV per degree for small angles is in good agreement with experiment.

### HL 15.6 Tue 11:15 H36

Dielectric screening effects on the exciton binding-energy and exciton diffusion in a 2D material — •LUKAS GÜMBEL, PHILIP KLEMENT, and SANGAM CHATTERJEE — Institute of Experimental Physics I and Center for Materials Research (ZfM/LaMa), Justus Liebig University Giessen, Heinrich-Buff-Ring 16, Giessen D-35392, Germany

Two-dimensional semiconductors have proven to be candidates for numerous applications in the field of optoelectronics. Especially transition-metal dichalcogenides such as WS₂ have attracted extensive research due to the direct band-gap emerging in the monolayer limit. The optoelectronic properties are dominated by tightly-bound excitons denoted as A, B, and C. As the electric field lines of the excitonic states extend into the surrounding material, the energy states are subject to dielectric screening effects. Here we show that stronger dielectric screening equally shifts the excitonic ground state energies of the A-, B-, and C-excitons in WS₂ to lower energies. We find a shift of 20 meV in monolayers encapsulated in hBN and observe a non-hydrogenic Rydberg-series yielding a quasiparticle band-gap energy of 2.33 eV with an 1s excitonic binding energy of 0.30 eV. Additionally, we study exciton diffusion in different dielectric environments yielding a diffusion coefficient of 9 cm²/s. These results complement the underlying theory and may pave the way to a deeper understanding of screening effects in various 2D-Materials.

HL 15.7 Tue 11:30 H36

Brightening of a dark monolayer semiconductor via strong light-matter coupling in a cavity — •HANGYONG SHAN¹, IVAN IORSH², BO HAN¹, FALK  $\begin{array}{l} { Ellenberger}^{4}, \ Martin \ Esmann^{1}, \ Sebastian \ Klembt^{3}, \ Sven \ Höfling^{3}, \\ { Carlos \ Antón-Solanas}^{1}, \ Ivan \ A. \ Shelykh^{2}, \ and \ Christian \ Schneider^{1} \end{array}$ -  1 Oldenburg University, Oldenburg, Germany.-  2 St. Petersburg, Russia-  3 Universität Würzburg, Würzburg, Germany-  4 Friedrich Schiller University, Jena, Germany

We study the modification of the material properties via strong coupling and demonstrate an effective inversion of the excitonic band-ordering in a monolayer of WSe2 with spin-forbidden, optically dark ground state. In our experiments, we harness the strong light-matter coupling between cavity photon and the high energy, spin-allowed bright exciton, and thus creating two bright polaritonic modes in the optical bandgap with the lower polariton mode pushed below the WSe2 dark state. We demonstrate that in this regime the commonly observed luminescence quenching stemming from the fast relaxation to the dark ground state is prevented, which results in the brightening of this intrinsically dark material. We probe this effective brightening by temperature-dependent photoluminescence, and we find an excellent agreement with a theoretical model accounting for the inversion of the band ordering and phonon-assisted polariton relaxation.

HL 15.8 Tue 11:45 H36

Broadband pump-probe microscopy at 1.5 MHz repetition rate - •Devapriyo Mithun¹, Michael Frosz², and Giancarlo Soavi¹ – ¹Institute of Solid State Physics, Friedrich Schiller University Jena, Jena, Germany — ²Max Planck Institute for the Science of Light, Erlangen, Germany

Ultrafast pump-probe spectroscopy is one of the most commonly used techniques to resolve photoinduced excited states dynamics: a pump pulse excites the system under investigation, which is then monitored by measuring the changes in the differential reflection ( $\Delta R/R$ ) of a temporally delayed probe pulse. Here, we discuss the realization of a pump-probe setup, which exhibits high sensitivity operating with a temporal resolution of  $\approx$  100 fs and spatial resolution of  $\approx$  3  $\mu$ m with 515 nm pump and a broadband probe spectrum in the range 650-1000 nm, generated with a photonic crystal fiber.

We modulate the pump pulse at 1.5 MHz using an acousto-optic modulator. By doing this, we achieve a sensitivity, defined as the minimum detectable  $\Delta R/R$ , of  $10^{-7}$  at 10 ms integration time. Finally, we implemented a Fourier transform based interferometric detection scheme to achieve a fast measurement of  $\Delta R/R$ over the entire broadband spectrum.

Our pump-probe setup provides a powerful tool for broadband pump-probe microscopy with high sensitivity and high temporal resolution, which is ideal for the study of nanostructures such as carbon nanotubes and layered materials.

### HL 17.1 Wed 9:30 H32

Highly Pure and Bright Emission of a Telecom C-Band Quantum Dot in a Circular Bragg Grating Cavity — • RAPHAEL JOOS, CORNELIUS NAWRATH, SASCHA KOLATSCHEK, STEPHANIE BAUER, PASCAL PRUY, ROBERT SITTIG, PONRAJ VI-JAYAN, JIASHENG HUANG, MICHAEL JETTER, SIMONE L. PORTALUPI, and PETER MICHLER — Institut für Halbleiteroptik und Funktionelle Grenzflächen (IHFG), Center for Integrated Quantum Science and Technology (IQST) and SCoPE, Universität Stuttgart

Quantum communication schemes, which can prospectively guarantee secure communication by physical laws, rely on the availability of single-photons utilized as flying qubits. For this purpose, InAs quantum dots (QDs) can be employed as single-photon source, particularly, providing access to emission at telecom wavelengths which is highly sought-after for fiber-based applications and will, thus, most probably be the operating regime for real-world applications. However, simple planar QD structures suffer from a low collection efficiency due to the high refractive index contrast at the semiconductor/air interface. This issue can be tackled by the application of photonic nanostructures. This contribution deals with the optical and quantum optical investigation of telecom Cband QDs embedded in circular Bragg grating cavities, which allow for strongly increased light collection in a broad range of wavelengths as well as Purcell enhanced emission of the QDs. In this way, QD emission with a near perfect single-

photon purity as well as very high collection efficiency is achieved leading to megahertz count rate of actual single-photons available for further applications.

### HL 17.2 Wed 9:45 H32

Realization of Gaussian-shaped micro-cavities for Quantum Dots emitting in the telecom C-band — •JENS JAKSCHIK — Institut für Halbleiteroptik und funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology (IQST) and SCoPE, University of Stuttgart, Germany

Semiconductor quantum dots (QDs) are a prime candidate for the generation of efficient single, indistinguishable photons. When utilizing these QDs for e.g. long-distance quantum communication, it is important to operate at the transmission loss minimum of the existing global optical fiber network. Therefore, the QDs have to emit in the telecom C-Band (~1550 nm). To keep the advantages of the mature GaAs technology, the QDs are grown on an InGaAs metamorphic buffer (MMB) layer with high In-content on GaAs. The emission of QDs can be optimized by confining them into cavities. In this work novel Gaussianshaped micro-cavities based on high-reflective DBRs are used. To reach high quality factors and increase the extraction efficiency in Gaussian-shaped cavities, the radial symmetry given by the wet-chemically etched Gaussian-shaped microlens, forming the center of the cavity has to be preserved over multiple layers of top DBR growth. This has to be realized despite the varying growth rates of

InGaAs along different crystal axes. In this contribution, we present the results of the optical simulations for optimizing these cavities for the telecom C-Band, as well as the effect of different growth conditions on the overgrowth of InGaAs on wet-chemically pre-structured substrates to enable the fabrication of novel Gaussian-shaped micro-cavities.

HL 17.3 Wed 10:00 H32

Optically induced in-situ strain-tuning of InGaAs quantum dots for nanophotonic devices — •CHING-WEN SHIH¹, MARCO HOLZER², IMAD LIMAME¹, LASSE KOSIOL¹, SOURISH BANERJEE², ARIS KOULAS-SIMOS¹, VEERESH DESHPANDE², CATHRINE DUBOURDIEU^{2,3}, and STEPHAN REITZENSTEIN¹ — ¹Institut für Festkörperphysik, Technische Universität Berlin, Berlin, Germany — ²Helmholtz-Zentrum Berlin für Materialien und Energie GmbH, Berlin, Germany — ³Freie Universität Berlin, Physical Chemistry, Berlin, Germany

Self-assembled semiconductor quantum dots (QDs) have been widely incorporated in solid-state cavities to enable quantum technologies. However, the nature of self-assembled QDs poses a big challenge to achieving controlled emitter-cavity and emitter-emitter coupling as it not only requires an accurate spatial positioning, but also a precise spectral matching of the system. Here, we report on the MOCVD growth and fabrication of micropillar-like nanophotonic light sources consisting of strain-tunable InGaAs QDs with ALD-deposited HfO2 thin film cladding. We show that the emission energy of QDs can be in-situ tuned by thermally annealing the HfO2 film with a focused laser beam integrated in a  $\mu$ -photoluminescence setup under cryogenic temperature. We demonstrate a tunability up to 2 meV without QDs degradation. Furthermore, we successfully tuned two separated QD emission peaks from the same structure into resonance. The developed technique paves the path for scaling up the number of coupled QDs in semiconductor nanophotonic devices.

HL 17.4 Wed 10:15 H32 Optical properties of In(Ga)As QDs emitting in the telecom C-band grown on a non-linear metamorphic buffer layer — PRSCAL PRUY, CONSELUS

on a non-linear metamorphic buffer layer — •PASCAL PRUY, CORNELUS NAWRATH, ROBERT SITTIG, SIMONE LUCA PORTALUPI, MICHAEL JETTER, and PETER MICHLER — Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology(IQST) and SCopE, University of Stuttgart, Allmandring 3, 70569 Stuttgart

Semiconductor Quantum Dots (QDs) are excellent structures for the generation of non-classical light states with outstanding performance regarding singlephoton purity, photon indistinguishability and entanglement fidelity, making them promising sources for currently researched subjects such as quantum computation and quantum communication. The telecom C-band (1530-1565 nm) spectral regime is especially sought-after for fiber-based implementations of these applications due to the absorption minimum in the globally used silica fiber network. On the mature and promising GaAs material platform, the telecom C-band can be reached using a metamorphic buffer (MMB) layer and the recent progress on such QDs has attracted great interest.

While so far MMBs with a thickness of 1080nm have been employed resulting in a nominal 3- $\lambda$  cavity, a 1- $\lambda$  cavity would be greatly beneficial for more elaborate photonic structures regarding brightness and coherence. Here we report on the optical properties such as brightness, coherence and purity of In(Ga)As Quantum Dots emitting in the telecom C-band spectral regime on a novel metamorphic buffer layer compatible with 1- $\lambda$  cavities.

#### HL 17.5 Wed 10:30 H32

**Optical properties of semiconductor quantum dots embedded in an open, fiber-based cavity emitting in the telecom regime** – •JULIA WECKER¹, THOMAS HERZOG¹, JONAS GRAMMEL², PONRAJ VIJAYAN¹, ROBERT SITTIG¹, MICHAEL JETTER¹, SIMONE LUCA PORTALUPI¹, DAVID HUNGER², and PETER MICHLER¹ – ¹Institut für Halbleiteroptik und Funktionelle Grenzflächen, Center for Integrated Quantum Science and Technology (IQST) and SCOPE, University of Stuttgart, Stuttgart, Germany – ²Physikalisches Institut, Karlsruher Institut für Technologie (KIT), Karlsruhe, Germany

Enhancing the brightness of quantum emitters can be achieved by coupling them to optical microcavities. Together with an enhanced light extraction, shortening of the spontaneous emission rate can be achieved via the Purcell effect. In this work, we investigate In(Ga)As quantum dots embedded in an open fiber-based Fabry-Pérot cavity. On the bottom distributed Bragg reflector, quantum dots operating at the telecom O- and telecom C-Band are grown, while the top mirror is deposited on a silica fiber which can be moved with nanometric precision across the sample. Therefore, the cavity mode can be tuned in order to achieve spatial and spectral matching with the investigated emitter. The emitted photons are then directly coupled into the telecom fiber, making this fiber-coupled single-photon source promising for quantum communication applications.

#### HL 17.6 Wed 11:15 H32

GaSb quantum dots surrounded by AlGaSb with indirect-direct bandgap crossover at telecom range — •LUCIE LEGUAY and ANDREI SCHLIWA — Institut für Festkörperphysik, Technische Universität Berlin

We report the modeling and theoretical characterization of a new type-I semiconductor material based on GaSb quantum dots embedded into AlGaSb with GaSb as substrate. The calculations are performed by the nextnano++ solver, using both the effective mass and the 8-band k-p method.

Experimental work shows the formation of nano-holes with a wide range of tunability in depth and density by the local droplet etching of a surface of AlGaSb by liquid gallium [1]. Then, optically active quantum dots are obtained by filling those nano-holes with GaSb and by the deposition of a GaSb quantum well on top [2].

Our calculations demonstrate an indirect-direct bandgap crossover as the thickness of the quantum well increases, which allows control of the system's luminescence. In the direct bandgap regime, the quantum dots emit narrow excitonic spectral lines in the telecom wavelength range. These properties, as well as the low density of the quantum dots, show a lot of promise for applications in the field of infrared quantum optics.

HL 17.7 Wed 11:30 H32

Coherent Spin Control in InAs Quantum Dots Emitting in the Telecom C-Band — •JOHANNES MICHL¹, ŁUKASZ DUSANOWSKI^{1,3}, CORNELIUS NAWRATH², MICHAEL JETTER², SIMONE L. PORTALUPI², TOBIAS HUBER¹, PETER MICHLER², and SVEN HÖFLING¹ — ¹Technische Physik, Julius-Maximilians University of Würzburg — ²Institut für Halbleiteroptik und Funktionelle Grenzflächen (IHFG), University of Stuttgart — ³Princeton University

Semiconductor quantum dots can be used as spin-photon interfaces, enabling the preparation of photonic cluster states with a single spin in the quantum dot acting as the entangler. This leads the way towards memory-less quantum repeater protocols for quantum network applications. InAs quantum dots can be grown on metamorphic buffer layers, leading to strain relaxed growth and therefore light emission directly into the telecom C-band. Here we show magneto and polarization resolved photoluminescence experiments conducted to characterize the different charge complexes in a single quantum dot. Furthermore, we implement laser pulse sequences to gain full coherent control over a hole qubit.

#### HL 17.8 Wed 11:45 H32

Quantum Dot Localization Methodology based on Imaging — •MARC SARTI-SON, EVA SCHÖLL, LUKAS HANSCHKE, IOANNIS CALTZIDIS, OSCAR CAMACHO IBARRA, and KLAUS D. JÖNS — PhoQS, CeOPP, and Department of Physics, Paderborn University, Germany

Since the discovery of the triggered generation of single photons in 2000, quantum dots have proven to be one of the most versatile quantum light sources for pure, indistinguishable, entangled photons while maintaining high brightness. Before developing deterministic integration techniques, high yield in device fabrication remained elusive due to the statistical growth properties in high-quality self-assembled growth modes. Several methods have been developed, providing the quantum dot location and its spectral information, namely in-situ optical lithography, in-situ electron beam lithography, and quantum dot localization using quantum dot imaging. Our work describes a methodological workflow using computational, and image processing approaches in python to precisely determine the quantum dot position concerning pre-deposited metal marker structures. Here, we investigate different hardware, marker geometries, and software methods. Furthermore, we quantify the expectable upper bound accuracy for device integration. Importantly, our presented methods are not developed for a fixed emitter wavelength or type. With the right choice of optical elements within the setup, it is possible to cover the wavelengths from the visible up to the telecom C-band. The presented technique can, in principle, be applied to any type of solid-state quantum emitters.

### HL 17.9 Wed 12:00 H32

Fabrication and Electrical Characterisation of Junctionless Nanowire Transistors for Detection of Atmospheric Radicals and Other Gases — •SAYANTAN GHOSH¹, MUHAMMAD BILAL KHAN¹, VAISHALI VARDHAN², ULRICH KENTSCH¹, SLAWOMIR PRUCNAL¹, SUBHAJIT BISWAS², JUSTIN HOLMES², ARTUR ERBE¹, and YORDAN M. GEORGIEV^{1,3} — ¹Institute of Ion Beam Physics and Materials Research, Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany — ²School of Chemistry, University College Cork, Cork, Ireland — ³Institute of Electronics, Bulgarian Academy of Sciences, Sofia, Bulgaria

Silicon junctionless nanowire transistors (JNTs) have shown excellent sensitivity to record-low concentrations of the protein streptavidin in liquid phase. However, JNTs have not yet been tested for sensing in gas phase. Here we present the fabrication and initial electrical characterisation of JNT-based electronic sensors for detection of atmospheric free radicals such as hydroxyl (*OH) and nitrate (*NO3), which are the main drivers of chemical processes in the atmosphere. The aim of this work is to develop small, low-cost JNT-based nanosensors for radical detection. Silicon-on-insulator wafers were doped by ion implantation and flash-lamp annealing. Device patterning was based on electron beam lithography, inductively-coupled reactive ion etching, metal deposition and lift-off. Initial electrical characterisation and gas sensing experiments on fabricated devices proved their good performance and potential suitability for detection of atmospheric free radicals.

### HL 17.10 Wed 12:15 H32

Single photons from Semiconductor Quantum Dots in Circular Bragg Gratings for Quantum Cryptography — •DANIEL VAJNER, LUCAS RICKERT, TIMM GAO, KORAY KAYMAZLAR, JAN-NIKLAS DONGES, JOHANNES SCHALL, SVEN RODT, STPEHAN REITZENSTEIN, and TOBIAS HEINDEL — Institut für Festkörperphysik, Technische Universität Berlin, 10623 Berlin, Germany Semiconductor quantum dots are an excellent source of single photons for future quantum networks [1]. In order to enhance their properties they are typically incorporated into photonic structures. Among these, circular bragg gratings (CBG) are a promising way to further enhance the outcoupling efficiency [2]. Additionally, they are especially suited for fiber-coupling to achieve more compact plug-and-play single photon sources [3]. In this work we deterministically integrate single InGaAs quantum dots in CBG structures, which have been numerically optimized beforehand. We characterize the properties of the CBGs and quantify the purity and indistinguishability of the emitted photons. Finally, we aim for the implementation of cryptographic primitives such as strong quantum coin flipping using single photons.

## HL 18: Oxide Semiconductors (joint session HL/KFM)

Time: Wednesday 9:30-12:30

### HL 18.1 Wed 9:30 H33

Heavily doped Zinc Oxide with plasma frequencies in the telecommunication wavelength range — •ALEXANDER KOCH¹, HONGYAN ME1², JURA RENSBERG¹, MARTIN HAFERMANN¹, JAD SALMAN², CHENGHAO WAN^{2,5}, RAYMOND WAMBOLD², DANIEL BLASCKE³, HEIDEMARIE SCHMIDT³, JÜRGEN SAALFELD⁴, SEBASTIAN GEBURT⁴, MIKHAIL KATS^{2,5,6}, and CARSTEN RONNING¹ — ¹Institute for Solid State Physics, Friedrich Schiller University Jena, 07743 Jena, Germany — ²Department of Electrical and Computer Engineering, University of Wisconsin Madison, Madison, Wisconsin 53706, USA — ³Leibniz Institute of Photonic Technology, 07745 Jena, Germany — ⁴Innovavent GmbH, 37077 Göttingen, Germany — ⁵Department of Materials Science and Engineering, University of Wisconsin Madison, Madison, Wisconsin 53706, USA — ⁶Department of Physics, University of Wisconsin Madison, Madison, Madison, Wisconsin 53706, USA

We demonstrate high doping of ZnO by a combination of Ga ion implantation using a focused ion beam (FIB) system and post-implantation laser and flash lamp annealing. While ion implantation allows for the incorporation of impurities with nearly arbitrary concentrations, the additional optical annealing processes enable dopant activation close to the solid-solubility limit of Ga in ZnO. By this means, we achieved highly-doped ZnO:Ga with free-carrier concentrations of  $9.5 \cdot 10^{20}$  cm⁻³, which results in a plasma wavelength shorter than the telecommunication wavelength of 1.55  $\mu$ m. Thus, ZnO:Ga is a very promising plasmonic material for optical applications in the near-infrared spectral region.

#### HL 18.2 Wed 9:45 H33

Side-by-side display of optical and resistive  $H_2S$  gas sensing properties of pristine and gold functionalized ZnO nanowires — •ANGELIKA KAISER¹, TANJA MAURITZ¹, JOACHIM BANSMANN³, ULRICH HERR¹, and KLAUS THONKE² — ¹Institute of Functional Nanosystems, University Ulm, 89081 Ulm, Germany — ²Institute of Quantum Matter, Semiconductor Physics Group, University Ulm, 89081 Ulm, Germany — ³Institute for Surface Chemistry and Catalysis, University Ulm, 89081 Ulm, Germany

We investigate the mechanism of hydrogen sulfide  $(H_2S)$  gas sensing in pristine and gold functionalized zinc oxide (ZnO) nanowires (NW), two potent nanomaterial systems with an enlarged surface-area-to-volume ratio for medical breath analysis in the sub-ppm regime through the "electronic nose" approach. Pristine ZnO NWs (ZnO(NM)) are grown by high-temperature chemical vapor deposition (CVD) and functionalized with gold (Au) nanoparticles by magnetron sputtering (ZnO(Au)). The sensor response is studied by photoluminescence (PL) and electrical conductivity measurements of as-grown ZnO NWs and open gate ZnO NW ChemFET structures. A systematical side-by-side comparison of PL-intensity-time measurements and current-time measurements reveal a twostep detection process between 1 ppm of H₂S and ZnO(NM)/ZnO(Au) NWs. Temperature series hints at underlying gas adsorption/desorption processes. Additional X-ray photoelectron spectroscopy (XPS) confirms the beneficial gassensitive affinity between Au functionalization and H₂S gas, which leads to a significant improvement of the sensitivity for H₂S detection.

### HL 18.3 Wed 10:00 H33

Growth window of α-Ga₂O₃ on m-plane sapphire by pulsed laser deposition — •C. Petersen, S. Vogt, M. Kneiss, H. von Wenckstern, and M. Grundmann — Universität Leipzig, Felix Bloch Institute for Solid State Physics, Semiconductor Physics Group, Leipzig, Germany

Due to its high bandgap of 4.6-5.3 eV and high predicted breakdown field of 8 MV/cm [1], much attention is drawn to the wide bandgap semiconductor  $Ga_2O_3$  for applications in high-power devices. However, besides the well-studied thermodynamically stable monoclinic  $\beta$ -phase of  $Ga_2O_3$ , the metastable

Location: H33

α-polymorph with corundum structure is gaining scientists' interest. Since it is isostructural to Al₂O₃, miscibility over the entire composition range of α-(Al_xGa_{1-x})₂O₃ can be achieved [2] and the growth on cost-effective sapphire substrates becomes feasible. Thereby m-plane sapphire facilitates the growth of the corundum phase [3] and allows for thin films with electron mobilities as high as 65 cm²(Vs)⁻¹ [4]. We present phase-pure α-Ga₂O₃ thin films grown on m-plane sapphire over a wide temperature range of 565 °C up to 750 °C with high cristallinity and surface roughnesses as low as 0.7 nm (RMS). We further demonstrate that for oxygen partial pressures above 0.001 mbar the formation of the monoclinical β-phase and spinel-defective γ-phase occurs and provide a corresponding phase diagram. Resulting samples were investigated employing X-ray diffraction, reciprocal space maps and atomic force microscopy. [1] Hi gashiwaki, Sc. Sci. Tech., 034001, 2016. [2] Hassa, pss-b, 2000394, 2020. #### HL 18.4 Wed 10:15 H33

Simulation of Switching Processes Inside Bilayer Valence Change Memory Cells by a Drift-Diffusion Model — •NILS SOMMER¹, STEPHAN MENZEL¹, and RAINER WASER^{1,2} — ¹Peter Grünberg Institut 7, Forschungszentrum Jülich, Germany — ²Institut für Werkstoffe der Elektrotechnik 2, RWTH Aachen, Germany

Valence change memory (VCM) cells are promising candidates for future nonvolatile storage devices [1]. VCM cells are characterized by their ability to switch between at least two stable resistance states by applying suitable bias voltages. A special structure of VCM cells are bilayer cells consisting of two semiconducting oxide layers, with one oxide serving as a tunnel barrier. Experiments show that a change in resistance of the cell can be caused by the exchange of oxygen between the two oxide layers [2]. However, the processes taking place are not yet well understood. We use a drift-diffusion model to simulate the movement of oxygen inside the semiconductor to gain a better understanding of the exchange process between the layers. We investigate the internal electric fields acting as a driving force on the oxygen, as well as the oxygen diffusion process that causes it to return to an equilibrium state. We show that an oxygen exchange deforms the shape of the tunnel barrier and by this changing the resistance of the cell. Further, we show that the change in resistance depends on the permittivity of the oxides.

### HL 18.5 Wed 10:30 H33

**Phonons, Isotope Effects, and Point Defects in** β-**Ga2O3** — •BENJAMIN M. JANZEN¹, PIERO MAZZOLINI^{2,3}, ROLAND GILLEN⁴, ANDREAS FALKENSTEIN⁵, VIVIEN F. S. PELTASON¹, HANS TORNATZKY¹, DANIEL CIERPINSKY¹, ANDREA ARDENGHI², MANFRED MARTIN⁵, JANINA MAULTZSCH⁴, ROBERTO FORNARI^{2,3}, ZBIGNIEW GALAZKA⁶, OLIVER BIERWAGEN², and MARKUS R. WAGNER¹ — ¹Technische Universität Berlin, Institute of Solid State Physics, Berlin, Germany — ²Paul-Drude-Institut für Festkörperelektronik, Leibniz-Institut im Forschungsverbund Berlin e.V, Germany — ³Department of Mathematical, Physical and Computer Sciences, University of Parma, Italy — ⁴Chair of Experimental Physics, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany — ⁵Institute of Physical Chemistry, RWTH Aachen University, Germany — ⁶Leibniz-Institut für Kristallzüchtung, Berlin, Germany

We present a combined experimental and theoretical study of lattice vibrations in a homoepitaxial  $\beta$ -Ga2O3 thin film grown by MBE with different oxygen isotopes (16O, 18O). Using polarized first- and second order micro-Raman spectroscopy, we identified all 15 first-order Raman modes of  $\beta$ -Ga2O3. In combination with density functional perturbation theory calculations, we identify the atomistic origins (Ga-Ga, Ga-O or O-O) of all Raman active phonon modes in  $\beta$ -Ga2O3 by quantifying the isotopically-induced relative frequency shifts of the individual Raman modes and investigate the presence of point defects on specific lattice sites.

HL 18.6 Wed 10:45 H33

**Epitaxial ZnO thin films and NWs** — •MAXIMILIAN KOLHEP¹, MARGIT ZACHARIAS¹, and JÜRGEN BLÄSING² — ¹Laboratory for Nanotechnology, Department of Microsystems Engineering (IMTEK), University of Freiburg, Freiburg 79110, Germany — ²Otto-von-Guericke-University Magdeburg, Institute of Physics, Magdeburg, Germany

Due to its high piezoelectric coefficient and direct band gap of 3.37 eV, ZnO and especially ZnO nanowires are of interest for numerous future applications. We demonstrate the epitaxial growth of ZnO on Si(111) substrates using an AlN buffer layer by atomic layer deposition (ALD). ALD is a promising technique as it allows the deposition of extremely thin films with precise thickness control and excellent conformality over large areas. The crystalline quality of ZnO thin films determined by XRD increases with increasing deposition temperature and an additional post-annealing step. These thin films have a great potential as a substrate for the subsequent catalyst-free and epitaxial growth of ZnO NWs by CVD. The influence of growth parameters on the morphology of ZnO NWs will be discussed.

### HL 18.7 Wed 11:15 H33

Investigation of  $\text{CuBr}_{x} I_{1-x}$  thin films and CuI bulk material — •MICHAEL BAR¹, EVGENY KRÜGER¹, STEFFEN BLAUROCK², STEFAN MERKER², HOLGER VON WENCKSTERN¹, HARALD KRAUTSCHEID², and MARIUS GRUNDMANN¹ — ¹Universität Leipzig, Felix-Bloch Institute, Germany — ²Universität Leipzig, Institute of Inorganic Chemistry, Germany

Oxide based wide-bandgap materials with suitable transparency in the visible range are typically unipolar, such that heterostructures are needed for complementary devices. The search for a suitable p-type candidate has led to copper iodide (CuI), which unites transparency in the visible spectral range with exceptional hole mobility, therefore sharing and yet complementing typical properties of oxides. Fabrication methods include sputtering, spin coating and molecular beam epitaxy. [1,2] We present structural, electrical and optical properties of CuI bulk material, and thin films which were grown by pulsed laser deposition (PLD). Furthermore, alloyed thin films of CuBr_xI_{1-x} were deposited with a segmented target PLD approach and investigated using x-ray diffraction, transmission and photoluminescence measurements. This PLD approach allows for deposition of thin films in the full composition range using only a single target without the need of sintering. [3] A systematic shift of lattice constants as well as the excitonic features can be observed as function of alloy composition.

### HL 18.8 Wed 11:30 H33

A Koopman's compliant exchange correlation potential for semiconductors — •MICHAEL LORKE¹, PETER DEAK², and THOMAS FRAUENHEIM² — ¹Institute for Theoretical Physics, University of Bremen, Germany — ²BCCMS, University of Bremen, Germany

Density functional theory is the workhorse of theoretical materials investigations. Due to the shortcoming of (semi-)local exchange correlation potentials, hybrid functionals have been established for practical calculations to describe surfaces, molecular adsorption, and defects. These functionals operate by mixing between semi-local and Hartree-Fock exchange semi-emprically. However, their parameters have to be optimized for every material separately. To treat materials with a more physics driven approach and without the need of parameter optimization is possible with many-body approaches like GW, but at an immense increase in computational costs and without the access to total energies and hence geometry optimization.

We propose a novel exchange correlation potential[1] for semiconductor materials, that is based on physical properties of the underlying microscopic screening. We demonstrate that it reprocuduces the low temperature band gap of several materials. Moreover it respects the required linearity condition of the total energy with the fractional occupation number, as expressed by the generalized Koopman's theorem. We also show that this novel functional can be used as a kernel in linear response TDDFT to reproduce excitonic effects in optical spectra [1] Physical Review B 102 (23), 235168 (2020)

### HL 18.9 Wed 11:45 H33

The role of defects in polaron hopping transport in epitaxial BiVO4 for solar water splitting — •MALTE LUCA WEBER, VIKTORIA FRANZISKA KUNZELMANN, and IAN SHARP — Walter Schottky Institute, TUM, Am Coulombwall 4, 85748 Garching, Germany

Use of green hydrogen as a fuel, energy storage medium, and reactant in chemical industry is one of the key strategies on the way to a sustainable economy. In this regard, solar driven water splitting using semiconductor photoelectrodes is a promising approach for sustainable production of hydrogen. Among various investigated semiconductor photoelectrodes, BiVO4 offers several desirable characteristics, including favourable band edge energetics, high carrier separation efficiency, and potential for stable operation under photoelectrochemical conditions. However, the material is characterised by very low carrier mobilities due to self-trapping formation of small polarons. Here, the effect of intentionally introduced defects on charge carrier mobility is investigated. Using a novel solution-based synthesis technique, high-quality epitaxial BiVO4 thin films were grown on YSZ (001). Post-synthetic vacuum annealing enables tuneable introduction of tuneable concentrations of oxygen vacancy defects. Optical characterisation by photothermal deflection spectroscopy clearly indicates an increase of the sub-bandgap absorption for an increasing defect concentration, leaving unaltered the bandgap. Temperature-dependent electrical conductivity measurements indicate a thermally-activated hopping behaviour, which is characterised by higher conductivities and lower hopping behaviours with increasing native point defect concentrations.

HL 18.10 Wed 12:00 H33

Conduction channels in polycrystalline copper iodede thin films — •TILLMANN STRALKA — Universitiät Leipzig, Felix Bloch Institute for Solid State Physics, Linnéstr. 5, 04103 Leipzig, Germany

The search for high-performance, transparent p-type conductive materials has been a major challenge for decades [1]. Copper iodide (CuI) or alloys based on CuI [2] could offer a solution, since CuI does outperform all other known p-type TCMs, concerning transmittance in the visible spectrum as well as electrical conductivity at room temperature [3]. In this contribution polycrystalline CuI thin films, grown by sputtering, are investigated. Hereby we try to understand and differentiate the contribution of grains and grain boundaries (GBs) to electrical transport. Extended structural defects such as GBs lead to a depletion of majority charge carriers in their vicinity and even a localised inversion (two dimensional electron gas) within GBs was reported [4]. To acquire morphological (grain and GBs) and electrical properties with a high spatial resolution we employ current probe atomic force microscopy and Kelvin probe force microscopy. We evaluate these measurements with a novel approach that offers the possibility to correlate topographic and electrical properties over a whole series of scans in dependence on an externally applied voltage [5], measuring temperature, probe force, plasma treatment and degradation over time.

First-Principles Studies of Defects in Bismuth Vanadate — •NICKLAS ÖSTERBACKA¹, FRANCESCO AMBROSIO², and JULIA WIKTOR¹ — ¹Chalmers University of Technology, Gothenburg, Sweden — ²University of Salerno, Fisciano, Italy

Bismuth vanadate, a transition-metal oxide semiconductor with a bandgap of 2.4 eV, has shown great promise as a water-splitting photocatalyst. Its practical performance remains limited due to slow hole transfer, high charge recombination rates, and low conductivity, however. An atomistic understanding of the relationship between the material's structure and its properties is key to solving these issues. To this end, we have performed first-principles calculations on the native defects of bismuth vanadate, revealing their structural complexity and highlighting the importance of taking charge localization into account for this class of materials. Additionally, we show that oxygen vacancy-induced distortions in the material complicates phase identification of synthesized samples by making powder X-ray diffraction ambiguous.

HL 19.1 Wed 9:30 H34

Quantum Interference of Identical Photons from Remote GaAs Quantum Dots — •GIANG NAM NGUYEN¹, LIANG ZHAI¹, CLEMENS SPINNLER¹, JULIAN RITZMANN², MATTIAS C. LÖBL¹, ANDREAS D. WIECK², ARNE LUDWIG², ALISA JAVADI¹, and RICHARD J. WARBURTON¹ — ¹Department of Physics, University of Basel — ²Lehrstuhl für Angewandte Festkörperphysik, Ruhr-Universität Bochum

Efficient generation and detection of coherent single photons are key to advances in photonic quantum technologies such as quantum computation, quantum simulation, and quantum communication. For applications, a significant roadblock is the poor quantum coherence upon interfering single photons created by independent emitters.

Here, we present near-unity two-photon interference visibilities from two separate GaAs quantum dots [1]. This high visibility (~93%) is achieved under rigorous conditions: there is no Purcell enhancement, no temporal post-selection, no narrow spectral-filtering, nor frequency stabilization. Using photons emitted from two remote quantum dots, we demonstrate a photonic CNOT gate. Interfering photons in this quantum logic gate, we generate an entangled two-photon state using photons from separate semiconductor chips. We obtain an entanglement fidelity of (85 + 1)%, exceeding the CHSH threshold for violating Bell inequalities. This result highlights the importance of the high two-photon visibility for high fidelity entanglement operations.

**Optimizing quantum teleportation with imperfect quantum dot sources** – •FRANCESCO SALUSTI¹, FRANCESCO BASSO BASSET², LUCAS SCHWEICKERT³, MICHELE B ROTA², DAVIDE TEDESCHI², SAIMON FILIPE COVRE DA SILVA⁴, EMANUELE ROCCIA², VAL ZWILLER³, KLAUS D JÖNS¹, ARMANDO RASTELLI⁴, and RINALDO TROTTA² – ¹Department of Physics, Paderborn University, Paderborn, Germany – ²Department of Physics, Sapienza University of Rome, Rome, Italy – ³Department of Applied Physics, Royal Institute of Technology, Stockholm, Sweden – ⁴Institute of Semiconductor and Solid State Physics, Johannes Kepler University, Linz, Austria

All-optical quantum communication protocols such as teleportation and entanglement swapping require the generation of entangled photons. Quantum dots, with their on-demand generation and low unwanted multi-photon emission are excellent candidates to realize these protocols. However, finding quantum dots with near-perfect quantum optical properties remains challenging. Instead, in our work we demonstrate that it is possible to improve a quantum teleportation protocol by acting exclusively on the experimental setup. [1] Despite selecting a source with non-ideal figures of merit, we have been able to enhance the overall protocol fidelity. The obtained values agree with our developed model, taking the quantum dot properties into account. Our model provides predictive power for future source optimization. Reference: [1] F. Basso Basset, F. Salusti et al., npj Quantum Information 7, 7 (2021)

### HL 19.3 Wed 10:15 H34

Time Dependent Redfield Dynamics of Semiconductor Quantum-Dot Molecules — •STEFFEN WILKSEN, ISABELL HÜLLEN, FREDERIK LOHOF, and CHRISTOPHER GIES — Institute for Theoretical Physics, University of Bremen, Bremen, Germany

Semiconductor quantum dots provide a promising platform for applications in quantum information technologies, like quantum repeaters, which enable secure quantum communication over long distances. Two quantum dots, seperated by a small tunneling layer, can be combined into so-called quantum dot molecules (QDMs) which exhibit properties similar to classical molecules. These properties can be tuned by applying an external electric field, which allows to perform switching operations on QDM-based qubits.

The QDM can not be treated in isolation, since the electron-phonon interaction plays a crucial role in the systems dynamics. We thus treat the QDM as an open quantum system coupled to the external phonon reservoir. The application of a time-dependent electric field not only changes the QDM's properties, but also the form of the electron-phonon interaction, which allows for a time dependent tuning of dissipative effects.

We investigate the behaviour of the system for different switching speeds of the electric field using a time-dependent Redfield master equation approach. Slow switching leads to predictable and controlled adiabatic behaviour but limits the clock rate of the quantum repeater, whereas fast switching allows for higher clock rates but leads to non-adiabatic behaviour.

HL 19.4 Wed 10:30 H34

Three-dimensional electrical control of the excitonic fine structure for a quantum dot in a cavity — •MARTIN ESMANN^{1,2}, HÉLÈNE OLLIVIER¹, PRIYA PRIYA¹, ABDELMOUNAIM HAROURI¹, ISABELLE SAGNES¹, ARISTIDE LEMAÎTRE¹, OLIVIER KREBS¹, LOIC LANCO¹, DANIEL LANZILLOTTI-KIMURA¹, and PASCALE SENELLART¹ — ¹Université Paris-Saclay, CNRS, Centre de Nanosciences et de Nanotechnologies (C2N), Palaiseau, France — ²Institut für Physik, Universität Oldenburg, Germany

The excitonic fine structure plays a key role for the quantum light generated by semiconductor quantum dots, both for entangled photon pairs and single photons [1]. Controlling the excitonic fine structure has been demonstrated using electric, magnetic, or strain fields, but not for quantum dots in optical cavities, a key requirement to obtain high source efficiency and near-unity photon indistinguishability [2]. Here, we demonstrate the control of the fine structure splitting for quantum dots embedded in micropillar cavities. We propose and implement a scheme based on remote electrical contacts connected to the pillar cavity through narrow ridges. Numerical simulations show that such a geometry allows for a three-dimensional control of the fine structure, a crucial step for the reproducibility of quantum light source technology.

HL 19.5 Wed 10:45 H34 Design study of electrically contacted quantum dot circular Bragg gratings — •QUIRIN BUCHINGER, TOBIAS HUBER, and SVEN HÖFLING — Technische Physik, Universität Würzburg, 97074 Würzburg, Germany

Recently, photonic quantum networks receive a lot research interest. Semiconductor quantum dots offer a local memory, utilizing single spins and are highly efficient single or entangled photon sources. Therefore, they are among suitable candidates for a scalable hardware platform for quantum networks. To enhance brightness and extraction efficiency the quantum dots are typically embedded into microcavities, here circular Bragg gratings. By incorporating the quantum dots into a diode structure they can be charged with a single electron or hole and thus generate a ground state spin qubit [1]. This provides opportunity for spin photon coupling [2]. To apply voltage to the quantum dot inside of a circular Bragg grating, bridges through the etched rings have to be leaved unetched as a path for the current to the central disc of the microcavity. We discuss different layouts of these bridges and their influence on cavity wavelength, quality factor and polarisation.

HL 19.6 Wed 11:30 H34

Influence of extended defects on the formation energy, hyperfine structure, and zero-field splitting of NV centers in diamond — WOLFGANG KÖRNER¹, •DANIEL URBAN¹, and CHRISTIAN ELSÄSSER^{1,2} — ¹Fraunhofer Institute for Mechanics of Materials IWM, Wöhlerstr. 11, 79108 Freiburg, Germany — ²University of Freiburg, Freiburg Materials Research Center (FMF), Stefan-Meier-Straße 21, 79104 Freiburg, Germany

We present a density-functional theory analysis of nitrogen-vacancy (NV) centers in diamond, which are located in the vicinity of extended defects, namely, intrinsic stacking faults, extrinsic stacking faults, and coherent twin boundaries on 111 planes in diamond crystals [1]. Several sites for NV centers close to the extended defects are energetically preferred with respect to the bulk crystal. This indicates that NV centers may be enriched at extended defects. We report the hyperfine structure and zero-field splitting parameters of the NV centers at the extended defects, which typically deviate by about 10% but in some cases up to 90% from their bulk values. Furthermore, we find that the influence of the extended defects on the NV centers is of short range: NV centers that are about three double layers (corresponding to  $\sim 6$  Å) away from defect planes already show bulklike behavior.

**Topological insulator based axial DC SQUID quantum interferometer structure** – •ERIK ZIMMERMANN^{1,2}, BENEDIKT FROHN^{1,2}, JAN KARTHEIN^{1,2}, GER-RIT BEHNER^{1,2}, ABDUR REHMAN JALIL^{1,2}, TOBIAS SCHMITT^{2,3}, MICHAEL SCHLEENVOIGT^{1,2}, GREGOR MUSSLER^{1,2}, PETER SCHÜFFELGEN^{1,2}, HANS LÜTH^{1,2}, DETLEV GRÜTZMACHER^{1,2,3}, and THOMAS SCHÄPERS^{1,2} – ¹Peter Grünberg Institut (PGI-9), Forschungszentrum Jülich, 52425 Jülich, Germany – ²JARA-Fundamentals of Future Information Technology, Jülich-Aachen Research Alliance, Forschungszentrum Jülich and RWTH Aachen University, Germany — ³Peter Grünberg Institut (PGI-10), Forschungszentrum Jülich, 52425 Jülich, Germany

Three-dimensional topological insulators (TIs) form a new material class that may enable robust topological quantum computing when combining them with a superconductor by using so-called Majorana zero modes. Recently, Josephson junctions and SQUIDs using a TI as a weak link are investigated for interface characterization. We present the in-situ fabrication of an interferometer structure formed by an axial DC SQUID that is based on a ternary TI with a  $Bi_{0.18}Sb_{1.82}Te_3$  composition. For the in-situ fabrication shadow mask techniques and selective area growth by molecular beam epitaxy are used. Furthermore, magnetotransport measurements are shown, revealing induced superconductivity in both Josephson junctions and an in-plane magnetic field dependent interference pattern corresponding to SQUID oscillations. Lastly, the Shapiro response of the device is investigated.

Silicon, a ubiquitous material in modern computing, is an emerging platform for realizing a source of indistinguishable single-photons on demand. The integration of recently discovered single-photon emitters in silicon into photonic structures is advantageous to exploit their full potential for integrated photonic quantum technologies [1] [2]. Here, we show the integration of an ensemble of telecom photon emitters in a two-dimensional array of silicon nanopillars. We developed a top-down nanofabrication method, enabling the production of thousands of individual nanopillars per square millimeter with state-of-the-art photonic-circuit pitch, all the while being free of fabrication-related radiation damage defects. We found a waveguiding effect of the 1278 nm G-center emission along individual pillars accompanied by improved brightness, compared to that of bulk silicon.

### HL 19.9 Wed 12:15 H34

Large hBN single-photon emitter arrays fabricated by capillary assembly — •JOHANN ADRIAN PREUSS, EDUARD RUDI, JOHANNES KERN, ROBERT SCHMIDT, RUDOLF BRATSCHITSCH, and STEFFEN MICHAELIS DE VASCONCELLOS — University of Münster, Institute of Physics and Center for Nanotechnology, Wilhelm-Klemm-Str. 10, 48149 Münster, Germany

Convenient and readily available quantum light sources are a crucial building block for quantum photonic technologies. Recently, single-photon emitters have been discovered in hexagonal boron nitride (hBN), which efficiently emit single photons even at room temperature. Controlling the positioning of nanocrystals hosting these light emitters is an important technique for the bottom-up fabrication of functional nanostructures. Here, we demonstrate the fabrication of  $mm^2$ -sized rectangular arrays formed by tens of thousands of hBN nanoplatelets [1]. Using capillary assembly, we arrange commercially available hBN nanopowder. Positioning yields of >95% are achieved on individual fields. We find stable and spectrally narrow quantum optical light emitters in 16% of the positions. Our preparation method opens the way for the combination of quantum light emitters in hBN with further fabrication steps for integrated photonic chips, which can provide thousands of single-photon sources at different emission energies. HL 19.10 Wed 12:30 H34

Single-electron Shuttling by Si/SiGe Quantum Bus — •RAN XUE, INGA SEI-DLER, TOM STRUCK, SIMON HUMPHOL, TOBIAS HANGLEITER, HENDRIK BLUHM, and LARS R. SCHREIBER — JARA-FIT Institute for Quantum Information, Forschungszentrum Jülich GmbH and RWTH Aachen University, Aachen, Germany

The electron-spin in gate-defined quantum dots in a Si/SiGe heterostructure is one of the most promising qubits for scalable quantum computing. Qubit gates beyond the error-correction threshold have been widely investigated, however, the long range coupling of qubits remains challenging. Here we study the feasibility of single electron shuttling by forming a propagating sinusoidal potential in a gate-defined 1-dimensional channel. A  $99.42 \pm 0.02\%$  high single-electron shuttle fidelity over a distance of 420 nm has been demonstrated in our recent research. [1] It provides adiabatic movement of a quantum dot filled by a single electron representing the qubit. An extension to  $10 \, \mu m$  long devices is in progress. The number of control lines is intrinsically independent from the shuttle length, therefore, no additional scalability complexity regarding signal generation and wiring is expected. Our concept is compatible with industrial CMOS fabrication lines and ultimately might lead to transport spin qubit information without much loss of spin-coherence.

**Dark exciton anti-funneling in monolayer transition metal dichalcogenides** – •Roberto Rosati¹, Robert Schmidt², Samuel Brem¹, Raül Perea-Causín³, Iris Niehues⁴, Johannes Kern², Johann Adrian Preuss², Robert Schneider², Steffen Michaelis de Vasconcellos², Rudolf Bratschitsch², and Ermin Malic^{1,3} – ¹Philipps-Universität Marburg – ²University of Münster – ³Chalmers University of Technology – ⁴CIC nanoGUNE BRTA

Current nanoelectronics relies on transport. While charged carriers can be controlled by electric fields, atomically thin semiconductors are governed by excitons, which are neutral electron-hole pairs. Recently, strain engineering has been introduced to manipulate exciton diffusion [1] and propagation [2] in monolayer transition metal dichalcogenides. Strain-induced energy gradients give rise to exciton funneling up to a micrometer range. Combining spatiotemporal photoluminescence measurements with microscopic theory, here we track the way of excitons in time, space and energy. Surprisingly we find that in WS₂ excitons move away from high-strain regions, contrary to what we observe in MoSe₂ [2]. This anti-funneling behavior can be ascribed to dark excitons, whose straininduced energy variations are opposite compared to bright excitons. Our findings open new possibilities to control transport in exciton-dominated materials. [1] R. Rosati et al., 2D Mater. 8, 015030 (2021).

HL 20.2 Wed 9:45 H36

Ultrafast nanoscopy of a Mott transition in twisted bilayer  $WSe_2 - \bullet$ SVENJA NERRETER¹, THOMAS SIDAY¹, FABIAN SANDNER¹, SAMUEL BREM^{2,3}, MARTIN ZIZLSPERGER¹, FELIX SCHIEGL¹, RAUL PEREA-CAUSIN³, MARKUS PLANKL¹, PHILIPP MERKL¹, FABIAN MOOSHAMMER^{1,4}, MARKUS A. HUBER¹, ERMIN MALIC^{2,3}, and RUPERT HUBER¹ — ¹Department of Physics and Regensburg Center for Ultrafast Nanoscopy, University of Regensburg, Germany — ²Department of Physics, Philipps-Universität Marburg, Germany — ³Department of Physics, Chalmers University of Technology, Gothenburg, Sweden — ⁴Department of Physics, Columbia University, New York, USA

The density-driven transition of an exciton gas into a Fermi liquid of unbound electron-hole pairs has formed a compelling testing ground of many-body physics. Layered transition metal dichalcogenides feature advantageous conditions, yet nanoscale inhomogeneities have complicated quantitative studies of this elusive transition. Here, we use ultrafast polarization nanoscopy to trace optically bright and dark electronhole pairs during an exciton Mott transition in a twisted homobilayer of WSe₂. At elevated densities, initially monomolecular recombination dynamics of optically dark excitons continuously evolve into the bimolecular recombination of unbound electron-hole pairs. We directly reveal how the Mott transition varies over nanometer length scales, evidencing strong spatial disorder in stacked monolayers and demonstrating the capabilities of our technique to resolve the local interplay of strong electronic correlations.

### HL 20.3 Wed 10:00 H36

Rashba excitons in the 2D Ruddlesden-Popper perovskite (BA)MAPI – •PHILIPP MOSER¹, MARTIN SCHALK¹, ATSUHIKO MIYATA², JOACHIM WOSNITZA², ANDREAS STIER¹, and JONATHAN FINLEY¹ – ¹Walter Schottky Institute, Garching, Germany – ²Helmholtz-Zentrum Dresden-Rossendorf, Dresden, Germany

Two-dimensional organic-inorganic perovskites have emerged as remarkable materials for energy conversion, optoelectronic and spintronic applications. Recently, the role of spin-orbit (SO) coupling and the resulting effects on the bandstructure and dark/bright optical transitions has become a key topic of interest. The necessary structural inversion asymmetry for SO-coupling is predicted to stem from the organic cations comprising the crystals. As a result, dark excitons, red detuned from the bright exciton, have been discussed in this material system. Here, we investigate the exciton physics of the 2D Ruddlesden-Popper perovskite (BA)MAPI. By performing one-photon absorption, -PL and two-photon PLE spectroscopy, we investigate the optical transitions close to the R-point of the Brillouin zone and find distinct 2-photon transitions blue detuned from the ground state exciton that can be explained by a Rashba-split band-structure. Utilizing high-field magneto-spectroscopy up to B=60T, we determine that these absorption features are due to Wannier excitons. We determine the size and binding energy from the diamagnetic shift of the features and obtain evidence that 2D (BA)MAPI hosts strongly bound Rashba excitons.

### HL 20.4 Wed 10:15 H36

Ultrafast pseudospin quantum beats in multilayer WSe2 and MoSe2 — •SIMON RAIBER¹, PAULO E. FARIA JUNIOR², DENNIS FALTER¹, SIMON FELDL¹, PETTER MARZENA¹, KENJI WATANABE³, TAKASHI TANIGUCHI⁴, JAROSLAV FABIAN², and CHRISTIAN SCHÜLLER¹ — ¹Institut für Experimentelle und Angewandte Physik, Universität Regensburg, D-93040 Regensburg, Germany — ²Institut für Theoretische Physik, Universität Regensburg, D-93040 Regensburg, Germany — ³Research Center for Functional Materials, NIMS, Tsukuba, Japan — ⁴International Center for Materials Nanoarchitectonics, NIMS, Tsukuba, Japan

We present investigations of excitonic transitions in mono- and multilayer WSe2 and MoSe2 materials by time-resolved Faraday ellipticity (TRFE) with in-plane magnetic fields, of up to B = 9 T. In monolayer samples, the measured TRFE time traces are almost independent of B, which confirms a close to zero in-plane exciton g factor, consistent with first-principles calculations. In stark contrast, we observe pronounced temporal oscillations in multilayer samples for B > 0. Remarkably, the extracted in-plane g factors are very close to reported out-of-plane exciton g factors of the materials, namely |g< 1s| = 3.1 + /- 0.2 and 2.5 +/- 0.2 for the 1s A excitons in WSe2 and MoSe2 multilayers, respectively. Our first-principles calculations nicely confirm the presence of a non-zero in-plane g for the multilayer samples. We propose that the oscillatory TRFE signal in the multilayer samples is caused by pseudospin quantum beats of excitons, which is a manifestation of spin- and pseudospin layer locking in the multilayer samples.

### HL 20.5 Wed 10:30 H36

**Nonlinear Exciton Dynamics in Layered Heterostructures** — •VIPIN KRISHNA¹, XIAO CHEN², TARLAN HAMZAYEV¹, SILVANA BOTTI², and GIANCARLO SOAVI¹ — ¹Institute of Solid state Physics,Friedrich-Schiller-University,Jena — ²Institute of Theoretical Solid State Theory and Optics,Friedrich-Schiller-University,Jena

Transition-metal-dichalcogenides and related heterostructures(HS) are promising candidates for photonic and optoelectronic applications owing to strong light-matter coupling and electrically-tunable carrier dynamics. However, the presence of intense nonlinear effects such as Exciton-Exciton Annihilation(EEA)[1] limits the maximum realizable exciton-density, and is particularly efficient for interlayer-excitons(IL) due to their out-of-plane dipole nature[2].In this work,we systematically study the onset of EEA in type-II WS2/WSe2 HS by steady-state and nonlinear time-resolved PL.We infer that in HS the generation-rate is at least one order of magnitude larger for interlayer compared to intralayer-excitons for a given excitation-fluence, as expected from the ultrafast interlayer-charge-transfer and consequent IL formation. However, we do not observe stronger EEA for interlayer compared to intralayer-excitons and observe that for HS the recombination-dynamics are identical for both, suggesting that the EEA mechanism is dominated by the total excitonic-density via intra and interlayer-exciton interactions.Our work provides new insights on EEA mechanism, which is of paramount importance for optoelectronic-devices and study of excitonic-condensates with layeredmaterials.[1]Kuechle et.Al.J.OMX(2021),12.[2]Sigl et.Al.Phys.Rev.B 105,035417.

Tunable exciton-polaritons emerging from WS₂ monolayer excitons in a photonic lattice at room temperature — •LUKAS LACKNER¹, MARCO DUSEL², OLEG EGOROV³, BO HAN¹, HEIKO KNOPF³, FALK EILENBERGER³, CARLOS ANTON-SOLANAS¹, SVEN HÖFLING², and CHRISTIAN SCHNEIDER¹ — ¹University of Old-enburg, Oldenburg, Germany — ²University of Würzburg, Würzburg, Germany — ³Friedrich Schiller University Jena, Jena, Germany

The engineering of non-linear light-matter states in optical lattices has emerged as a key research strategy for the exploration of Hamiltonians in the spirit of ultrafast- and possibly quantum-simulation. It furthermore has revealed its potential to probe non-trivial topology phenomena. Excitons in atomically thin crystals have emerged as an ideal active medium for such purposes, since they couple strongly with light, and bear the potential to harness giant non-linearities and interactions.

In this work, we present an experiment conducted at room temperature in an open optical cavity of high quality, with an implemented one-dimensional photonic lattice. In our present work we integrate an atomically thin layer of  $WS_2$  in such a device. We discuss the emergence and tunability of a lattice-band-structure in the tight-binding configuration at room temperature, fuelled by the emission from monolayer excitons[1].

**Optical Spectroscopy of Colloidal Transition Metal Dichalcogenides** — •ANDRÉ PHILIPP FRAUENDORF¹, ANDRÉ NIEBUR², JENS HÜBNER¹, JANNIKA LAUTH^{2,3}, and MICHAEL OESTREICH¹ — ¹Institut für Festkörperphysik, Leibniz Universität Hannover — ²Institut für Physikalische Chemie und Elektrochemie, Leibniz Universität Hannover — ³Institut für Physikalische und Theoretische Chemie, Universität Tübingen

Atomically thin transition metal dichalcogenides (TMDs) are at the forefront of a new generation of two-dimensional semiconductor systems and experience an increasing research interest due to their unique optical properties. As an additional fabrication approach the wet-chemical synthesis has emerged as a promising method for the straightforward solution-processing of these materials. [1] Nevertheless, the optical properties of colloidal TMD mono- and few-layer structures have been sparsely studied.

Here, we demonstrate room-temperature micro-photoluminescence of colloidal TMD nanosheets. Both, mono-and multilayer photoluminescence are observed rendering these delicate structures fully competitive with conventionally fabricated TMDs. [1] In addition temperature-dependent transient absorption measurements are presented as a convincing technique for the exploration of the ultra-fast recombination dynamics of two-dimensional materials. Capacitively and inductively coupled excitons in bilayer  $MoS_2$  – •Lukas Sponfeldner¹, Nadine Leisgang¹, Shivangi Shree², Ioannis Paradisanos², Kenji Watanabe³, Takashi Taniguchi⁴, Cedric Robert², Delphine Lagarde², Andrea Balocchi², Xavier Marie², Iann C. Gerber², Bernhard Urbaszer², and Richard J. Warburton¹ – ¹Department of Physics, University of Basel – ²Université de Toulouse, INSA-CNRS-UPS, LPCNO – ³Research Center for Functional Materials, National Institute for Materials Science – ⁴International Center for Materials Nanoarchitectonics, National Institute for Materials Science

Exciton-exciton couplings in semiconductors lead to a plethora of phenomena such as nonlinear optical effects and quantum condensation. Transition-metal dichalcogenides constitute a versatile platform to study these effects as the excitons are very robust and their couplings can be controlled by exploiting their spin and valley properties.

Here, we probe exciton-exciton couplings in gated-homobilayer  $MoS_2$ . Using a driven-coupled oscillator model it is shown that the measured optical susceptibility reveals both the magnitude and the phase of the coupling constants. The interlayer excitons (IE) and intralayer B-excitons couple via a 0-phase (capacitive) coupling; the IE and the intralayer A-excitons couple via a  $\pi$ -phase (inductive) coupling. Using the IE as a sensor, the A-B intravalley exchange coupling is determined, a result which is also relevant for a monolayer. Finally, we realize a bright and highly tunable lowest-energy momentum-direct exciton at high electric fields.

**Controlling the non-linearity in two dimensional materials** — •MATHIAS FEDEROLF and SVEN HÖFLING — Technische Physik, Universität Würzburg, 97074 Würzburg, Germany

Recently Datta et al. [1] have shown that exciton-polaritons in bilayer  $MoS_2$  experience a blueshift due to interacting with other exciton-polaritons. The observed blueshift is non-linear with respect to the laser power used for excitation.

Due to the bilayer's nature interlayer-excitons can occur, which exhibit an out of plane dipole moment. Using an electric field along the out of plane axis those dipoles can be aligned and used to influence the exciton-exciton interaction. By using a varying electric field, we map the parameter space to gain deterministic

control over the blueshift. Understanding and controlling the system allows us to tune the polariton-polariton interaction such that they can be used in future application i.e., single-photon sources.

Copper iodide (CuI) is a promising candidate for transparent optoelectronic applications due to its large band gap of 3.1 eV and high exciton binding energy of 62 meV [1]. Here we present spectral- and time-resolved measurements of the near-band-edge luminescence of CuI bulk crystals for temperatures between 10 K and 250 K. The line shape of the emission lines at low temperatures is interpreted in terms of defect-bound exitons and exciton-polaritons [2]. The different decay characteristics of free and localized exciton states are explained by their coupled interaction. Based on the rise time of bound excitons, the defect density is estimated to be about  $1 \times 10^{17} \text{ cm}^{-3}$ , which is in good agreement with the density of free holes at room temperature. The decay times of the free exciton polaritons, decay times between 180 ps and 380 ps are observed at low temperatures.

Coherent phonon oscillations and transient critical-point parameters in femtosecond pump-probe ellipsometry spectra — •S ZOLLNER¹, C EMMINGER^{1,2,3,4}, S ESPINOZA⁵, S RICHTER^{3,5,6}, M REBARZ⁵, O HERRFURTH^{3,7}, M ZAHRADNIK⁵, R SCHMIDT-GRUND⁸, and J ANDREASSON⁵ — ¹NMSU, Las Cruces, NM, USA — ²Masaryk University, Brno — ³Uni Leipzig — ⁴Humboldt Universität, Berlin — ⁵ELI Beamlines, Dolni Brezany, Czech Republic — ⁶Lund University — ⁷Active Fiber Systems GmbH, Jena — ⁸TU Ilmenau

Spectroscopic ellipsometry measures the dielectric function of materials, which is related to the electronic band structure of semiconductors, and allows the study of critical points and their parameters (energy, broadening, amplitude, phase angle). At ELI Beamlines, femtosecond pump probe ellipsometry measurements can be performed with a white-light continuum probe beam, resulting in a time resolution of 120 fs. We report the transient dielectric function of Ge as a function of delay time between the pump and probe beams near the  $E_1$  and  $E_1 + \Delta_1$  critical points. The changes of the critical-point amplitudes are attributed to band filling at the *L*-point, intervalley scattering, carrier diffusion, lattice heating, and recombination. We also calculate the derivatives of these spectra using a novel Fourier analysis technique and determine the critical point parameters. We find oscillations of the critical-point energies with a period of 11 ps, related to the propagation of coherent acoustic phonons (strain waves) generated by the pump pulse. The amplitude of 0.1%.

### HL 21.3 Wed 15:30 H32

Temperature dependence of the mid-infrared dielectric function of InSb from 80 to 800 K — Melissa Rivero Arias¹, Cesy Zamarripa¹, Jaden Love¹, CAROLA EMMINGER^{1,2,3,4}, and •STEFAN ZOLLNER¹ — ¹New Mexico State University, Las Cruces, NM, USA — ²Masaryk University, Brno, Czech Republic — ³Uni Leipzig — ⁴Humboldt Universität, Berlin

We describe measurements of the mid-infrared dielectric function of bulk InSb near the direct band gap using Fourier-transform infrared spectroscopic ellipsometry from 80 to 800 K in an ultra-high vacuum cryostat. Indium antimonide is the zinc blende compound semiconductor with the smallest direct band gap ( $E_0$ =0.18 eV at 300K) due to its heavy elements, the large resulting spin-orbit splitting and Darwin shifts. It has a low melting point of 800 K. Previously, the band gap of InSb has only been measured up to room temperature and estimated from Hall effect measurements of the effective mass up to 470 K. Calculations indicate that InSb should undergo a topological phase transition from semiconductor to semi-metal at 600 K. It is interesting to see in the data if this transition occurs below the melting point of InSb.

HL 21.4 Wed 15:45 H32

Ultra-fast change of the absorption onset in undoped cubic GaN — •ELIAS BARON¹, MARTIN FENEBERG¹, RÜDIGER GOLDHAHN¹, MICHAEL DEPPE², DONAT J. As², SHIRLY ESPINOZA³, and MARTIN ZAHRADNÍK³ — ¹Institut für Physik, Otto-von-Guericke-Universität Magdeburg, Germany — ²Department Physik, Universität Paderborn, Germany — ³ELI Beamlines, Institute of Physics, Czech Academy of Science, Dolní Břežany, Czech Republic

Nitride semiconductors are essential for modern applications, which means that an example for nitride research is necessary. For this, the cubic zincblende phase is predestined on account of isotropic properties. We present our investigation of thin film zincblende GaN, deposited by plasma-assisted molecular beam epitaxy on 3C-SiC/Si substrates in (001) orientation, by time-resolved spectroscopic ellipsometry, based on a pump-probe approach in the visible and ultra violet spectral range. The 266nm pump beam excites the cubic GaN far above the band gap and therefore creates up to  $\approx 5 \times 10^{20} \rm cm^{-3}$  electron-hole pairs, which influence the dielectric function due to many-body effects like band gap renormalization and Burstein-Moss shift. By varying the delay time between pump and probe beam from femto- to nanoseconds, a time-resolved change of the absorption onset due to the relaxation and recombination of electron-hole pairs in the context of many-body effects is observed and concur with comparable steady-state measurements of highly n-type doped GaN.

**Strain-induced bandgap transition in III-V semiconductors** — •BADAL MONDAL and RALF TONNER-ZECH — Wilhelm-Ostwald-Institut für Physikalische und Theoretische Chemie, Universität Leipzig, 04103 Leipzig, Germany

In the interest of a deep and thorough understanding of the effect of strain on the electronic properties, we have developed a systematic strategy for the analysis of composition-strain-bandgap relationship in III-V semiconductors. Using the tool of computational method, modern *ab-initio* density functional theory (DFT), we have shown that depending on the nature and strength of applied strain in the system the material behavior can change substantially. Namely, a direct bandgap semiconductor can transform to an indirect bandgap semiconductor and vice versa. This ultimately enables us to construct the 'bandgap phase diagram' [1] by mapping the different direct-indirect transition points with composition and strain. By combining the advanced tools of machine learning with DFT, we have further developed an efficient approach to extend the scope in multinary systems. In combination with the thermodynamic phase diagram, we have shown that this new way of mapping the effect of strain will significantly improve the future developments in terms of strategic choice of certain application-oriented best-suited material systems or vice versa.

Probing free carrier and exciton dynamics in bulk gallium selenide with two-dimensional electronic spectroscopy — •JONAS ALLERBECK^{1,2}, THOMAS DECKERT², LAURENS SPITZNER³, and DANIELE BRIDA² — ¹nanotech@surfaces Laboratory, Empa, Überlandstrasse 129, 8600 Dübendorf, Switzerland — ²Department of Physics and Materials Science, Université du Luxembourg, 162a Avenue de la Faïencerie, L-1511 Luxembourg, Luxembourg — ³Department of Physics, University of Konstanz, Universitätsstrasse 10, 78457 Konstanz, Germany

Multidimensional optical spectroscopy employing a sequence of three or more pulses is a powerful technique to disentangle energetic correlations. While the technique has been used to study molecular systems, its application to femtosecond dynamics in solid state materials remains new. In this work, we investigate the ultrafast response of excitons and free carriers in the technologically important semiconductor gallium selenide (GaSe) with 10 fs temporal and 1 THz (4 meV) spectral resolution. 2D spectra resolve the excitation energy of broadband pulses and reveal strong bleaching at the exciton resonance, which is hidden by the free carrier response in standard pump-probe measurements, allowing to extract an exciton relaxation time of 112 fs at room temperature. Our quantitative

mapping of carrier thermalization shows the interplay of spectral diffusion, induced absorption and dephasing, motivating ongoing theoretical investigation and paving the way for future investigation of quasiparticle correlations in functional material systems.

### HL 21.7 Wed 16:45 H32

Multistable, co- and counterflowing currents of polariton condensates in concentric ring-shaped and elliptical potentials — •FRANZISKA BARKHAUSEN, MATTHIAS PUKROP, XUEKAI MA, and STEFAN SCHUMACHER — Department of Physics and CeOPP, Paderborn University, Germany

Vortices occur in a broad range of nonlinear systems. They have been widely investigated in many physical systems and different materials for their fundamental interest and for applications in data storage and information processing. In polariton condensates in semiconductor microcavities vortices can be supported and trapped by including a ring-shaped potential, for example optically induced using spatially structured non-resonant excitation [1]. Here we theoretically study vortices excited non-resonantly in different fabricated ring-shaped and elliptical external potentials. These kinds of potentials trap the polariton condensate such that different steady-state solutions, oscillating or co- and counterrotating solutions can be formed, depending on the size and number of the potential wells. A single ring potential can stabilize multistable solutions carrying different orbital angular momenta (OAM) which can lead to the beating of different modes and spatially rotating solutions. A concentric arrangement of many rings enables the excitation of Bessel-like solutions [2]. Embedding a standard ring potential in an elliptical one gives rise to phase differences of the condensates in the two rings and to counterflowing condensate currents.

Optical properties of transition metal oxide perovskites by the Bethe-Salpeter equation — •LORENZO VARRASSI¹, PEITAO LIU², ZEYNEP ERGÖNENC YAVAS³, Menno Bokdam⁴, Georg Kresse², and Cesare Franchini^{1,2} - ¹Department of Physics, University of Bologna — ²Faculty of Physics, University of Vienna ³Turkish Aerospace Industries- Department of Materials Engineering ⁴University of Twente, Faculty of Science and Technology

The accurate account of optical spectra of semiconductors and insulators requires the explicit treatment of the electron-hole (e-h) interaction. This talk will present a systematic investigation of the role of excitonic effects on the optical properties of transitions metal oxide perovskites. A representative set of fourteen compounds has been selected, including 3d, 4d, and 5d perovskites. Optical conductivities and exciton binding energies are calculated through the Bethe-Salpeter equation (BSE) based on G0W0 approximation. Results are compared with the experimental data.

The origin of spectra's main peaks are investigated through the analysis of the e-h coupling coefficients. A particular emphasis in our analysis was placed on how differences between the electronic bandstructures of the studied compounds impact the optical properties and e-h coupling coefficients.

A computationally cheaper model-BSE approach, based on a model dielectric screening, was employed for the calculations of the excitonic binding energies. The quality and validity of the the approach was assessed through a comparison with reference G0W0+BSE values.

Dynamics of phase defects trapped in optically imprinted or- bits in dissipative binary polariton condensates — • JAN WINGENBACH, MATTHIAS PUKROP, STEFAN SCHUMACHER, and XUEKAI MA - Physics Department and CeOPP, Paderborn University, Germany

Polaritons are quasiparticles, formed due to the strong coupling of photons and excitons in planar semiconductor microcavities. In polariton condensates, quantized vortices can form, which makes them promising candidates for novel quantum technological devices [1]. By nonresonant excitation of the condensate, periodic potentials can be generated, which can be used to trap vortices and stabilize phase defects, so-called dark solitons [2]. We study the dynamics of phase defects trapped in a finite, optically imprinted ring lattice in binary polariton condensates. Depending on their topological charge a Magnus force leads to the circulation of vortices in these orbits. This is investigated considering the cross interaction (CI) between the condensates in different spin components and the spin-orbit interaction (SOI). We observe elongated vortices and frozen phase defects, which resemble dark solitons showing finite size in both spin components. When the entire orbit is occupied, a snake instability is triggered, leading to the decay of the dark ring solution. In our system, the motion of vortex constellations is affected by the SOI. [1] X. Ma, et al., Nature Communications 11, 1 (2020). [2] X. Ma, et al., Phys. Rev. Lett. 118, 157401 (2017).

### HL 21.10 Wed 17:45 H32

Optimization of Silicon Nanoantenna for Optical Phased Arrays -•ANDREAS STRAUCH, HENNA FARHEEN, VIKTOR MYROSHNYCHENKO, and JENS  $\label{eq:Forstner} F\"{o}rstner - University\ Paderborn\ -\ Department\ of\ Electrical\ Engineering\ and$ Information Technology, Paderborn, Germany

The classical microwave phased array is a proven antenna technology since the beginning of the last century. Among other things, it leads to significant improvements in radar technology as well as mobile, radio and satellite communications. Beyond that, this principal is not limited to the microwave band and can transfer into the optical spectrum, such as for light detection and ranging (LIDAR). The specific, technical features of the optical phased array (OPA) are the fast, non mechanical variation of directional characteristic (beam steering) during the operation and the great beam focusing through an ensemble of sophisticatedly, interacting single antennas. Besides them, the usage of serveral single antennas increases the redundancy and gives a high operational reliability and signal-to-noise ratio.

We designed, numerically analyzed, and optimized an efficient Silicon on Insulator (SOI) based photonic light transmitter, working in the infrared band, with high antenna gain and sidelobe attenuation (super resolution in principle), high redundancy and noise robustness and most important an electronically, configurable farfield characteristic. In comparison to a reference design, we increased the radiation efficiency from 2.66 to 9% by numerical optimization using evolutionary and natural analogue approaches.

Spatially Resolved Dynamics of Intra 3d Luminescence of Co in ZnO Nanowires Revealed by Nanoscale X-ray Analysis – •CHRISTIAN PLASS¹, Valentina Bonino², Maurizio Ritzer¹, Lukas Jäger¹, Jaime Segura-Ruiz², Gema Martinez-Criado², and Carsten Ronning¹ – ¹Institut für Festkörperphysik, Friedrich-Schiller-Universität Jena, Max-Wien-Platz 1, 07743, Jena – ²ESRF - The European Synchrotron, 71 Avenue des Martyrs, 38043 Grenoble, France

Color centers in semiconductors have drawn a lot of interest in recent years. They are able to provide high quality single photon sources. Such color centers can for example be obtained by doping ZnO with Co. The underlying emission processes have to be determined in order to achieve quantum emission by such a system. Hence, there is a strong need to evaluate how the dynamics of the luminescence is influenced by elemental composition and local environment of the color centers. High resolution synchrotron based methods like X-ray fluorescence (XRF) and X-ray excited optical luminescence (XEOL) enable insight into such compositional and functional variations. Simultaneous XRF and XEOL measurements of Co doped ZnO nanowires were conducted: The highly focused X-ray nanobeam at the ID16B-NA station of the European Synchrotron Radiation Facility scanned the nanowire and by analyzing the emitted X-ray fluorescence radiation together with the corresponding optical luminescence correlating maps were obtained. As the spatial resolution is about 50nm, we can show how the local composition influences the spectral dynamics of the obtained emission.

HL 21.12 Wed 18:15 H32 Fröhlich polarons in cubic materials — •B. GUSTER¹, P.M.M.C. MELO², B.A.A. MARTIN³, V. BROUSSEAU-COUTURE⁴, J.C. DE ABREU², A. MIGLIO¹, M. GIANTOMASSI¹, M. CÔTÉ⁴, J.M. Most works on polaron models, to understand their characteristics such as radius, effective mass, mobility and energy dispersion, have focused on the original Fröhlich model. Real cubic materials have electronic band extrema that are often degenerate, or anisotropic. In this work, we keep the continuum hypothesis inherent to large polaron models, but go beyond the existing isotropic and nondegeneracy hypotheses, and also include multiple phonon modes. For polaron effective masses, we provide (i) the analytical result for the case of anisotropic electronic energy dispersion, with two distinctive effective masses (uniaxial), (ii) an approximate expression for the case of three distinctive axes (ellipsoidal), (iii) numerical simulations for the 3-band degenerate case, typical of III-V and II-VI semiconductor valence bands. We also deal with the strong-coupling limit, using a variational treatment: we propose trial wavefunctions for the three abovementioned cases as well, providing polaron radii and energies. We gauge such approaches for the case of a dozen of II-VI and III-V semiconductors, and oxides.

Band-gap and strain engineering in GeSn alloys using post-growth pulsed laser melting — •O. STEUER¹, D. SCHWARZ², M. OEHME², J. SCHULZE³, H. MACZKO⁴, R. KUDRAWIEC⁴, I. FISCHER⁵, R. HELLER¹, R. HÜBNER¹, M. KHAN¹, Y. GEORGIEV¹, S. ZHOU¹, M. HELM¹, and S. PRUCNAL¹ — ¹Helmholtz-Zentrum HZDR, GER — ²University of Stuttgart, GER — ³Fraunhofer IIS, GER — ⁴Wroclaw University, POL — ⁵TU Cottbus-Senftenberg, GER

Alloying Ge with Sn enables effective band-gap engineering and improves significantly the charge carrier mobility. The pseudomorphic growth of Ge1-xSnx on Ge causes in-plane compressive strain, which degrades the superior properties of the Ge1-xSnx alloys. Therefore, efficient strain engineering is required. In this talk, we will present strain and band-gap engineering in GeSn alloys grown on a Ge virtual substrate using post-growth nanosecond pulsed laser melting (PLM). Micro-Raman spectroscopy and X-ray diffraction show that the initial in-plane compressive strain is removed. Moreover, for PLM energy densities higher than 0.5 J cm-2, the Ge0.89Sn0.11 layer becomes tensile strained. Simultaneously, as revealed by Rutherford Backscattering spectrometry, crosssectional transmission electron microscopy investigations and X-ray diffraction, the crystalline quality and Sn-distribution in PLM-treated Ge0.89Sn0.11 layers are only slightly affected. Additionally, the change of the band structure after PLM is confirmed by low-temperature photoreflectance measurements. The presented results prove that post-growth ns-range PLM is an effective way for bandgap and strain engineering in highly-mismatched alloys.

#### HL 22.2 Wed 15:15 H33

Reconfigurable Complementary and Combinational Logic based on Monolithic and Single-Crystalline Al-Si Heterostructures — •RAPHAEL BÖCKLE¹, MASIAR SISTANI¹, MARTINA BAŽÍKOVÁ¹, LUKAS WIND¹, ZAHRA SADRE-MOMTAZ², MARTIEN I. DEN HERTOG², CORBAN G.E. MURPHEY³, JAMES F. CAHOON³, and WALTER M. WEBER¹ — ¹Institute of Solide State Electronics, TU Wien, Vienna, Austria — ²Institut Néel, CNRS, Grenoble, France — ³Department of Chemistry, University of North Carolina, Chapel Hill, North Carolina, United States

Overcoming the difficulty in reproducibility and deterministically defining the metal phase of metal-Si heterostructures is among the key prerequisites to enable next-generation nanoelectronic devices. Here, the formation of monolithic Al-Si-Al heterostructures obtained from Si nanowires and Al contacts is presented. Transmission electron microscopy and energy-dispersive X-ray spectroscopy confirmed both the composition and crystalline nature of the presented Al-Si-Al heterostructures, with no intermetallic phases formed during the exchange process in contrast to state-of-the-art metal silicides. In this context, reconfigurable field-effect transistors (RFET), capable of dynamically altering the operation mode between n- or p-type are realized. Having devised symmetric on-currents as well as threshold voltages for n- and p-type operation as a necessary requirement to exploit complementary reconfigurable circuits, selected implementations of logic gates such as inverters and combinational wired-AND gates are built from single elementary RFETs.

### HL 22.3 Wed 15:30 H33

Investigations on graphene-oxide-silicon structures for field emission — •ALEXANDER MAI¹, FLORIAN HERDL², SIMON EDLER¹, ANDREAS SCHELS², MICHAEL BACHMANN¹, FELIX DÜSBERG¹, ANDREAS PAHLKE¹, and GEORG DUESBERG² — ¹Ketek GmbH, Hofer Str. 3, 81737 Munich, Germany — ²University of the Bundeswehr Munich, Institute of Physics, Werner-Heisenberg-Weg 39, 85577 Neubiberg, Germany

In field emission (FE) electrons can tunnel through a potential barrier by applying a large electric field (> 1 V/nm), which is required to obtain a reasonable current. Therefore, often high voltages (> 300 V) and sharp tip geometries are used. However, a high sensitivity to poor vacuum makes these emitters unsuitable for many applications. Planar devices like graphene-oxide-semiconductor (GOS) structures are promising candidates as they are independent on the ambient pressure level. The necessary electric fields are achieved by applying a low operation voltage (< 20 V) on a thin oxide barrier (5 - 20 nm). The maximum emission to tunnel current ratio (efficiency) achieved in a GOS structure to this date is 48.5%. In this presentation, results of recent measurements and simulations on GOS structures are shown. The measured structures show efficiencies between 0.1 and 23%, mainly depending on the thickness of the gate electrode, while an emission current of at least about 1 nA was achieved in most samples. Simulations show a voltage drop near the contact pad resulting from the sheet resistance of the gate electrode, which limits the maximum tunnel current in the GOS structure.

**Topological photonics for optoelectronic sensing** – •JAKOB LINDENTHAL^{1,2}, JOHANNES BENDUHN¹, and KARL LEO^{1,2} – ¹Institute of Applied Physics, Technische Universität Dresden – ²ct.qmat - Würzburg-Dresden Cluster of Excellence

Topological properties of photonic systems are a quickly emerging research field. The physical realisation of topological invariants allows the creation of photonic states with strong protection of the state's existence against perturbation. The energy levels of topological states can be made highly sensitive to external influences, enabling the design of novel optoelectronic sensing devices. Theoretical concepts of different topological photonic systems are discussed, and experimental systems are showcased. The presentation reports about an optoelectronic pressure sensor developed at the Institute of Applied Physics at TU Dresden and other devices fabricated by partnering organisations. Key concepts and technological advantages of topological systems are summarised, highlighting the prospects for incorporating topology in optoelectronic sensing devices.

#### HL 22.5 Wed 16:00 H33

Interplay of anomalous strain relaxation and minimization of polarization changes at nitride semiconductor heterointerfaces — YUHAN WANG^{1,2}, •MICHAEL SCHNEDLER^{1,2}, QIANQIAN LAN^{1,2}, FENGSHAN ZHENG^{1,2}, LARS FRETER^{1,2}, YAN LU^{1,2}, UWE BREUER³, HOLGER EISELE⁴, JEAN-FRANÇOIS CARLIN⁵, RAPHAËL BUTTÉ⁵, NICOLAS GRANDJEAN⁵, RAFAL E. DUNIN-BORKOWSKI^{1,2}, and PHILIPP EBERT^{1,2} — ¹Peter Grünberg Institut, Forschungszentrum Jülich GmbH, 52425 Jülich, Germany — ²Ernst Ruska Centrum, Forschungszentrum Jülich GmbH, 52425 Jülich, Germany — ³Zentralinstitut für Engineering, Elektronik und Analytik (ZEA-3), Forschungszentrum Jülich GmbH, 52425 Jülich, Germany — ⁴Institut für Festkörperphysik, Technische Universität Berlin, Hardenbergstrasse 36, 10623 Berlin, Germany — ⁵Institute of Physics, Ecole Polytechnique Fédérale de Lausanne, 1015 Lausanne, Switzerland

Polarization and electron affinity changes at  $Al_{0.06}Ga_{0.94}N/GaN$  and  $In_{0.05}Ga_{0.95}N/Al_{0.06}Ga_{0.94}N$  interfaces are quantified by combining off-axis electron holography in transmission electron microscopy, scanning tunneling microscopy, and simulations of the electrostatic potential and electron phase maps. The  $In_{0.05}Ga_{0.95}N/Al_{0.06}Ga_{0.94}N$  interface reveals, as expected, biaxial relaxation as well as polarization and electron affinity changes. However, at the  $Al_{0.06}Ga_{0.94}N/GaN$  interface anomalous lattice relaxations and vanishing polarization and electron affinity changes occur, whose underlying physical origin is anticipated to be total energy minimization by the minimization of Coulomb interactions between the polarization-induced interface charges.

### 30 min. break

HL 22.6 Wed 16:45 H33 **Determination of relaxation in thin InGaAs-films by Raman spectroscopy** — •JOHANN FRIEDEMANN SCHULZ¹, TOBIAS HENKSMEIER², MARTIN FENEBERG¹, ELIAS KLUTH¹, DIRK REUTER², and RÜDIGER GOLDHAHN¹ — ¹Otto von Guericke University, Institute of Physics, Universitätsplatz 2, 39106 Magdeburg, Germany — ²Paderborn University, Department of Physics, Warburger Str. 100, 33089 Paderborn, Germany

Semiconductor heterostructures suffer inherently from differences in their lattice parameters. This causes strain and, in the worst case, crystal defects in the material, rendering it potentially unusable for electronic or optical devices. The relaxation of thin mismatched films is therefore important for assessing the crystal quality. One possibility to experimentally access the degree of relaxation is to accuractely determine the phonon frequencies of the strained material, as Phonon frequencies depend on composition and lattice parameters. Such measurements can be carried out quickly and easily using Raman spectroscopy. Here, we present results on  $\ln_x Ga_{1-x} As$  grown on GaAs-substrates by molecular beam epitaxy. We investigate different strained films with varied composition and several different film thicknesses. We find Raman spectroscopy a viable tool to determine the degree of relaxation even in films which are too thin for usual reciprocal space map experiments.

#### HL 22.7 Wed 17:00 H33

**Time-resolved measurement of propagating exciton-polariton condensates in confined systems using a streak camera** — •CHRISTIAN MAYER, SIMON BETZOLD, PHILIPP GAGEL, TRISTAN H. HARDER, MONIKA EMMERLING, ADRIANA WOLF, FAUZIA JABEEN, SVEN HÖFLING, and SEBASTIAN KLEMBT — Technische Physik, RCCM and Würzburg-Dresden Cluster of Excellence ct.qmat, University of Würzburg, Germany

Strong coupling between photons and excitons in an optical microcavity leads to the formation of hybrid light-matter quasiparticles called exciton-polaritons. In the low-density regime, these particles follow bosonic statistics and can therefore

undergo dynamical condensation above a critical particle density by stimulated relaxation to the ground state. The low effective mass of polaritons compared to excitons, which results from the photonic fraction, leads to comparatively long diffusion lengths. The excitonic fraction, on the other hand, is responsible for relevant polariton-polariton interaction, which leads to a repulsive behavior. Exciting non-resonantly with a pulsed laser results in an additional repulsive force at finite wavevector due to the exciton reservoir. These factors can lead to a significant propagation of the polariton condensate, with relevant effects already taking place on the time scale of a few picoseconds.

Here, we utilize electron beam lithography and etching techniques to form potential landscapes such as coupled resonator lattices and waveguides. We use a streak camera to resolve and visualize the propagation of polaritons in these systems.

### HL 22.8 Wed 17:15 H33

Towards predictive modeling of optical properties of quantum dots under externally applied stress — •PETR KLENOVSKY^{1,2}, XUEYONG YUAN³, SAIMON FILIPE COVRE DA SILVA³, and ARMANDO RASTELLI³ — ¹Department of Condensed Matter Physics, Faculty of Science, Masaryk University, Brno, Czech Republic — ²Czech Metrology Institute, Brno, Czech Republic — ³Institute of Semiconductor and Solid State Physics, Johannes Kepler University Linz, Austria

GaAs quantum dots (QDs) have been found in the past to be an exceptionally good platform for construction of the light emitters. They have also advantageous properties for spin physics because of the absence of strain and strain inhomogeneity. Still, strain is important to achieve quadrupolar splitting, e.g., to build up a quantum register with nuclear spins. Understanding and quantitative prediction of strain-induced effects will be important to guide future optimization, since a trial and error procedure is not acceptable in view of the huge parameter space available for GaAs QDs (e.g. WL thickness tunable at will). Former attempts have qualitatively reproduced results but failed to achieve the quantitative agreement, e.g., bright-dark exciton splitting or used unphysical assumptions. That was further exacerbated by the lack of knowledge of the exact applied strain configuration.

Here we go beyond by combining precisely determined strain and QD properties with dedicated calculations using  $\mathbf{k} \cdot \mathbf{p}$  and correlated configuration interaction (CI) methods. We show for the first time quantitative agreement between experiment and theory for strained GaAs QDs.

### HL 22.9 Wed 17:30 H33

**Growth of epitaxial GaN by reactive magnetron sputtering** — •RALF BORGMANN, FLORIAN HÖRICH, JÜRGEN BLÄSING, ARMIN DADGAR, ANDRÉ STRITTMATTER, ANJA DEMPEWOLF, FRANK BERTRAM, JÜRGEN CHRISTEN, and GORDON SCHMIDT — Otto-von-Guericke-Universität Magdeburg, Universitätsplatz 2, 39106 Magdeburg, Germany For high power transistors GaN is an excellent base material semiconductor with a high bandgap and a high breakdown field which is often realized on Si substrates. A specific buffer arrangement is needed for MOVPE grown structures, to achieve these properties. Especially doping with Fe or C is essential for insulating sheets. In comparison with reactive magnetron sputtering uses pure metal targets and does not necessarily require Fe or C doping to achieve highly insulating GaN. We investigated growth parameters like growth temperature and reactive gas flow on various templates. An important parameter determining the material quality is the reactive gas. Ga droplets occur on the wafer surface, when using nitrogen. Investigations on growth temperature reveal a narrow growth window. An optimum growth temperature was by around 715 °C. With low ammonia gas flow the AFM measurement shows a grainy surface. By using a higher ammonia gas flow, the growth rate decreases and a closed meandering surface structure appears. Full sputtered undoped layers show a vertical breakdown field strength of > 2.5 MV/cm for 200 nm AlN 2x 200 nm transition layer AlGaN and 820 nm GaN.

### HL 22.10 Wed 17:45 H33

Ultrafast transient spectroscopy of Cu(In,Ga)Se₂ coupled to different buffer layers. — •PIRMIN SCHWEIZER, RICARDO ROJAS-AEDO, ALICE DEBOT, PHILIP DALE, and DANIELE BRIDA — Department of Physics and Materials Science, University of Luxembourg, 162a avenue de la Faïencerie, L-1511 Luxembourg, Luxembourg

The dynamic parameters of photo-induced electron-hole pairs, such as recombination time and charge conductivity, play a major role in the efficiency of photovoltaic devices. Among thin film materials for photovoltaics, one of the most interesting is the p-type Cu(In,Ga)Se2 alloy (CIGS) on which an n-type buffer layer is deposited, forming the initial part of the device p-n junction. The intermaterial transport dynamics strongly depend on how the band structure is affected by the buffer layer, and also on the quality of the CIGS / buffer layer interface which may contain defects. In our experiments we have compared the ultrafast transient reflectivity on CIGS epitaxially grown on a GaAs substrate. New Cd free buffer layers In₂S₃ and band offset tunable Zn(O,S), are compared to the most commonly used buffer layer, CdS. The transient reflection measurements allows for the extraction of the electronic transport dynamics at the interface with the buffer. This study allows us to draw conclusions about the pair formation capacity mediated by the transport properties between the CIGS and the buffer layer. The results can guide the development of Cd free buffer layers thus reducing the environmental impact caused by CdS in traditional CIGS solar cells.

### HL 23: Perovskite and Photovoltaics 2 (joint session HL/CPP/KFM)

Time: Wednesday 15:00-18:15

## HL 23.1 Wed 15:00 H34

Electronic structure analysis of the interface of a  $TiO_2$  electrontransport layer with a perovskite CsPbI₃ photovoltaic absorption layer — •AMIRHOSSEIN BAYANI¹, JULIAN GEBHARDT¹, and CHRISTIAN ELSÄSSER^{1,2} — ¹Fraunhofer Institute for Mechanics of Materials IWM, Wöhlerstrasse 11, 79108 Freiburg, Germany — ²Freiburg Materials Research Center (FMF), Albert-Ludwigs-University Freiburg, 79104 Freiburg, Germany

Lead-based hybrid perovskite halides are currently the most promising light absorbing materials to supplement or even replace Si in next generation solar cells. With intensive research of the bulk material properties in recent years, a strong interest emerges in studying the interfaces to the contact layers in order to reach the final boost of solar efficiency in devices. Here, we study the interface of CsPbI₃ with TiO₂ as model interface for a perovskite with an electron transport layer. In particular, we investigate the rutile-TiO₂(001)[001] / CsPbI₃(001)[100] interface using self-energy corrected density functional theory. By this state-of-the art modeling technique, we analyze the alignment of work-functions and investigate the band alignment at the interface.

### HL 23.2 Wed 15:15 H34

Influence of the Ionic Liquid  $BMIMBF_4$  on the film formation and optoelectronic properties of  $MAPbI_3$  — •SIMON BIBERGER, KONSTANTIN SCHÖTZ, PHILIPP RAMMING, NICO LEUPOLD, RALF MOOS, ANNA KÖHLER, HELEN GRÜNINGER, and FABIAN PANZER — University of Bayreuth, Bayreuth, Germany Today, metal halide perovskite solar cells (PSCs) are one of the most promising emerging photovoltaic technologies. However, their still limited stability is a main hurdle for their successful commercialization. In the past, various approaches have been developed to improve the long-term stability and performance of PSCs. Here ionic liquids (IL) as additives have attracted much attention as they passivate defects and suppress ion migration. In this work, we investigate the effect of the IL  $BMIMBF_4$  on the film formation and optoelectronic properties of the model halide perovskite  $MAPbI_3$ . By multimodal in situ optical spectroscopy, we investigate the formation of the perovskite film during solution processing via one-step spin coating and a solvent engineering approach and how the film formation alters when the IL is added to the precursor solution. We find that the IL does not impact the formation of perovskite-solvent complexes, but the perovskite growth rate decreases with increasing IL content in the precursor solution. Additionally, we reveal that the IL already interacts with precursor materials and changes the evolution of the  $PbI_4^{2-}$  properties. Thus,

Transversal halide motion enables sharp optical absorption profiles in halide perovskites — •SEBASTIÁN CAICEDO-DÁVILA, CHRISTIAN GEHRMANN, XI-ANGZHOU ZHU, and DAVID A. EGGER — Department of Physics, Technical University of Munich, Garching, Germany

our work provides important insights into how decisive ILs impact the sensitive

interconnection between precursor properties, film formation process and final

optoelectronic functionality of perovskite thin films.

Despite their strong vibrational anharmonicity, halide perovskites (HaPs) exhibit favorable optoelectronic properties, which facilitate their outstanding performance in solar cells, comparable to high-quality inorganic semiconductors. In this contribution, we explore the mechanisms and consequences of dynamic structural flexibility in CsPbBr₃ using first-principles molecular dynamics based on density-functional theory. We show that large Br displacements occur on planes that are transversal to the Pb-Br-Pb bonding axis. This *transversality* is concurrent with vibrational anharmonicity, results in short-ranged disorder correlations, and sharpens the joint-density of states rise at finite temperature.

Location: H34

Finally, we contrast these results to the case of PbTe, which shares key properties with  $CsPbBr_3$  but cannot exhibit any *transversality*, to show that this system features wider band-edge distributions and longer-ranged disorder correlations. These findings are relevant for connecting the structural flexibility and bonding of the halide perovskite structure with the sharp optical absorption of these materials.

### HL 23.4 Wed 15:45 H34

Investigating underlying mechanisms of K doping on stability of singleand mixed-cation perovskite solar cells with experimental and computational informed modelling — SAIED MOLLAVALI, MOHAMMAD MOADDELI, and •MANSOUR KANANI — Department of Materials Science and Engineering, School of Engineering, Shiraz University, Shiraz, Iran

Recent studies revealed that the interstitial occupancy of potassium in single/mixed-cation based perovskite structures could hinder the ion migration mechanisms near interfaces, and therefore leads to a better structural stability. However, the underlying stability enhancement mechanisms and probable side effects of additional K atoms in corporate with other organic/inorganic constituents, with a long-range electronic bonding character, is not clear completely. In this study, the effect of doping K on the structural, morphological, electronic, and optical properties of different perovskite structures is investigated experimentally and computationally. The beneficial effect of interstitial K atom on long-range bonding of I atoms with organic molecules is observed. Furthermore, no degradation from additional K is detected for specific range of doping. This result opens a new insight on constructive impact of inorganic dopant on stability issue in perovskite solar cells. SEM, XRD, Photoluminescence and optical absorbance analysis were performed on the perovskite layer. The one layer-based experimental data incorporation with DFT based results were informed into the SCAPS-1D solar cell simulator package to predict cell efficiency, systematically.

### HL 23.5 Wed 16:00 H34

**Revealing efficiency losses due to mobile ions in perovskite solar cells** — •SAHIL SHAH, JARLA THIESBRUMMEL, and JONAS DIEKMANN — University of Potsdam, Germany

Perovskite semiconductors are distinct from most other semiconductors due to a large number of mobile ions in the active layer (e.g., iodide and methylammonium ions and vacancies, and others). Thus, ion dynamics have a critical impact on the performance and stability of perovskite-based applications.

In this work, we will show how the ionic density and induced losses change with device degradation under elevated temperatures and continuous light illumination. This is investigated via a simple and newly developed method *fast-hysteresis* which is a JV scan at a faster rate (~1000 Vs-1) which prevents the perturbation of mobile ions and we get the true ion free potential of the device. The fast-hysteresis measurements are corroborated by transient charge extraction and capacitance measurements as well as numerical simulations, which provide important insights into the dynamics of free electronic charges and mobile ions. We will then demonstrate how the mobile ions affect a range of commonly used mixed cation metal halide perovskite compositions and how the ionic losses vary with the charge transport layer.

Overall, the proposed methods quantify the ion-induced field screening, shed light on the complex device degradation process and PCE losses allow for a better understanding of several key phenomena in perovskite solar cells, and open up a large range of future experiments.

#### HL 23.6 Wed 16:15 H34

Dissecting Ultrafast Polarization Responses in Lead Halide Perovskites via the THz-induced Kerr Effect — •MAXIMILIAN FRENZEL¹, MARIE CHERASSE^{1,2}, JOANNA URBAN¹, FEIFAN WANG³, BO XIANG³, LEONA NEST¹, LUCAS HUBER³, MARTIN WOLF¹, X.-Y. ZHU³, and SEBASTIAN F. MAEHRLEIN¹ — ¹Fritz Haber Institute of the Max Planck Society, Department of Physical Chemistry, Berlin, Germany — ²LSI, CEA/DRF/IRAMIS, CNRS, Ecole Polytechnique, Institut Polytechnique de Paris, Palaiseau, France — ³Columbia University, Department of Chemistry, New York City, USA

The microscopic origin of the surprising optoelectronic properties of lead halide perovskite (LHP) semiconductors is still under debate. One hypothesis is that the highly polar and anharmonic lattice of LHPs influences their optoelectronic properties through dynamic charge carrier screening. We therefore study the ultrafast polarization response of the hybrid LHP MAPbBr₃ when exposed to transient electric fields in the form of intense, single-cycle THz pulses. By probing the THz-induced Kerr effect (TKE), we observe strong THz polarizability and complex ultrafast polarization dynamics. We perform 4-wave-mixing simulations, which show that it is crucial to account for anisotropic and dispersive light propagation for the correct interpretation of the measured TKE signals. Finally, we unveil a coherent phonon response in MAPbBr₃, which we assign to the inorganic cage and conclude to be the dominating polarizable mode in this material. This finding highlights the role of the inorganic lattice for dynamic carrier screening and the related mechanism of charge carrier protection.

Calculating the temperature-dependent band gap of the halide perovskite  $CsPbBr_3 - \bullet$ Stefan Seidl, Christian Gehrmann, Xiangzhou Zhu, Sebastian Caicedo Davila, and David A. Egger — Department of Physics, Technical University of Munich, Garching, Germany

Theoretical calculations based on density functional theory (DFT) can predict thermal effects in the electronic structure by considering important phenomena, such as thermal lattice expansion and electron-phonon coupling. The latter can be calculated using a Monte-Carlo (MC) sampling approach that is formally rooted within the harmonic approximation, which has recently been shown to yield accurate temperature-dependent band gaps for inorganic semiconductors [1]. A complementary approach to predict thermal effects in the electronic structure is first-principles molecular dynamics (MD), which can account for vibrational anharmonicity that is an important effect for certain technologically relevant materials. Here, we assess the temperature-dependent band gap of the halide perovskite CsPbBr₃ in the cubic and orthorhombic phases employing the two different methods, MC and MD, and compare our findings with experimental results. This includes a discussion about the role of anharmonicity and the contributions from spin-orbit coupling and thermal lattice expansion.

HL 23.8 Wed 17:15 H34

Electronic structure prediction of hybrid organic-inorganic metal halide perovskites using cost-effective DFT-1/2 method — MOHAMMAD MOADDELI und •MANSOUR KANANI — Department of Materials Science and Engineering, School of Engineering, Shiraz University, Shiraz, Iran

Hybrid organic-inorganic metal halide perovskites (OIHPs) have attracted much attention in the last decade because of tunable photovoltaic performance and low fabrication cost. Regarding the tunable parameters for controlling the fundamental properties of OIHPs, recent computational and data-driven based approaches can accelerate new material prediction procedure significantly. Density functional theory (DFT) is considered as fundamental block of many multiscale, high-throughput and data-driven approaches typically. However, because of complexity of electronic orbital in OIHP as well as high sensitivity of regarding properties to atomistic configuration, employing conventional computational approaches faces many obstacles or needs very expensive corrections. Underestimation of routine functionals used in DFT calculations push people apply expensive approaches such as hybrid functionals and GW approximation. Here, DFT-1/2 method with a normal computational cost has been used for determining not only the band gap but also the true form of valence and conduction bands of OIHPs. The results showed that, the method could preserve the known Rashba band splitting in the conduction band of mixed-cation perovskites, which is the source of longer carrier lifetime behavior.

### HL 23.9 Wed 17:30 H34

**Phonon Signatures for Polaron Formation in an Anharmonic Semiconductor** — •FEIFAN WANG^{1,2}, WEIBIN CHU³, JIN ZHAO³, and X.-Y. ZHU¹ — ¹Columbia University, New York, NY, 10027 USA — ²Dept. of Materials, ETH Zurich, Switzerland — ³University of Science and Technology of China, Hefei, Anhui 230026, China

Polaron formation, in which charge carriers are dressed by a cloud of lattice distortions, is partially responsible for the long carrier lifetimes and diffusion lengths in the lead halide perovskite (LHP), a superior optoelectronic material. Considerations of ferroelectric-like phonon anharmonicities of this system lead to the recent proposal of ferroelectric large polarons, which attributes efficient charge-carrier screening to the extended ordering of dipoles associated with inversion-symmetry-breaking unit cells. Here, we study electron-phonon coupling in Bi2O2Se, a semiconductor which bears resemblance to LHPs in ionic bonding, band transport with long carrier diffusion lengths, and dynamical phonon disorder as revealed by low-frequency Raman spectroscopy. Using coherent phonon spectroscopy, we show the strong coupling of an anharmonic phonon mode to photo-excited charge carriers, while the Raman excitation of this mode is symmetry-forbidden in the ground-state. Density functional theory calculations verify that the phonon mode originates from the symmetry reduction after charge injection and indicate the local dipole ordering induced by photo-excited electrons. This study provides an initial attempt to generalize the proposed charge-carrier screening model to account for the outstanding optoelectronic properties of defect-tolerant semiconductors.

**Tuning Perovskite Crystallization in the Hybrid Route** — •MOHAMED MAH-MOUD, PATRICIA SCHULZE, ANDREAS BETT, and OUSSAMA ER-RAJI — Fraunhofer ISE

In 2009, perovskite solar cells were discovered in the solid-state that can be used not only as a single junction absorber but also in tandem configuration thanks to their bandgap tunability. It is a combination of organic and inorganic lead halide materials and they have the advantage of a strong absorption edge, defect tolerance and potential cheap production due to easy production methods such as spin coating or slot-die coating as a highly scalable production method. In the

### Semiconductor Physics Division (HL)

industry, double-sided textured silicon (DSTS) is commonly produced to overcome the reflection losses at surfaces. Spin coating of perovskite on top of DSTS resulted in low conformality which resulted in shunts and non-working solar cells. To overcome this issue, the hybrid route was developed, in which inorganic materials are co-evaporated using the thermal vapour deposition technique and then organic materials are spin-coated. By doing that, the high conformality of the thin film on top of the c-Si is achieved. However, the resulting perovskite grain size is in the nanometer scale. To increase the grain size - which results in higher short circuit current, lower grain boundaries and thus a more stable device - thermodynamics of the crystallization process need to be studied. In this work, using the thermodynamics fundamentals of crystallization, we tune the grain size of perovskite deposited via the hybrid route. In addition, we study the consequences of different grain sizes on the efficiency of the solar cell and especially on the stability.

Lead halide perovskites are promising for applications in spintronics due to the nanosecond coherence time of the resident carriers [1]. The primary source of losing spin coherence is the interaction with the fluctuating nuclear spin environment [2]. Optically oriented carrier spins polarize nuclei, which create an Overhauser field. Due to the different strengths of the hyperfine interaction with the nuclear spins, the electron and hole experience different magnitude and directions of the Overhauser field. To study the degree of nuclear spin polarization and fluctuation, we investigate the interaction of resident and optically created carrier spins with nuclei using the Hanle effect in the tilted magnetic field in bulk formamidinium caesium lead iodine bromide.

### HL 24: Functional Semiconductors for Renewable Energy Solutions (joint session HL/KFM)

Time: Wednesday 15:00-18:30

HL 24.1 Wed 15:00 H36 A facile freeze-thaw ultrasonic assisted circulation method of graphite flakes prepared by anode graphite from spent lithium-ion batteries — •YU QIAO^{1,2}, ZHONGHAO RAO^{3,4}, HUAPING ZHAO¹, and YONG LEI¹ — ¹Fachgebiet Angewandte Nanophysik, Institut für Physik & IMN MacroNano, Technische Universität Ilmenau, 98693 Ilmenau, Germany — ²School of Electrical and Power Engineering, China University of Mining and Technology, 221116, Xuzhou, China — ³School of Energy and Environmental Engineering, Hebei University of Technology, 300401, Tianjin, China — ⁴Hebei Key Laboratory of Thermal Science and Energy Clean Utilization, Hebei University of Technology, 300401, Tianjin, China

Lithium-ion batteries (LIBs) have been widely employed in fast-growing mobile devices, stationary storage devices and electric vehicles. However, limited by particular service life, the booming increase in LIBs production will result in a large retirement wave. As the most common anode material in LIBs, waste graphite has also developed into a mode of high production capacity with the retirement of spent LIBs. Anode graphite (AG) of spent LIBs has the characteristics of large layer spacing and ease of being intercalated due to the reduced interlamination force after repeated charge and discharge cycles. This study presents a facile freeze-thaw ultrasonicassisted circulation method to prepare two-dimensional low-layer graphite flakes (GFs) using AG from spent LIBs. The results indicate that the freeze-thaw ultrasonic-assisted circulation method is feasible for preparing two-dimensional laminar materials.

### HL 24.2 Wed 15:15 H36

How could the heating process reduce the crystal damage of semiconductors? — •KHALID LAHMIDI, JALE SCHNEIDER, ANDREAS BRAND, SEBASTIAN RODER, and ANDREAS BETT — Fraunhofer Institute for Solar Energy Systems, Heidenhofstr. 2, 79110 Freiburg, Germany

Laser material processing can no longer be imagined away from the production chains in semiconductor industries. While being a precise, fast and wear-free processing tool, high intensity laser irradiation can also induce damage within the material, e.g. crystal damage, compromising the device quality. However, this damage can partly be healed or even prevented by an accompanying (laser) heating process.

In our laser lab, we built up a flexible laser heating setup with a spatial light modulator (SLM) as the core element. The setup allows to locally heat work pieces with different beam shapes with an intensity up to 220 W/cm* employing a cw-infrared laser source. Current research focuses on the temperature distribution in dependence of beam shape and beam dwell time on a specific position. Comsol based simulations support the experiments. Eventually, the heating beam will be overlaid to the process beam in use cases such as laser contact opening at lowered ablation thresholds or laser metal bonding for solar cell manufacturing. The damage after laser process with and without heating will be analyzed via microscopy.

### HL 24.3 Wed 15:30 H36

Energy landscape of the Boron and Indium single-atom defects in Silicon calculated by DFT — •AARON FLÖTOTTO, WICHARD BEENKEN, and ERICH RUNGE — Institut für Physik, Technische Universität Ilmenau, Weimarer Str. 32, 98693 Ilmenau, Germany

The III group elements Boron and Indium form not only substitutional defects, which are important as electron acceptors, but also interstitial defects. Differ-

ent configurations are possible for a single impurity atom: (i) the impurity atom on an interstitional site, (ii) a substitutional impurity near a single interstitial Si atom, or (iii) the impurity and one Si atom form a pair of interstitials around an empty lattice point. We calculated within DFT the stable configurations of these defects for the Si:B and the Si:In system. We utilized the Nudged Elastic Band algorithm for finding minimal paths between these energetic minima in order to explore the energy landscape and to derive transition probabilities. The results are discussed with respect to the dynamical model suggested by K. Lauer et al. [1] for the explanation of PL-spectra of In-doped Si. Effects of Defects on the Optoelectronic Properties of  $Ta_3N_5$  Thin Films — •Lukas M. Wolz, Gabriel Grötzner, Laura I. Wagner, Ian D. Sharp, and JOHANNA EICHHORN — Walter Schottky Institut, Technische Universität München

For photoelectrochemical energy conversion, metal nitride semiconductors have the potential to overcome several limitations associated with the more intensively investigated class of metal oxides. Among these materials, Ta3N5 is especially promising, possessing a bandgap of ~2.2 eV and effective long-range charge transport. However, the (opto)electronic and photoelectrochemical properties of Ta3N5 photoelectrodes are often dominated by defects, such as oxygen impurities, nitrogen vacancies, and low-valent Ta cations. To identify the impact of such defects on the material properties, we prepare Ta₃N₅ via two different synthetic routes. As precursor,  $Ta_x N_y$  and  $Ta_x O_y$  thin films were deposited by magnetron sputtering and were subsequently annealed at high temperatures in NH₃ to form Ta₃N₅. Both films are homogenous and reveal the formation of phase-pure orthorhombic Ta₃N₅. Compared to nitride-derived Ta₃N₅, the oxide-derived films are characterized by higher structural disorder as well as higher oxygen and lower nitrogen concentrations. Despite these higher defect concentrations, the oxide-derived Ta3N5 films exhibit improved stability under photoelectrochemical operation conditions, though both films show similar photoelectrochemical performance. The improved understanding of defect properties and their impact on PEC stability provides a path to tailored optimization of photoelectrode properties.

### HL 24.5 Wed 16:00 H36

Investigation of various quenching materials on the P-line — •DOMINIK BRATEK, KATHARINA PEH, KEVIN LAUER, AARON FLÖTOTTO, DIRK SCHULZE, and STEFAN KRISCHOK — Institut für Physik, Technische Universität Ilmenau, Weimarer Str. 32, 98693 Ilmenau, Germany

Solar-grade Si shows degradation effects and a lowering of the charge carrier lifetimes after illumination [1]. For In implanted Si this effect was shown to be connected to the P-line in photoluminescence spectra [2]. This P-line can furthermore be influenced by applying a strong quenching after an anneal. The intensity of the P-line increases by several orders of magnitude depending on the cooling rate [3]. In this contribution we investigate the influence of four different quenching liquids on the P-line. From an experimental point of view we discuss the applicability of each used liquid in consideration of P-Line intensity and probe integrity. [1] C. Möller and K. Lauer, Physica Status Solidi (RRL) 7, 461 (2013). [2] K. Lauer, C. Möller, D. Schulze, and C. Ahrens, AIP Advances 5, 017101 (20125). [3] M. L. W. Thewalt, U. O. Ziemelis, and P. R.
